International Group for Lean Construction

FOREWORD

When planning the 32nd Annual Conference of the International Group for Lean Construction (IGLC32) in New Zealand, we anticipated challenges due to its remote location. Reflecting on the dip in participation seen at IGLC23 in Perth, Australia, we were prepared for a potentially smaller turnout. However, we are delighted to report that this year's conference attracted significant global participation. While this year's 110 published papers mark a decrease from last year's record of 150 in Lille, France, the number aligns well with recent trends at IGLC conferences.

This year's proceedings reflect contributions from authors affiliated with institutions in over 25 countries, as detailed in Table 1. Notable themes include the integration of lean principles with emerging technologies, such as digital twins, artificial intelligence, and BIM, highlighting how these innovations enhance decision-making and workflows. The synergy between lean and sustainability is another key focus, with studies addressing circular economy practices, waste reduction, and carbon emissions.

Table 1 Papers published per country

Country of the first author's institution	Published papers
Brazil	16
Australia	10
Peru	10
USA	10
Finland	8
Germany	7
New Zealand	6
Norway	6
United Kingdom	6
Canada	5
Chile	5
Denmark	3
India	3
Indonesia	3
Israel	2
Colombia	1
Estonia	1
France	1
Ireland	1
Japan	1
Mexico	1
Qatar	1
South Africa	1
Switzerland	1
Zimbabwe	1
TOTAL	**110**

Production system optimization continues to be a vital area of research, with significant work on takt planning, cycle time variability, and modular construction. The human aspect of lean is also well-represented, with papers exploring collaboration, communication, and psychological safety within construction teams. Education and knowledge transfer, critical for lean adoption, are emphasized in studies on effective training programs, while lean's impact on health, safety, and quality remains a cornerstone of ongoing research.

Table 2 Papers per track

Track	Papers submitted	Papers accepted
Lean Theory	5	3
Product Development, Value and Design Management	5	4
Contract and Cost Management	9	8
Production System Design	9	7
Production Planning and Control	29	24
Health, Safety and Quality	4	3
Supply Chain Management	2	2
BIM and Enabling Lean with Innovative Technology	20	16
Modular and Off-Site Construction	11	10
Lean and Green	13	13
People, Culture and Change	20	17
Learning and Teaching Lean	3	3
TOTAL	**130**	**110**

A rigorous double-blind peer review process ensured the quality of these proceedings. This would not have been possible without the dedicated efforts of our 12 track chairs (Table 2) and 143 reviewers from 35 countries, who contributed their time and expertise. Their contributions reflect the collaborative spirit of the IGLC community.

Table 2 Track chairs

Track	Track chair name and affiliation
Contract and Cost Management	Thais Alves *San Diego State University, USA*
BIM and Enabling Lean with Innovative Technology	João Soliman Junior *University of Huddersfield, UK*
Lean Theory	Olli Seppänen *Aalto University, Finland*
Health, Safety and Quality	Fidelis Emuze *Central University of Technology, Free State, South Africa*
Learning & Teaching Lean	James Smith *Brigham Young University, USA*
People, Culture and Change	Paz Arroyo *DPR Construction, USA*
Production Planning and Control	Farook Hamzeh *University of Alberta, Canada*
Product Development, Value and Design Management	Rodrigo Herrera *Pontificia Universidad Católica de Valparaíso, Chile*
Production System Design	Carlos Formoso *Federal University of Rio Grande do Sul, Brazil*
Lean and Green	Professor Kristen Parrish *Arizona State University, USA*
Supply Chain Management	Emmanuel Daniel *University of Wolverhampton, UK*
Modular and Off-Site Construction	Beda Barkokebas *Pontificia Universidad Catolica de Chile*

We extend our heartfelt gratitude to the local organizers at the Auckland Institute of Technology, whose dedication made this event possible. In particular, we would like to thank the Conference Chair, Mani Poshdar, for his exceptional leadership and commitment. Their hard work ensured that this conference not only succeeded logistically but also fostered an engaging and inspiring environment for participants.

We hope these proceedings inspire continued innovation and collaboration, advancing lean construction toward a more efficient, sustainable, and inclusive future.

Zelenko, D. & Maxwell, D. (2024). Lean Construction and Innovation: A Systematic Review. In D. B. Costa, F. Drevland, & L. Florez-Perez (Eds.), *Proceedings of the 32nd Annual Conference of the International Group for Lean Construction* (IGLC32) (pp. 1–12). doi.org/10.24928/2024/0111

LEAN CONSTRUCTION FOR INNOVATION: A SYSTEMATIC REVIEW OF IGLC PROCEEDINGS

Darcy Zelenko [1] and Duncan Maxwell [2]

ABSTRACT

The implementation of Lean Construction (LC) is hindered by a lack of comprehensive understanding of innovation in the built environment, making it hard for firms to implement potential improvements. This paper contests that a consideration of LC as innovation can stimulate greater uptake, because it encourages firms to think more broadly about its implementation. The study aims to understand contributions to innovation scholarship from the perspective of LC, and to build an argument for considering LC as innovation to increase uptake. Papers published in IGLC conferences across the last 25 years form the basis for a systematised literature review (SLR), that utilises thematic analysis to synthesise understandings about innovation from the LC community. From the findings, six major themes emerge relating to innovation that are prominent in the reviewed literature: Relationship of LC to Innovation, Innovation Models, Barriers, Drivers, Innovation Strategy Essentials, and Collaborative Efforts. The paper argues that LC be considered an innovation for construction in and of itself, and a theoretical model is presented to aid understanding of LC as innovation. Future research pathways are identified, for example workshops with LC experts and practitioners to verify and expand the findings of this paper.

KEYWORDS

Innovation, Lean construction, Built Environment

INTRODUCTION

LC is a production management philosophy that seeks to minimise waste and increase value (Koskela et al., 2002). It has been demonstrated to be a contributor to addressing issues of stagnant productivity in the construction sector (Li et al., 2012). It is based on the following underpinning principles; value, value stream, flow, pull, and perfection (Bertelsen & Koskela, 2004) These principles are enacted through implementing key lean practices of; Just In Time (JIT), Total Preventative Maintenance (TPM), Total Quality Management (TQM), and Human Resource Management (HRM).

The term Lean Production (LP) was coined by John Krafcik in his Master's thesis and came to prominence as a catch-all for the principles underpinning Ohno's Toyota Production System as a result of the influential study of Womack et al., published as *The Machine That Changed The World* (Leong et al., 2015). LP can be considered a form of managerial innovation (Belfanti, 2018), and first radically transformed the Japanese automotive industry. The adoption of Lean's counterpart in construction has yet to take hold in the sector — in as comprehensive

[1] PhD Candidate, Future Building Initiative, Monash University, Melbourne, Australia, darcy.zelennko@monash.edu, https://orcid.org/0009-0008-4700-3467
[2] Director, Future Building Initiative, Monash University, Melbourne, Australia, duncan.maxwell@monash.edu, https://orcid.org/0000-0002-9039-1441

a way as the global automotive production sector — and productivity in the sector continues to stagnate. Reasons for the inability for Lean to take hold in construction relate to insufficient knowledge, a lack of sufficient training, and issues relating to maturity of the concept. Across the past decade, studies have demonstrated an industry awareness for LC in a general sense (Gao et al., 2020) but practitioners are less aware of specific associated principles and tools and as a result uptake has remained limited (Ahmed et al., 2020). Although Lean can be likened to a tool to enable innovation, in construction this been limited to minor changes of a technical nature.

INNOVATION

Influential economist Joseph Schumpeter developed an understanding of *"innovation"* as "any *"doing things differently"* in the realm of economic life" (Schumpeter, 1939). He details these differences as five types of innovation:

- Introduction of a new good, or a new quality to an existing good.
- Introduction of a new process to a specific industry
- Inception of a new market
- Creation of new supply lines of input materials
- Organising industry in a new way

Innovation in construction is often linked to the interpretation of the sector as a 'product system' (Blayse & Manley, 2004). The prevailing definition of the term in construction is that proposed by Slaughter (1998) as *"…the actual use of a nontrivial change and improvement in a process, product, or system that is novel to the institution developing the change."* Xue et al. (2014) calls for a more holistic understanding of innovation, absent in recent contributions. Innovation diffusion theory offers holistic ways to consider the diffusion of new methods or technologies (Rogers et al., 2014). This knowledge is used by firms and institutions to inform decisions about innovation investment to ensure the most optimal allocation of resources in pursuit of growth (Sundbo, 1995). Schumpeter established a wide range of interpretations of innovation, however the prevalent interpretation by Slaughter constrains the meaning. The is a gap of understanding between what innovation can be perceived as more generally, and the construction-specific interpretation of the term. As a broad production management philosophy, LC provides a more holistic lens from which to broaden interpretation of innovation.

SCOPE OF INVESTIGATION

This scope of this paper is limited to describe innovation across the construction value chain and focuses on activities that are crucial to the creation of buildings. Despite this narrow focus, there are influences of construction innovation, situated within the wider built environment. The nomenclature used in this paper reflects this thinking.

Koskela (1992) defines construction as a production-focussed sector, involving the design, and assembly of objects that are by nature, fixed in place. The products of construction are unique due to the combination of production-based factors that differentiate buildings (physical structures) from other things that humans create. Bertelsen and Koskela (2004) outlines 'peculiarities' that differentiate construction projects from the outputs of other production-based sectors as; possessing a one-of-a-kind nature, existing in situ, through the cooperation of temporary multi-disciplined teams.

OBJECTIVES AND STRUCTURE

The objectives of this paper are: to understand the contributions to innovation theory made by the IGLC community; to discern if there is precedent within the community for the philosophy of LC to be considered as innovation; and if so, to understand how can this precedent can be used to increase innovation uptake in the construction sector.

A SLR and thematic analysis is used to analyse innovation scholarship from the IGLC proceedings database — representing the state-of-the-art in LC research and practice — from the past 25 years. The results are synthesised into six themes that help to address the objectives. The discussion reflects on the results of the SLR to make the argument for considering LC as innovation. Such a consideration allows for a more holistic approach to be taken to understand and implement LC. The construction innovation model being developed as part of a PhD research project is then refined, utilising the inputs of the SLR to present an LC-specific innovation model to assist LC practitioners increase implementation. The paper contributes new knowledge to innovation theory from the IGLC community, and makes the argument to consider LC as a form of management innovation to enable greater uptake. The paper concludes by outlining implications for research, discussing limitations of the study, and highlighting potential opportunities for future work to verify and refine the findings.

METHODOLOGY

The approach to research taken by the study was to utilise a SLR, and thematic analysis to synthesise the findings. SLRs provide a structured and transparent process to undertake a qualitative analysis, that is reproducible and reliable (Tranfield et al., 2003). Thematic analyses are useful in the context of this paper because they enable the extraction of common themes and divergent perspectives from a wide array of studies, essential for synthesising broad research findings (Braun & Clarke, 2006).

The following research question was formulated to direct the SLR:

What is the relationship between LC and innovation from academic literature, across the past twenty-five years?

To answer this question the IGLC database was searched for papers mentioning ‘innovation’ across the past 25 years through Google Scholar and Publish or Perish (Harzing, 2007). For efficiency, a majority (300) of the 514 entries returned (according to Google Scholar ranking) were selected for review. These 300 papers contained no duplicates and were initially screened for eligibility. The criteria for initial eligibility were that a paper had to propose new knowledge about innovation in the built environment, through the inclusion of model, framework, or formulated understanding, that was not part of a literature review, or background section. The initial screening process reduced the pool of papers down to 24 for subsequent thematic analysis. QSR Nvivo 14 was the platform chosen to analyse the data collected (QSR International, 2024). A ‘lean-coding’ approach was utilised for the researcher to create a focused initial pool of themes and codes to commence data analysis, that was then refined or expanded as necessary (Creswell, 2013).

RESULTS

SAMPLE ANALYSIS

Thematic analysis was used to analyse the 24 eligible papers from the IGLC database and derive codes relating to the furthering the understanding of innovation in the built environment. The distribution of publications from 1999 to 2023 (Figure 1) shows that research activity concerning Lean Construction and innovation has been ongoing. There is a wide geographical distribution of papers (Figure 2) across different continents suggesting the potential for international collaboration. The United States is the country that has produced the most amount of research about innovation in the context of IGLC proceedings.

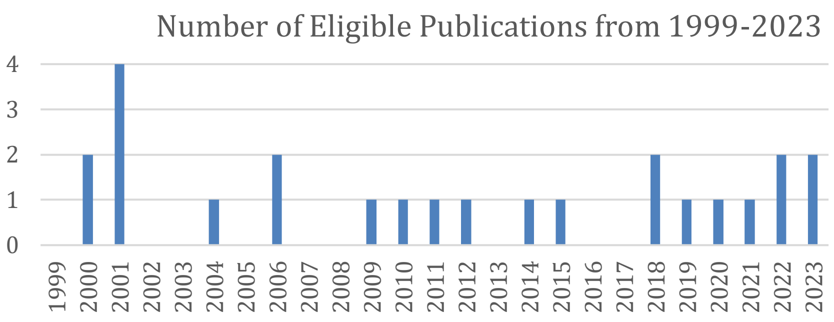

Figure 1 - Number of publications per year, from 2010 to 2021

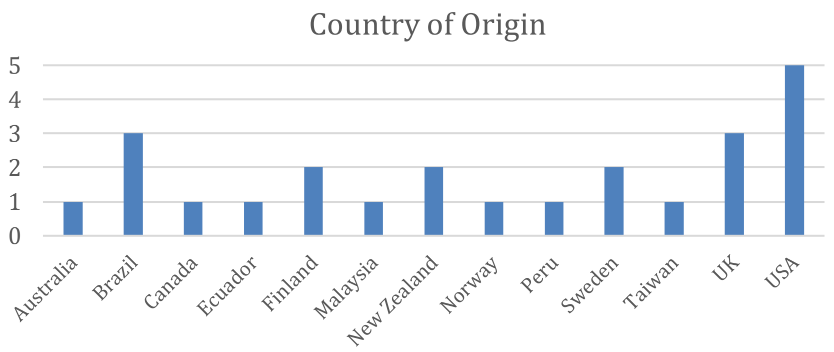

Figure 2 - Number of publications per year, from 2010 to 2021

A synthesis of data was derived through grouping similar codes into categories that based on similar concepts and meanings (Allen, 2017). The categories were then reviewed and refined by revisiting the dataset of eligible papers, that resulted in the emergence of key themes. The key themes were then constructed and underwent a further review process to ensure they adequately captured the meaning of the constituent codes.

DEVELOPED THEMES

The developed themes are as follows:

Relationship of LC to Innovation

- The first theme synthesises the relationship between LC and Innovation, derived from IGLC literature (Table 1), the thematic analysis of the SLR established that Lean *is* a form of managerial innovation in itself, and can provide support to facilitate broader innovation.

Innovation Operations - Existing LC Context

- The second theme identifies operational understandings of innovation in the LC context, in IGLC literature. The SLR identified 7 examples of different understandings used to describe aspects relating to innovation (Table 2).

Barriers to innovation

- The third theme identifies barriers to innovation in IGLC literature (Table 3).

Drivers of Innovation

- Theme 4 concerns drivers of innovation, prevalent in IGLC literature, outlined Table 4.

Innovation Strategy Essentials

- The fifth theme identified, points towards a systemic approach that is required for innovation to drive sector-wide change, one that shifts away from siloed, project-centric endeavours (Table 5).

Collaborative Efforts

- The sixth and final theme that emerged from IGLC literature that stressed the importance of collaborative efforts in driving innovation (Table 6).

Table 1: Innovation and LC

Lean is a form managerial innovation

- LP is viewed as a radical managerial innovation (Gomez, 2009; Koskela & Vrijhoef, 2000)
- Lean Production (LP) is innovative approach to the management of production systems (Hirota & Fomoso, Carlos T., 2001)
- Lean can form part of an innovation strategy (Iordanova et al., 2020)

Lean is a facilitator of innovation

- Lean is a tool for establishing an environment for innovation (Etges & Caten, 2023)
- LC can help drive innovation (Etges & Caten, 2023; Hirota & Fomoso, Carlos T., 2001).
- Incorporation of lean principles would drive industry-wide innovation (Hunt & Gonzalez, 2018)
- Implementing Lean principles both before and during the innovation process is essential for minimising flow waste and enhancing teamwork (Roman & Li, 2014).
- Lean theory can be used as a conceptual foundation to explain innovative practices in construction (Etges & Caten, 2023; Tommelein & Beeche, 2001).
- Last Planner System (an innovation) generated using LC principles (Hunt & Gonzalez, 2018)

Table 2: Innovation in Existing LC Context — Operational focus

Model Name	Description of model
Technological Capability (Freitas & Heineck, 2012)	Classifies innovation by level of technology
Implementation Scheduling (Ballard, 2001)	Implementation strategy combined with Target Cycle Time
Creative Process Support (Berg et al., 2018)	Teamwork and brainstorming methods used to generate new ideas
Problem-space Framework (Etges & Caten, 2023)	A “Double Diamond” approach to identify pain-points and propose innovative solutions
Drivers of Change (Henrich et al., 2006)	Implementation model considering absorptive capacity, and drivers
Manufacturing Templates (Koskela & Vrijhoef, 2000)	Explains transfer of production templates from manufacturing to construction
Simplified Diffusion Model (Poshdar et al., 2019)	Diffusion model from the perspective of the user

Table 3: Innovation barriers as identified

Boom-bust Cycle
• Inhibits investment and companies can't take a long-term view (Hunt & Gonzalez, 2018)
• Margins are low in bust, and actors are too busy in boom (Leiringer, 2001)
Organisational Culture
• Ingrained culture of operation inhibits innovation (Hunt & Gonzalez, 2018)
• Inherent organisation of construction, and theory deficiencies (Koskela & Vrijhoef, 2000)
• Organisations don't want to jeopardise control and often maintain status quo (Leiringer, 2001)
• Unwillingness to share IP amongst project actors (Hunt & Gonzalez, 2018)
• Inability or reluctance to address problems (Koskela & Vrijhoef, 2000)
• Myopic supply chain management, and the diffusion challenges posed by organisational and institutional structures (Koskela & Vrijhoef, 2000).
Operations
• Working practices of construction managers – too task oriented with not enough time allotted for reflection (Hirota & Fomoso, Carlos T., 2001)
• Planning effectiveness Schedule deviation (Castillo et al., 2015)
• Potential for innovation initiatives to collide (Leigard & Pesonen, 2010)
• Hard to measure efficiency in construction, and benchmark data (Henrich et al., 2006)
Cost
• Projects need to be viable, ahead of consideration for innovation (Kennedy et al., 2023)
• Competitive bidding pushes down budget for innovation (Leiringer, 2001)

Table 4: Main drivers of innovation in LC

A Culture to Support Innovation
• Companies can foster a culture of innovation by improving professionalism and efficiency. This can be practically achieved through improved onsite practices, the introduction of quality assurance practices and safety rules (Davey et al., 2000).
• Develop a culture that facilitates innovation, by fostering a willingness to take risks, experiment, but also acknowledging and learning from failures (Hamzeh, 2011).
• Action Learning can be used to drive cultural change to foster innovation (Davey et al., 2000).
• Role of change agents (Leigard & Pesonen, 2010; Poshdar et al., 2019).
• Reform the patent process to create innovation-friendly culture (Stevens, 2022).
• There is a negative hierarchal relationship that separates consultants and clients, from contractors, inhibits innovation from occurring (Hunt & Gonzalez, 2018)
• Achieving buy-in from entire team in required to implement an innovation(Hunt & Gonzalez, 2018; Roman & Li, 2014)
Unique Project Requirements
• The adoption of innovation by contractors was due to site specific issues, with one contractor stating "We look for innovation when we are forced to" (Hunt & Gonzalez, 2018)
• The project nature of construction provides the ability to silo innovation trials, facilitating a "narrow and deep approach" (Arbulu & Zabelle, 2006).
• Innovation should also consider the inherent advantages* of construction of; zero stock, high flexibility, and satisfactory social needs (Chang & Lee, 2004)

Table 4 continued: Main drivers of innovation in LC

Role of Client

- Clients can be an important innovation enabler due to a combination of their experience, and technical knowledge (Hunt & Gonzalez, 2018).
- Improved engagement between academia and industry for networking to incubate research collaboration, both in regards to LC and innovation more generally (Hunt & Gonzalez, 2018).
- Theory of Inventive Problem Solving as an enabler of innovative ideas (Roman & Li, 2014)

Market Forces

- Competitive pressures, market pull, and technology push all drive firms to adopt new technologies (Chang & Lee, 2004)
- Push-driven innovations come from pressure from customers, suppliers, or regulators. Pull-driven innovations arise from recognized performance gaps (Henrich et al., 2006)
- New materials and/or equipment launched into the market usually trigger innovation initiatives in construction (Henrich et al., 2006).

Table 5: Innovation Strategy Essentials

Need for Government Reform

- Government needs to take a larger role in fostering innovation in the built environment at all stages. ie support for inventors, incentives for innovation, and the allowance of innovation on construction projects through the use of performance-based specifications (Stevens, 2022).
- Construction contract structures, such as design-bid-build inhibit innovation due to the separation of design, and construction (Hunt & Gonzalez, 2018).

Strategies for Adapting and Managing Innovation

- Innovation (technical change) in construction should; be driven my market pull, should be limited to construction component standardisation, and consider the available labour market (Chang & Lee, 2004).
- Highly impactful innovation (radical or organisational innovations) from other industries need to be abstracted, then adapted to fit a new context (Koskela & Vrijhoef, 2000).
- Efficient information exchange for efficient innovation management (Castillo et al., 2015).
- Creativity is necessary to foster innovation, and needs to be defined clearly by management, and what creative practice aims to achieve(Berg et al., 2018).

Knowledge Management and Market Alignment

- Trivialisation of innovation due to a loss of credibility coming from a saturation of ‘low-quality’ information (Etges & Caten, 2023).
- Firms should dedicate time to understanding real market need ahead of adopting a technology for sake of technology-push (Chang & Lee, 2004).
- Organising a company's learning processes in a considered manner facilitates the accumulation of technological capability, that is needed to generate and manage innovation (Freitas & Heineck, 2012).
- Translating knowledge into formalised structures and disseminating via dedicated roles leads to better accumulation and continuity, despite staff turnover (Freitas & Heineck, 2012).
- Companies that are seen to be innovative attract staff (Bou Hatoum et al., 2022).

Table 6: Collaborative Efforts

Strategic Partnerships Create Opportunities for Innovation
• Partnering to deliver tailored technological solutions across projects (Freitas & Heineck, 2012)
• Increased levels Industry-led research partnerships, that combines public resources and industry knowledge creates a more innovative environment, (Gomez, 2009; Stevens, 2022)
• Collaborative work involving universities, suppliers, and companies is essential for innovation development (Roman & Li, 2014).
Construction Firm Networks are Important for Diffusion of Innovation
• Large enterprises have the capacity to utilise R&D investment to drive innovation (Etges & Caten, 2023; Poshdar et al., 2019). SME don't have this ability, and instead need to rely on clusters and networking to innovate (Poshdar et al., 2019).
• SMEs adopt the innovation successes of market leaders (Etges & Caten, 2023)
• The interrelated nature of SMEs on construction projects can facilitate or impede innovation diffusion (Poshdar et al., 2019) .
Innovation Collaboration Requires Support and Resources
• Collaboration, through structured settings like workshops with practitioners from across different firms, has been demonstrated to help develop skills to further innovation strategy (Etges & Caten, 2023).
• Collaborative practices help discover, facilitate and implement innovation, but are time consuming (Berg et al., 2018; Hunt & Gonzalez, 2018; Stevens, 2022)

DISCUSSION

Viewed as a whole, the SLR points towards how innovation can be more deliberately pursued in LC. The resulting IGLC Innovation Model compiles the data to present an holistic pathway for this journey where Lean is both a strategic and managerial enabler of innovation, a path that has drivers as well as barriers, and where collaboration is an key factor in a broader suite of more operationally-focused understandings.

The SLR supports the earlier claim by Belfanti that Lean has been considered a managerial innovation (Table 1). LC creates an environment for innovation to occur, the SLR revealed how Lean principles, and LPS act as innovation drivers. Furthermore, Lean theory was suggested as useful in explaining innovative practices in construction.

Current understandings of innovation in IGLC literature are not holistic in scope, and instead tend to concentrate on singular, technical focus areas. The aspect of implementation was most prevalent in identified operational-focused understandings of innovation in LC, ahead of ideation and classification (Table 2).

Major innovation barriers that the SLR identified fell under four classifications. These barriers primarily related to the organisational culture and operations of construction (Table 3). The boom-bust cycle of construction, and cost, were identified as secondary barriers.

A number of innovation drivers emerged as a result of the SLR (Tables 4-6). First, the role of culture in supporting innovation were identified by a significant number of papers as an innovation driver (Table 4). Also, the role of the client, market forces, and unique project requirements of construction, were identified by a lesser number of papers as drivers of innovation.

Additionally, the key role of strategy was identified as a prominent driver of innovation across a number of different levels (Table 5). The management of knowledge to; accumulate technological capacity, and to best understand market needs, was identified prominently in the SLR. The SLR also identified strategies for adapting and managing innovation, and need for government reform to a lesser amount as possessing strategic importance to driving innovation.

Finally, the importance of collaborative efforts was identified in by the SLR as a key driver for innovation in IGLC literature (Table 6). The use of strategic partnerships was seen as important to create opportunities for innovation. Networks of construction firms were also seen as crucial to the diffusion of innovation across the sector. A need to adequately support and resource Collaborative efforts was identified as important for their viability.

The content generated from themes three to six can be synthesised into a model of influencing factors on innovation, as described by IGLC literature (Table 7).

Table 7: IGLC Innovation Model

Themes	Sub-themes
Strategy Essentials	Government Reform, Strategies for Adapting and Managing Innovation, Knowledge Management and Market Alignment
Drivers	Role of Client, Unique Project Requirements, Culture, Market Forces
Barriers	Boom-bust Cycle, Organisational Culture, Operations, Cost
Collaborative Efforts	Strategic partnerships, Construction firm networks, Adequate resources

The work of this paper contributes to an ongoing PhD research project that is examining the value of understanding and pursuing innovation in an holistic way, across the built environment disciplines. Holistic thinking enables firms to identify outside factors that can be valuable to consider When applied to the innovation process, holistic thinking can a targeted pursuit of more impactful innovation, and the increased economic growth it brings (Mazzucato, 2011). What this IGLC Innovation Model reveals is the importance to LC innovation and implementation when considered from a similarly connected and holistic standpoint. Such a perspective can consider the multi-factorial benefits of lean that sit across the value chain and work from the strategic level of business down to the operational benefits felt in projects.

When considered together, the themes and sub themes proposed in the IGLC Innovation Model shifts practitioner thinking away from an operational level, towards taking a broader approach to pursuing innovation. Such an approach is useful because the selection, analysis, and comparison of potential innovations for implementation can be informed by more-informed thinking. The holistic approach proposed in this paper encourages firms to devote time to strategising innovation through first developing capacity in knowledge management to build technological capacity, and recognising the important role of collaboration, through aspects such as construction firm networks, can play in achieving successful innovation implementation. This is alongside considering other aspects of innovation, that feature more prominently in construction innovation literature, like drivers, and barriers.

The emerging model proposes a way to consider innovation from an holistic standpoint in a LC-specific context and can be useful to managers to facilitate the adoption of LC, increase its uptake/utilising, or to explore specific technical process innovations that LC can support. The model can be used to assist firms in understanding wider factors, associated with innovation implementation. This can help managers to better make the case for both LC, and other innovation, within the wider construction sector.

The themes covered in the SLR present a guide, showing the relationship of LC to Innovation, revealing that innovation models already exist and are supporting LC, but also identify barriers and drivers of innovation. To increase uptake of innovation the final themes identify the need for a strategic approach and one that is inherently collaborative. The IGLC Innovation Model links LC and innovation. This is interesting because it represents a combination of two related efforts in the built environment, both broadly aimed at improving construction productivity. As the construction sector continues to evolve, the IGLC Innovation model can be useful to practitioners in guiding the adoption of innovation that meet the demands of future construction projects.

CONCLUSION

This paper examines the relationship between LC and innovation in the construction sector, utilising a SLR of IGLC proceedings from the last 25 years. The findings of the SLR were bundled into six key themes that represent the major contributions towards innovation theory from the perspective of LC scholarship. The findings are used to support positioning LC as a form of managerial innovation. The argument is made that this allows innovation theory to be utilised to help increase uptake through increasing an understanding about the role of LC for managers. The research uses the findings of the SLR to introduces an IGLC-specific Innovation Model, that is aimed at enhancing comprehension and increased uptake. Considering LC as innovation can allow for a greater body of research to be drawn upon to facilitate greater diffusion in industry. Correspondingly, augmenting built environment innovation theory with LC theory also sees a combined approach taken to boost innovation uptake. While a connection has been established, the research is limited by its theoretical nature. Further work is needed to strengthen the case for the IGLC Innovation Model. Empirical studies are needed to build-out the argument, and test the validity of the Model. This should be complimented with expert workshops to feed-in input from industry that can be used for further refinement, and help contribute to Lean Theory to improve productivity in the construction sector.

TAKT TIME PLANNING IN CONSTRUCTION AND ITS IMPACT ON THE WORK-LIFE BALANCE FOR INDIVIDUALS AND FAMILIES

Samuel F. Merrill[1], James P. Smith[2], Clifton B. Farnsworth[3] and Evan D. Bingham[4]

ABSTRACT

This paper explores the time management challenges in construction management, emphasizing the prevalence of crisis-oriented work, stress, and burnout. Integrating Takt Time Planning (TTP), a method that establishes production cadence, proves to be transformative in effective construction scheduling. TTP yields benefits like the establishment of flow, enhanced problem detection, and waste reduction. Despite a growing body of research on TTP, there is a notable gap regarding its impact on the ability of individuals to achieve and maintain a healthy work-life balance in the construction industry. The focus of this paper is to explore current research and literature to investigate the connection between TTP and its impact on work-life balance and emotional health. Through a literature review and synthesis of information, the authors identified a likely connection between TTP implementation and an improved well-being for construction professionals and their families.

KEYWORDS

lean, takt, construction, scheduling, work-life balance, family life

INTRODUCTION

TIME MANAGEMENT IN CONSTRUCTION MANAGEMENT

Time management is a crucial aspect in the lives of construction managers because it enables the manager to prioritize their tasks, improve their productivity, and by so doing, reduce their stress and maintain a healthy work-life balance (Jex, et al., 1999). In the popular book, *The 7 Habits of Highly Effective People*, Covey presents the notion that all tasks can be categorized by two factors: urgency and importance. To help his readers visualize this concept, Covey used an Eisenhower Matrix (Refer to Figure 1) to show how and where people spend their time.

According to Covey, those who are most effective at time management spend much of their time in quadrant two and spend as little time as possible in the other quadrants (Covey, 1990). Construction managers, however, tend to find themselves spending the majority of their time in quadrant one. This is especially true once their project falls behind schedule. In the book, *Construction Scheduling: Principles and Practices*, Newitt writes that oftentimes project managers "…go from crisis to crisis, with the project managing them rather than them

managing the project…Most managers tend to live and die in quadrant one" (Newitt, 2009, p. 7).

Newitt elaborated on this concept further when he went on to write, "One of the major concerns with construction managers is the total control that projects seem to take over the manager's life. It is not uncommon for project managers to find themselves consumed by a project. Many work 60 to 80 hours per week, with 65 to 70 hours the standard. These long hours, in addition to the associated pressures of meeting the project objectives, tend to take their toll on managers. This type of lifestyle, if it continues over several years, threatens not only the personal health of the manager but also the manager's relationship with his or her family. "Burnout" is a problem in the management circles of many construction companies. As stated earlier, the key is to learn to control your projects so they do not control you." (Newitt, 2009, p. 8)

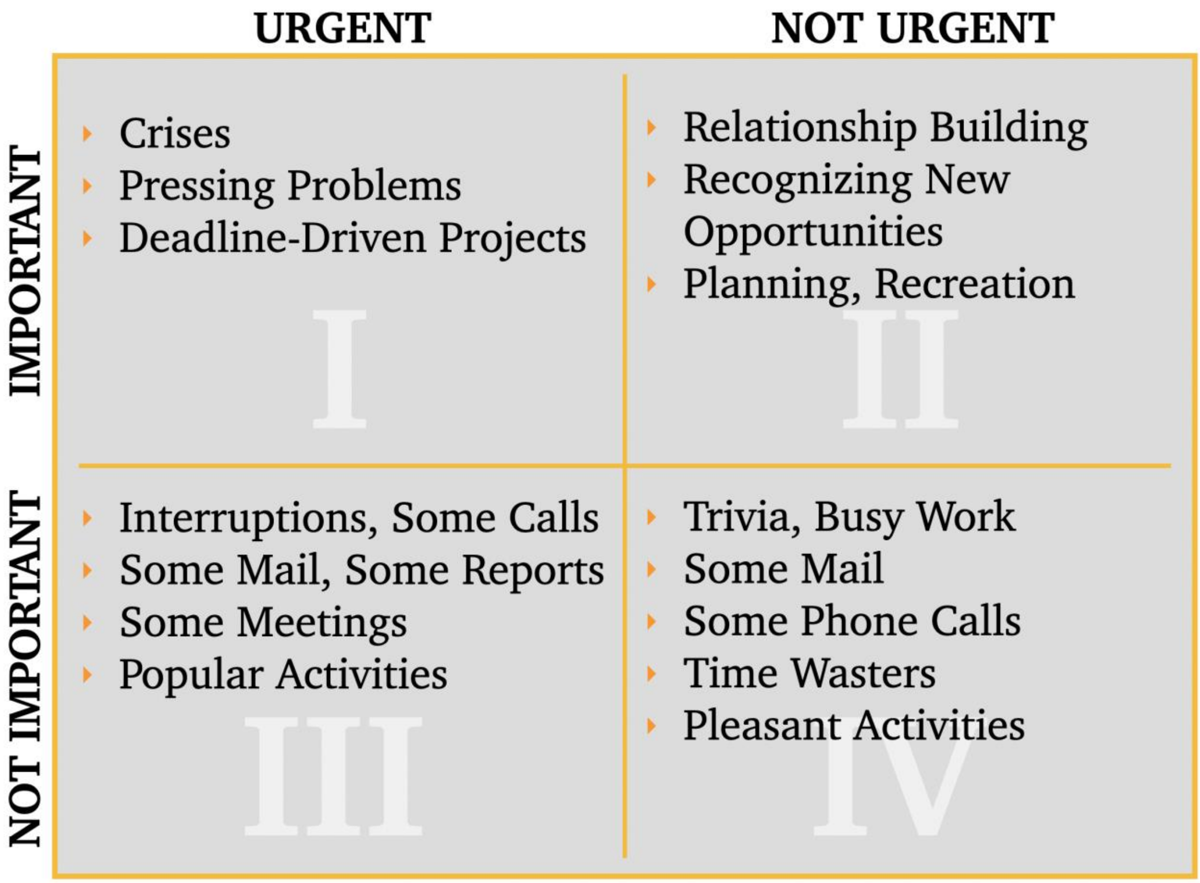

Figure 1: The Time Management Matrix (Covey, 1990)

The main means by which construction managers control the various aspects of their projects is through effective scheduling. Scheduling is the primary tool for organizing, coordinating, and communicating the planned methods and procedures that will ensure project objectives are met and accomplished. While good scheduling establishes a structured and controlled process for which the necessary tasks are to be accomplished, effective scheduling seeks to establish a process that enables the project to be completed in the most productive manner possible. Effective scheduling thus empowers managers to spend the majority of their time in quadrant two and less time addressing the crises and pressing problems that usually arise from ineffective scheduling.

TAKT TIME PLANNING

Takt time planning in construction is a work structuring method that aligns the production rates of trades by pacing work through a set of spatial areas in a set sequence. By so doing, project teams can create a continuous workflow, reliable handoffs, and an opportunity to continuously improve the production system (Frandson, 2019). When incorporated into construction scheduling and used in conjunction with principles from systems such as the Last Planner® System (LPS) and Scrum, Takt is a tool that project managers can use to shift their time and energy towards the more productive tasks of quadrant two. Takt Time Planning is a powerful instrument in the hands of the construction manager because it enables project teams to take control of their projects through the establishment of rhythm, consistency, and continuity (Binninger et al., 2019).

The word Takt comes from the German word 'Taktzeit' which means beat, rhythm, or cadence (Haghsheno et al., 2016). Takt refers to the cadence or regularity in which activities are to be completed. Since the early 1900s, Takt has been an important practice in the manufacturing industry (Tommelein et al., 2022). Takt is not a new method in the field of construction. In fact, the first recorded use of Takt, in the United States, was in 1930 when work commenced on the Empire State Building (Haghsheno et al., 2016). While reflecting on the speed and efficiency of the construction of this famous New York City structure, Flyvbjerg wrote that in "an era when people marvelled at the efficiency of factories churning out cars…the Empire State designers were inspired to imagine their process [for building the Empire State building] as a vertical assembly line – except that the assembly line did the moving …while the finished product stayed in place" (Flyvbjerg et al., 2023, p. xvi). Although the implementation of Takt into project schedules has been increasing in popularity (in the US) since the completion of the Empire State Building, Critical Path Method (CPM) continues to be the dominant method that is utilized in construction scheduling and planning. A survey conducted in 2003 found that 98.5% of the top 400 ranked contractors, in the construction industry, utilized CPM in their scheduling and planning needs (Kelleher, 2004).

Despite the benefits and widespread adoption of CPM, many construction companies still struggle to complete their projects on schedule. One publication reported that large projects typically take 20 percent longer to finish than originally scheduled (Agarwal et al., 2016). While another study, conducted by Dodge Data & Analytics, found that a staggering 61% of typical projects finish behind schedule (Lean Construction Institute, 2024). While CPM is useful in visualizing a project's workflow it does not enable project teams to clearly see and manage the project's trade flow (Kujansuu et al., 2020) and logistical flow (Tommelein et al., 2022). As shown in Figure 2, TTP allows for the visualization of and control over all three types of flow.

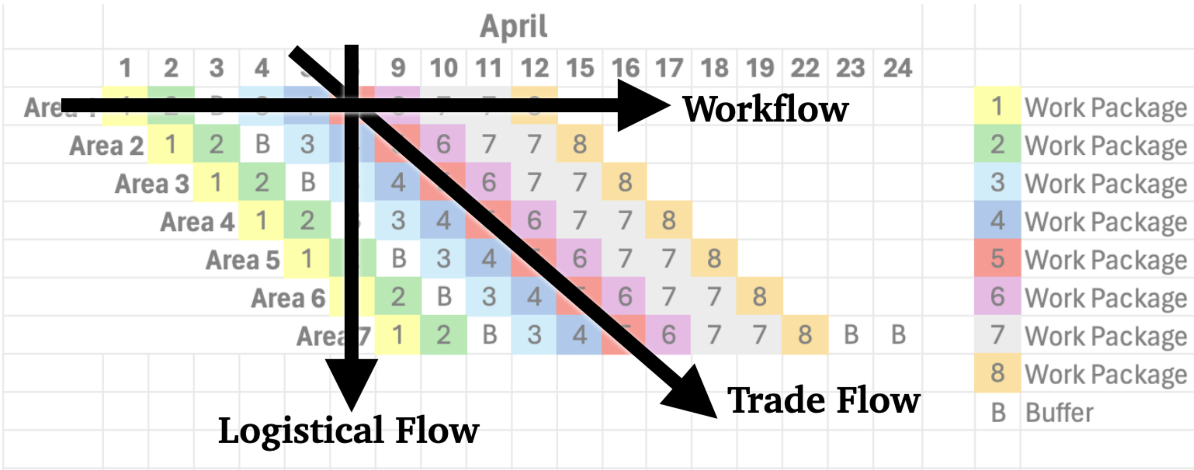

Figure 2: Types of flow that are visible and manageable when using TTP in a schedule

This paper is a literature review that is focused on exploring current research and literature surrounding the benefits of Takt Time Planning. This is done in an effort to investigate and better understand a possible connection between TTP and improved emotional health/work-life balance for construction managers. While TTP likely produces similar results for the tradesmen or labourer in the field, this paper only focuses on the relationship between TTP and project management (project managers, superintendents, foremen, and project/field engineers).

LITERATURE REVIEW

METHODOLOGY AND OVERVIEW

To investigate and better understand a possible connection between TTP and its impact on the work-life balance and emotional health of project managers, the authors explored current research and literature discussing the benefits of TTP. Over one-hundred and ten papers were reviewed that discuss TTP in construction. It's worth noting that of those papers, ninety-seven were published in an IGLC conference. An additional thirty papers, examining the topic of work-life balance, were also reviewed.

When reviewing the papers discussing TTP, abstracts were read and any mentions of a benefit surrounding the use of TTP in construction were recorded by tallying a table. Those papers were then read to ensure that the paper examined one or more benefits of TTP. The authors found that twenty-eight papers specifically addressed benefits of TTP (Refer to Figure 3). A breakdown of those papers, into broad categories, is as follows: 35% improvement to flow and duration, 18% improved communication, 18% enhanced problem detection, 14% improved accountability, 11% increased waste reduction, and 4% improved jobsite cleanliness.

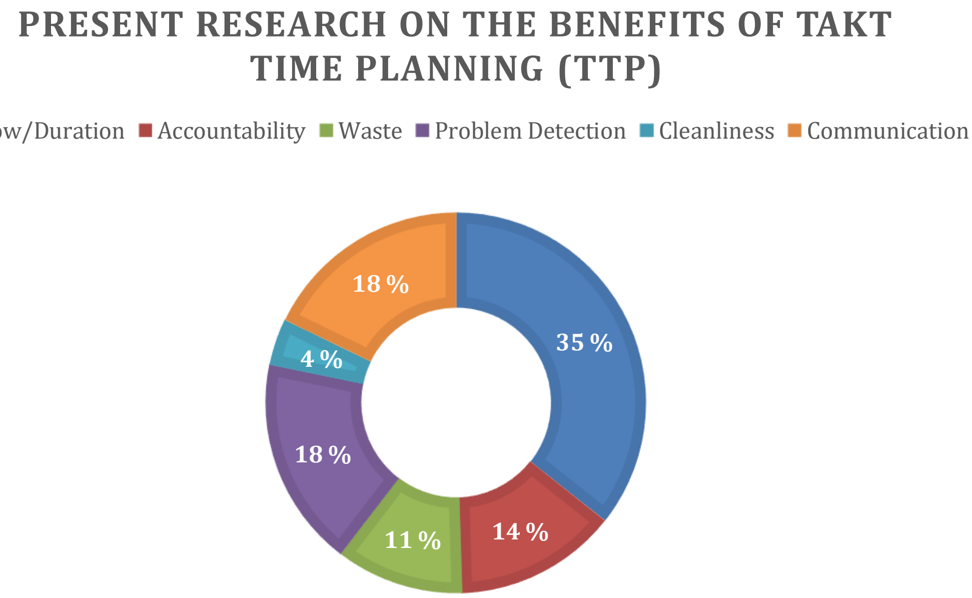

Figure 3: Research papers addressing the various benefits of Takt Time Planning

Researchers seem to have spent substantial efforts and resources exploring the benefits of TTP. For example, as TTP takes advantage of several production laws and principles, including Little's law, the law of Bottlenecks, the law of Variation, and Kingman's formula (Modig et al., 2011), it has been possible for researchers to demonstrate the mathematical underpinning and theory behind the application of TTP (i.e., Wardell, 2003).

BENEFITS OF TTP

During the review of existing literature, on Takt Time Planning, eight key advantages or benefits were identified by the authors. The existing body of research does not, however, make any connections between the use of TTP and an improved work-life balance for project managers. The eight identified benefits of TTP are:

1. Establishes Trade and Logistical Flow

   By activities being worked on at the same rate and work areas released at standardized times and at a sustainable pace, trade flow is established (Kujansuu et al., 2020). Aspects such as pull planning, buffering, levelling, and packaging help to establish realistic and sustainable project durations. When aspects of the Last Planner® System (LPS), such as weekly work planning and pull planning, are used in conjunction with TTP, workflow reliability is established and the handoffs between the trade partners are defined (Ballard et al., 2021). As TTP makes the logistical flow of the project more visible to project management, logistical challenges can be planned for and addressed (Tommelein et al., 2022).
2. Enables One-Process Flow

   If work areas are released to only one trade at a time, a ‘finish as you go’ approach becomes the standard. This minimizes ‘work in progress’ (Faloughi, et al., 2015) and can result in higher expectations for quality/craftsmanship and fewer rework/punch items. Fewer rework/punch items often result in fewer schedule delays, costs, and unnecessary movement of the trades.
3. Enhances Problem Detection

   Problems, anomalies, and issues are easy to identify in the visual organization of TTP. TTP highlights what needs to be done and what stands in the way of completing those tasks (Frandson et al., 2014). As problems are detected earlier, in what is known as a ‘Make Ready Process’ (MRP), a culture to address issues before they become a problem is established (Frandson, 2019). An increased standard of accountability for all members of the project reinforces the practice of early problem identification and remediation.
4. Establishes Accountability

   As TTP clearly outlines the work/trade/logistical flows, trade partners can be held accountable for material procurement, adequate worker counts, and meeting the established production outputs. Because of the increased transparency in the construction process, for all parties, (Dlouhy et al., 2016) the general contractor can track the project’s progress and review key indicators with their trade partners to identify shortcomings and encourage improvement and ownership.
5. Reinforces Healthier Project Durations

   TTP is based upon mathematical production equations and production laws (Tommelein et al., 2022). These laws and principles (combined with the implementation of buffers/pull planning/levelling/packaging) create realistic project durations that can be held and maintained. Through the optimization that comes from the production laws and principles, the overall project duration can be reduced significantly. In a recent case study, TTP was able to reduce the, “planned and actual construction durations up to ~70% of the total work days” (Apgar et al., 2023).
6. Reduces Waste

   The construction industry is a big culprit when it comes to waste. The industry often struggles to fully conceptualize the true extent of the waste that it generates (Viana et al., 2012). Typical forms of construction waste include material, time, and money. Excessive material inventory and storage on jobsites, is one common predecessor to waste generation. Time can be wasted as workers spend extra time sifting through materials in order to find the right material and/or because of improper staging they will spend extra time moving materials around in order to gain access to the needed materials. Waste of material can occur because materials are more likely to become damaged, stolen, or temporarily lost amongst the other materials and/or materials are thrown away more readily because of the natural perception that there is still plenty of available material. Excessive material storage often results in waste of financial resources as it costs money to remedy damaged, stolen, or misplaced materials. Additionally, extra man hours are needed to organize/find/access materials. TTP enables contractors to enforce 'just in time' delivery. This ultimately increases worker productivity, supports jobsite cleanliness, and decreases project waste. (Kujansuu et al., 2020) When materials arrive only when needed, variability is decreased and the stability of the production is increased (Haghsheno et al., 2016).

7. Increases Jobsite Organization/Cleanliness

   TTP is a location-based schedule. At times, project managers will arrange for multiple trades to work in the same area at the same time. However, TTP can be used to sequence trades to flow from one area to the next and in such a manner that the trades are never working in the same area as another trade. Therefore, each trade is solely accountable and responsible for the zone (area) they are in. As such, trades can be kept accountable for maintaining jobsite cleanliness in their work areas. This is often done through a lean process referred to as the 5S's. Clean and organized workplaces have been proven to increase productivity and better the work environment (Sanchez et al., 2023). Clutter wastes time and hinders standardization. Clean jobsites not only help improve safety and satisfaction (for both the builders and those that have commissioned the building) but also improve productivity. Jobsite cleaning methods, such as composite cleans, will become unnecessary to implement.

8. Enhances Communication and Organization

   TTP schedules are easy to understand and interpret. As TTP gives the fieldcraft a transparent view of production, they will always understand where they should be working (Kujansuu et al., 2020). When TTP schedules are communicated, on a daily basis (with every trade partner), cohesion and coordination are greatly improved, unlocking the energy and potential of a unified team (Wandahl et al., 2023). Because the trade partners are equipped with the knowledge of what needs to be done and where, they can think and act for the benefit of the project as a whole.

LIMITATIONS OF TTP

It is important to note that several studies have recorded issues arising in projects utilizing TTP (Kujansuu et al., 2020). One such paper, reported that workers felt an increased amount of stress when TTP was implemented because of stricter timelines and workflows (Frandson et al., 2015). Another paper noted that while TTP results in greater efficiency, a failure to identify realistic construction rates resulted in significant schedule delays (Binninger et al., 2019; Apgar et al., 2023). While these types of papers cast some doubt on the effectiveness of TTP, other research papers have provided seemingly contradictory findings (Kujansuu et al., 2020).

Any methodology that improves time management, when implemented correctly, will likely have a positive impact upon work-life balance (ie the Last Planner® System). TTP is not the exclusive solution to improving work-life balance. However, the preponderance of research has found that implementation of TTP can be successful and is beneficial to the various parties involved in construction projects. In one study, where a Norwegian contractor had tested TTP on several of their projects, the employees were asked at project completion if they would be interested in using TTP on future projects. "They were unanimously positive, and wanted to contribute to making it work better. They realized that in order for TTP to work it is essential that everyone got on board with it…" (Vatne et al., 2016, p. 180). In addition to the importance of getting all parties engaged and bought in on the adaption of TTP, there are several other conditions that must be met before the implementation of TTP will be successful (Apgar et al., 2023). This includes appropriating proper efforts toward planning before the project commences and then dedication to monitoring, controlling, and making continuous improvements/adjustments during the execution of the project (Lehtovaara et al., 2022). Like implementing any new practice, one must expect a period of adjustment as project teams become familiar with the new processes and iron out the initial kinks. With time, the unfamiliar will transform into familiarity, and the adoption of TTP can be successful - leading to enhanced project efficiency and success.

WORK-LIFE BALANCE AND FAMILY LIFE

Maintaining a good work-life balance is a well-researched topic amongst government and educational institutions. Research by the Australian Government found that long hours of work have serious negative effects on the institution of the family, relationships, and society (Pocock, 2001). Research conducted by members of the University of Maryland concluded that "…regardless of how flexible employees' schedules were or how much responsibility they bore for home and family duties, the more hours a week they worked, the more work interference with family they reported" (Major et al., 2002, p. 434). Research suggests that long work hours are related to increased conflicts at the home, the workplace, and indirectly to psychological distress.

When a proper work-life balance is established and maintained, individuals have an increased ability to be healthy and productive in all areas of their lives. Identifying the ideal allocation of hours needed in order to establish a work-life balance is difficult to do. However, the general principle is that a surfeit amount of time spent at work will interfere with one's private life and vice versa, an excess amount of time spent in one's private life will interfere with work.

Maintaining a work-life balance is essential in preserving familial relationships and in the positive development of future generations. In a study submitted to the Queensland Department of Industrial Relations, the authors noted that long working hours restrict the number of hours that parents can spend with their children which may have a negative impact upon the emotional and intellectual development of the child (Pocock, 2001). The family is the basic unit and building block of society. Research has found that good family relationships aid parents when coping with stress, seeking to develop healthier habits, and/or growing their self-esteem (Thomas et al., 2017). As such, preserving a healthy family life is a worthwhile endeavor that ensures that individuals, communities, and nations will flourish and thrive.

Maintaining a work-life balance is also important for the individual. Hobbies, exercise, recreation, and personal/decompression time are all dependent on a work-life balance. Individuals who are able to pursue these aspects and areas of their lives will find that they will have more motivation, energy, focus, and patience at work. In the United Kingdom, sixty-one companies participated in a four-day working week pilot program. Out of the sixty-one companies that participated, fifty-six companies (92%) decided to continue the four-day work week after the pilot program had ended. Companies found that while business performance and productivity were maintained, their employees reported significant declines in burnout, stress, anxiety, fatigue, and improved mental and physical health (Frayne, et al., 2023). TTP benefits may have the potential to allow for the implementation of a four-day work week in the construction industry.

TTP and an Improved Work-Life Balance

The implementation of TTP in construction scheduling not only enhances project efficiency but it also likely plays a pivotal role in establishing a healthier work-life balance for construction professionals. As the relationship between TTP and an improved work-life balance has not yet been studied by researchers, at this time it is not possible to confirm such a correlation. Given the existing body of knowledge, it is possible to identify causality between effective time management and an improved work-life balance.

One of the fundamental reasons for the potential correlation, between TTP and an enhanced work-life balance, lies in TTPs ability to establish realistic and sustainable durations for project schedules. The careful planning and allocation of resources, through TTP methods, minimizes the likelihood of unforeseen delays and disruptions. TTP thereby reduces the likelihood that construction professionals will need to work extended hours to recover lost time. TTP helps project teams to focus on the important/nonurgent tasks before they become important/urgent (Refer to Figure 1). This proactive approach to project management helps foster a more stable work environment, enabling project teams to have the ability to allocate time towards their personal and family commitments.

Furthermore, TTP encourages an effective communication and accountability framework throughout the lifecycle of the project. Effective communication and coordination are crucial for addressing issues promptly. These efforts help avoid any last-minute crises that will often result in construction professionals working extended hours. The open lines of communication and coordination that are facilitated by TTP foster an engaging work environment, where everyone on the project is aware of the needs of the project and is empowered to identify and think through potential issues. This proactive approach to identifying problems allows for problems to be resolved before they are compounded and push project milestones to the right.

Taking into account the various advantages that TTP brings to the table, such as project optimization and efficiency, one can begin to see how TTP fosters an environment and culture that directly contributes to the improved well-being of project teams.

Current TTP Trends

As mentioned in the introduction, presently, TTP is an underutilized project management tool. This is unfortunate as TTP serves as a leukocyte that defends against project pathogens which lay dormant but, because of ineffective construction practices and error, often arise to wreak havoc upon projects and their teams (Love et al., 2009). While TTP has been growing in popularity, especially in European countries like Germany, (Haghsheno et al., 2016) it seems that the majority of contractors in the United States have yet to fully embrace the adoption of TTP as a standard practice in their means and methods. This includes all areas of construction: residential, commercial, industrial, heavy civil, etc. As many construction projects fall short of the project objectives, there is a need for contractors to more fully adopt and implement lean construction methods like TTP (Högnabba, 2021).

Additional Benefits Of TTP

Researchers have recently begun studying mental health in the construction industry. One such researcher noted that, “The construction industry is particularly vulnerable to mental health issues, as the [construction] environment contains many occupational stressors such as: high production pressures, dangerous work, [and] complex decision-making” (Sherratt et al., 2018; Oswald et al., 2019, p. 1050). As mental health and well-being have been linked to a healthy work-life balance, TTP will likely emerge a critical tool in future efforts to improve the mental health and well-being of individuals in the construction industry.

In the same manner of increasing accountability between the general contractor and their trade partners, TTP also has the potential to improve the accountability between the contractors and the project owners. Research has found that, "Negotiating a fair and concise contract minimizes ambiguities and consequently, reduces disputes. As such, the contract serves as both sword and shield - a sword to enforce action and compliance when necessary, and a shield to prevent straying from agreed work scope and obligations" (Ottesen et al., 2015, p. 4). TTP both sharpens the sword and hardens the shield. Schroeder highlighted this when he wrote, "Unaccountable people, teams, and companies want roadblocks hidden so they can more easily transfer blame and costs. Accountable people, teams, and companies will love Takt planning and knowing the truth in bringing roadblocks to the surface so we can manage around them as a team…" (Schroeder et al., 2021, p. 13). TTP brings to light the actions (or inactions) of the party that interrupted the project's flow and caused a delay in schedule and/or an increase to the project's cost. TTP encourages all parties to collaborate in a Make Ready Process so that roadblocks and issues can be identified and addressed before they become a problem. This ultimately shifts project teams from reacting to crises (quadrant one) to being proactive and focused on the tasks of quadrant two.

CONCLUSION

While conducting a comprehensive review of existing research on Takt Time Planning, the authors identified eight core benefits associated with its implementation. Although the benefits of TTP have been well-documented, there is a notable gap in academic research concerning the positive effects that TTP has on individuals, families, and work-life balance. Establishing a direct connection between TTP and the assumed benefits of improved personal/family life and work-life balance is challenging due to the numerous external factors. However, as further research is conducted and data is collected, a compelling argument will likely be constructed that links reduced working hours (from the use of TTP) to an enhanced family life and work-life balance. A carefully designed survey conducted on subjects using TTP, to its capabilities, will likely find a reduction in normal working hours. Further research could then confirm any correlation between TTP and the improved well-being of individuals and families who are involved in projects utilizing TTP. As developers, owners, investors, general contractors, trade partners, and members of the construction industry in positions of influence and power better understand the implications of adopting Takt Time Planning for their employees and those in their stewardship, it is the hope of the authors that they will see TTP as an essential component of effective project management and adopt it into their standard operating procedures and contracts.

ACKNOWLEDGMENTS

The researchers wish to give heartfelt thanks to their peers, friends, and families who supported this endeavor to improve the work-life balance in the construction industry.

THE DESIGN-CONSTRUCTION COMMUNICATION LOOP: A CONCEPTUAL MODEL FOR COMMUNICATION ERROR ANALYSIS

Frode Drevland[1] and Fredrik Svalestuen[2]

ABSTRACT

The paper introduces a novel conceptual model designed to analyse and mitigate communication errors within the design-construction interface of construction projects. Recognising the complexity of communication in construction projects, the model integrates three foundational theories: Koskela's Transformation-Flow-Value (TFV) theory, Gero's Function-Behaviour-Structure (FBS) model, and Shannon and Weaver's communication theory. This interdisciplinary approach allows for a comprehensive examination of the information flow between the design and construction processes, highlighting potential transformation and flow errors at each stage. The model categorises errors into transformation errors, intrinsic to specific processes, and flow errors, which result from upstream issues, providing a framework for targeted quality control measures and root cause analysis. However, the model acknowledges its limitation in addressing the temporal aspects of communication, a critical factor in construction project management. The paper argues that, despite this limitation, the model offers significant insights for academics and practitioners by providing a structured method to identify, analyse, and address communication errors, thereby enhancing the efficiency and effectiveness of information exchange in construction projects.

KEYWORDS

Lean construction, theory, construction communication, information flow

INTRODUCTION

Studies from around the world point to poor and lacking communication as one of the main culprits for various issues in construction projects – including being a leading cause of delay (Doloi et al., 2012), rework (Yap & Tan, 2021), dispute (Gamil & Abd Rahman, 2022), poor productivity (Al-Rubaye & Mahjoob, 2020), as well as one of the main barriers to the implementation of sustainable construction (Susanti et al., 2019). Other studies point to the unique characteristics of construction projects - such as their complexity (Cakir et al., 2022) and having a multicultural workforce (Loosemore & Lee, 2002) – being the cause of significant communication issues.

While there is no lack of literature pointing to communication as a substantial issue for the construction industry, there is generally a dearth of research on communication in construction projects (Emmitt et al., 2009). In the literature review leading up to the paper, we found few papers reporting in-depth empirical studies nor trying to develop any further theoretical understanding of communication issues in construction projects.

In the lean construction community, authors often mention communication. However, little of the published research is primarily concerned with communication issues. Of all the papers published through the Lean Construction Journal and the proceedings of the annual IGLC conferences, nearly eight per cent include the word “communication” in the abstract. However, less than half a per cent includes the word in the title.

Furthermore, lean construction-related papers about communication tend to focus on the practical use of concrete methods, tools or technologies for improving communication – such as Design Thinking (Spitler & Talbot, 2017), Last Planner System (Lagos et al., 2022), Stakeholder Management (Sosa & Torre, 2021), Design Metrics (Mulholland et al., 2022), and tablets (Aasrum et al., 2016).

Tools and technologies can undoubtedly alleviate communication issues. However, there are areas where they have fallen short. According to Dainty et al. (2007), the flow of information between the design and construction processes is a particular problem in the building industry. Even with newer collaborative contracts and faster communication with ICT- tools like BIM, the industry fails to rectify the problem. We would argue that this failure can be attributed to a failure to understand the communication taking place properly. Before developing tools and technologies to support communication better, we must clearly understand what is being communicated and the very nature of the communication process.

The advent of lean construction brought production science back into project management, and construction projects are now commonly referred to as production systems (Koskela & Ballard, 2003). We would argue that the design and construction processes of construction projects can be considered distinct but tightly coupled production systems. One produces an immaterial product – the design – and the other produces the physical manifestation – the built facility. Furthermore, we would argue that understanding the communication between the design and construction processes can require understanding the coupling between them from a production-theoretical point of view.

While several frameworks have been developed to support communication processes in the construction industry (Zerjav & Ceric, 2009), none consider such aspects. Common for them all is that they “are based on identifying a series of project phases in terms of communication’s form and content that is taking place during a particular phase”. We would argue that such models work well for prescriptive purposes – to define what information should be delivered, when, and how. However, they do little to help us understand or analyse communication errors in construction projects.

This paper introduces a conceptual model designed to serve as an analytical framework for identifying and addressing communication errors within the design-construction production system interface. This endeavour synthesises insights from three seminal theories across production, design, and communication: Koskela’s Transformation-Flow-Value theory, Gero’s Function-Behaviour-Structure framework, and the Shannon-Weaver communication model. Integrating these foundational models lays the groundwork for a comprehensive understanding of the flow of information and immaterial products at the critical juncture between design and construction processes.

The paper begins by describing the three foundational models. Subsequently, we articulate the development of our integrated model, the Design-Construction Communication Loop (DCCL), emphasising its capacity to elucidate the complexities and potential pitfalls in communication between the design and construction process. We then introduce a typology based on the DCCL, which categorises common communication errors at the design-construction interface. In the concluding sections, we explore the practical implications of the DCCL, highlighting its potential to improve information flow and project efficiency in construction. While we recognise the model's contributions, we also address its limitations, such as not accounting for time, paving the way for future research to refine and expand the DCCL's applicability.

FOUNDATIONAL MODELS

This section introduces the three fundamental communication, production, and design models. These form the basis of the Design-Construction Communication Loop (DCCL) model, detailed in the next section. We have chosen each model for its significant impact in its respective field, and together, they provide a solid framework for understanding communication between the design and production processes in construction projects. This section aims to succinctly outline the key features of these models, setting the groundwork for our integrated approach in the subsequent part of the paper.

PRODUCTION – THE TFV THEORY

Koskela's (2000) Transformation-Flow-Value (TFV) theory has been instrumental in shaping our understanding of production in lean construction, making it a natural choice for our model's foundation.

Koskela identified three distinct conceptualisations or views of production: transformation, flow, and value. He integrated these into the TFV theory, offering a comprehensive framework for examining production systems. The traditional view, which he termed "transformation", sees production as converting inputs into outputs, breaking down larger processes into smaller, optimisable parts. However, this view often overlooks non-value-adding activities like transportation and waiting, which Koskela addresses in the "flow" aspect. This second concept focuses on streamlining the movement of materials and resources, identifying and minimising waste.

The third concept, "value", challenges the potential sub-optimisation of focusing solely on transformation. It emphasises understanding and fulfilling customer needs, both internal and external, ensuring that each step in the production process contributes to the end goal.

Koskela extends the TFV theory to all production systems, including design work. He argues that design activities are transformations—designers turn customer needs into solutions. The flow in a design process is typically the flow of information between each designer, and the value aspect is a means to an end discussion between designer and customer.

COMMUNICATION – THE SHANNON–WEAVER MODEL

Communication theory is a diverse field encompassing various perspectives and models. Craig (1999) notes that while there are numerous theories, they generally align with one of seven traditions, each offering a different lens through which to view communication:

1. Rhetorical – Communication as a practical art of discourse
2. Semiotic – Communication as intersubjective mediation by signs
3. Phenomenological – Communication as the experience of otherness
4. Cybernetic – Communication as information Processing
5. Sociopsychological – Communication as expression, interaction, and influence
6. Sociocultural – Communication as the (re)production of social order
7. Critical – Communication as as discursive reflection

Of these seven conceptualisations, modern models for communication theory tend to belong to the cybernetic tradition (Craig, 1999). In the cybernetic tradition, communication is understood as the exchange of information and knowledge among individuals. – essential in complex building projects. While authors have proposed various refinements and variants, the existing models all track back to Shannon & Weaver's (1949) seminal work, *The Mathematical Theory of Communication*. Figure 1 shows their model.

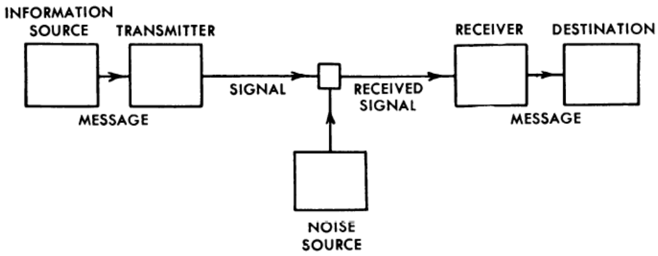

Figure 1: Schematic diagram of a general communication system (Shannon et al., 1964)

Shannon & Weaver's model, initially developed at Bell Labs, was primarily focused on the accurate transmission of signals, not necessarily as a comprehensive communication theory (Ritchie, 1986). However, it inadvertently became foundational in the field of communication, providing insights into both engineering and human interaction aspects. Despite its widespread application, the model has been critiqued for its limited capacity to fully represent human communication complexities (Heath & Bryant, 2013)

Addressing these critiques, various adaptations have been proposed over the years. This paper particularly references a variant by Kaufmann and Kaufmann (2009), which introduces significant modifications to the original model. The primary distinctions in this variant include a feedback loop and the recognition that noise can impact any part of the communication process, not solely the transmission channel.

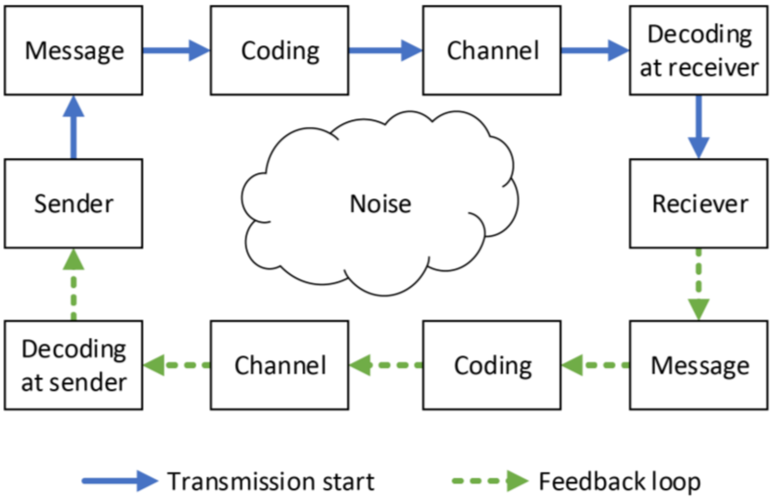

Figure 2 Components of the communication process (based on Kaufmann & Kaufmann, 2009)

Shannon and Weaver's original model centred on noise as information loss during transmission. Subsequent interpretations by other authors, such as Coupland, Giles, and Wiemann (1991); Fiske (1990); and O'Sullivan (1994), have broadened this concept to include losses due to faulty encoding or decoding. While different authors acknowledge the difference between noise in the channel and other noise (Brogan, 1974; Coupland et al., 1991; O'Sullivan, 1994; Pearson et al., 2005), there are no standard naming conventions. Since encoding and decoding are internal processes with the sender and receiver, this paper refers to noise affecting encoding and decoding as *internal noise* and noise affecting the transmission through a channel as *channel noise*.

Channel noise tends to be physical (O'Sullivan 1994). Common examples include background traffic noise during a conversation or sunlight obscuring a projection screen. Such noise is usually overt and can be relatively easily addressed. For instance, if a phone call is marred by poor reception, the receiver might suggest hanging up and calling back or switch to a different communication medium. Therefore, channel noise often leads to delays rather than direct errors, provided the communication process incorporates feedback mechanisms.

In contrast, internal noise encompasses a variety of more subtle interferences. One key type is semantic noise, defined by O'Sullivan (1994) as disruptions caused by differences in meaning. Differences in meaning can arise from language issues, such as inconsistent or ambiguous wording, or socio-cultural disparities between the sender and receiver, with professional jargon as a prime example. Another significant category is psychological noise, which pertains to interference from personal biases and assumptions (Rothwell, 2004). This noise stems from an individual's preconceptions and can significantly distort the intended message. Understanding and addressing both channel and internal noise is crucial for effective communication in complex environments like construction projects.

DESIGN – THE FBS MODEL

Design research, emerging formally in the 1960s and 1970s, initially grappled with significant challenges. According to Gero and Kannengiesser (2014), early efforts in this field were hindered by the lack of established terminologies and universally accepted concepts. Additionally, the prevailing perception among researchers was that design was a unique, irregular process lacking consistent patterns or principles.

This perspective shifted as subsequent studies delved deeper, focusing not just on the superficial aspects of design but on uncovering its inherent regularities. Researchers started recognising patterns and consistencies within the design process, moving towards a more structured and theoretical understanding of design as a discipline. This evolution marked a critical transition in design research, laying the groundwork for developing more refined and comprehensive design theories and models.

One of the foremost examples of this approach is the Function-Behaviour-Structure (FBS) model, conceived by Gero (1990). The model represents a significant leap in conceptualising the design process, offering a framework that deciphers the ontology of design across various applications. The FBS model has evolved considerably since its initial introduction. This paper defers to the version of Gero and Kannengiesser (2014).

The Function-Behaviour-Structure (FBS) model, as depicted in Figure 3 and elaborated by Gero and Kannengiesser (2014), provides a systematic approach to design. It begins with identifying the purpose or requirements (R) of an artefact, for example, a building. Designers then determine the functions (F) the artefact needs to fulfil these requirements. The design process's ultimate goal is to create a comprehensive design description (D) that encapsulates these functions.

However, the FBS model posits that a direct transformation from function to description is not feasible in a design system. Before developing a description, there must be a defined structure (S) – a detailed arrangement of the artefact's components and their interrelationships. For example, in architectural design, this structure includes elements like doors, windows, walls, and their spatial and functional connections.

A direct transformation from function to structure is rare and, according to Gero and Kannengiesser (2014), does not constitute design in the traditional sense; it is akin to selecting a ready-made solution from a catalogue. Instead, the design process involves deriving expected behaviours (Be) from the set of functions. These behaviours provide a framework for how the artefact should operate to fulfil its functions.

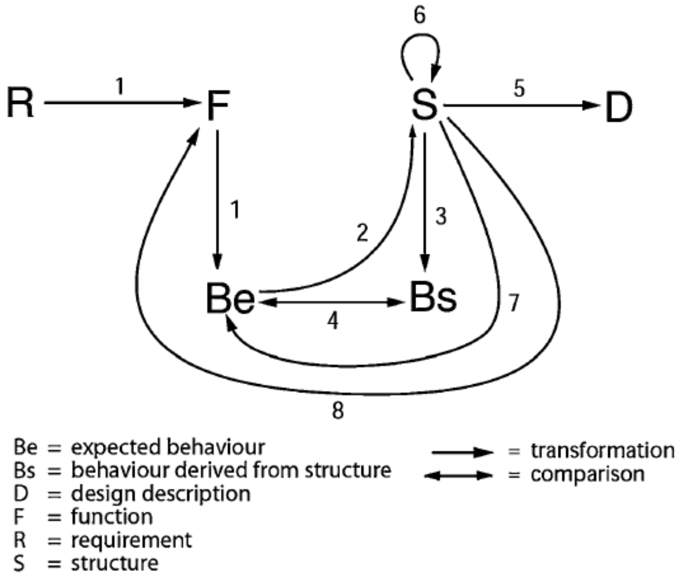

Figure 3: Gero's FBS-model for design (based on Gero and Kannengiesser 2014)

Designers then work on synthesising a structure that aligns with these expected behaviours. Once a structure is proposed, its likely behaviour (Bs) is analysed. If this actual behaviour aligns with the expected one, the design is considered successful, leading to the final design description (D). If not, the process involves reformulation, which may include iterating on the structure or revisiting the expected behaviours and functions.

The FBS model is outlined through eight key transformation processes:

- Formulation (R to F, and F to Be)
- Synthesis (Be to S)
- Analysis (S to Bs)
- Evaluation (Be compared with Bs)
- Documentation (S to D)
- Reformulation Type 1 (S to a revised S)
- Reformulation Type 2 (S to a revised Be)
- Reformulation Type 3 (S to a revised F, via Be).

THE DESIGN-CONSTRUCTION COMMUNICATION LOOP

We will start explaining the developed DCCL model by considering the relationship between design and construction using Koskela's TFV theory. The DCCL model considers both design and construction as transformation processes. The design process transforms customer requirements – including end-users needs and specifications from the construction process – into an intangible product, the building design. The construction process then converts this design into a tangible product, the physical building.

Key to this transition is the concept of flow, particularly in the movement of the design to construction. Unlike physical products, the design, an intangible entity, is transmitted not through physical means but via communication. Communication is the vital link between the design and construction stages, akin to a conveyor belt in a manufacturing setting.

The third aspect of the TFV theory is value. It might seem evident that the value produced by the design process is embodied in and equal to the drawings and descriptions the design process produces. However, we propose that these elements are better understood as communication artefacts. Design is about creating knowledge; thus, the actual product and value created lies with Gero's structure (S) of the FBS model. This idea implies that while designers may conceive an effective solution, translating or encoding this solution into drawings and descriptions is critical. This transition from Structure to Description in Gero's model is akin to encoding in communication theory.

This understanding leads to the DCCL model depicted in Figure 4, where various flow shapes represent transformations, actions, documents, and products. The model encapsulates the journey of a customer requirement being transformed by the design process into a solution, which the designer process encodes into a communicable form. The construction process decodes this information and transforms it into a physical product based on its interpretation of the communicated design. Importantly, this model emphasises two-way communication: the construction process also communicates back to the design team, potentially requesting new solutions or seeking clarifications, thus completing the design-construction communication loop.

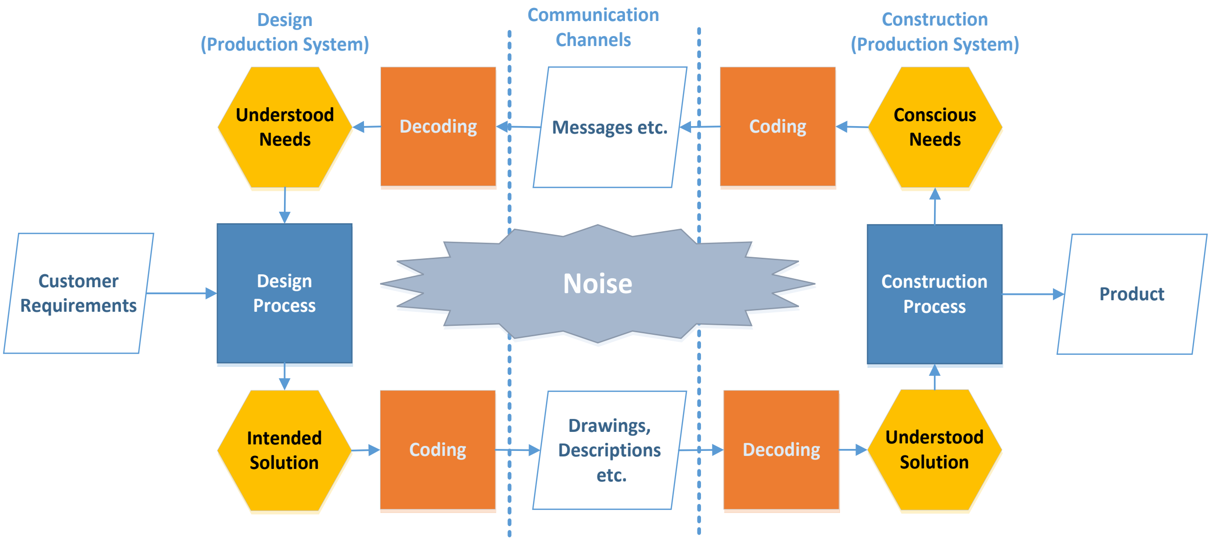

Figure 4: The DCCL model

The DCCL model has three main interconnected parts: the design production system, the construction production system, and the communication channels linking them. The model begins with the **Customer Requirements,** the needs and specifications driving the entire process. These requirements are akin to the Requirements (R) in Gero's FBS model and form the basis for the subsequent **Design Process**. It is important to note that defining these needs typically occurs in a pre-design phase, which is outside the scope of the DCCL model.

The Design Process transforms the Customer Requirements into an **Intended Solution**. This process mirrors the FBS model, where Requirements (R) are converted into a Structure (S). In other words, this step in the DCCL models phase encapsulates several steps of the FBS model, representing a high-level abstraction.

The Intended Solution, the output of the design process, corresponds to the Structure (S) in the FBS model. The next step, **Coding**, involves translating this solution into communicable forms like drawings, descriptions, or models, effectively serving as the transmitter in Shannon & Weaver's terms.

These outputs, **Drawings, Descriptions, etc.,** represent the media travelling through the communication channel. The channel varies, from face-to-face meetings to digital platforms like email or document servers.

The **Decoding** step is where the construction team interprets these transmitted designs. This process involves transforming the explicit design descriptions into an implicit understanding of the solution, laying the groundwork for the construction process.

The **Understood Solution** is the outcome of the decoding step, forming the basis for the **Construction Process** – the physical transformation of materials into the built facility, based on this interpreted design.

Conscious needs arise within the construction process, reflecting the team's need for additional information, clarifications, or modifications from the design team. These needs may range from requests for more detailed descriptions to identifying and addressing design errors.

Finally, **Messages etc.** represent the media used to convey these conscious needs from the construction team back to the design team, completing the communication loop and ensuring a dynamic, responsive process.

To illustrate the model with a practical example, consider this scenario: The project owner has a specific requirement for an elevator that can lift 10 people or 1200kg up three floors from the basement. This requirement is conveyed to the design team, which then transforms it into a detailed intended solution. The designers encapsulate their solution in a description using the most appropriate medium, such as a Building Information Modeling (BIM) model. This BIM model is then transmitted via a suitable communication channel, such as email or a shared digital server.

Upon receiving the BIM model, the construction team accesses and interprets the encoded data to understand the design intent. If the construction team finds the information sufficient and clear, they proceed with building the elevator. However, if there are perceived issues, such as missing details or impracticalities in the design, they will initiate a feedback loop. They articulate their concerns in a message, which is then sent back to the designers through a communication channel like email. Upon receipt, the designers decode the feedback and make necessary adjustments to either the design itself or its description, ensuring it aligns with the construction team's needs and clarifications.

This sequence of interactions highlights multiple potential points of failure that could lead the final product to deviate from the project owner's initial requirements. The following section will introduce a categorization scheme designed to help identify and address these potential discrepancies.

CATEGORISATION OF COMMUNICATION ERRORS

In the context of the DCCL, we created a typology for categorising communication errors between the design and construction processes, as detailed in Table 1. This categorisation framework identifies the different outputs from the model's stages and associates two primary types of errors with each output: transformation errors and input errors. This division draws from Hopp and Spearman (2011), who differentiate between process and flow variability.

Transformation errors, in our context, are those that originate entirely within a specific transformation process. They are intrinsic to the process in which they occur. For example, a flaw in the construction phase, such as incorrect implementation of the design, would be categorised as a transformation error

Input errors, on the other hand, are errors that are not inherent to the process itself but are consequences of preceding issues, i.e. somewhere in the preceedcing flow of transformations. For instance, a flaw in the final product might stem from a number of different upstream issues, such as a fundamental flaw in the initial design concept, or errors in how the design was communicated (encoded) in the design documents. Similarly, issues might arise during the construction phase due to misinterpretation (decoding) of the design documents.

Table 1 Typology of communication errors in the DCCL model

	Transformation	Input
Design process	Errors in transforming customer requirements and construction process needs into a viable design solution, such as design flaws or oversight of critical requirements; failure to recognise the need for additional information or clarification.	A well-executed design process, but based on misinterpretation, ambiguity, or omission of customer requirements and construction needs, leading to an incomplete or inadequate design solution.
Coding of Design Solution	Inaccurate representation of the design in drawings, descriptions, or models, such as incorrect details or omissions.	The intended design solution is correctly encoded, but the solution itself is inherently erroneous or incomplete.
Communication Channel (Transmission of Design):	Technical issues like data corruption or loss during the transmission of design documents.	Flawless transmission, but propagating errors from previous stages, such as transmitting outdated or incorrect design documents.
Decoding of Design Solution (Construction Process' Interpretation):	Misinterpretation or misunderstanding of the design documents by the construction process.	Correct interpretation of received design documents, but the documents themselves are flawed or incomplete.
Construction process	Errors in the physical construction process: E.g. implementation of the design, use of wrong materials, or construction faults; failure to recognise the need for additional information or clarification.	Correct execution of the understood solution, but the solution was misunderstood, degraded in transmission, inaccurately described the intended solution, or contained inherent design flaws.
Coding of Conscious Needs (Construction Feedback)	Inaccurate representation of the construction team's needs or issues.	The conscious needs are correctly encoded, but they do not represent the true needs of the construction process.
Communication Channel (Conscious Needs)	Technical issues in the transmission of needs, like data corruption or loss.	Propagation of errors from earlier stages, such as sending outdated or incorrect requests for information (RFIs).
Decoding of needs (Design Process' Interpretation)	Misinterpretation by the design process of the needs communicated by the construction process.	Correct interpretation of received needs description, but the description itself is flawed or incomplete.

By categorising errors in this way, we can more accurately pinpoint their origins and address them effectively. This categorisation can aid in distinguishing between errors arising from the inherent nature of a process (transformation errors) and those propagated from earlier stages (input errors), thereby facilitating a more targeted approach to mitigating communication errors in construction projects.

DISCUSSION AND CONCLUSION

This paper developed a conceptual model to serve as a framework for understanding and analysing communication errors at the interface between design and construction in production systems. Our approach integrated insights from three critical areas: production, communication, and design theory. This integration aimed to create a unified model that encapsulates the information flow dynamics between design and construction, an aspect not comprehensively addressed by existing models.

The DCCL model posits that the root cause of communication errors in construction projects often resides in complex causal chains. By dissecting these chains, the model helps academics and practitioners better comprehend and address these errors. The model can serve as a foundation for developing strategies and tools to identify and mitigate these errors, enhancing the efficiency and effectiveness of information flow between the design and construction processes. For example, we believe the model could be particularly beneficial for conducting root cause analysis of communication-related issues.

However, the DCCL model was developed using a purely conceptual approach. While we believe in its utility, empirical research is essential to ascertain its full applicability and effectiveness. Such research would involve validating the model in real-world construction projects and assessing its utility in identifying, analysing, and addressing communication errors. A crucial aspect of this validation is ensuring that the model has sufficient coverage to accurately capture and describe all communication errors across a variety of scenarios.

One known limitation in this regard is that the model focuses solely on the 'what' and 'how' of communication and does not consider the 'when.' Timing is a critical factor in the construction industry, where delays in communication can lead to significant inefficiencies and challenges (Gamil & Abd Rahman, 2022). Incorporating a temporal dimension into the model could provide a more complete understanding of communication dynamics in construction projects. However, doing so runs the risk of overcomplicating the model. A conceptual model is meant to “facilitate the comprehension or the teaching of systems or states of affairs in the world” (Greca & Moreira, 2000). Adding more aspects or details to the DCCL model likely makes it less suitable in this regard.

Nevertheless, excluding temporal aspects from the core model does not preclude their consideration in empirical research and practical applications. One possibility is to integrate the DCCL model with Value Stream Mapping, where each step of the DCCL could be mapped as processes or outputs on a value stream map.

In conclusion, the DCCL model presents a promising advancement in conceptualising information flow within construction projects. However, its potential to significantly impact the field hinges on rigorous empirical validation. The model's theoretical insights must be tested and refined through practical application and empirical research to ensure its efficacy and relevance in real-world settings. Such validation is crucial to substantiating the model's utility as a tool for enhancing communication and improving efficiency in the construction industry. This process will confirm its applicability and refine its components to better address the nuanced challenges faced by practitioners.

OPTIMIZATION OF DESIGN COORDINATION PROCESSES FOR A 7-STORY MULTIFAMILY BUILDING USING VIRTUAL DESIGN AND CONSTRUCTION (VDC)

Alvaro Enrique Merino Chocano[1], Diego Alfredo Fernández Bustamante[2], and Alexandre Almeida Del Savio[3]

ABSTRACT

Traditional construction and property companies often find themselves bound by conventional project management and design techniques, which can lead to delays during the design phase. This situation needs to be avoided. This study presents a process optimization for the design stage of multifamily buildings using Virtual Design Construction (VDC) - a collaborative project management approach. Focused on a case study involving two residential buildings developed by the same property company in Lima, Peru, this research commences with a comprehensive analysis of the existing design processes from the projects. By pinpointing key sources of variability and streamlining the design flow, the proposed VDC implementation aims to enhance compliance with project timelines and the approval of design drawings. The optimized process yielded tangible results, significantly reducing design time, completing tasks ahead of the scheduled deadline, and improving the delivery of technical files by 25%. These outcomes underscore the benefits of this optimized process, including enhanced project efficiency and improved design quality, thereby making a compelling case for applying VDC in similar construction projects by property companies.

KEYWORDS

VDC, BIM, collaboration, concurrent engineering, process optimization.

INTRODUCTION

The construction industry, a dynamic field where professionals always look for innovative tools and methodologies to streamline and automate processes (Hermida, 2022), has witnessed the emergence of a potential game-changer, Virtual Design and Construction (VDC). This approach, which involves a shift from traditional 2D drawings to a comprehensive 3D model that integrates all project information (Del Savio, 2018), holds the promise of revolutionizing the industry. The transformative potential of VDC becomes evident when an integrated team collaborates in creating and managing information and decision-making using this approach.

Despite the constant evolution of new technologies, traditional property companies have not fully adopted these changes (Cantó, 2017). Various challenges in the development of residential

3 Full Professor, Civil Engineering Department, Universidad de Lima, Lima, Peru, delsavio@gmail.com, https://orcid.org/0000-0002-6067-6606

building projects include, in addition to productivity issues, low design quality, inconsistent drawing production (Alvarez et al., 2021), incompatibilities between specialties (Bravo & Ramirez, 2019), lack of clarity in information (Almonacid et al., 2015), delays and cost overruns (Figueroa et al., 2021).

One key factor contributing to these issues is the deficient stakeholder communication during the design stage. The lack of efficient communication leads to delays as team members focus on individual objectives rather than project ones (Del Savio et al., 2022). Incompatibilities and team fragmentation hinder the maximization of project performance (Ma et al., 2018).

This study explores a collaborative management method to address previously discussed issues, focusing on the VDC methodology. VDC is a project management framework developed at the Centre for Integrated Facility Engineering (CIFE) at Stanford University, aiming to enhance the design, construction, and operation of projects via Building Information Modeling (BIM), Integrated Concurrent Engineering (ICE) and Project Production Management (PPM) (Del Savio et al., 2022). From a design perspective, VDC provides an integrated objective among the team, guiding them to the client's specific needs and generating production metrics to measure the results of the processes (Majumdar et al., 2022a). This involves delivering the project design on the agreed-upon date using BIM, ICE, and PPM (Majumdar et al., 2022b).

Motivated by the challenges presented within the construction sector, this work investigates the effect of implementing VDC to enhance stakeholder communication during the design coordination stage, aiming to reduce the overall time spent in this phase. The general objective of this research is to optimize the processes of the design stage for a residential building using VDC as a collaborative project management methodology. It involves analyzing the existing processes of the property company, identifying key sources of variability, and focusing on a more coordinated design flow to ensure compliance with delivery time and approval of the design drawings of the project.

This investigation starts by describing the methodology and the case study. Then, it analyzes the existing literature on VDC. Next, it explains the proposal for implementing VDC and its application in optimizing the design coordination processes in the case study. The results obtained from the VDC-based process were compared against the traditional process used in the former project of the property company under study. Finally, discussions and conclusions showed how VDC can enhance the design coordination process.

LITERATURE REVIEW

Fosse, Ballard, and Fischer (2017) investigated the benefits of utilizing collaborative work methods with digital tools and explored the factors driving this work and its limitations. The benefits of VDC implementation were measured using quantifiable metrics.

Kunz and Fischer (2020) examined the adoption of VDC in the construction industry and analyzed its economic impact. The study measured the benefits of using the VDC framework in the construction industry and assessed the global growth of VDC adoption.

Del Savio et al. (2022) provided an updated approach to the VDC methodology, offering a comprehensive review of current tools and methodologies. The approach is supported by its benefits related to client and project objectives, specifically regarding project costs and timelines. Implement VDC in a project starts from the client's objective, which is examined according to the relationship between the product (P), the organization (O), and its processes (P) within the POP matrix to create the foundation from which the VDC framework is developed (Del Savio et al., 2022). Once the framework's objectives are established, each component is studied in detail to develop production objectives, controllable factors, and metrics that enable the project to achieve its goals.

Balcazar et al. (2023) studied the construction process optimization of concrete structural elements using VDC, solving 60 possible clashes before construction. Quinteros Perez et al. (2023) studied the optimization of time in the processes of plumbing systems with VDC, reducing design time by 5% and execution time by 23%. Salazar et al. (2023) studied time optimization in diamond drilling operations in mining projects using VDC, resulting in a time optimization in operations of 10%. Barcena et al. (2023) studied optimizing the construction process time of a reinforced concrete reaction slab using VDC, resulting in a time reduction of 44 days. Palpan et al. (2022) studied a project's time reduction with an industrial process managed with BIM, resulting in a time reduction of 16%. Tuesta et al. (2022) studied the reduction of structural rebars' assembly time using VDC, resulting in a time reduction of 31%. Bustamante et al. (2023) proposed a VDC framework for curtain wall construction process optimization.

RESEARCH METHODOLOGY

This research is exploratory (Morales, 2015), analyzing the benefits of implementing a collaborative management methodology in the design stage of a residential building developed by a property company. The goal is to reduce variability and delays by identifying key optimization factors in the traditional workflow. This experimental research is quantitative (Babativa, 2017) and involves the implementation of the VDC methodology in a building project. The impact was measured through data collected using performance metrics. See Figure 1 to follow the research methodology.

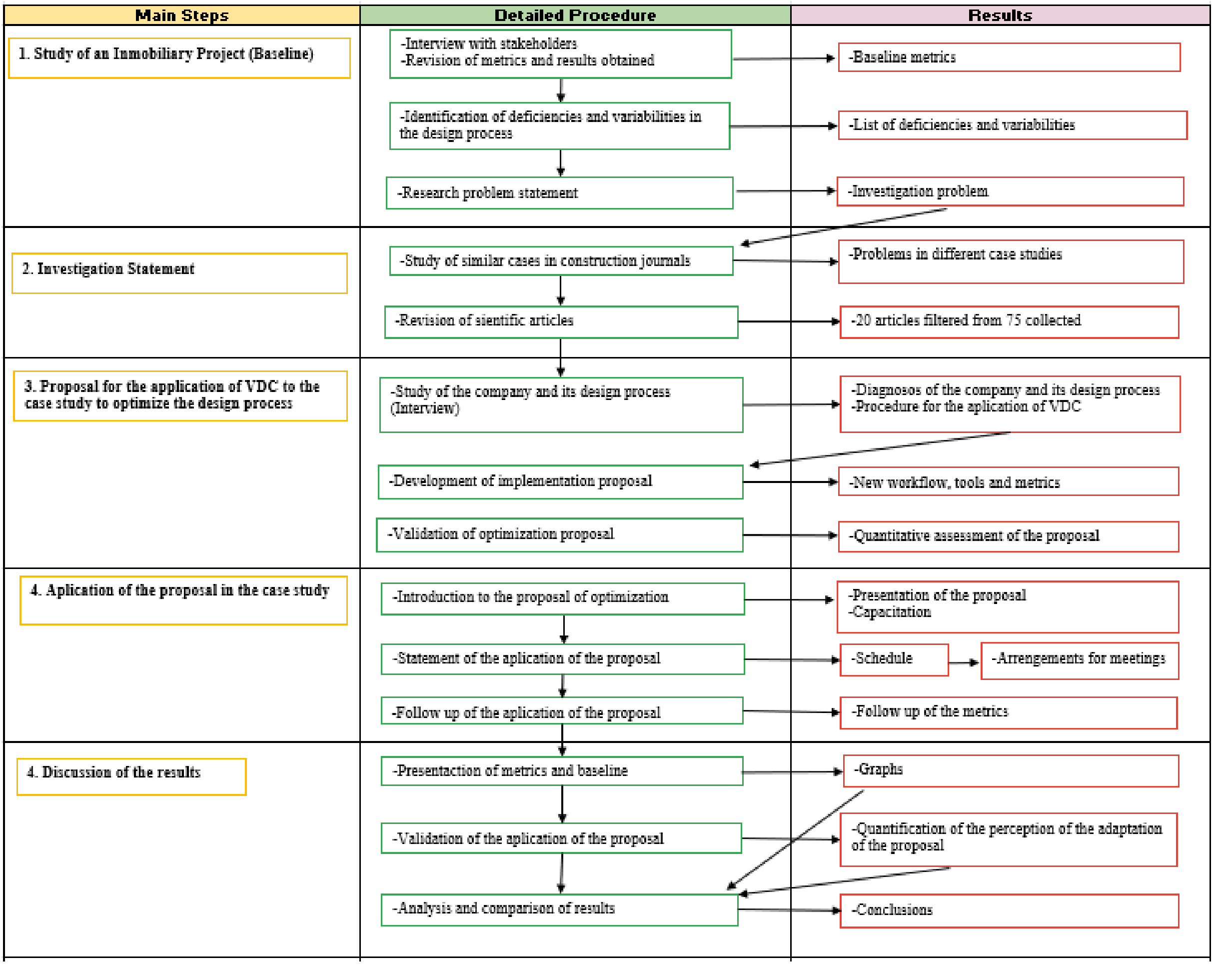

Figure 1: Research Framework.

To formulate the research problem, an in-depth examination of a building project in the design phase was conducted. Interviews with stakeholders, revision of metrics and results of previous projects, and identifying deficiencies and variabilities in the design process were carried out. The case study was initiated to test the hypothesis about a new company project. The development of a new workflow for project design began with interviews with the designers and project management teams to diagnose the current work methodology of the company.

For the optimization proposal, an interview with the construction manager, a Civil Engineer with more than 10 years of experience in building projects, provided insights into the company and its design process. A literature review of the VDC methodology applicable to the design process was conducted. Combining this review with interview data, an optimization proposal for the design process was crafted. The proposal started by elaborating a POP matrix and a VDC framework. The proposal was presented and then validated through a survey directed at participants in the design phase of the new project.

Following the proposal, a training process for staff and a schedule planning for the design process were executed. The planned changes in the workflow were implemented, and their application was monitored throughout the design stage with recorded metrics defined in the VDC framework. Performance metrics results were compared with those of the previous project to verify if improvements in the design process had occurred. The criteria for comparing both projects during their design phase included:

- Difference between approval of the preliminary project design and the delivery of the final technical file of the specialties involved in the design stage.
- Differences in drawing versions of the designers created to deliver the technical file.
- Difference in time between change requests from the company and drawing updates from the designers.

Finally, a survey was conducted to gauge the satisfaction levels of individuals involved in the design phase. Based on 13 questions, it provided valuable insights into the overall design process. In conclusion, a summary of the main findings about the improvements in the drawing delivery and stakeholders' satisfaction with the VDC implementation was presented, in addition to further research recommendations and limitations.

CASE STUDY

This study is based on two projects located in the district of Surco in Lima, Perú. Both buildings are residential projects from a property company that uses traditional methods, including 2D models for designing and coordinating their residential buildings and non-integrated working methods in their processes.

The projects are:

- A new project started in 2023 and finished in 2024. It has 7 stories, 2 units per story, and a land area of 1700 m2.
- A former project (benchmark project) started in 2021 and finished in 2022. It has 5 stories with 2 units per story, having a land area of 1900 m^2.

Both projects were carried out by "Venti Grupo Inmobiliario" (the Company).

RESULTS

The POP Matrix and the VDC framework were developed with the client and project objectives as its focal point and the production metrics table that guided the methodology implementation during the design phase. Subsequently, the obtained results for each component during the implementation were presented. Finally, a comparison was drawn between the results of the design phase implementing the VDC methodology in the new project and those obtained in the former project of the Company.

CLIENT AND PROJECT OBJECTIVES

As a result of the interview with the project manager, it was identified that the Company aimed to initiate the presale of the new project units to obtain bank financing for starting construction in August 2023. With this in mind, the project objective was identified as reducing the time of the design stage to achieve the final architectural design by June 2023.

POP MATRIX

The company's information was graphed and integrated into the POP Matrix, as shown in Table 1, to facilitate the client's objective of understanding its operation.

Table 1: POP Matrix for the new project.

	Function	Form	Behavior
Product	Final project design deadline delivery date: June 2023	Optimizing the effectiveness of project coordination by replacing the use of CAD drawings with a BIM model.	Successfully implement BIM to replace the traditional interference detection procedure (CAD).
Organisation	Start pre-sale campaign date: June 2023	Having increased effectiveness and reduced the time for plan updates.	Having resolved issues presented within an established time frame.
Process	Improve productivity in the design stage and reduce time spent	Having established a continuous flow of drawing production to meet the established schedule.	Meeting the deadlines for deliverables for the designers.

VDC FRAMEWORK

The information obtained and graphed in the POP Matrix supported the development of the VDC framework of component objectives. Figure 2 identifies the client and project objectives based on their needs, and the proposed uses of ICE, PPM, and BIM tools aim to integrate operations among stakeholders to accomplish these objectives.

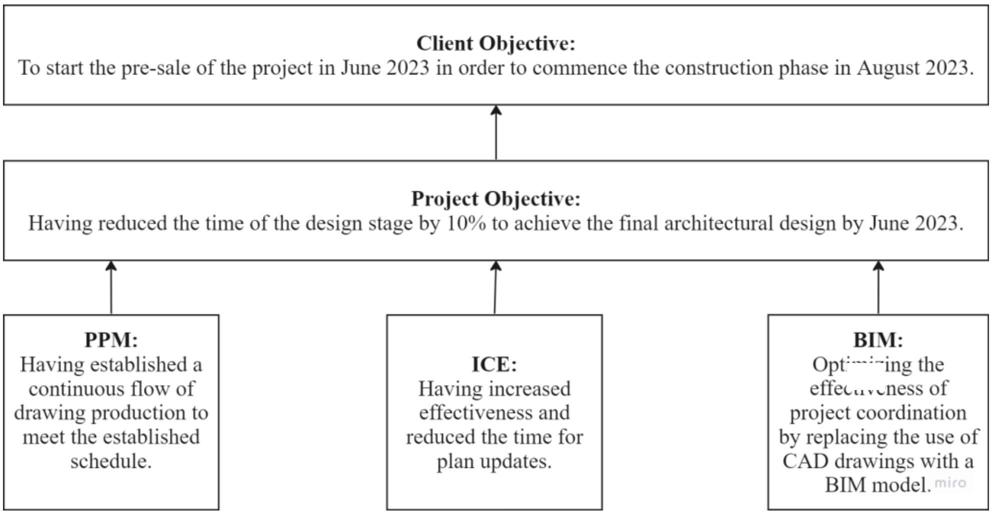

Figure 2: VDC Framework for the new project.

Next, Tables 2, 3, and 4 present the production objectives (PO) and controllable factors (CF) for PPM, ICE and BIM, respectively, along with their respective goals and sources of information.

PROJECT PRODUCTION MANAGEMENT (PPM)

Existing Process

The workflow was graphed based on the information the project manager gave in his interview (Figure 3). The timeline of the workflow is divided into three stages:

1. Planification: This stage's initial architectural design is carried out. This phase defines the provisional architectural design that serves as the basis for commencing the design of other specialties.
2. Stage 1: The process phase is where the specialty drawings are initially designed according to the architectural plan. Subsequently, the compatibility process begins. This process is repeated until the majority of incompatibilities and interferences are resolved.
3. Stage 2: This stage occurs after the technical file is delivered to the Municipality Office (responsible for the licenses to build) and continues until the start of construction. It may include drawing updates if required by the Municipality Office.

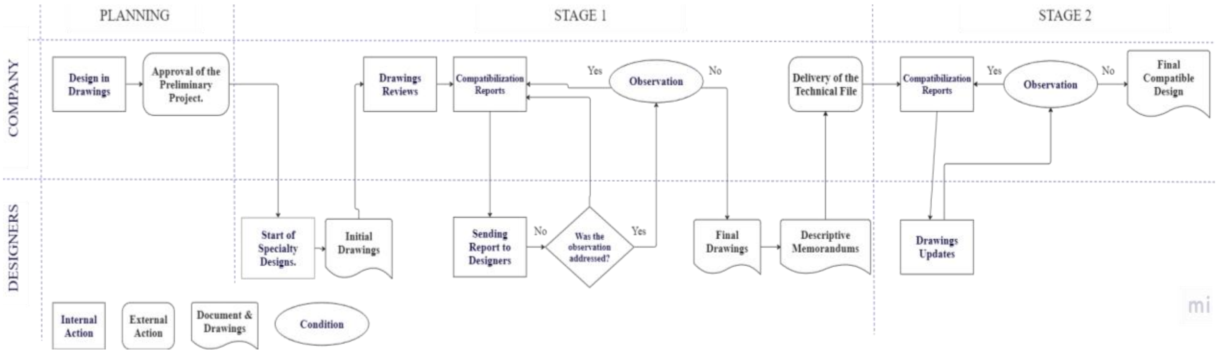

Figure 3: Traditional design workflow.

To initiate pre-sales ahead of schedule, it was necessary to reduce the time related to the design development. In the pre-sale context, obtaining architectural distribution drawings at the earliest opportunity became essential.

Proposed Process

Implementing VDC improved the design workflow using tools to enhance productivity at different process stages, as shown in Figure 4.

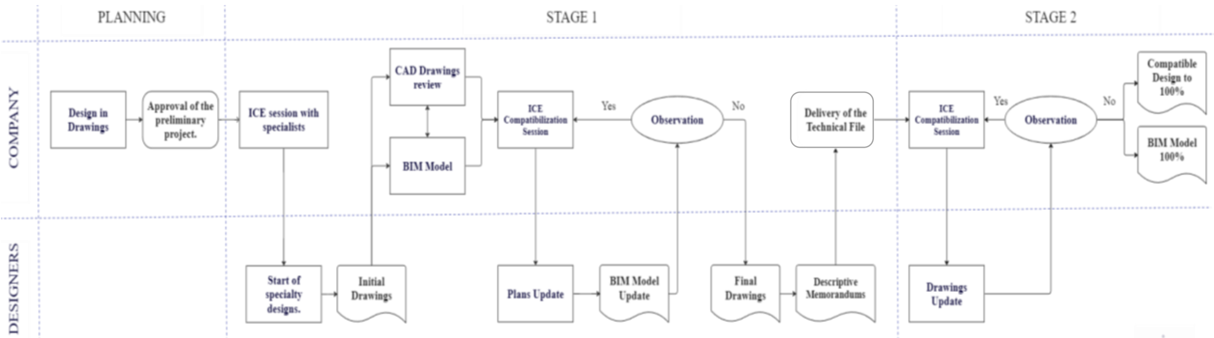

Figure 4: Improved design workflow with VDC.

The integration of the VDC methodology improved the design workflow. The proposal was presented to the Company and explained how it would improve the project's design stage. Then, the stakeholders were surveyed to validate the proposal, resulting in a 96% approval.

Utilizing a BIM model throughout the workflow allows for clarity in information among project members, enhancing coordination and information exchange in the process.

Additionally, using ICE sessions instead of email requests fosters an environment of integrated decision-making.

On the other hand, the PPM helped to complete the scheduled milestones. To achieve this, the production control was carried out using Lookahead and Takt-Time Planning tools (see Figure 5) to monitor activities performed by each designer. These activities were scheduled and worked in each ICE session. Tasks included updating drawings, preparing the descriptive memorandum, and addressing observations from non-executable tasks. The ICE sessions helped to coordinate the due tasks for the upcoming weeks and the delivery date deadlines for the design deliveries.

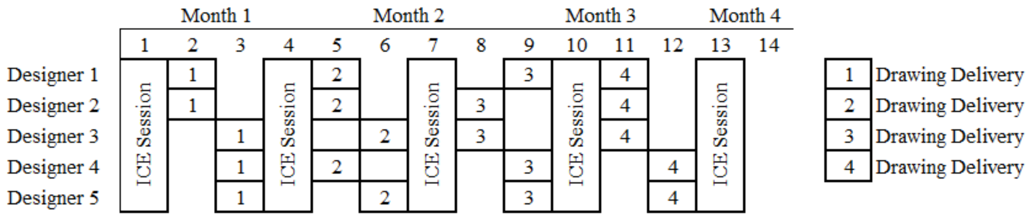

Figure 5: Takt Time Planning for task deliveries.

In the sequence, Table 2 presents the metrics table developed for the PPM component and Figure 6 shows the results obtained. The PPM production metric was tracked based on classifying the activities before the ICE sessions, which helped identify activities that could be addressed during the sessions.

Table 2: Summary of metrics for production objectives and controllable factors of PPM.

		Description	Metric	Target Value	Source of information
PPM	PO	Meeting the deadlines for deliverables from the designers.	Number of working days for the delivery of updated plans.	≥6 working days	Schedule
	CF	Classifying Lookahead activities into constrained and unconstrained activities.	Percentage of classified activities.	100% ± 10%	Lookahead

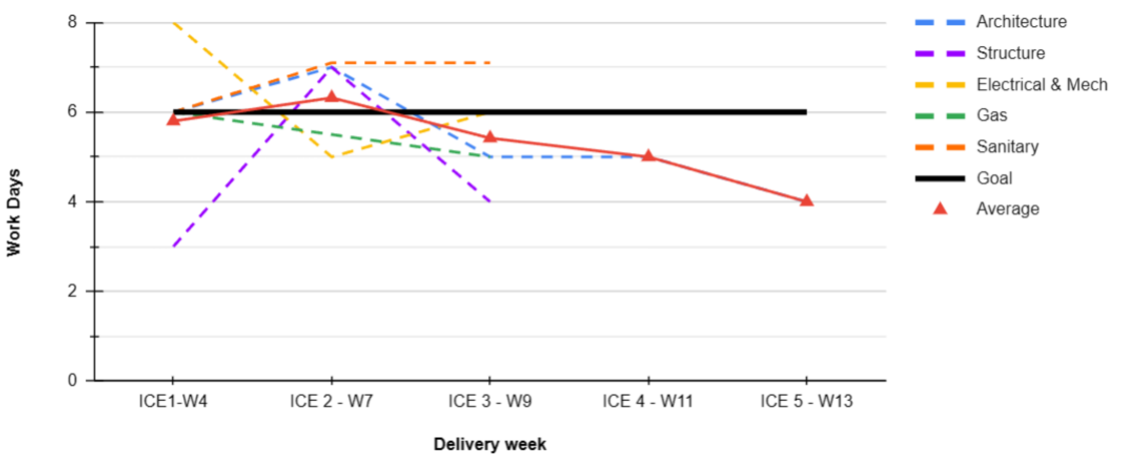

Figure 6: PPM Production Objectives: Drawings updated.

INTEGRATED CONCURRENT ENGINEERING (ICE)

Implementing ICE sessions helped to reduce issue-solve time latency by replacing email communication with sessions for real-time query resolution. These sessions were coordinated within the project management team and scheduled with relevant designers to address the decisions, such as interferences in the design.

The required information to carry out the session was provided to the designers at least three working days before the sessions, ensuring they could prepare potential solutions for discussed interferences and maximize session efficiency. Table 3 outlines ICE production metrics. To register the metrics, a control record document was employed to register all discussed issues and attendance.

ICE sessions were conducted in the project, including an initial ICE 0 session to introduce the project objective and schedule potential dates. The sessions lasted between 1 and 2 hours, during which observations were addressed, current progress was analyzed, and plans with the raised observations were scheduled.

Table 3: Summary of metrics for production objectives and controllable factors of ICE.

		Description	Metric	Target Value	Source of information
ICE	PO	Having resolved the scheduled issues during ICE sessions.	1. Percentage of issues resolved per session.	100% ± 10%	Interference Log
			2. Percentage of guest attendance.	100% ± 10%	Sessions Documentation
	CF	Working days in advance for the delivery of necessary information for the ICE session	Number of working days in advance for the delivery of information.	3±1	Emails with information submissions

Building Information Modeling (BIM)

BIM helped to maximize project coordination efficiency through powerful visualization and understanding of the project within the VDC framework. This was achieved using BIM to involve the comprehensive detection and solution of interferences in the design.

BIM implementation in the project focused on the Company's transition from CAD to BIM. To assess this shift, usage incidence was compared between the two during various ICE sessions throughout the design stage. Table 4 presents the production metrics for the BIM component. The number of 2D sheets modeled measured the progress of the modeled information, and the interference log kept track of the method for detecting the incompatibility.

Table 4: Summary of metrics for production objectives and controllable factors of BIM.

		Description	Metric	Target Value	Source of information
BIM	PO	Replace the traditional interference detection procedure with the VDC proposal.	Percentage of incompatibilities detected with the BIM model.	≥75% ± 10%	Interference Log
	CF	Generate a 3D LOD 300 model to detect interferences.	Percentage of modeled information.	100% ± 10%	Revit Model

Figure 7 shows the number and percentage of interferences identified by BIM and CAD tools. Since the second session, most interferences have shifted to be identified with BIM.

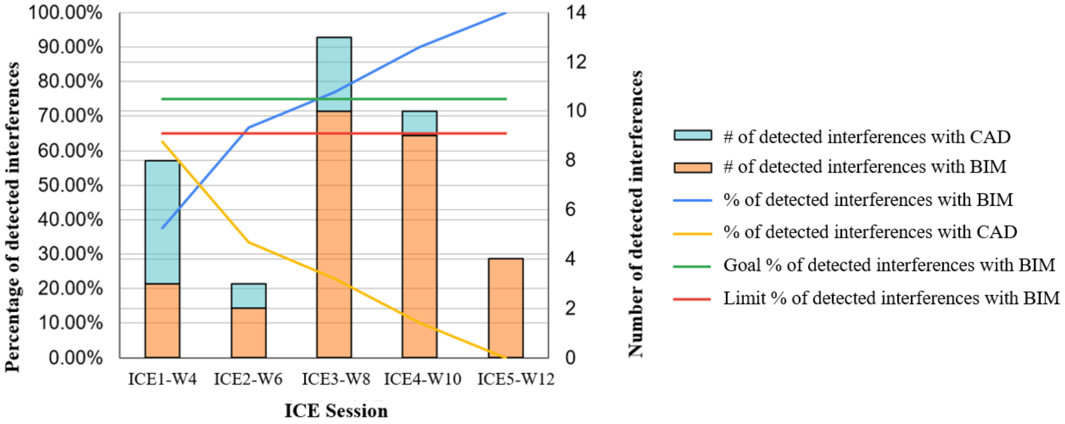

Figure 7: BIM Production Objective: incompatibilities detected.

Satisfaction with the VDC Application

Key project stakeholders were surveyed using 13 questions to evaluate the VDC application. As depicted in Figure 8, the findings show that the stakeholders expressed high satisfaction levels for nearly all questions - 12 out of 13 received the top satisfaction rank of 5 out of 5.

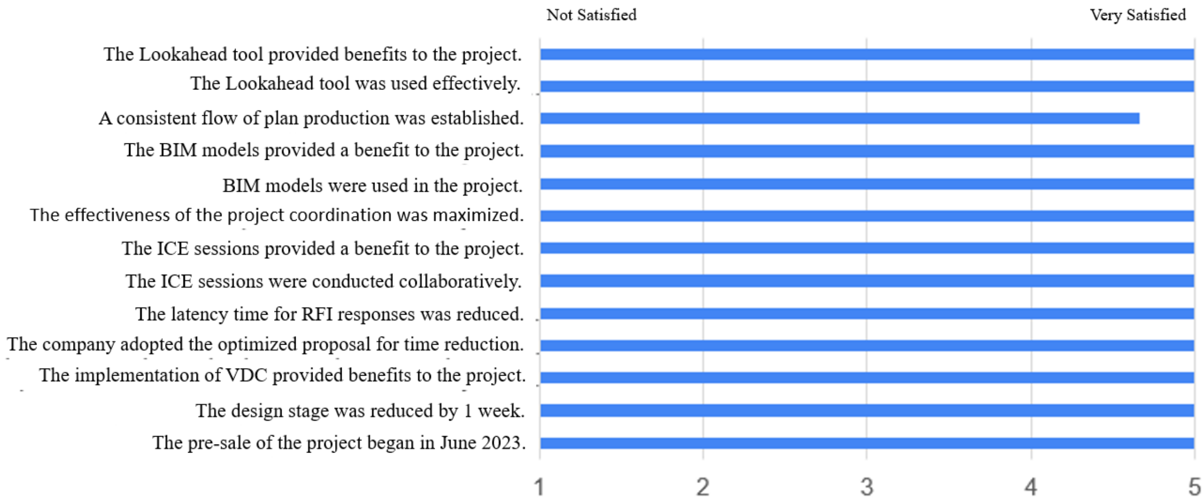

Figure 8: Stakeholder survey on the VDC application.

Comparison of Results

Figure 9 presents the average time required to update the drawings to assess the effectiveness of the optimized workflow for the new project using VDC compared to the traditional approach used in the former project.

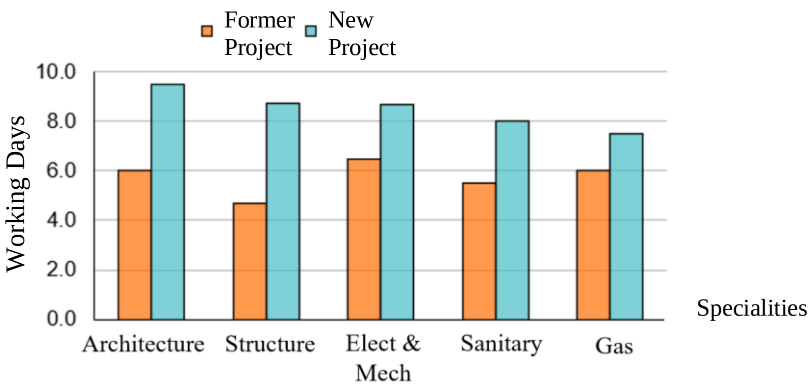

Figure 9: Average time comparisons to update drawings between the new and former projects.

DISCUSSION

The analysis of the Company's design process for the former project revealed the opportunities for improvement in several areas, including:

- Enhancing efficiency by minimizing downtime between email responses to expedite decision-making tasks.
- Streamlining the identification and solution of interferences to eliminate bottlenecks and facilitate a smoother project design process.
- Improving communication to reduce the need for constant redesigns of architecture and other specialties.
- Establishing clear information channels among participants to enhance overall clarity.
- Ensuring timely delivery of the technical files by addressing and mitigating delays in the planned schedule.

As for the results obtained, the production objectives were monitored throughout the design phase, looking to meet the objective and striving for continuous improvement. During the ICE sessions, issues were resolved using CAD or BIM. PPM production metric was tracked based on classifying the activities before the ICE sessions, facilitating identifying activities that could be addressed during the session.

The lookahead application was successful, achieving the 100% target for the controllable factor of classified tasks. This allowed identifying non-executable tasks and the respective coordination to ensure interferences could be resolved in the ICE session. In addition, a consistent production flow was maintained. Thus, achieving the goal of on-time deliveries on most agreed-upon dates resulted in a total compliance rate of 84%, above the minimum limit of 75% (see Figure 7).

The surge in BIM utilization exhibited a direct correlation with the percentage of project information that was modeled. The targeted percentage was achieved during ICE session 3 (week 8, ICE3-W8), as depicted in Figure 7, with the complete design being modeled. This contrasts ICE session 2 (week 6, ICE2-W6), where only 72% of the required information had been modeled by that point.

CONCLUSIONS

Implementing the VDC methodology has proven to be instrumental in enhancing the efficiency of the project's design stage, resulting in a remarkable 25% improvement in the time taken to deliver technical files. This notable achievement can be attributed to the systematic reduction of variability in the drawings update process, the effective identification and resolution of interferences through BIM, collaborative problem-solving in ICE sessions, and the establishment of standardized production timelines for updated drawings using PPM.

The proposed optimized process, designed for ease of use as a collaborative management tool, holds significant potential for property companies during the design stage. This is corroborated by the high satisfaction levels and adaptability expressed by the project stakeholders in surveys conducted on VDC implementation.

Furthermore, the pivotal role of BIM in detecting project interferences is underscored, with the degree of success directly proportional to the availability and modeling of project information. This proactive approach allows for the improved detection of most interferences in the project's early stages.

Emphasizing the critical nature of active stakeholder participation in ICE sessions, the research highlights the necessity of collaborative decision-making to resolve interferences promptly. The ICE sessions facilitate real-time problem-solving and ensure the timely updating of drawings, contributing to the project's overall success.

This research's main contribution is an optimized design process with VDC that can be applied in similar construction projects. It addresses construction industry challenges with the application of VDC and demonstrates its effectiveness in reducing design delivery time, resolving interferences and improving stakeholders' satisfaction.

This investigation is limited to projects and companies sharing similar characteristics. It is important to note that more complex and bigger projects can face different problems, and their application process could differ. The project's design phase schedule limited the resources and times for the proposal and the VDC framework application. Additional resources and time can enable the development of procedures and manuals for the current application.

For future investigations, it is recommended that an economic evaluation of the proposed implementation be conducted, which should include the additional costs and savings generated by the optimized process.

EXPECTATIONS AND PERCEPTIONS – DAILY MANAGEMENT MEETINGS IN DESIGN

Joonas Särkilahti[1], Olli Seppänen[2] and Eelon Lappalainen[3]

ABSTRACT

Daily Management (DAM) has generated many benefits in construction, but it has been less used and studied in design management. This case study of a Finnish structural design firm provides insights into the expectations of designers regarding DAM and Daily Management Meetings (DMM), as well as their perceptions during a short experiment on implementing DAM and DMM in daily structural design work. The research data for the case study were collected through interviews, observation, and a survey conducted with the company's larger structural design group. The main expectations of survey respondents and interviewees included improving the identification of design constraints, ensuring and enhancing the flow of information and increasing trust and team spirit. Interviewees who participated in the experiment highlighted the importance of being able to estimate their own workload and task duration, as well as gain improved knowledge of the concurrent work of other team members. Interestingly, in a larger group with many design managers, the benefit of improving the evaluation of each designer's workload was not anticipated as a significant benefit. This study contributes to highlighting DAM's implications for designers' self-management of their work.

KEYWORDS

Lean construction, construction design process management, daily management, daily management meetings, design management

INTRODUCTION

Efficient construction design process management (CDPM) is hindered by several different factors, such as poor communication among team members (Sousa et al., 2017; Galaz-Delgado et al., 2021), lack of trust (Uusitalo et al., 2019), inefficient information flow (Pikas et al., 2020), and insufficient knowledge of process' progress and others' work (Tauriainen et al., 2016; Svalestuen et al., 2018). These challenges can be mitigated by utilizing lean design management (LDM) (Tauriainen et al., 2016; Pikas et al., 2020; Fosse & Ballard, 2016).

An important part of lean-based management is daily management (DAM), which consists of many different tools, methods, and practices (Nicholas, 2018; Charron et al., 2014; Kennedy, 2019). One of the essential practices of DAM are daily management meetings (DMM) (Kennedy, 2019; Nicholas, 2018).

Daily meeting practices have been adapted and utilized in many different fields for a long time compared to the construction industry (Mariz et al., 2019). In recent years, the effects of DMM have begun to be more widely studied in the construction industry (Wandahl et al., 2023;

[1] Master of Science, Department of Civil Engineering, Aalto University, Finland, joonas.sarkilahti@gmail.com, orcid.org/0009-0000-1363-7957
[2] Associate Professor, Department of Civil Engineering, Aalto University, Finland, olli.seppanen@aalto.fi, orcid.org/0000-0002-2008-5924
[3] Doctoral Candidate, Department of Civil Engineering, Aalto University, Finland, eelon.lappalainen@aalto.fi, orcid.org/0000-0002-7573-344X

Zender & de Soto, 2021). Studies carried out in the construction industry have yielded many promising results regarding the benefits of DMM. There have, however, only been a few studies conducted in the context of CDPM (Lappalainen et al., 2022; Streule et al., 2016). While these studies have identified the positive effects of DMM, such as improved communication among design teams and enhanced detection of constraints, they do not specifically focus on the benefits and drawbacks of DMM. Both aforementioned studies, in addition to examining DMM, discuss various other practices and tools. This broad scope limits the extent to which the results can be attributed solely to the DMM. The aim of this study is to address this research gap.

DAILY MANAGEMENT

DAM is an important tool of Lean management (Liker & Convis, 2012). DAM aims for efficient process execution and monitoring and for the continuous improvement of operations (Kennedy, 2019; Charron et al., 2014; Nicholas, 2018). This is pursued via various tools, methods, and practices. Of these, the following are the most relevant and most discussed in the Lean literature: Appropriate Measures, Daily Management Meetings, Visual Management, Leader Standard Work, Problem-solving & Learning, and Tiered Accountability. (Kennedy, 2019; Nicholas, 2018; Charron et al., 2014; Liker & Convis, 2012; Gao & Low, 2014.)

According to Nicholas (2018) and Kennedy (2019), DMM is an especially important part of DAM. Nicholas (2018) also points out that the comprehensive implementation of DAM is a long process that changes the operating culture of the entire company. Therefore, it is not recommended to try to implement all the tools and methods of DAM at once; instead, the process should start by trying out individual tools, such as DMM, and adapting them to suit the company's operations (Nicholas, 2018).

DAILY MANAGEMENT MEETINGS

DMMs usually consist of briefly discussing the previous day's performance and possible challenges, as well as setting goals for the coming day and ensuring that the work can be carried out without problems. The goal of a DMM is to enhance the identification of different problems and constraints related to the work, thus enabling problem-solving, learning, and continuous improvement, which is the ultimate purpose of DAM. (Kennedy, 2019; Nicholas, 2018; Charron et al., 2014; Gao & Low, 2014.)

DMM has been implemented and applied in many different fields for a long time compared to the construction industry (Mariz et al., 2019). The effects and benefits of DMM have been studied over the years, especially in the manufacturing industry (Poksinska et al., 2013; Wester & Hitka, 2022), in the healthcare sector (Donnelly et al., 2017; Schatz & Bergren, 2022), and in the software development industry (Stray et al., 2016). These studies have found that implementing DMM improves communication and information flow, enhances the identification of constraints and problems, increases the team members' awareness of the progress of the process, enhances the team members' commitment, and increases trust and team spirit.

DAILY MANAGEMENT MEETINGS IN CONSTRUCTION

In the construction industry, lean construction is often associated with the Last Planner System® (LPS), which was developed in the industry in the early 1990s for project production control (Daniel et al., 2015; Ballard, 1994). Since then, LPS has started to be used in the industry not only for production control but also as an aid for CDPM (Fosse & Ballard, 2016; Daniel et al., 2015). LPS is based on versatile, structured, complementary, and regularly held meetings on a monthly, weekly, and daily basis (Fosse & Ballard, 2016; Hamzeh et al., 2009). Although daily meetings have been part of LPS for over 20 years (Ballard & Howell, 2003), research into their benefits has remained remarkably low in the construction industry compared to many other industries (Mariz et al., 2019; Wandahl et al., 2023).

Although studies that deal at least in part with DMM can already be found in the construction industry in the early 2000s (Salem et al., 2005), similar studies have become more common only in the last 10 years or so. Only a very small part of these studies (Wandahl et al., 2023; Ghosh, 2014) deal exclusively with DMM and their effects. In most of the studies where DMM is a part of the topic, DAM is reviewed comprehensively (Mariz et al., 2019; Lappalainen et al., 2022) or different Lean construction tools and their effects are compared (Salem et al., 2005; Noorzai, 2023). The use of DMM has increased in construction sites in recent years with the implementation of Takt production (Dlouhy et al., 2016; Haghsheno et al., 2016). Keeping pace and the quick reaction it requires are ensured with the help of daily Takt meetings (Haghsheno et al., 2016).

In studies conducted within the construction industry, DAM and DMM are often reviewed in relation to Lean and LPS (Wandahl et al., 2023; Gao & Low, 2014). However, in recent years, DMM has also been implemented in construction projects via the Scrum system originating from the IT sector based on Agile management (Streule et al., 2016; Zender & de Soto, 2021). Although there are several differences between LPS and Scrum and their use, the systems are relatively similar in terms of DAM and DMM (Lappalainen et al., 2022; Zender & de Soto, 2021; Streule et al., 2016).

Implementing DMM has yielded many of the same benefits in the construction industry as in other industries. The most relevant of these are related to increasing and improving communication between team members (Salem et al., 2005; Ghosh, 2014; Streule et al., 2016) and to the developed ability of teams and individuals to identify and solve problems and constraints (Mariz et al., 2019; Lappalainen et al., 2022; Noorzai, 2023). Streule et al. (2016) and Ghosh (2014) also identified as one of the positive effects of DMM that it helps team members get a better understanding of what work others are doing, which also increases understanding of the entire process and its progress.

Based on the results achieved in the construction industry, as well as in other fields, DMM could potentially reduce many of the challenges of CDPM. However, most studies in the industry that deal with DMM are limited to construction. Despite a few isolated studies (Lappalainen et al., 2022; Streule et al., 2016), DMM or DAM in general have not yet been extensively researched in the context of CDPM. Therefore, the aim of this research was to investigate the benefits and possible drawbacks of DMM in CDPM. The investigation is based on interviews, a survey, and a case-project experiment.

METHODS

The research method chosen was a case study of the structural design unit of a Finnish engineering firm. In the case study, a survey and six semi-structured interviews (SSIa) were first conducted to elicit expectations of the benefits and possible drawbacks related to DMM. The survey and interviews focused on the staff of the regional offices. After investigating the expectations, a week-long experiment was carried out in a case project to investigate the perceived benefits and drawbacks of DMM. Related to the experiment, data were collected via participant observation, as well as four semi-structured interviews (SSIb). The experiment and interviews were conducted with a small design team in one of the offices.

The case study aimed to obtain a real-world perspective on the relationship between expectations and perceptions of DAM and DMM in a design context (Yin, 2018). According to Yin (2018), case studies are essential for explaining real-world interventions and illustrating specific themes of evaluation. The design firm chosen as the case study is part of a joint industry–university research consortium of researchers and the Finnish construction industry (Lavikka et al., 2020), and when researchers asked for volunteers in the consortium workshop, the case company representative volunteered their company for the study. The company employs about 2200 people and has a turnover of about 220 M€.

The questions of the semi-structured interviews (SSIa) and the survey related to expectations were designed based on a literature review. Feedback on the survey questions was requested and obtained from the development manager of the case study company. The survey and interviews aimed to find out what people's expectations are regarding the benefits and drawbacks associated with DMM. It was possible to participate in the interviews face-to-face or via the Microsoft Teams application. The responses were grouped into themes. The survey was conducted on a company development day using the Mentimeter electronic survey tool. At the beginning of the event, the lead author introduced the background information of the survey to the participants. The survey results were reviewed with the participants during the event, and the data were evaluated separately by the researchers after the event. The theming was done in an Excel spreadsheet.

In the case project chosen for the experiment, DMM had not been utilised before, and the participants had no previous experience of DMM. The lead author conducted participant observations during the meetings and wrote down observations in field notes, which, according to Flick (2006), is the most common and effective way to document observational data. The questions of the semi-structured interviews (SSIb) were designed to elicit the experiences of the participants in the experiment regarding how they perceived the use of DMM in their design work. The interview questions were developed based on the observations made during the experiment as well as the information obtained earlier related to the expectations. The interviews were recorded and transcribed. It was possible to participate in the interviews face-to-face or via the Microsoft Teams application. The interview responses were evaluated and grouped into themes in an Excel spreadsheet. The research process is presented in Figure 1.

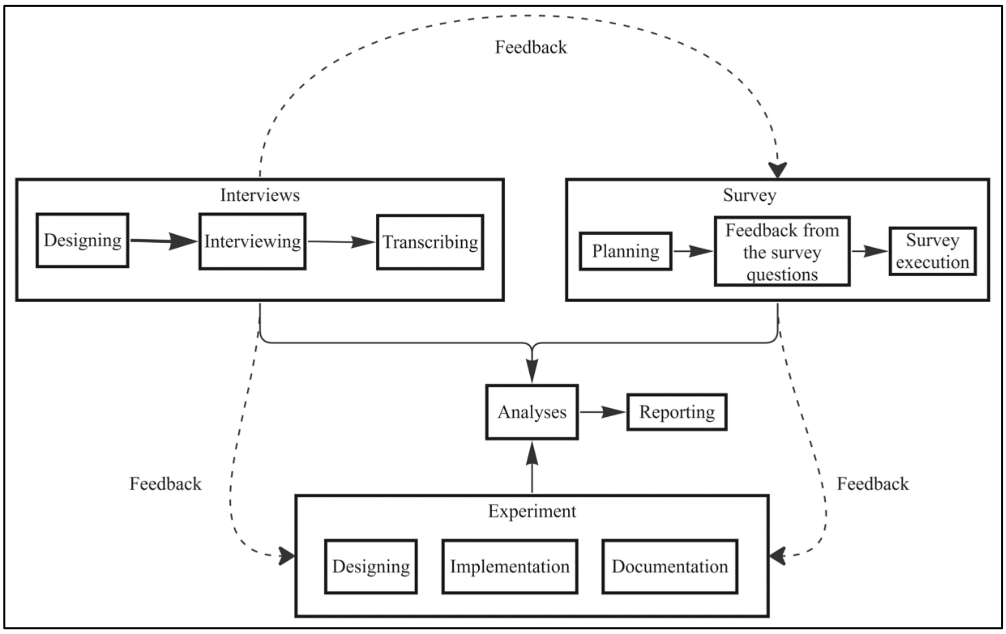

Figure 1. Research design.

This study uses a combination of research methods, which increases the validity of the study by examining several different perspectives, with common points indicating a closer description of reality, as Jack and Raturi (2006) argue. By triangulating results from literature reviews, interviews, and surveys, the inherent weaknesses of each method are compensated for, following the approach recommended by Turner et al. (2017). As argued by Yin (2018), the findings and conclusions of the case study gain reliability from being drawn from this diverse set of data sources rather than from individual methods.

FINDINGS

In this section, expectations regarding the benefits and drawbacks of DMM are presented. These were elicited using a survey and interviews (SSIa). The survey was conducted during a 1-day design manager workshop. The interviews were conducted over a period of 45 days. Two of these were carried out face-to-face, while four were held remotely via Microsoft Teams. All interviews were recorded and subsequently transcribed. The longest interview lasted 72 minutes, and the shortest was 27 minutes in duration. On average, the interviews lasted 44 minutes.

After presenting the main expectations, the results of the experiment are reviewed. The experiment aimed to obtain information about the perceptions of DMM in a real context by implementing them in a case project. The results were elicited by interviewing (SSIb) the members of the case project. The lead author also participated in the DMMs held during the experiment as an observer. This enabled the investigation of possible challenges and drawbacks related to DMM and its implementation. The interviews were conducted over a period of 4 days, and two of them were held face-to-face, while the other two were held remotely via Teams. Again, all interviews were recorded and subsequently transcribed. The longest interview lasted 26 minutes, and the shortest was 15 minutes in duration. On average, the interviews lasted 20 minutes.

EXPECTATIONS

A survey (n=34) and interviews (n=6) were utilized to determine expectations regarding the benefits and drawbacks of DMM. Table 1 presents the themes that came up the most regarding the benefits, as well as the proportions of answers related to them.

Table 1: Expected benefits of daily management meetings

Theme	Survey (n=34)	Interviews, SSIa (n=6)
Improves communication	6 %	83 %
Enhances information flow	18 %	67 %
Enhances identification of dependencies between tasks	12 %	17 %
Ensures workflow	15 %	50 %
Improves assessment of own workload	6 %	-
Enables better monitoring of progress	9 %	33 %
Enhances identification of constraints and problems	24 %	-
Increases trust and team spirit	12 %	33 %

There is a noticeable distribution in the answers to the survey and the interviews regarding which themes were emphasized the most. For example, only a small portion of the survey answers (n=34, 6 %) related to improving communication, while in the interviews this theme came up distinctively the most (n=6, 83 %). In the survey, enhancing the identification of constraints was seen as the greatest potential of DMM (n=34, 24 %), while in the interviews this theme did not come up directly at all. Themes that received a relatively large number of responses in both sets of collected materials were enhancing information flow, ensuring workflow, and increasing trust and team spirit.

The survey and interviews also aimed to obtain information about the expected challenges and drawbacks of DMM. In the survey, there were fewer responses (n=30) regarding these compared to the benefits (Table 1). Table 2 presents the themes that came up most regarding the drawbacks, as well as the proportions of answers related to them. The implementation of DMM is expected to be challenging, especially due to time constraints. In the interviews, the most cited (n=6, 67 %) drawback of DMM was that they would take too much time away from other daily work. The problem of finding a standard time that suits everyone every day was frequently mentioned in both the survey (n=30, 33 %) and the interviews (n=6, 50 %). One of the reasons identified in the survey (n=30, 13%) for this drawback is that designers and project managers often work on several different projects simultaneously.

Table 2: Expected drawbacks of daily management meetings

Theme	Survey (n=30)	Interviews, SSIa (n=6)
The meetings require too much time daily	17 %	67 %
Challenging to find a time slot that suits everyone's schedule	33 %	50 %
Difficult to get everyone to commit to the practice	20 %	50 %
Challenging to get designers to critically evaluate their own work and performance	10 %	33 %
Designers may experience the practice as an excessive supervision of their performance	7 %	17 %
There might not be new things to go through in the meetings every day	7 %	33 %

As can be seen in Table 2, there are also expected to be many other drawbacks regarding DMM. In two interviews, it was discussed that it can be challenging to get people to commit to the practice due to the other challenges presented in Table 2. In the survey (3 responses, 10 %) and in one of the interviews, it was pointed out that DMM might be perceived more openly if everyone was aware of their benefits.

PERCEPTIONS POST-EXPERIMENT

A week-long experiment was conducted to obtain concrete results about the benefits and drawbacks of DMM. In the experiment, DMMs were implemented in a structural design case project, where a similar practice had not been utilized before. The main project team consisted of four members. The case project members were interviewed (SSIb) after the experiment to determine how they perceived the DMM. Table 3 presents the key perceived benefits that stood out in these interviews.

DMM were consequently perceived to have positive effects especially on the planning and execution of work tasks. This was also felt to have a positive effect on the ability to estimate the amount and duration of work. The design project manager also found it to be beneficial that with DMM, they knew more precisely every day what everyone was going to do, as this made it easier for them to follow the progress of the process more closely.

The DMM experiment was conducted efficiently in terms of time-consumption. The average duration of the meetings was only 8 minutes, with the shortest lasting 6 minutes and the longest lasting 11 minutes. This, to some extent, refutes the expectation that DMMs require a lot of time each day.

Table 3: Key perceived benefits of the daily management meeting experiment

Key perceived benefits	Interviews, SSIb (n=4)	Extracts from interviews
Facilitates the planning and execution of work tasks	75 %	*"…easier to plan and complete your own work…each day. Working is also more efficient when you think before you do."*
Develops the ability to evaluate workload and task durations	50 %	*"… clearer picture of what you were going to do that day…easier to estimate how much time the work required."* *"… you can also regularly observe in the meetings whether your own estimations have gone right or wrong, which further develops your assessment ability."*
Helps especially the project manager in monitoring the progress	25 %	*"[The project manager] could hear and see what goals everyone set for the day, and how the tasks were going, which made it easier to keep in track with the process progress."*

Although the DMM experiment was successfully implemented, there were also some drawbacks associated with the new practice. Perhaps the most significant challenge that emerged during the experiment was scheduling a meeting that all members of the case project team could attend. While there were no days when no one attended, there was almost always at least one team member with scheduling conflicts, often due to other meetings or site visits. One of the most expected drawbacks of DMM was that it could be challenging to find a time slot compatible with everyone's schedule. The experiment's findings thus confirm that this is a real obstacle. In contrast with construction workers, designers tend to have several meetings during the day, for instance, with other designers or with the client. They also often work on several projects at the same time. The project manager of the case project recognized in their interview that flexible working hours also pose a challenge for scheduling DMMs. Holding these meetings first thing in the morning ensures that there are no interruptions in the workflow (Ghosh, 2014; Wandahl et al., 2023). However, this is quite difficult in design offices compared to construction sites, where workers typically arrive at the site at the same time, as employees in design offices may start their workdays at different times. Finding a common time is, therefore, particularly difficult in design.

Observations of the meetings revealed that the same topics and issues were frequently discussed, often without significant new additions. This issue also emerged during the investigation of the expected drawbacks of DMM, as noted in Table 3. In their interviews, the majority of the case project team members (3 out of 4) attributed this to the compact size of their project team. They noted that they naturally discuss things with one another even without the necessity of DMM.

DISCUSSION

This exploratory study showed that various benefits can be achieved by implementing DMM in CDPM. The findings propose that the main expected benefits of DMM include improved workflow, better information flow, and enhanced trust and team spirit. The findings from the experiment reveal that DMM facilitates more efficient planning and execution of work tasks, aids in evaluating the amount and duration of tasks, and is particularly beneficial for project managers in monitoring progress. These outcomes generally align with the initial expectations, highlighting DMM's positive impact on design management efficiency. However, while one of the main findings of the experiment was that DMM had positive effects on the participants' ability to evaluate their own workload and task durations, this theme only barely came up in the survey (n=34, 6 %). It is also noteworthy that there were no remarks relating to this theme in the six interviews (SSIa) regarding the expected benefits. There can be several different explanations for this. The prominence of this theme in the experiment may be attributed to factors such as the type of case project and the working methods of its members.

The findings also indicate that there are various design-specific challenges and drawbacks associated with DMM. Based on the responses from the survey and interviews (SSIa), it is expected that DMM will consume too much time from other daily work. The findings from the experiment refute this expectation, with the average duration of the held meetings being under 10 minutes. However, it is important to consider the compact size of the case project team. The meetings could be quite easily kept short, since there was usually not much to discuss with only a few participants involved. Numerous studies, particularly those focusing on Scrum, emphasize the importance of using a pre-prepared agenda to maintain efficiency in DMM (Stray et al., 2016; Streule et al., 2016). Using a ready-made agenda could be recommended, especially with larger project teams, where the scope of discussion can be more extensive.

The findings show that integrating DMM into everyone's schedule is expected to be particularly challenging. The experiment confirmed this common expectation, as finding a suitable time for everyone proved particularly challenging. This was primarily due to issues specific to design, such as flexible working hours and members working simultaneously for multiple projects. Unfortunately, there is no direct solution to this challenge. Stray et al. (2016) suggest that DMM should be organized in a manner that minimizes disruption to team members' daily work. The most suitable time for DMM consequently depends on the situation and should be agreed upon collectively by the project team before implementing the practice. Although it would be useful to hold a meeting first thing in the morning to ensure an efficient workflow, as previously discussed, the meeting can also be scheduled later in the day if it better accommodates everyone's schedule. For instance, Stray et al. (2016) noted that their study's case project team found holding a meeting just before lunch to be the most effective practice. This timing could perhaps also be more suitable for design teams that operate under flexible working hours.

While the findings of this study provide valuable insights into the benefits and challenges of DMM in CDPM, there are some limitations and areas for improvement. First, the study's focus on a single design unit of a Finnish engineering firm may limit the generalizability of the findings. Cultural and organizational factors specific to the firm may influence the outcomes, which might differ in other contexts. Second, the experiment period was relatively short, which may not capture the long-term effects and adaptations of the DMM practice. The experiment focused on only one case project, which also limited the generalizability of the findings. However, the validity and reliability of the related findings was increased by combining several data collection methods (Turner et al., 2017). This was realized in both phases of the empirical research process, as data related to the expectations were collected by combining interviews and a survey, and data related to the perceptions were collected by combining interviews and observation. Finally, the study relies heavily on qualitative data from interviews and a survey, which, while insightful, may benefit from the inclusion of quantitative measures to provide a more comprehensive analysis.

The findings of this research are relevant and valuable for both industry and academia. For the construction industry, this study establishes that various benefits can be achieved by implementing and utilizing DMM in CDPM. Previous research in the industry has yielded many promising results regarding the benefits of DMM and DAM in general (Wandahl et al., 2023; Mariz et al., 2019; Lappalainen et al., 2022; Ghosh, 2014). The findings of this study generally align with the results of previous research. For instance, Lappalainen et al. (2022) found that the reliability of task execution increased when DMM and DAM were implemented. The findings obtained through the practical experiment in this study align with this, thus validating the results of Lappalainen et al. (2022). The experiment also demonstrated the positive effects DMM have regarding the work of the design project manager. This, in turn, confirms the results of Wandahl et al.'s (2023) study, according to which DMM facilitates construction site managers' work and time management.

Although the effects of DMM have been researched in the industry, the topic has not yet been extensively researched in the context of construction design processes. This study affirms that the positive results achieved on the production side of construction are also valid in design, although there are unique challenges, such as finding a common time. Consequently, the study provides a general basis for the topic, and the findings can be used as an aid for further research, thus alleviating the research gap.

The topic can be approached from many different perspectives, offering numerous avenues for further research. For instance, comparing the effects of DMM across different design processes in the construction industry could illuminate the generalizability of the benefits and applicability of DMM within the CDPM context. Another compelling topic for future research would be investigating whether Wandahl et al.'s (2023) findings on DMM's impact on construction site crew productivity are also applicable to construction design teams. To ensure a robust and comprehensive analysis, such research could benefit from utilizing quantitative methods or a combination of qualitative and quantitative approaches.

Hopefully, this short paper will inspire design project managers to explore the use of DMM, perhaps in conjunction with other DAM practices, in their future projects. Broader adoption of such practices would facilitate advancing the much-needed further research on the topic.

CONCLUSION

This study aimed to investigate and compare the expectations and actual experiences of DMM in CDPM, consequently addressing a significant research gap in the field. This objective was pursued by conducting a case study of the structural design unit of a Finnish engineering firm.

The findings obtained through a survey and interviews showed that various benefits are expected to be gained when implementing DMM in design. Based on this study, these expectations are especially related to enhancing information flow, ensuring workflow, and increasing trust and team spirit. The findings also show that there are various expected challenges regarding the implementation of DMM in design. These especially relate to time consumption and scheduling.

The findings obtained through a practical experiment showed that DMM facilitates the planning and execution of work tasks, which in turn develops the ability to assess workload and estimate task durations. DMM can also help, especially the project manager, to monitor the progress of the process. The experiment also confirmed the expected challenges regarding the scheduling of meetings, proving that finding a common time for DMM is particularly difficult in design.

Although the research has some limitations, the findings provide valuable insights regarding the benefits and drawbacks of DMM in the context of construction design processes. Therefore, this study can be used as a basis for more comprehensive further research.

ACKNOWLEDGMENTS

We thank Ramboll Finland Oy's structural design unit, and especially the design team that participated in the daily management meeting experiment with an open mind. We also extend our gratitude to the designers and design project managers, whose survey and interview responses served as significant sources of data in this study.

BUILT ENVIRONMENT DESIGN KNOWLEDGE FRAMEWORK SUPPORTIVE OF RESILIENT HEALTHCARE

Natália Ransolin[1], Tarcísio Abreu Saurin[2], Carlos Torres Formoso[3], Robyn Clay-Williams[4] and Frances Rapport[5]

ABSTRACT

Although the evidence-based design (EBD) literature investigating the influence of the built environment (BE) on health services performance and outcomes is extensive, its contribution to resilient healthcare is scarce. This work presents a framework of BE design knowledge supportive of resilient healthcare. Firstly, a systematic literature review based on EBD, complexity, and resilience resulted in generic BE design knowledge that represented the role of BE in supporting resilient healthcare at different levels of abstraction. Next, the knowledge was used for thematic analysis in case studies in two teaching hospitals, tailored to workflows that occurred in the connecting areas to and from an intensive care and other hospital units of a large public hospital in Brazil and the surgical service of a private hospital in Australia. Joint findings allowed the development of a framework hierarchically composed of four meta-principles, seven principles, seven prescriptions, and 181 practical examples emphasizing a systems perspective that considers intra and inter-hospital workflows and areas. The resulting knowledge guides designers of both BE and operations phases during decision-making to support resilient health services. As a limitation, the framework was not applied during those phases, representing one of the main suggestions for future work.

Evidence-based Design, Built environment, Complexity, Resilient Healthcare.

INTRODUCTION

Health services are Complex-Socio Technical Systems (CSSs) in which care provision is possible due to dynamic interactions between human, technical, and organisational elements influenced by the external environment (Braithwaite, 2018). An emerging property that arises from these interactions in CSSs is resilient performance (RP), a phenomenon that, in the context of health services, is investigated underneath the realm of resilient healthcare - i.e., *"the ability of the healthcare system (a clinic, a ward, a hospital, a county) to adjust its functioning prior to, during, or following events (changes, disturbances or opportunities), and thereby sustain*

required operations under both expected and unexpected conditions" (Hollnagel et al., 2013). In the myriad of interactions, the built environment (BE) is a technical system that supports activities and shapes the relationships between processes, technologies and stakeholders (Hicks et al., 2015; Hollnagel, 2014; Real et al., 2017). Therefore, BE should support resilient healthcare, as its relevance for the performance of health services has been acknowledged by several studies on BE influence on both patient outcomes and caregivers´ performance (Real et al., 2017; Machry et al., 2021).

The body of knowledge on the influence of BE on health services has been produced under the umbrella of evidence-based design (EBD) (Ulrich et al., 2008; Zhang et al., 2017). The EBD literature focuses on the BE impacts on efficiency and safety of care provision from factors such as privacy, noise, light, access to outdoor spaces, accessibility, and layout (to the external environment, accessibility, and layout (Rybkowski; Greer et al., 2021). From the viewpoint of lean construction, EBD is useful for generating value to stakeholder - e.g., patients and staff members - and workflows - e.g. health services (Zhang et al., 2016). Nonetheless, EBD studies are commonly criticized for neglecting the complexity of health services, overlooking the interactions that occur in the BE and missing the need to support RP (Halawa et al., 2020; Łukasik and Porębska, 2022). From a resilient healthcare perspective, this EBD drawback is a failure to acknowledge the gap between work-as-imagined (WAI) in design and protocols and work-as-done (WAD) in reality (Ransolin et al., 2020; Machry et al., 2021; Joseph et al., 2022). This gap arises from the everyday variability of complex systems, a condition that requires RP – which is commonly unveiled in the successful outcomes of WAD and highlighted by resilient healthcare (Bueno et al., 2021). However, EBD tends to produce knowledge based on the WAI formalised in guidelines rather than the WAD on site, which leads to a lack of comprehension of the complexity and resilience during the design of health systems. Moreover, while EBD is a source of knowledge for designers, it is bound to a specific context and does not provide a standard for repetition, which contributes to the fragmentation of EBD knowledge (Zhang et al., 2016).

Therefore, *the aim of this paper is to propose a framework of BE design knowledge supportive of resilient healthcare***.** It is based on a systematic literature review (SLR) and two empirical studies carried out in different hospital units, on in Brazil and the other in Australia. The SLR investigated EBD studies on complex socio-technical systems and resilient healthcare resulted in a generic BE design knowledge supportive of resilient healthcare (Ransolin et al., 2022). The corresponding knowledge is structured according to different levels of abstraction, from high-level general design guidance, to low-level practical solutions that are highly context-dependent. Then, the knowledge was applied as a heuristic device for data analysis, being tailored to the specific context of two empirical studies. Thus, the case studies investigated the WAD of hospital workflows in (i) the connecting areas to and from an intensive care unit (ICU) of a large public hospital in Brazil (Ransolin et al., 2024a), and (ii) the surgical service of a private hospital in Australia (Ransolin et al., 2024b). This investigation is relevant for design management, a traditional lean construction topic that can explore the resulting framework to develop theories and practices for designing resilient healthcare.

DESIGN KNOWLEDGE FOR RESILIENT HEALTHCARE

The myriad of complex interactions in health services cannot be completely controlled and anticipated, but they can be partially subject to the influence of design (Plsek & Greenhalgh, 2001; Wachs et al., 2016). Similarly, resilience emerges partly from CSS self-organisation dynamics and partly from intentional design decisions to support it. This latter is associated with the concept of Design for RP, defined as "*the use of design principles to support integrated human, technical, and organisational adaptive capabilities*"(Disconzi and Saurin, 2022).

Albeit not addressing RP, the EBD framework proposed by Zhang et al. (2019) was devised according to design principles (e.g., 'comfortable environment'), followed by design parameters (e.g., 'light'), which gave rise to sub-parameters (e.g., 'daylight'). Saurin et al. (2013) developed guidelines for coping with complexity based on resilience theory (Table 1), so they were used as a point of departure for this research work that applies to health services.

Table 1: Guidelines for coping with complexity and their definitions (Saurin et al., 2013; Bueno et al., 2019).

	Guidelines for coping with complexity	Definitions
1	Supporting visibility of processes and outcomes	Promotion of real-time visibility to either formal or informal work practices for a user-intuitive CSS functioning (Clegg, 2000; Galsworth, 2017).
2	Designing slack	Human or technical for absorbing uncertainty - i.e., spare resources that can be activated when necessary (Nohria & Gulati, 1996; Formoso et al., 2021).
3	Encouraging diversity of perspectives when making decisions	Diversity of perspectives helps to manage uncertainty and requires high levels of trust, low power differentials, and apt decision-makers (Page, 2010).
4	Monitoring and understanding the gap between work-as-imagined (WAI) and work-as-done (WAD)	Awareness of the daily variabilities in performance and outcomes implied in CSSs. The reasons and consequences of this gap should be investigated (Hollnagel, 2017).
5	Monitoring unintended consequences of improvements and changes	Interventions interact between themselves and the environment, creating negative or positive unintended consequences (Perrow, 1984; Ogrinc et al., 2015).

The design knowledge framework presented in this paper comprises meta-principles (i.e., the guidelines of Saurin et al., 2013), principles, prescriptions, and practical examples. Design principles are at a higher abstraction level and refer to a group of prescriptions that share similar goals (Kuechler and Vaishnavi, 2012; Ransolin et al., 2022). According to Vaishnavi and Kuechler (2015), a design prescription is a suggestion for action in a given circumstance to achieve an effect. Instantiations of the prescriptions in a particular context are practical examples at the lowest level of abstraction (Ransolin et al., 2022).

RESEARCH METHOD

RESEARCH DESIGN

This research work used qualitative methods as their utility to uncover complexity has been recognised (Rapport and Braithwaite, 2020). Firstly, a SLR explored how the EBD literature addresses complexity and resilience in BE health services (Ransolin et al., 2022). Furthermore, case studies allow for developing both generalizable and context-specific knowledge (Yin, 2017), which is consonant to develop BE design knowledge across different levels of abstraction. Then, two case studies were successively conducted in teaching hospitals, investigating the particularities of workflows in different hospital settings. The first case study was conducted in a large (around 6,000 employees) public and tertiary hospital in Southern Brazil, where we paid attention to the interactions between an adult ICU and other hospital units - e.g., in-patient wards and non-clinical areas such as warehouse - across a three-building complex (Ransolin et al., 2024a). The second case study was undertaken on the first floor of a medium-sized private hospital in NSW, encompassing elective surgical service flows (Ransolin et al., 2024b). Both empirical studies followed two major stages: (i) characterisation of the health service flows and BE, and (ii) development of the design knowledge. The joint analysis of the findings from the SLR and the case studies allowed the identification of emerging patterns that gave rise to a design knowledge framework to address the main research objective.

DATA COLLECTION AND ANALYSIS

In Ransolin et al. (2022), an SLR followed the steps proposed by the Preferred Reporting Items for Systematic reviews and Meta-Analyses (PRISMA) (Moher et al., 2009), which are: 1) identification of the papers; 2) screening; 3) eligibility; and 4) inclusion. From 2412 records identified from seven databases and five manual inclusions, 2220 were screened, 397 were fully assessed, and 43 papers were selected for qualitative analysis. The search string was composed of variations of keywords related to the following domains: study object (e.g., built environment, EBD); context (e.g., health services); approaches (e.g., complexity, resilience); outcomes (e.g., safety, well-being); and stakeholder (e.g., patients, staff). The selection of publications was not limited by year; papers were filtered in English and related to similar areas (e.g., engineering, social science, business and management, arts and humanities). The screening considered four exclusion criteria: (i) non-scientific texts; (ii) conference proceedings; (iii) literature reviews; and (iv) content unrelated to healthcare facilities (e.g., ethical aspects), or the research aims (e.g., risk analysis). In the eligibility step, the resulting publications were scanned in order to exclude papers that did not contain any of the following keywords in the full text: Complex*; Resil*; Flex*; Adapt*; Flow; Evidence-based Design (EBD). Finally, the included publications were fully analysed.

Empirical data collection was carried out by the first author after the ethics committees of both hospitals approved the respective research projects, and participants provided written informed consent before being interviewed. Table 2 presents the total hours of data collection in each case study, according to the sources of evidence used. In total, 133 hours of data were gathered using all data collection techniques in both empirical studies (Ransolin et al., 2024a/b).

Table 2 – Total of data collection (hours) of case studies associated with the sources of evidence.

Data collection	Sources of evidence				
	Document analysis	**Non-participant observations**	**Semi-structured interviews**	**Meetings with hospital staff**	**Total (hours)**
1st case study – ICU connecting areas (Ransolin et al., 2024a)	-	50	30	1	81
2nd case study – Surgical service (Ransolin et al., 2024b)		30	16	6	52
					133

Documents considered for analysis were Brazilian and Australian BE design regulations, guidelines, and architectural floor plans of both hospitals of the case studies. Non-participant observations were conducted during visits and walkthrough sessions to observe workflows performed by frontline staff members. Semi-structured interviews involved two main questions: (1) Could you give an overview of your daily work and the relevant workflows for this hospital unit? and (2) how does the BE facilitate or hinder everyday work regarding these workflows? Please illustrate these implications with a situation experienced by you or a colleague.

Interviewees were divided into five categories: management, administrative/supporting, engineering, clinical assistance, and patients/family members. Meetings with hospital staff helped identify interviewees, defining workflows and areas from which data would be collected, and presenting and discussing the design knowledge framework.

Data collected in the SLR and the case studies was subjected to a content analysis (Pope et al., 2000). This process encompassed familiarisation, identifying themes, coding, charting, mapping and interpretation and was performed successively according to the development of each study. Familiarisation involved multiple readings of primary and secondary data - i.e., papers selected in the SLR, regulations, interview transcripts, and observation notes. Themes were defined previously and imposed for analysis as a heuristic device, being performed successively, allowing tailoring it to each study context. In the SLR (Ransolin et al., 2022), themes corresponded to the guidelines for coping with complexity – i.e., design meta-principles (Table 1). Next, the first case study (Ransolin et al., 2024a) considered the seven design principles developed in the SLR as themes (Ransolin et al., 2022). Then, the second case study (Ransolin et al., 2024b) used as themes for analysis the design prescriptions developed in the previous case study (Ransolin et al., 2024a). Figure 1 illustrates the selection of themes for data analysis in each study of this research work, which corresponded to the levels of the design knowledge framework.

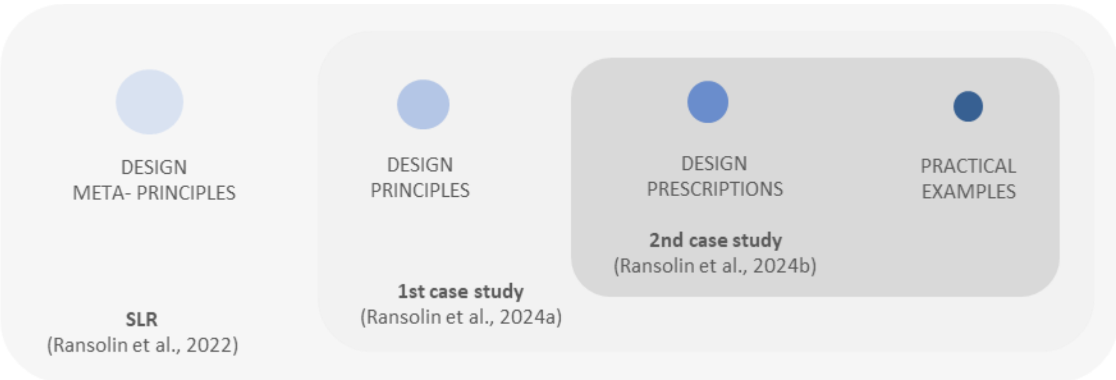

Figure 1: Thematic analysis of the studies in a successive and complementary order according to design knowledge framework levels.

Data coding was performed independently by at least two authors (e.g., NR and TAS) according to the themes defined for each study, based on agreements from meetings to achieve consensus. In the RSL, the coding stage was carried out in four steps with different levels of abstraction corresponding to design meta-principles, design principles, design prescriptions, and practical examples (Ransolin et al., 2022). The charting stage corresponded to the synthesis of findings from the previous stages of content analysis. In the RSL, the knowledge structure was established, representing the different levels of abstraction – i.e., design meta-principle, the corresponding principles, prescriptions and practical examples (results section). In the case studies, findings were schematically represented in Tables that associated the practical examples with each design prescription, tailored to different health services. Lastly, the mapping and interpretation stage related to the discussion of design knowledge resulted in each of the studies in light of the EBD and resilient healthcare literature. Details of methodological procedures can be found in the respective sources (Ransolin et al., 2022; Ransolin et al., 2024a/b).

RESULTS

Figure 2 presents the BE design knowledge framework for resilient healthcare. At the highest abstraction level, the four design meta-principles corresponded to the complexity guidelines

(Table 1). The seven design principles are applications of the guidelines for the BE in health services (Ransolin et al., 2022). In the two lowest abstraction levels, empirical data were linked to the structure, being useful in structuring the presentation of the findings in Ransolin et al. (2024a/b). The design prescriptions correspond to the application of the principles to a context. There is no one-to-one relationship between principles and prescriptions – e.g., the same prescription emerged from multiple principles. The resulting seven design prescriptions are tailored to the context of the case studies (Ransolin et al., 2024a/b). Then, the last framework level is composed of 181 practical examples of real situations where the BE is supportive of resilient healthcare in the health settings, linked with hospital workflows and areas (Ransolin et al., 2024a/b).

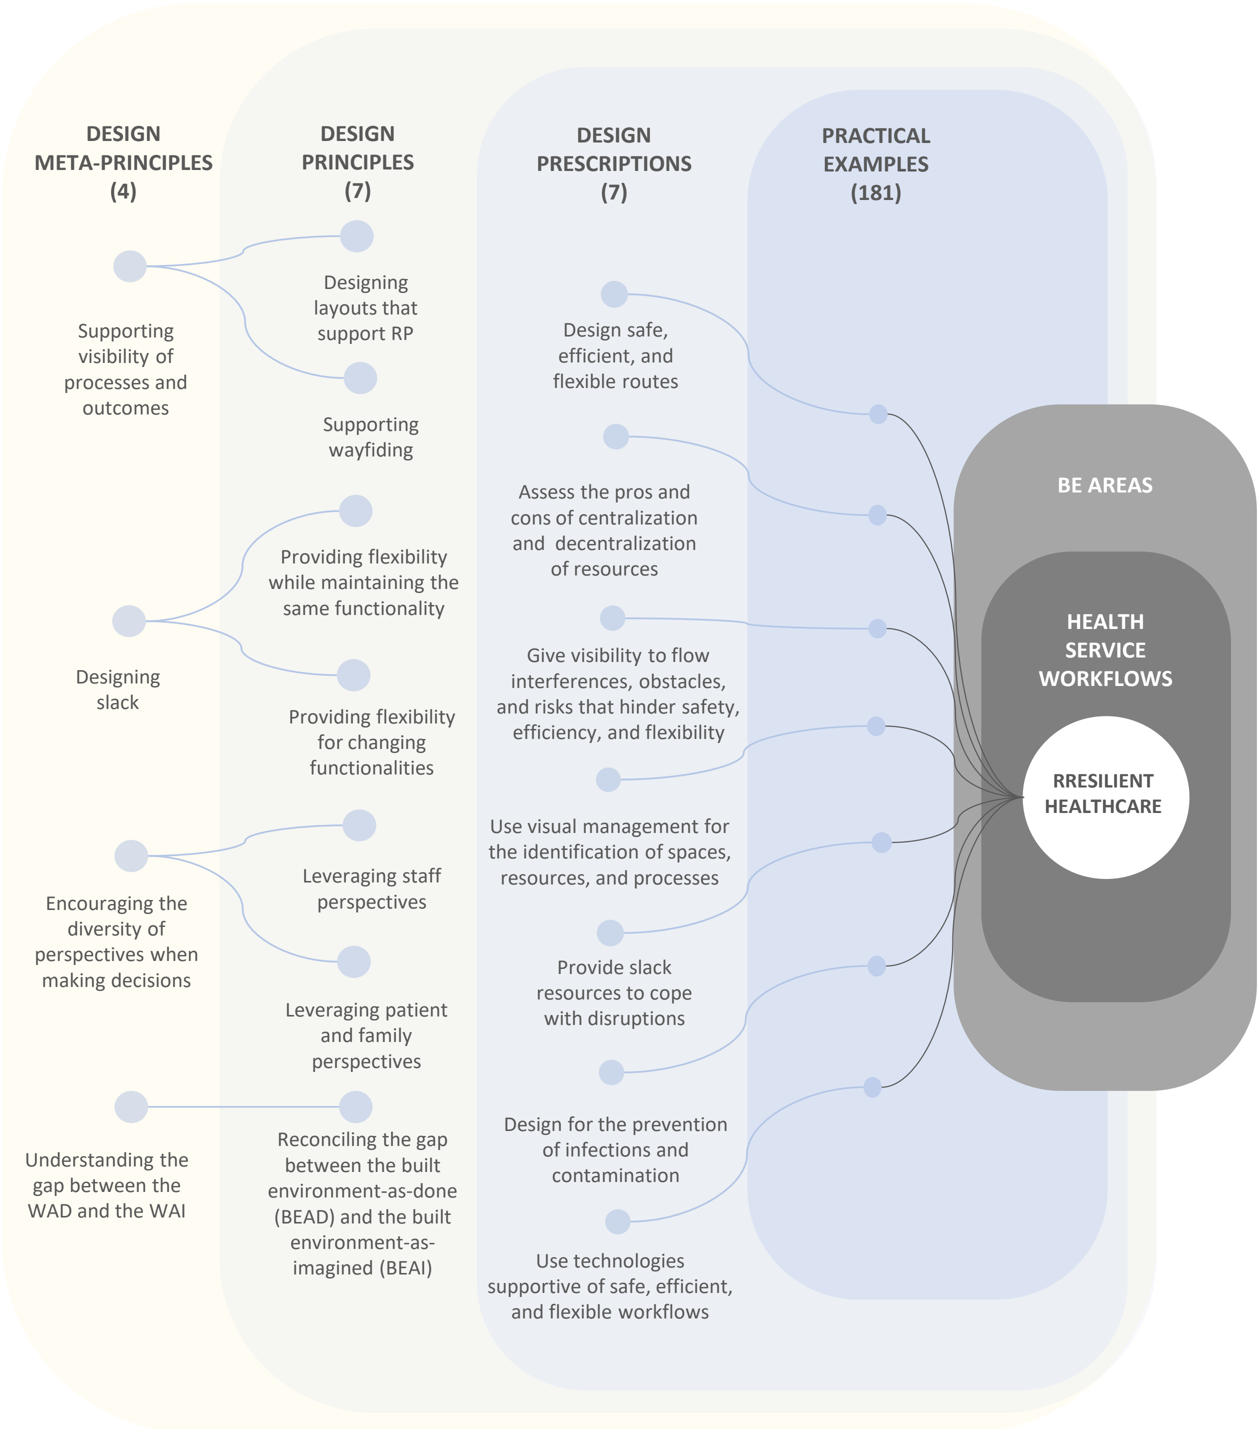

Figure 2: Framework of BE design knowledge for resilient healthcare.

The seven design principles were established in the SLR (Ransolin et al., 2022). The first design meta-principle - supporting visibility of processes and outcomes - derived into two design principles: ‘designing layouts that support RP’ and ‘supporting wayfinding’. The former is illustrated as BE configurations that improve the efficiency of operations and support users´ safety, well-being and interactions. Supporting wayfinding is associated with providing orientation and navigation of users across BE in health services. The second design meta-principle - designing slack - contributed to the design principles: ‘providing flexibility while maintaining the same functionality’, e.g., adaptation, customisation, and expansion, and ‘providing flexibility while changing functionalities’, i.e., changing the main purpose of spaces.

Then, the third design meta-principle - encouraging diversity of perspectives when making decisions - gave rise to two design principles related to ‘leveraging patient and family perspectives’ and ‘leveraging staff perspectives’. The fourth design meta-principle - monitoring and understanding the gap between work-as-imagined (WAI) and work-as-done (WAD) – is translated into ‘reconciling the gap between the built environment-as-done (BEAD) and the built environment-as-imagined (BEAI)’, as the BE design (i.e., BEAI) should be strongly based on the understanding of how people use the BE in reality (BEAD). Lastly, for the fifth design meta-principle - monitoring unintended consequences of improvements and changes - to be effective, this monitoring demands the application of all the design principles above mentioned.

The resulting seven design prescriptions are listed in Figure 2 and were refined to the context of hospital workflows in the ICU connecting areas and surgical services case studies – i.e., two empirical studies (Ransolin et al., 2024a/b). Table 3 presents similarities between some practical examples from the case studies to illustrate the relevance of the design prescriptions for different contexts.

The first design prescription is exemplified by designing direct connections between hospital units in different buildings - e.g., walkways on all floors (1st case study). Similarly, direct connections are necessary to promote ease of transfer and access among surgical phases, using back-of-house corridors – e.g., the ICU should be close to operating rooms to ensure quick patient transportation (2nd case study). Freeing corridor width according to requirements is also present in practical examples from both case studies, as follows: place workstations in the corridors while maintaining the minimum free width of corridors set by regulations (1st case study) and comply with corridor width requirements for clinical areas – e.g., corridors should be wider enough to fit ICU beds that are larger than regular ward beds (2nd case study). The second prescription encompasses practical examples from both case studies related to having a mix of centralised and decentralised storage to share resources among hospital units. For instance, the 1st case study shed light on the importance of designing supporting areas that serve more than one hospital unit, avoiding duplication of resources, and sharing expensive and scarce equipment or infrastructure between ICUs and other hospital units - e.g., tomography, defibrillators, crash carts, pharmacy. In turn, the 2nd case study presented the example of designing centralised storage for general items shared among surgical phases and decentralised storage areas for specific surgical items – e.g., drugs with a higher risk of misuse must be stored in a locked cabinet shared among the operating rooms, allowing control and ready access nurses. The third design prescription is associated with practical examples of preventing interactions between dirty and clean flows. The first case study illustrates the use of dedicated lifts for patients to avoid flow interferences and the design of separate storage for dirty clothes from clean clothes (1st case study). It is also exemplified by prioritising patient flows in corridors and lifts and the signage for the dedicated use of lifts for patient transportation during busy surgery days (2nd case study). This prescription also emphasizes the visual demarcation for equipment storage based on practical examples of signalising an allocated area for parking supply carts and unloading materials near the ICU pharmacy (1st case study) and demarcating visually with lines or colours on the floor and walls to indicate where equipment can be stored (2nd case study).

Table 3 – Illustration of similarities between practical examples from each empirical study (Ransolin et al., 2024a/b).

	Design prescriptions	**Similarities between practical examples from each empirical study** 1st case study - ICU connecting areas (Ransolin et al., 2024a)	2nd case study - Surgical service (Ransolin et al., 2024b)
1	Designing safe, efficient, and flexible routes	Design direct connections Free corridor width according to requirements	
2	Assess the pros and cons of centralisation and decentralisation of resources	Design a mix of centralised and decentralised storage to share resources among hospital units	
3	Give visibility to flow interferences, obstacles, and risks that hinder safety, efficiency, and flexibility	Prevent interactions between dirty and clean flows Provide visual demarcation for equipment storage	
4	Use visual management for the identification of spaces, resources, and processes	Design an intuitive signage	
5	Provide slack resources to cope with disruptions	Provide backup for expansion *Design multiuse spaces*	
6	Design for the prevention of infections and contamination	Distribute dispensers and PPE consistently Give visibility to sterile zones	
7	Use technologies supportive of safe, efficient, and flexible workflows	Provide devices to hold and open doors Avoid patient changes between stretchers Implement alerts to aware staff	
	Practical example "design multiuse spaces" from each case study	 Large warehouse for the storage of equipment and supplies during the COVID-19 pandemic	 Perioperative patient bay being temporarily used as equipment storage

The fourth prescription is related to practical examples from both empirical studies on designing intuitive signage. It can be achieved by self-explanatory direction signage for hospital flows and areas - e.g., using colours and symbols (1st case study) and progressive information disclosure at the right time to minimise the number of decisions required by users (2nd case study). The case study in the surgical service also presented practical examples of strategies to reinforce people's mental maps by demarcating boundaries of different with singular elements. The fifth prescription is connected with practical examples that will strengthen the need to anticipate backup for necessary expansions – e.g., ICU bed capacity during crises (1st case study), and extra inventory spaces (2nd case study) - and design multiuse spaces – e.g., spaces that can also serve as a warehouse of equipment and supplies during demand fluctuations (1st case study), and support areas that allow conversion to operating rooms (2nd case study). The sixth design prescription is grouped with examples from both case studies that share the concern of distributing dispensers and PPE and giving visibility to sterile zones. The 1st case study illustrated the need for placing hand sanitizers in the corridors and at the entrance of the hospital units and designing dedicated routes between restricted areas – e.g., transit of sterilized materials and access to the warehouse elevator. In turn, the 2nd case study underlined the consistent distribution of dispensers and PPE with ease of access across the service and using disposable drapes to cover the operating table, trolleys, light handles, and robot arms to make sterile zones visible.

The last design prescription is associated with practical examples that share three similar topics. Providing devices to hold and open doors is illustrated by the need to temporarily keep the fire door open during the team's passage in an emergency, e.g., a patient resuscitation call (1st case study), or to automatically open doors in high-traffic areas, e.g., between the operating room and induction room (2nd case study). Avoiding patient changes between stretchers is another shared topic of this prescriptions, illustrated by the use of flexible ICU beds that should accommodate the attachment of equipment for critical patient transportation between hospital units and allow procedures in the surgical centre (1st case study). The need for specific patient stretchers could be anticipated in the admission to reduce patient handling and stretchers in corridors – e.g., if a bariatric patient is admitted, a larger bed should be provided in the preoperative phase (2nd case study). Finally, implementing alerts to make staff aware is illustrated by notifications to indicate when storages of waste are full and need to be collected at the units (1st case study) and by call systems with buttons inside operating rooms to signalise the supporting areas that orderlies and clinical staff are needed and warn the surgical team that the patient waiting in the induction room is ready to enter the operating room (2nd case study).

The 1st case study, developed in the ICU connecting areas, linked 63 practical examples that were associated with 11 hospital workflows, as follows: people (resuscitation, exams, admission, discharge, visitors) and supplies (drugs and medical materials, dietary, sterilized materials, cleaning, clothing, waste) (Ransolin et al., 2024a). In turn, the case study on surgical services is associated with 60 practical examples with six main flows – i.e., patient/family, staff, supplies, equipment, sterile instruments and materials, and waste (Ransolin et al., 2024b). The complete list of the practical examples from each case study with details of their sources of evidence and associations with workflows and BE areas can be found in the respective papers.

DISCUSSION

Resilience should be supported across all levels of health services, namely macro (e.g., national healthcare system), meso (e.g., hospital workflows), and micro levels (e.g., hospital units) (Berg et al., 2018). However, understanding the interactions between these levels has been an under-explored topic (Ellis et al., 2019). Therefore, the framework is an original contribution to integrating the BE design knowledge across health service levels. At the micro level, the framework is relevant for the surgical services while considering the implications for the meso level when discussing the interactions with other hospital units – e.g., operating rooms should be close to the ICU to ensure quick patient transportation. At the meso level, the framework was developed for the hospital workflows in the interconnecting areas to and from the ICU and other hospital units such as corridors and warehouse. At the macro level, the framework can be useful for identifying BE requirements supportive of resilient healthcare.

Integrating these levels and the interconnection of elements at different levels of abstraction in the knowledge framework provide insights to orient decision-making – e.g., trade-offs between design prescriptions to assign priorities for interventions. Rather than a template for compliance, the framework should help to identify practical examples of the BE implications to RP that otherwise could have remained concealed in the successful WAD. The investigation of the WAD was possible through qualitative methods, in which case study stages and methodological techniques can be replicated in other health settings and resilient healthcare studies.

CONCLUSIONS

This paper presented a framework of BE design knowledge supportive of resilient healthcare based on a SLR and two empirical studies, on in Brazil and the other in Australia. It is hierarchically composed of four meta-principles, seven principles, seven prescriptions, and 181 practical examples. An international readership of academics and practitioners can benefit from the framework, as different contexts are discussed in light of complexity and resilient healthcare. The framework is expected to guide both BE and operations designers in health services.

Some limitations of this work must be highlighted: (i) the framework was conceived based on a resilient healthcare perspective, focusing on everyday work; thus, disasters were considered out of the scope of this work; (ii) the framework was not applied during the BE design or intervention of health services; and (iii) the influence of BE on resilient healthcare was not quantified in terms of the impacts on health outcomes and efficiency. Suggestions for future studies may include the application of the framework during the BE design or intervention of health services, using the framework to develop methods to evaluate the BE support for resilient healthcare, and creating an EBD repository to facilitate the integration and uptake of design knowledge.

LAST PLANNER SYSTEM: PULL PLANNING AS A DOCUMENTATION MANAGEMENT TOOL IN PHOTOVOLTAIC PROJECTS

João P. P Vieira[1], Fernanda M. Pimentel[2], Bernardo M. B. S. Etges[3], Jayane N. F. Silva[4], Pedro H. Bonkowsky[5], Cassiano Bronholo[6], Marcus C. T. Fireman[7] and Bogdan Bungardi[8]

ABSTRACT

The article discusses the application of the Last Planner System (LPS) in the context of infrastructure projects, focusing specifically on the renewable energy sector. A Brazilian company specialized in the design and construction of photovoltaic plants was chosen as the research scenario. LPS was introduced to the company as a tool for production control and management, providing stability to the production system. This article explores the application of LPS in design management, highlighting the complexity of the construction design process and proposing the integration of LPS principles into design management. Pull planning was incorporated into design management to establish a reliable flow in the iterative work performed by designers. The pull planning process is described in detail, including the creation of process flows, document analysis, board assembly, milestone definition, task segmentation of process flows, and weekly schedule structuring. Challenges were identified during the practical application of the tool, leading to the conclusion that there is room for improvement. In summary, this study demonstrates the potential of LPS and pull planning in improving the management of infrastructure projects, with a specific emphasis on documentation and design management in photovoltaic projects.

INTRODUCTION

Infrastructure projects are typically costly enterprises with great strategic importance for a region, country, or organization and high added value for the population (Dave et al., 2013). These projects have lower complexity than building projects, involve a more limited array of professionals, and encompass a wider variety of typologies, such as roads, bridges, and dams, among others (Yabuki, 2010). Interestingly, given their large scale and long execution cycles, infrastructure projects are highly conducive to improvement (Dave et al., 2013).

Improvement, as understood in the context of the Toyota Production System (TPS), focuses on increasing value to customers through waste elimination (Onho, 1988). For this, production systems need to operate in a stable and predictable manner (Onho, 1988).

Building upon this idea, Viana et al. (2010) presented the Last Planner System (LPS) as a tool for production control and management, providing a basic level of stability to the production system and enabling the implementation of more elaborate lean concepts. LPS converts activities that need to be carried out (long term) into tasks that can be effectively performed (medium term), eliminating anything that may prevent or limit production (restrictions) and identifying a set of activities to be undertaken as part of the weekly plan (short term), thereby lending greater reliability to established plans (Ballard, 2000).

A pull planning step and the term "should" were introduced to the LPS practice as a strategy to enhance the connection between long- and medium-term plans (Ballard, 1999). Pull planning offers a new perspective on collaboration and workflows, placing attention on what "can" be done in the current scenario of the project, rather than on what "should" be done (Silva et al., 2022).

Several studies have been conducted on LPS adoption in the civil construction sector. In the context of infrastructure projects, such studies are still incipient (Antonini et al., 2022). A recent study described the efforts put in place by the UK highways supply chain for the creation of numerous continuous improvement cells, in line with its commitment to improve performance and embrace lean construction principles (Tezel et al., 2018). As for infrastructure projects related to energy production, such as photovoltaic power stations, research is even more embryonic. A search carried out in the International Group of Lean Construction (IGLC) database for the keywords "solar," "photovoltaic," and "solar energy" retrieved only three publications related to the energy sector. However, the identified articles did not address themes related to lean principles. Furthermore, Construction of photovoltaic plants has some particularities that must be considered. This type of construction has a fast execution cycle and, as consequence, a short response time and a longer-term constraint analysis. Therefore, these characteristics need to be considered in the process of implementing LPS routines.

In view of these gaps, this study aimed to investigate the application of LPS in the context of photovoltaic projects. The objective is to identify how LPS and pull planning can aid in long-, medium-, and short-term planning for managing documentation (projects, bills of materials, manuals, regulations) over the entire course of implementation of solar photovoltaic plants.

The research is divided into three main sections. First, a brief literature review is presented on lean thinking and LPS, focusing on pull planning. Subsequently, the research context is described. Finally, the developed documentation management method and results are discussed. The article also suggests new perspectives for exploring lean practices in the solar energy farm sector.

DESIGN MANAGEMENT

In the field of construction, both the design process and the resulting product have high complexity (Bolviken et al. 2010). Designing requires an ongoing process of negotiation and adjustment (oscillation or conversation) between criteria and alternatives, resulting in the gradual determination of ends and means (Bolviken et al., 2010). Bolviken et al. (2010) stated that, in simple terms, the decision-making process can be seen as an integral part of the design process. Design management involves effectively overseeing the design process (Best 2006).

As design and construction phases are normally conceived separately (Alarcón & Mardones, 1998), it can be difficult to integrate design and construction information (Alshawi & Ingirige, 2003, as cited in Dave et al., 2008). Common challenges include disruptions at the design–construction interface, such as divergent production sequences and priorities, ultimately resulting in delays, rework, and waiting for project participants (e.g., designers, suppliers, and builders) (Biotto et al., 2022). Dave et al. (2015) suggested an improved design–construction interface, where design information is released with a pull from the master schedule.

To date, lean construction has had far more influence on production than on design. Nevertheless, we believe that it is possible to apply lean concepts to design management. This hypothesis was proposed by Bolviken et al. (2010), who argued that lean construction and LPS principles are equally relevant to design and production in construction.

In this paper, LPS will be used for design management according to a pull planning approach, following a reverse plan of each phase's task, pulling each task from the end milestone toward the phase start date (Alarcon et al., 2004). Pull planning in design is one of the newer additions to the lean thinking toolkit, aiming to establish a reliable flow in the iterative work performed by designers (Tvedt, 2020).

PULL PLANNING

Pull planning was incorporated into LPS to allow the structuring of a project phase or milestone collaboratively among stakeholders (Ballard, 2008). It connects the master and lookahead plans (Biotto et al., 2022). The term pull planning refers to the lean concept of "pull" as a request from downstream, in contrast to the topdown "push" applied in traditional practice (Tsao et al., 2014).

The pull plan can be scheduled using a diverse range of tools, such as Gantt charts (Knapp et al., 2006) or location-based schedule (LBS) techniques, such as line of balance (LOB) (O'Brien et al., 1985), flowline (Kenley & Seppänen, 2010), and takt time planning (Fiallo C & Howell, 2012). In agreement with Biotto et al. (2022), who suggested the use of LBS to plan the whole project in a reverse manner (from construction to design), the authors of this paper believe that LOB and LPS should encompass the entire project. For pull planning and line-of-balance scheduling, it is necessary to define zones, takt times, trade sequences, and trade durations and balance their workflow (Frandson et al., 2013).

Pull planning defines how work will be delivered from one project actor (owners, designers, contractors, suppliers, construction companies) to the next (Tsao et al., 2014). Furthermore, this tool provides the basic technique and approach for establishing "who should be doing what work and when" (Tsao and Tommelein, 2004) in order to achieve the proposed milestones. Pull planning also brings a new perspective on workflow, considering a collaborative approach that focuses on what can be done rather than on what should be done (Silva et al., 2022).

As recommended by Silva et al. (2022), the workshop for implementing pull planning should ideally be scheduled at least one month, if not two, before the beginning of the actual work. In a pull planning workshop, all parties involved in the implementation process should participate collaboratively. Working backward from an end milestone is challenging, especially for project teams that have not pull planned before. Therefore, at the beginning of the workshop, it is important to explain to attendees that the meeting will proceed in three phases, as described by Tsao et al. (2014). (1) The first step is the backward pass. It will define any work necessary to support the end milestone. (2) Subsequently comes the forward pass, when the attendees will check the workflow logic and include any additional activities required to support the end milestone. (3) The last phase is the tightening pass. In this step, the team will divide the work into smaller batches and balance workflows so as to reduce the overall duration. Even with the development of software options to aid in LPS implementation, Tsao and Howell (2022) still recommend the use of sticky notes on walls in pull planning sessions, as they provide a tangible and accessible means for first-line planners/foremen in design and construction to interact in a hands-on manner.

In this article, pull planning will be implemented in design management based on the milestones defined using the LOB technique. As described by Tvedt (2020), pull planning is used to increase productivity in the design phase. The primary objective is to establish a dependable flow in the iterative work conducted by designers, fostering collaborative engagement to formulate the optimal plan for the design phase. This process, in turn, aims to minimize waste (Tvedt, 2020).

RESEARCH METHOD

METHOD DESCRIPTION

This article adopted a design science research approach. This method assists in the search for solutions in the realm of innovation and continuous improvement (Carneiro et al. 2019) while attempting to fill the gap between theory and practice through the development of a reliable artifact (Rocha et al., 2012). Research development should be guided by its practical utility for both the organization and academia, fostering the cultivation and application of theoretical knowledge (Monteiro, 2015; Järvinen, 2007; Lukka, 2003).

As will be described in the next section, the research was conducted in a that integrates last planner routines with the design management.

DESCRIPTION OF THE STUDY COMPANY AND PROJECTS

The study company, hereafter referred to as Company X, stands out in the development and delivery of operational projects for national and international energy sectors under EPC contracts. From feasibility studies to project execution, Company X prioritizes quality, safety, and efficiency, seeking efficient and adaptable energy solutions. Adhering to high levels of quality and sustainability, it follows international standards, protects health and safety, adopts socioenvironmental practices, and holds certifications of excellence. The company is ISO 9001, 14001, 19600, 37001, and 45001 certified.

The study encompassed two projects (P and M) for the implementation of photovoltaic plants. Both projects had the same organizational structure, as shown in Figure 1. Pull planning was developed within the design sector. Project P (Figure 2) consists of a solar park in Ceará State, northeastern Brazil, covering an area of approximately 8.90 km^2. The park contains 443,190 modules, 4,345 trackers, and 13,035 strings, corresponding to a power generation of 295 MWp. The project started in February 2023 and has an execution period of 12 months. The second project, Project M, consists of a solar park located in Piauí State, covering an area of approximately 9.83 km^2. The park contains 676,566 modules, 6,633 trackers, and 1,716 string-inverters, corresponding to 445 MWp. The project started in February 2023 and has an execution period of 14 months.

The design sector is responsible for design management. The plans for Projects P and M were developed by an outsourced, independent project office. The design sector within Company X was in charge of the review, validation, decision-making, and internal approval of the designs.

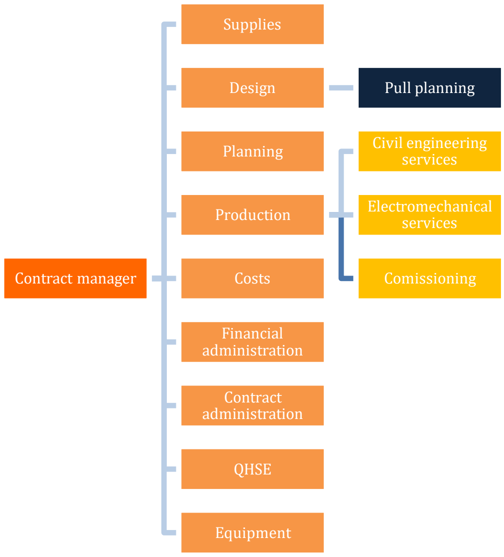

Figure 1: Organizational structure of Projects P and M in Company X

Figure 2: Aerial view of Project P

THE LEAN APPROACH IN COMPANY X

The implementation of the lean approach in Company X (Figure 3) began in February 2023, when the fundamental concepts of lean were applied in a pilot project. This was a crucial milestone for the dissemination of lean principles in construction, expanding their application to various areas of the company. The central goal was the gradual and sustainable integration of lean principles within the company.

The first phase of the project consisted of investigating the company's culture and processes. This phase was called the diagnostic phase, in which pull planning and long-term horizon sessions were applied. After the diagnosis, we focused our efforts on LPS implementation, dividing the actions into long-, medium-, and short-term goals. This period was fundamental to establish a solid foundation for application of LPS principles, referred to here as ramp-up.

In addition to LPS routines and with the objective of supporting its application, logistics studies were carried out to analyze productivity gains and promote integration between logistics and production teams. In this stage, called support, pull planning was carried out as described below.

Throughout the schedule, we dedicated several weeks to field actions through Kaizen events. These events challenged the team to achieve the predefined production rhythms, not only promoting immediate operational efficiency but also cultivating an organizational culture conducive to continuous improvement at all levels.

It is relevant to note that, during implementation of the lean approach, our scope increased, allowing the expansion of practices to different sectors of the company. This achievement highlights the flexibility and adaptability of the lean approach in the face of emerging challenges.

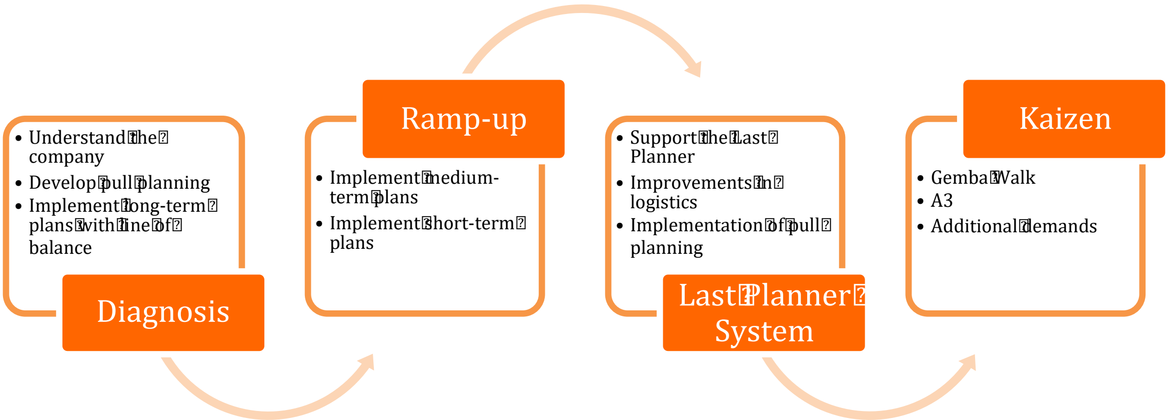

Figure 3: Implementation of lean construction in Company X

RESULTS

The business model of Company X is structured according to the contractual modality of Engineering, Procurement, and Construction (EPC) (Figure 4). Thus, the lean implementation project focused on the areas of supply and construction. LPS routines were used as supporting tools during implementation. The tasks performed by the engineering sector have a great influence on the development of construction and supply activities, generating an impact on job execution. Therefore, it was necessary to identify and structure the flow of tasks and deliveries performed in the field of engineering.

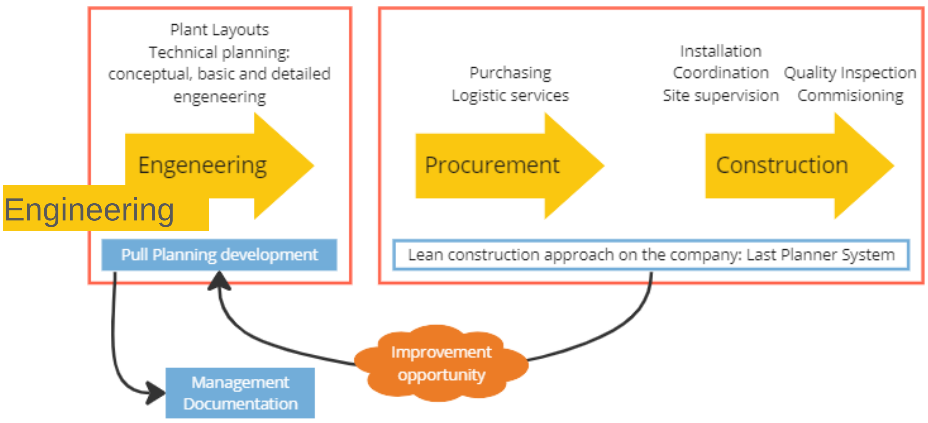

Figure 4: Lean implementation approach and opportunity for improvement

As mentioned, photovoltaic plant projects have specific characteristics. The fast execution cycle demands a short response time and a longer horizon for viewing constraints - in Project M, 8 weeks were analyzed. In supply sector, there was a high lead time for material procurement and production, and in engineering area, tasks focused on project management rather than development, as shown in Figure 5.

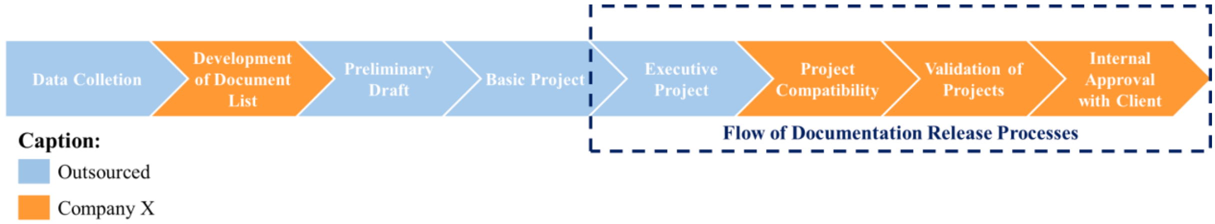

Figure 5: Flow of tasks performed by engineering

Given the need to improve the flow of tasks performed by the engineering sector (Figure 5), pull planning was proposed to improve the structuring of activities in the sector, with a focus on construction planning. Pull planning was implemented in five stages. The first four stages comprised pull planning sessions and the fifth comprised continuous monitoring of the developed plan. This tool allows creating a demand balance for an uninterrupted work system, in which value is obtained in the correct delivery flow (throughput) (Tsao et al., 2014). The workshop helps teams understand the constraints and bottlenecks of tasks and value collaboration. The planning process was carried out backward, taking as reference the milestones of the project, in a collaborative and multidisciplinary way (Tsao et al., 2014).

Pull planning was implemented through the following five stages: (i) definition of the flow of documentation release processes, (ii) documentation analysis (projects, manuals, etc.) and activity alignment, (iii) assembly of the pull planning board, (iv) definition of milestones and process flow for each activity, and (v) structuring of a weekly schedule to be monitored by the engineering sector. These steps are detailed below.

DEFINITION OF THE FLOW OF DOCUMENTATION RELEASE PROCESSES

This is the first step in the development of the engineering pull planning. The stages and flow of the development, analysis, and release of documentations are defined collaboratively with the engineering sector. Here, a flow composed of five activities was developed, encompassing the entire process (Figure 6).

Legend	Activity	Estimated time
	Begin the development of the project/document	Dependent on the document
	Internal analysis and revisions	5 days
	Collaborative posting	10 days
	Time to answer comments	5 days
	Posting for analysis of reviews – 2nd review by the client	3 days
	Released for work	1 day

Figure 6: Description of the activity flow in pull planning

ANALYSIS OF THE DOCUMENTATION LIST (PROJECTS, MANUALS, BILL OF MATERIALS, AND OTHERS) AND ALIGNMENT OF LOB

As mentioned in the chapter "The Lean Approach in Company X", during the diagnosis step, were conducted Long Term dynamics linked to the implementation of the Line of Balance. The objective was to use this tool as the Master Scheduling for the entire project, following the milestones already defined with the client. From the developed LOB, it was possible to map the Document List with all the services defined in this Master Planning. The focus was to identify each document, including projects, manuals, lists, and guidelines, needed for the execution of activities by production teams (Figure 7).

Figure 7: Description of the flow of activities in pull planning

Assembly of the Pull Planning Board

A pull planning board was assembled, in which the horizontal axis represents the timeline in days or weeks, as required by the project. The vertical axis is composed of the different activities and their respective documents, which are arranged in the order in which they will be executed (Figure 8).

The definition of the axes is the starting point for visualizing the flow of subsequent steps. This definition establishes the level of detail of monitoring activities in short-term planning to be developed at the last stage of the process.

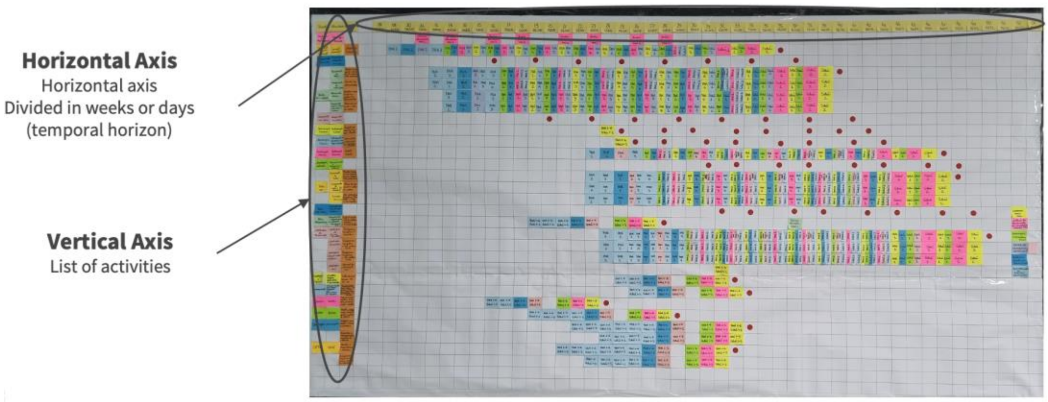

Figure 8: Pull planning board

Definition of Milestones and Process Flows per Activity

For each activity represented on the board, a delivery milestone was defined. In Project P, the milestone was validated according to the date defined in the document list. In Project M, the delivery was adjusted according to the production milestones defined by the balance sheet. It should be noted that, in this case, the unit of delivery of documentation was determined per sub-plot for most documents, as defined in the list of documents. The sub-plot unit is the same adopted in LOB planning, allowing for a better interface between the design and physical planning of the enterprise (Figure 9).

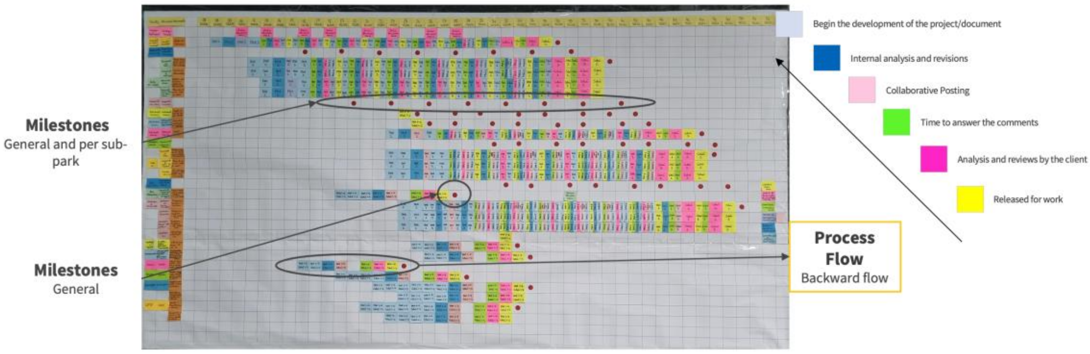

Figure 9: Pull planning board with process flow

Having defined the milestones, we determined the process flow in a backward manner, obeying the estimated delivery times of each stage. The process flow is the lined up colorful post-its that is signaled in Figure 9 as "Process Flow" and each post-it color represents a step of the process, as already explained in chapter "Definition of the flow of documentation release processes". This stage was developed collaboratively with the participation of the engineering sector coordinator, engineers, lean facilitator, planning manager, and lean consultant. With the completion of the process flow, the start date of the activity was determined, so as to meet contractual milestones.

STRUCTURING OF THE WEEKLY SCHEDULE

In the final stage, with the definition of long-term planning for engineering documentation, a weekly schedule was structured, taking into consideration the delivery times defined in each stage of the process (Figure 10).

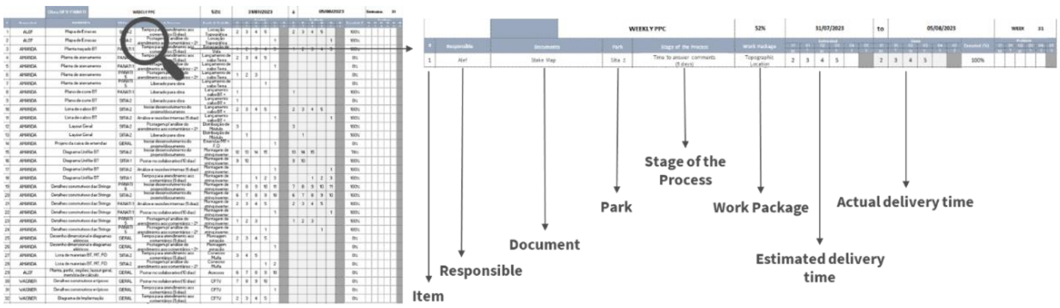

Figure 10: Process flow in the pull planning board

The definition of the weekly schedule allowed the engineering team to perform a short-term analysis for effective decision-making through percent plan complete (PPC) indicators, taking into account the completion of the activities scheduled for the week. In this case, the definitions that directly impact activity execution are communicated in advance to the leaders of the production team and the support team during medium-term planning.

IMPLICATIONS FOR PRACTITIONERS

Pull Planning is just the first step within the implementation of LPS as a routine in the Engineering area. As next steps, it is important that:

- Long Term: The document list and milestones of the Pull Planning continue to be aligned with the Line of Balance and the Master Scheduling;
- Medium Term: The activities developed in the Pull Planning are presented within the Lookahead routine to enable the analysis of constraints of these services by all sectors;

- Short Term: Execution of the Weekly Schedule, with the possibility of Check-in/Check-out, identifying problems for non-completion of the task, PPC and root cause analysis.

In Figure 11, you can see the PPC indicators of the Weekly Schedule of Project P. It is possible to identify that, as a pilot project, there is room for improvement, both in terms of adherence and in the concepts implemented.

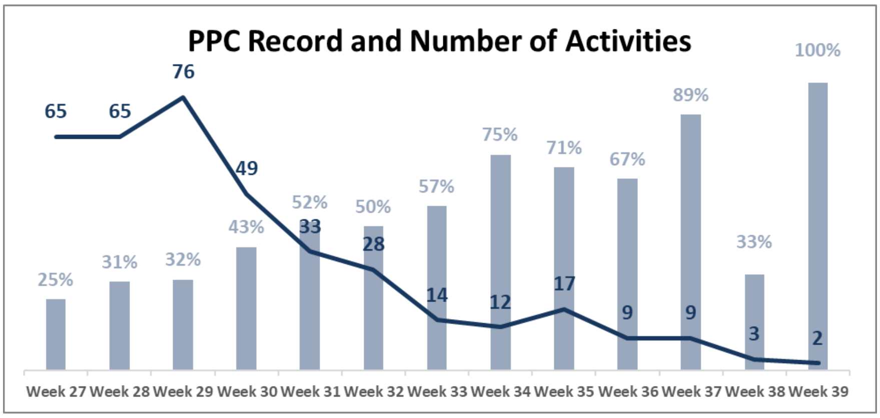

Figure 11: PPC record and number of activities from Project P from Weekly Schedule

CONCLUSIONS

Lean implementation in case study Company X effectively promoted LPS adoption and application of long, medium, and short-term tools. As already mentioned by Tsao et al. (2014) and Tsao and Tommelein (2004), the Pull planning sessions were successful in fostering collaboration and understanding among the entire team and we could understand that the prooseed tool and routine enable the better understanding and visualization of the whole project and the responsibilities considering the defined milestones. But, we could also identify that team members encountered challenges in utilizing pull planning as a management tool.

The proposed pull planning for design management provided the engineering team with greater clarity about the flow and time required for documentation, which directly influences production. Regarding the medium-term horizon, in both projects, teams had problems with anticipating constrains. The teams stopped reporting their delivery milestones in medium-term meetings, minimizing the visualization of constraints and bottlenecks for complying with the planned schedule. In the short-term management of Project M, there was insufficient compliance with the weekly schedule to produce noticeable results. In the case of Project P, the adherence was slightly higher. The planning team carried out the weekly monitoring tasks: the average PPC was 56%, and complementary data revealed an evolution of PPC as the volume of deliveries of the week reduced.

These findings revealed opportunities for improvement. A better connection of the Pull Planning for design management with the line of balance is an opportuninty. In this manner, it is possible to obtain project delivery milestones and use batches consistent with the work front attack plan. For more precise planning, it is advisable to conduct pull planning with the supply sector prior to the engineering sector, as discussed by Biotto et al. (2022). Therefore, the initial supply milestones may be used as the delivery date for the engineering pull planning. In this scenario, it is suggested that the list of documents be developed only after pull planning, to maintain the dates defined during planning.

In general, the Pull Planning for design management has great potential to align the expectations and needs of the various sectors of a project. Pull planning can generate collaborate|on and a better understanding of the demand and pace required by the client.

Additionally, it can function as a managerial tool for overseeing activities and to build a better connection between Engineering and Construction phases in EPC Projects.

A NEW AUTOMATED SYSTEM FOR RFI PROCESSING: LEAD TIME REDUCTIONS AND STAFF PERCEPTION

Oliver Pitman[1], Kasun Wijayaratna[2] and Cecilia G. da Rocha[3]

ABSTRACT

This paper presents the results of a New Automated System for managing the Request for Information (RFI) process for a Tier 1 Contractor in Australia. A before and after case study entailing two projects was carried out: one using a traditional system based on manual email exchanges (Project S) and one using the new proposed system (Project P). The results show considerable reduction in the standard deviation and average time for completing the requests for information, suggesting a streamlined and more reliable RFI process. Survey results also presented favorable outcomes, with staff noting that Project P encounters fewer delays or instances of unanswered requests. Staff also expressed greater confidence in the accuracy and reliability of responses, along with increased satisfaction regarding collaboration, communication, and the overall performance of the new system. This paper illustrates how lean principles such as "simplify" and "reduce lead time" in combination with a relatively simple innovation can create objective and subjective benefits. Furthermore, it provides practical example showcasing that such innovations do not need to be top-to-bottom driven but can be created and implemented by junior/entering level staff.

KEYWORDS

Request for Information (RFI), Lead Time, Automated system, Collaboration.

INTRODUCTION

Request for Information (RFI) processes are instrumental in guaranteeing the precision and comprehensiveness of construction documents, playing a pivotal role in project success. They are indispensable for averting delays and cost overruns, ultimately elevating the overall project performance. Al-keim (2017) underscores the vital role of RFI processes in project management, emphasizing their substantial influence on the efficiency and success of construction projects. The significance of this research extends beyond individual projects, resonating with the broader construction industry and its stakeholders.

The inspiration for this research stems from the tangible, real-world experiences acquired by the primary author during an internship program. To be precise, these experiences unfolded while actively contributing to a tender team overseeing Project S. Within this setting, the RFI process revealed several inefficiencies, such as delayed responses to technical queries and

internal disorganization leading to unanswered questions. These observations highlight the pivotal need for acquiring precise and timely information from vendors, a fundamental prerequisite for well-informed decision-making in the construction industry (Mostafa et al., 2020).

The following research paper, based on the final year undergraduate thesis developed by the first author of this manuscript, examines the impact of a newly developed automated system for RFIs processing within a major Tier 1 Construction Contractor in Australia. The system, crafted by the primary author was grounded in lean construction principles, particularly in reducing the number of steps and non-value adding activities (waste). The proposed system aims to consolidate all pertinent RFI data into a unified, easily accessible repository, simplifying workflows and significantly reducing the time dedicated to RFI coordination. The outcome was a notable improvement in efficiency and a substantial reduction in the time invested in RFIs management, leading to heightened productivity and the smooth execution of construction projects. This research thus contributes to the ongoing conversation about integrating automation technologies to enhance construction processes, aligning closely with lean construction principles, and echoing the sentiments expressed by Dowsett (2019).

LITERATURE REVIEW

In an ideal world, building designs would precise and complete with no ambiguities. Yet, this is rarely the case with documents most often being incomplete, having erroneous or conflicting information (Tilley 1997). Revisions and clarifications are thus required in the form of RFI, defined by Hanna et al. (2012) as a formal written request prompted by the contractor to acquire further information or clarification regarding matters concerning design, construction, or other contractual documents. RFIs are commonly utilized within the architecture, engineering, construction industry to address uncertainties and discrepancies, as well as to seek supplementary information (Morales et al. 2022).

From a lean viewpoint, RFI and its associated process can be viewed as a form of waste, more specifically as re-work, especially when related to incomplete, incorrect, or ambiguous information on the original design documentation (meaning this was not done right the first time). However, RFI is still a standard communication process used by companies (Gordon et al. 2023). Existing studies on this topic have mainly focused on this flow of information between architects/consultants and contractors/sub-contractors during construction (e.g. Tilley 1997, Hanna 2012, Chin 2009a, Aibinu et al. 2020). However, RFI also applies to the tender phase as examined on this paper.

RFIs are often pointed out in the literature as key performance metrics (e.g. Hanna et al. 2012, Aboseif et al. 2022). Hanna et al. (2012) develop benchmarks metrics for the assessment of transportation infrastructure projects and propose the following two quantitative metrics: (i) RFIs per million dollars of award contract and (ii) percentage of RFIs answered within the requested time period. Similarly, Aboseif et al. (2022) set out to define successful construction projects and suggest six metrics in four areas (cost, time, quality, and communication). For the last area, two of three metrics are: (i) RFI per million of dollars, and (ii) RFI processing time, with successful projects being defined by having less than 8.6 RFIs per million of dollars and of 7 days or less.

Existing investigations tend to examine RFI and its related process from a “value” lens (i.e. what are the types of RFIs, the impact they have, how to minimize/avoid them), etc but not a “flow” lens, with Chin (2009b) being one of few studies. The emphasis on the former lens is clearly justified and reasonable as we should first and foremost seek to eliminate this re-work waste, and secondly aim to reduce it to. Whitin the first lens, Tilley (1997) proposes RFIs to be classified in terms of types (alternative design solutions, approval, info clarifications, information, confirmation, others) and causes (conflicting info, incorrect info, insufficient info, and questionable info). Filho et al. (2016) organize RFIs types with regards to building systems (architecture, plumbing, fire protection and gas, electricity, etc) and/or interface between these systems. They also propose four general categories for RFIs (correction, omission, verification, and divergence) and five categories for RFIs in structural projects (poor alignment, conflicts, level difference, impracticable celling height, and structure absence), as well as ways to reduce these nine types of RFIs. Lastly, Morales et al. (2002) organizes RFIs in three categories: (i) impact (cost, time, scope, and quality), type (alternative solutions, approvals, clarification of information, others) and cause (conflict, incorrect, insufficient, questionable).

The recognition of these two lenses (value and flow) is also observed by Tilley (1997) in arguing that designs need be "effective" (i.e. serve the purpose for which they were intended) but also "efficiently" conveyed. This entails (Tilley 1997): (i) timeliness (information being supplied when required without delays), (ii) accuracy (free of errors and inconsistencies); and (iii) completeness (provision all the data required). Looking at ways to reduce such waste and increase the efficiency of RFIs processing falls under the "flow" lens. Chin (2009b) is a study example adopting this perspective. The refereed author uses Little's Law to examine Work-in-Progress levels (i.e. number of open RFIs request on a system on any given days) and its impact on delays (i.e. RFIs answered after the time frame required by the contractor, leading to delays in construction). It was found that (i) on-time response rates are low (around 50%) and processing times are unnecessarily long and (ii) delays are correlated to WIP levels, suggesting that a high WIP levels is a major cause of delays in RFI processing times (Chin 2009b).

The research carried out here also adopts a "flow" perspective and proposes a new automated system for RFIs processing. It recognizes that RFIs should be avoided in the first place by ensuring that design documentation is correct, complete, and unambiguous. However, given documentation is fail prone, this additional communication process is most often required. Thus, it becomes necessary to have it as efficient and streamlined as possible. The automated system presented was designed considering the lean principles (Koskela 2000) of (i) reducing the number of steps and (ii) reducing waste (particularly transportation, manifested here as numerous e-mail exchanges until the RFI reaches the recipient who can answer it). The main metric for assessing the success of the new system is the reduction in the cycle time (Koskela 2000), or in other words, the time required for RFI processing to be completed.

RESEARCH METHOD

This study analyzed data from Projects S and L, which utilized the traditional RFI via email and a proposed automated system, respectively. Project S focused on a major transportation initiative, aiming to establish an extensive, high-capacity rail network. The examined package included tasks such as excavating twin bored tunnels, constructing station boxes, creating cross passages, implementing viaduct underpinning for active rail lines, and installing a sewer protection structure. Project L was similar in nature to allow for comparison between the RFI methodologies. During a two-month period in 2023, staff encountered frustration due to delayed responses to vendors, leading to the collection of data tracking question timings and responses. An after-action review was conducted post-tender to evaluate perceptions of the current RFI process and assess potential enhancements for future systems.

The introduction of the new system occurred during the tender phase of a project focused on front-end engineering and design studies for the upstream production facilities of Project L (Battersby, 2023). These studies involved the development of two fields, including well pads and a central processing facility, along with the implementation of a carbon capture and sequestration scheme. Notably, the team was entirely composed of new members unfamiliar with the previous system, limiting the potential for bias. The new system collected RFI data stored in the bid directory folder within the company. The study spanned four weeks in 2023, strategically chosen to align with the busy mid-phase of the tender process, characterized by the highest number of supplier questions. This timing ensured a comprehensive dataset for thorough analysis.

Two main sources of evidence were used to assess the impact of the automated system for RFIs. First, a time delta comparison (differences between the moment an RFI is asked and when it is answered) was undertaken. In Project S this was carried out using the collected emails received and sent by procurement, then manually entering the information into an excel document. For Project P, this data was collected in the automated system. A total of 22 data points (or RFIs) for Project S (5 months, from September 2022 to February 2023) and 74 data points or (RFIs) or Project P (3 months, from August to October 2023) were collected. The RFI peak was during the middle of the tender for both projects. By examining these time intervals, insights were gained into the efficiency of the RFI process.

Furthermore, a survey with staff was carried out to gather subjective data and insights on the traditional and the automated system. Fourteen people from the infrastructure bidding team were interviewed. The survey for Project S focused on the delays and quality of responses to vendor. Eight people from Project P were interviewed were interviewed with the same questions to provide a direct comparison. The questionnaire entails a total of ten closed ended questions focused on: the average answer time of RFI, occurrence of RFI left unanswered or experiencing delays, confidence in the reliability of the RFIs process, etc. The findings for the eight core questions are summarized in Figure 6.

THE REQUEST FOR INFORMATION PROCESSES

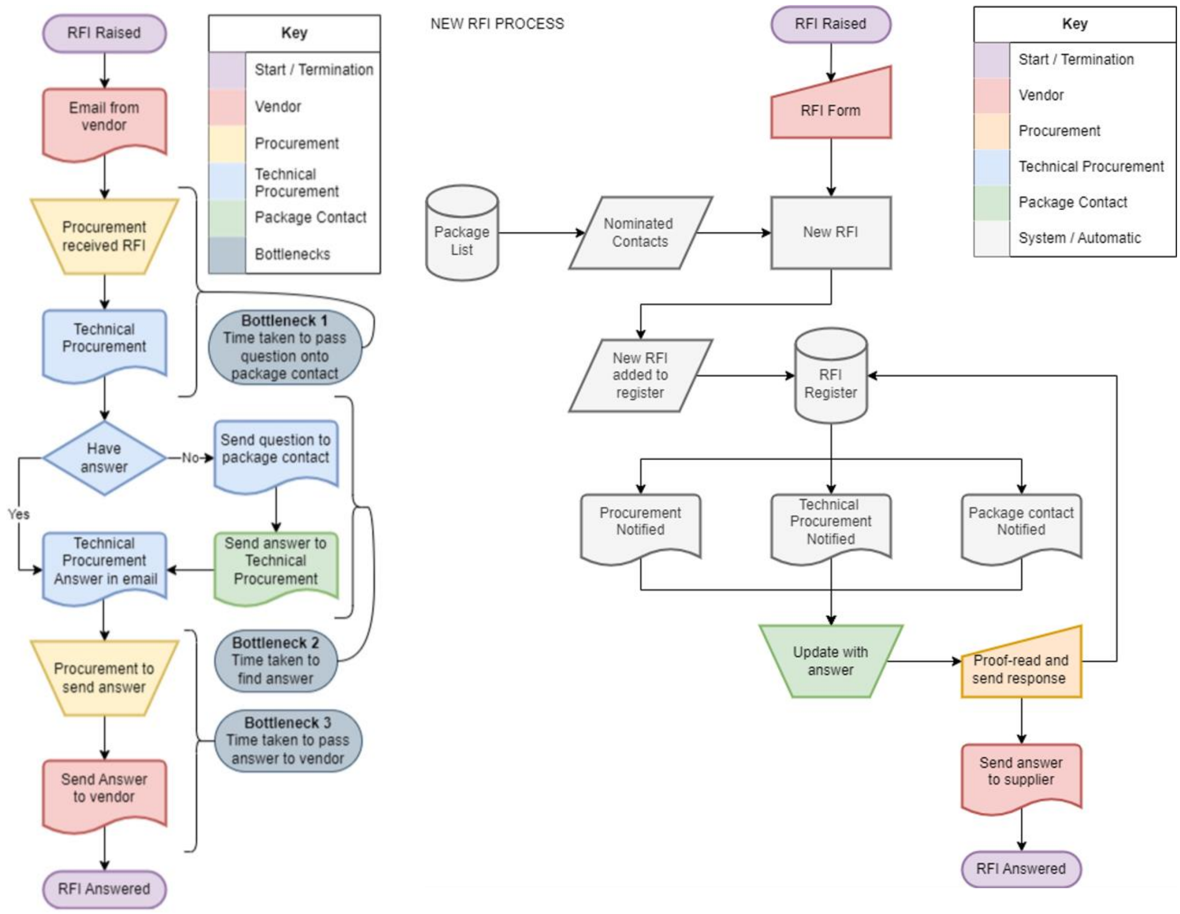
Figure 1 depicts the linear process in the Project S Tender, revealing potential bottlenecks. An RFI may go through up to four handovers before a response, necessitating relay through the same chain. Figure 2 proposes a streamlined solution with automated notifications, centralizing RFI information in a single repository. The top-to-bottom flowchart design aligns with standard principles in software development (Zen Flowchart, 2023).

BEFORE: MANUAL E-MAILS

The sequence commences with the vendor initiating contact through an email to the procurement department. Recognizing the need for a technical response, the procurement contact receives the RFI, either forwarding the request or completing an RFI document, which is then sent to the Technical Procurement team (depicted as bottleneck 1 in Figure 1a). Subsequently, the Technical Procurement team provides an answer or, if unavailable, collaborates with relevant sources like the package scope writer or other members of the construction team to acquire necessary information (indicated as bottleneck 2 in Figure 1a). Once the response is prepared, it is relayed to the procurement contact. Upon receiving the response, the procurement department promptly communicates with the vendor, indicating that the RFI has been addressed and answered (represented as bottleneck 3 in Figure 1a). All communication in this process occurs via e-mails.

AFTER: AUTOMATED SYSTEM

The system was designed using Microsoft Forms, SharePoint Lists, Microsoft Teams, Power Automate, Power BI, and PowerApps. The supplier initiates the RFI by completing a Microsoft Form (Figure 1b), which requires them to enter their details, specify the package of interest, and pose their query. Once this form is submitted, it triggers the generation of an RFI entry within the SharePoint and the request is cross-referenced with the corresponding package number to identify the designated contacts for that package. With every new entry in this list, an automated notification process is initiated, guiding the package contacts on how to maintain and update the RFI information within the list. Once the new RFI is added to the register, three simultaneous notification activities occur (Figure 1) and the RFI is directed to the procurement team for thorough review. Such team then collaborates with technical counterparts for a resolution. Once a suitable response is obtained, the procurement approves the RFI, they select the 'send' option, thereby dispatching the response to the suppliers, while simultaneously updating the RFI status to 'closed', signifying the completion of this process and marking the response time. Several challenges arise during the implementation of the system, notably the adherence of suppliers to the intended usage of the system, alongside the internal maintenance of up-to-date information within the system.



(a) (b)

Figure 1: Traditional RFI Manual Email (a) and Automated RFI (b) processes

RESULTS

PROBLEM DIAGNOSIS WITHIN PROJECT S (E-MAILS SYSTEM)

Figure 1b highlights the three bottlenecks in the former RFI process, specifically: transferring the RFI to technical procurement (1), the time to find the RFI answer (2), and the time taken to relay the answer to vendors (3). Figure 2 presents the distributions of time delays for each bottleneck type in Project S. The "X" denotes the median of the data, and the blue dot (Bottleneck 1) is classified as an outlier in the dataset. Notably, Bottleneck 2 constitutes 66% of the time required to answer an RFI. This extended duration is attributed to technical procurement, when lacking the answer, having to identify the responsible package owner and gather necessary information within the team. This often led to delays and unnecessary distractions for team members without the required information. Consequently, the automated system was developed to eliminate Bottlenecks 1 and 2. This involved streamlining notifications, removing the need to involve unnecessary team members, and concurrently tracking the package creator, who was likely to possess the answer.

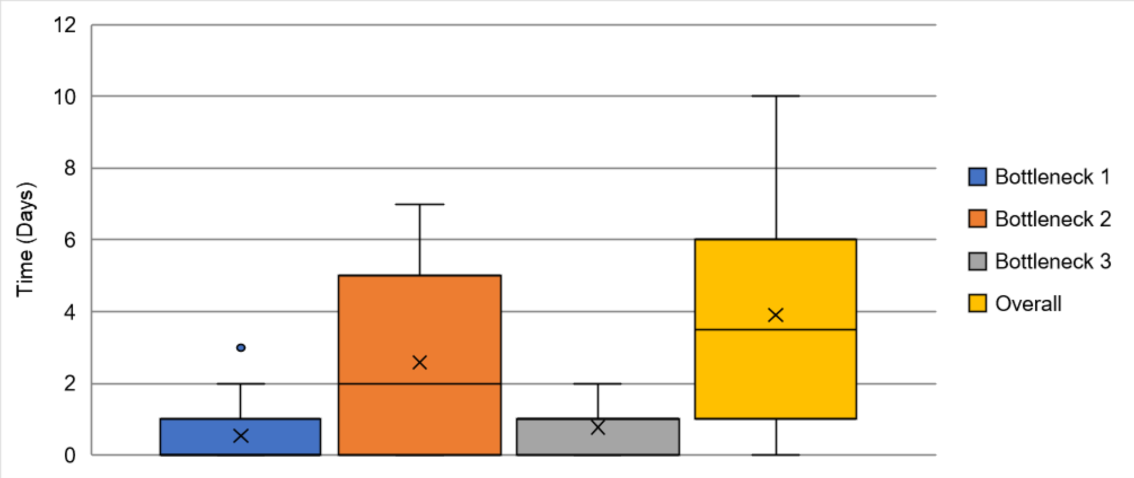


Figure 2: Bottlenecks for Project S (E-mails) based on Figure 1a

COMPARISON OF PROJECTS S AND P

The descriptive statistical analysis of the data gathered from both projects revealed a 49% improvement in mean response times: 3.91 days for Project S as compared with 2 days for Project P (Figure 2). Reliability in response times also improved across Project P, with a 9% reduction of the standard deviation of the response time data. It is important to note that there were many requests for Project P that were answered the day it was submitted resulting in a mode of 0.00, whereas the mode for Project S was 5.00 days.

Figure 3 displays the response time (t) for both the old RFI system (Project S) and the new automated RFI system (Project P) throughout the tendering period. The scatter plot for Project S appears erratic, lacking a discernible pattern. The trend line follows a mostly flat trajectory, with a notably low R2 value of 0.0009, indicating a minimal observable relationship. This suggests that RFIs are neither addressed better nor worse throughout the tender process, aligning with the idea that the previous RFI management approach hindered individuals from adapting to a systematic method, resulting in inconsistent performance. In contrast, Project P tender exhibits an observable learning curve associated with the adoption of the new system, resulting in more efficient responses over time.

Figures 4 and 5 provide a segmented analysis across fourteen-days rolling time intervals, focusing on the standard deviation and mean, respectively. This approach unveils the change in response time over specific time intervals, offering a valuable tool for identifying patterns, fluctuations, or shifts in performance that might be overlooked in longer-term averages. It aids in evaluating the impact of immediate changes or interventions on response times and detecting emerging trends that warrant further investigation.

A notable improvement associated with the New Automated System is evident with regards to mean response as shown in Figure 4. Such system creates significant enhancements as the tender progresses, with a substantial reduction in the mean average of response times as participants become accustomed to the system. For example, Project P's mean response time decreased from approximately 2.7 days to around 0.5 days. This improvement sharply contrasts with the old system, displaying fluctuations in mean response time ranging from 3 days to 7.5 days and no improvement as the tender progressed (response times even became more onerous for some time intervals). Consequently, the Automated System strongly leads to improved responsiveness with diminishing means over time. This pattern suggests that, for this case study, it took approximately 1 to 2 weeks to adapt to the new system, after which response times notably and significantly improved, as evidenced by the sharp reduction observed in Figure 4.

Figure 5 provides an insightful perspective, showing that initially, both projects had closely matched variability in response times during the first week of the tender. As participants adapted to the new system, there was a substantial reduction in response time variance. For example, Project P saw a decrease from approximately 3.3 days to about 0.5 days, a notable improvement compared to the old system, which maintained a standard deviation of around 3.5 days throughout the project duration. The results affirm that the automated system delivered efficiency and reliability benefits in response time for the case study.

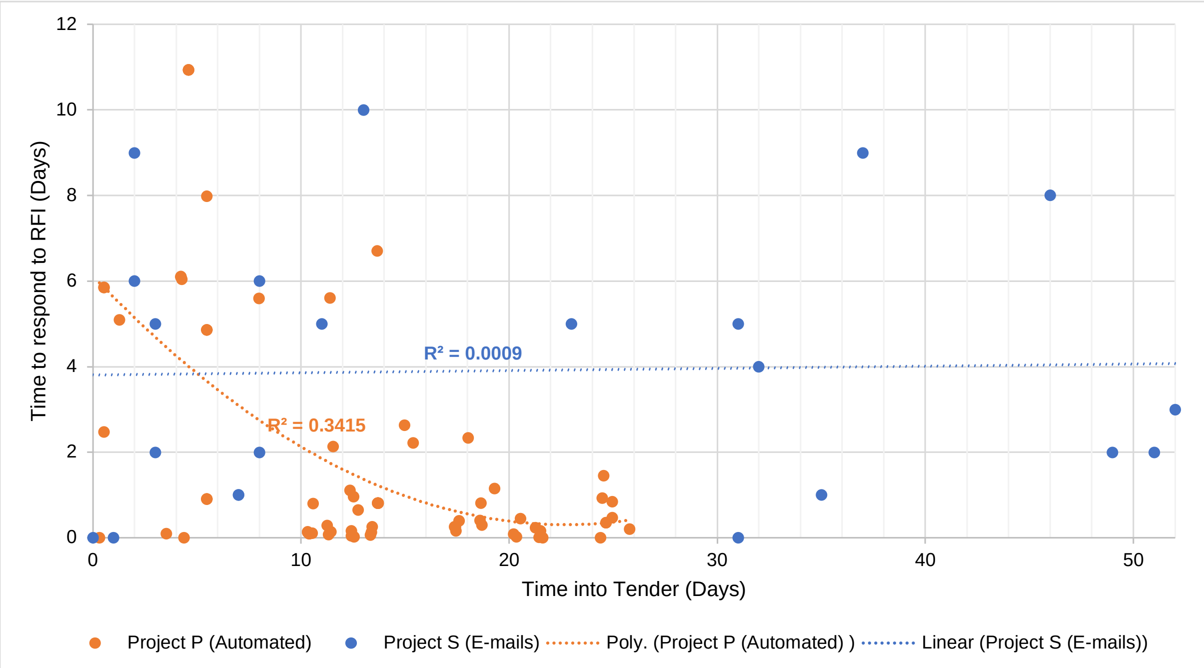

Figure 3: RFI Response Time Scatter Plot Comparison

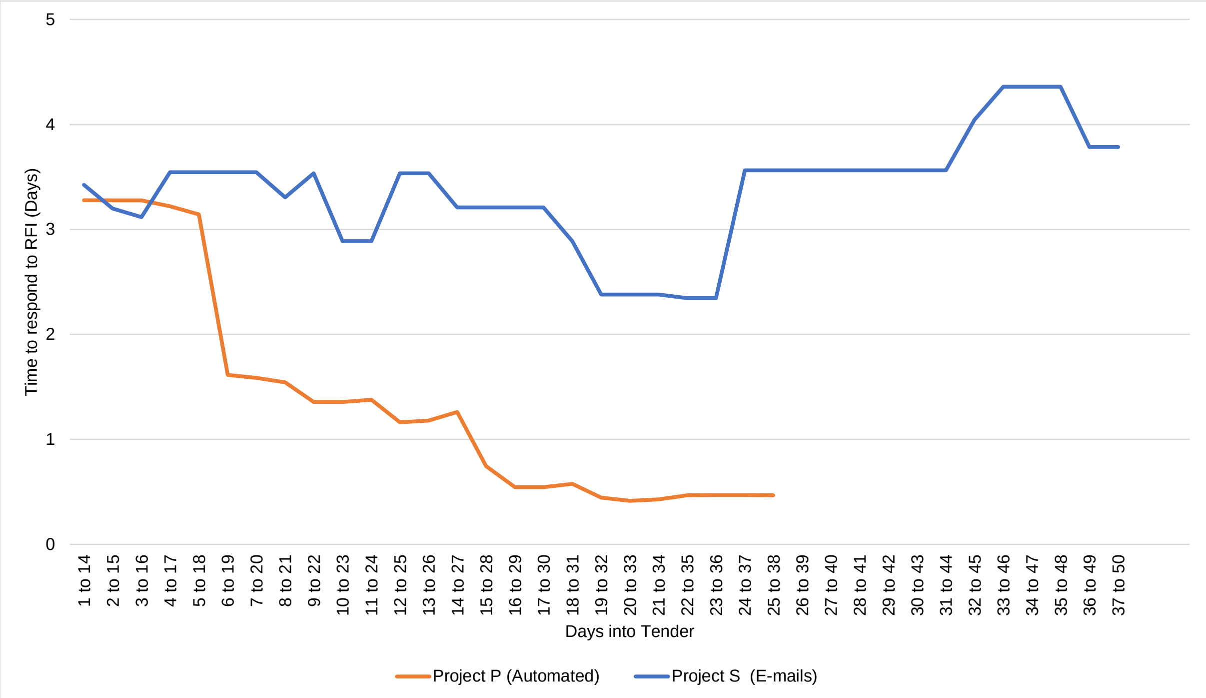

Figure 5: Fourteen days rolling tine horizon of the standard deviation

Survey Results

Figure 6 summarizes the survey results to assess the RFIs systems in Project S and P. Graphs (a) to (c) corroborate the improvements from Projects S to P noted in the objective data, detailed in the previous sections. Staff perceived a shorter lead time to respond to a technical question (a): 29% for 2-5 days for Project S and 38% for 3h or less for Project P. A noticeable decrease was also observed for RFIs that require additional clarification (b) and RFI left unattended or experiencing significant delays (c).

Project P also had a higher levels of confidence on the accuracy and reliability of the information (d) and satisfaction levels regarding the collaboration and communication (e), in comparison to Project S. Staff also perceived the confusion or misunderstandings regarding the status of RFIs or their resolutions to be less recurrent (Figure 6f): every few days in Project S (50%) versus a monthly occurrence for Project P (25%). Lastly, the Automated System (Project P) was consistently more highly rated than the traditional manual email exchange format (Figure 6h): very good or excellent (over 75%) versus poor to satisfactory (50%).

The new system was generally well-received by suppliers and staff, as individuals appreciated the establishment of a consistent and repeatable mode of interaction, in contrast to the previous chaotic and inconsistent nature of the manual system, which relied on email exchanges. Some resistance may have been encountered from smaller suppliers less accustomed to such systems. However, procurement representatives effectively guided them through the process, ultimately leading to improved response times, thereby largely satisfying suppliers with the outcomes.

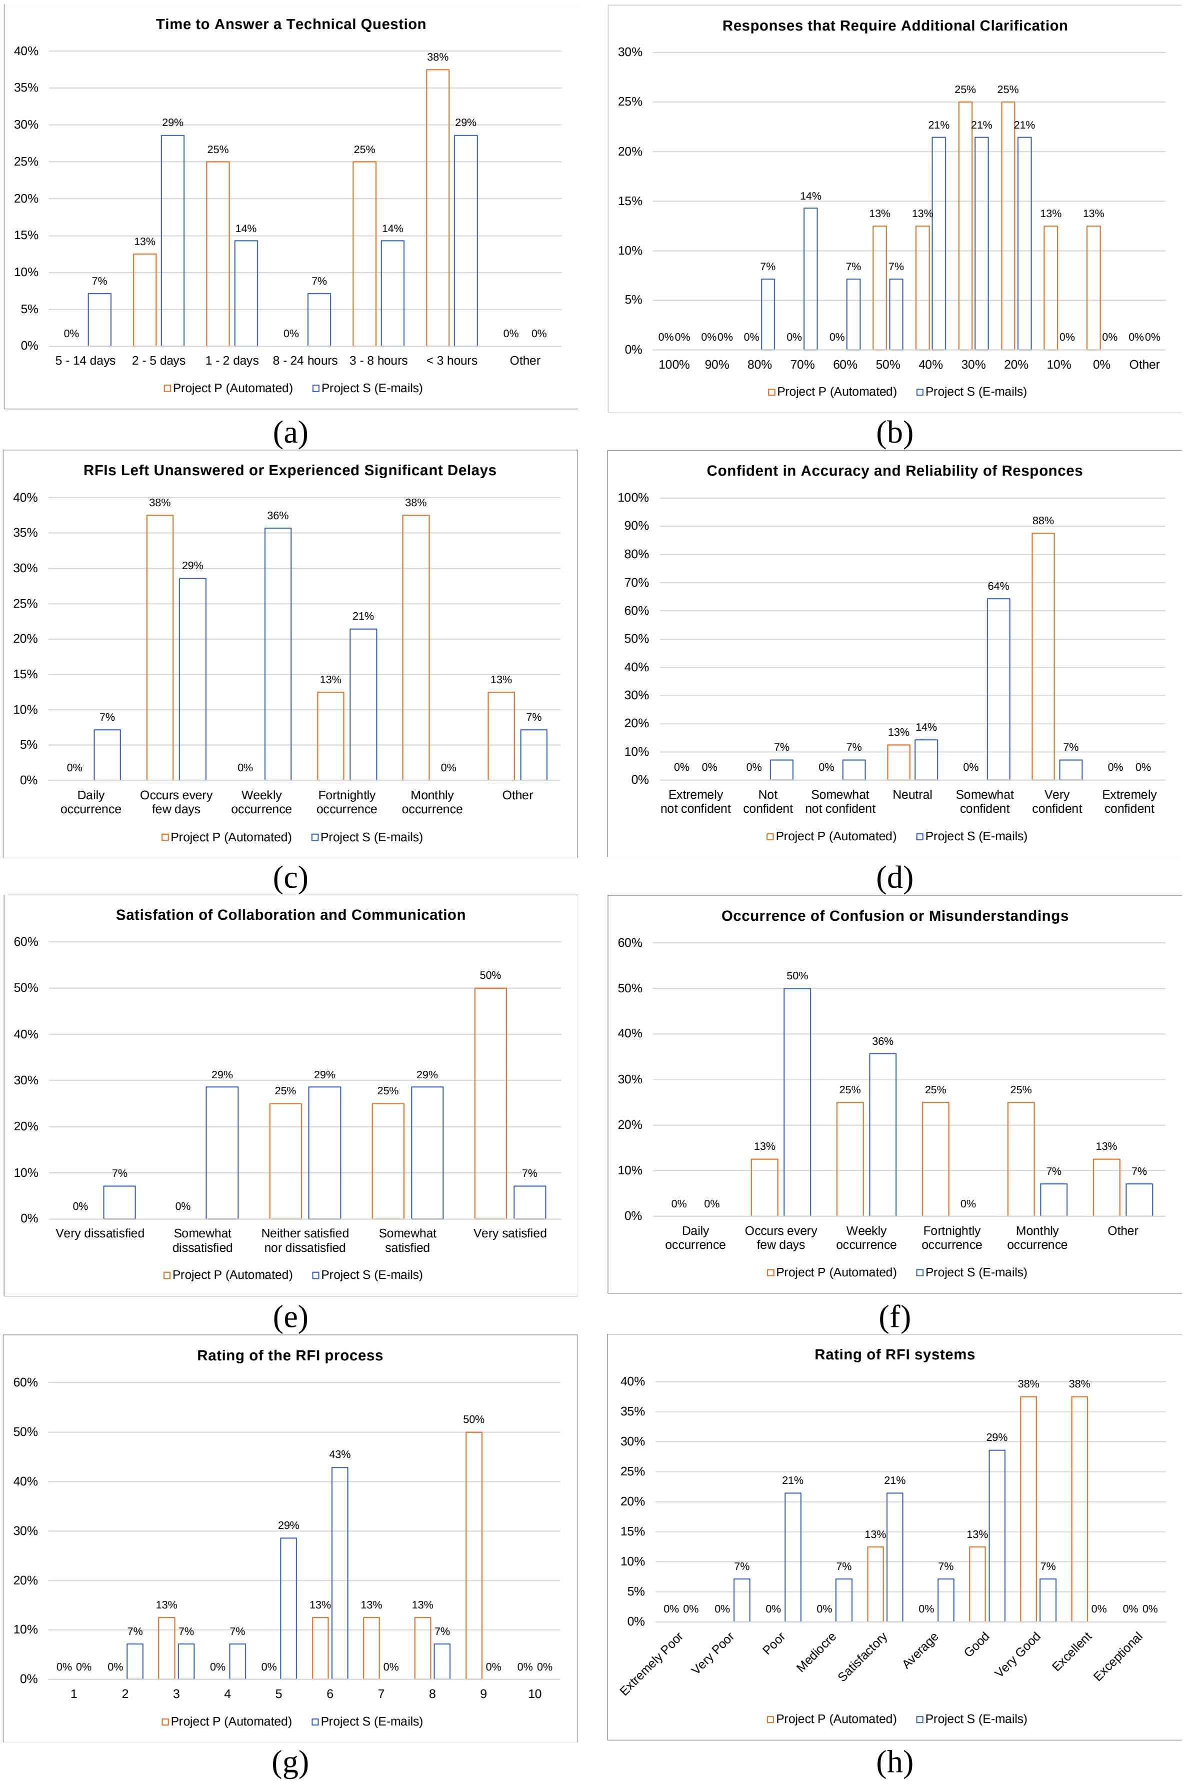

Figure 6: Survey results

CONCLUSIONS

This paper presents the results of a new automated system for RFI processing. A before and after case study, entailing both objective and subjective data, was carried out to assess the reduction in responses lead time and staff perception. Project S used a traditional system based on manual e-mail exchanges, while the new system designed according to lean principles was implemented in Project P. The objective data analysis focused on RFIs during the 3- and 5-months tendering periods for Project S and P, respectively. A reduction on the average lead time for RFI completion from 3.91 to 2 days was observed when comparing the two projects. The enhancements in the mean and standard deviations values can be clearly visualized in the fourteen day rolling averages (Figures 4 and 5). Regarding the subjective data, positive trends across all eight questions (Figure 6) were noted. The automated system was perceived to perform better than the manual e-mail process across all aspects examined, thus also corroborating the results observed for the RFIs data analysis.

In terms of limitations, certain factors, such as project size, complexity, type, prior supplier relationships, and the learning curve of the new system, were outside the scope of control for this study. Project size, complexity, and type could not be regulated due to the unique nature of each project within a feasible timeframe. Furthermore, altering these variables within such a timeframe would be impractical, given the rapidly evolving industry landscape. Different corporations also have varied supplier relationships, influenced by diverse joint venture arrangements, resulting in a range of supplier dynamics. Nonetheless, both projects underwent a fair and competitive procurement process following the company policy. The learning curve associated with implementing a new system is inevitable, as it takes time for all features to be fully utilised. In this sense, the improvements observed here are likely to be heightened if measured for upcoming project although further research is necessary to corroborate that.

Future research in automated RFI management systems for construction projects offers promising avenues for exploration. Building on the comparative analysis between traditional manual exchanges (Project S) and the automated system (Project P), further studies could delve into long-term effects on project timelines and budgets. Exploring user experiences and scalability, as well as integrating AI and machine learning, could enhance predictive capabilities. This research underscores the importance of ongoing innovation to optimise construction project management and outcomes. Lastly, this paper also showcases the potential to combine industry practice and research at an undergraduate level, ultimately, contributing to showcase and demonstrate the benefits of lean via a bottom-up route (i.e. conceptualisation and implementation of new system driven by an entry level staff).

PERCEPTIONS OF COLLABORATIVE CONTRACTS FROM THE PERSPECTIVE OF LEAN CONSTRUCTION IN CHILE

Italo Sepúlveda[1], Luis F. Alarcón[2] and Harrison A. Mesa[3,4]

ABSTRACT

Pursuing more efficient and collaborative methods in the construction industry has increased interest in collaborative contracts and Lean Construction. Despite their potential benefits, there is a lack of clarity in understanding and applying collaborative contracts in Chile. This study aims to assess the level of knowledge and perceptions about collaborative contracts among construction professionals in Chile and to explore how lean tools and principles support the implementation of these contracts. It employs a two-fold research methodology: a survey to gather empirical data, followed by a comprehensive literature. The survey focused on collecting data on the experience and perceptions of collaborative contracts, while the literature review sought to identify the intersection of these contracts with Lean Construction. The findings revealed a limited and varied understanding of collaborative contracts. Perceived benefits, such as improved efficiency and collaboration, aligned with the principles of Lean Construction. However, challenges were also identified, including the need for greater initial investment, cultural barriers, and complexity in managing multiple projects. The study emphasizes the need for a well-defined concept of collaborative contracts in Chile and posits Lean Construction as a vital tool to address challenges and bolster their implementation.

INTRODUCTION

Evidence from collaborative contracts demonstrates the superior performance of collaborative projects over traditional approaches (Bilbo et al., 2015; Ibrahim et al., 2020; Mesa et al., 2016). In this context, collaborative contracts emerge as a promising solution, aiming to improve the management and execution of projects through mutual trust, open communication, and better alignment of objectives among stakeholders. Parallel to this evolution, Lean Construction's principles may intersect with these collaborative contracts, suggesting a possibility for more efficient and less wasteful project management approaches. This study aims to assess the level of knowledge and perceptions about collaborative contracts among construction professionals

in Chile and to explore how lean tools and principles support the implementation of these contracts.

To explore and better understand these trends, a research study was conducted in collaboration with the Construction Technology Transfer Center (Centro de Desarrollo Tecnológico, CDT) of the Chilean Chamber of Construction (Cámara Chilena de la Construcción, CChC) and the Productivity Commission of the CChC.

CONCEPTUALIZATION OF COLLABORATIVE CONTRACTS

Collaborative contracts take various forms in the construction industry, such as strategic alliances, partnerships, relational contracting, and integrated teamwork (Suprapto et al., 2015). These forms, though varied, consistently promote mutual trust, joint problem-solving, and open communication. Specifically, relational contracting is based on recognizing mutual benefits and "win-win" scenarios through more cooperative relationships between the contracting parties (Ling et al., 2014; Palaneeswaran et al., 2003). Such contracts represent a unified yet flexible approach to project management, adapting to the unique demands of different projects and institutional logic and facilitating coordination among multiple parties and shared risk and reward structures (Matinheikki et al., 2019). These structures are tied to the value generated by the final product, creating a system of collaboration and shared responsibility (Cleves & Michel, 2009).

Specific types of collaborative contracts, including Early Contractor Involvement (ECI), Progressive Design Build (PDB), alliances, and Integrated Project Delivery (IPD), emphasize early and ongoing collaboration among all project participants, ensuring collaboration principles permeate every project stage (Woodhead et al., 2023).

Chan et al. (2011) highlight that, despite terminological differences, these contracts share essential elements that enhance project efficiency and performance, such as "Objective Alignment" to optimize project outcomes. Such collaborative approaches surpass traditional fixed lump-sum contracts in promoting "Trust and Transparency" (Larsson & Lasson, 2020; Yang et al., 2019). Additionally, they significantly contribute to risk management through "Risk Reduction" and "Conflict Minimization" (Macneil, 1985; Manu et al., 2015; Yang et al., 2019).

Bresnen (2007) observes that terms like 'partnership' and 'alliance' often overlap, but each captures the essence of long-term cooperative relationships. Recognizing these nuances is essential in grasping the multifaceted nature of collaborative contracts and their evolving role in the construction industry's landscape.

LEAN CONSTRUCTION AND COLLABORATIVE CONTRACTS

Lean Construction promotes efficiency and waste reduction through collaboration, aligning with the Collaborative Contracts ethos that encourages teamwork from the project’s inception (Koskela, 1992; Sarhan & Fox, 2013). While these contracts, including models like PPC2000 and NEC3, aim for mutual trust and shared goals, challenges such as the need for attitude shifts, complexity in intellectual property management, and the risk of non-binding agreements can pose significant obstacles (Woodhead et al., 2023).

Lean Construction and collaborative contracts, which seek to improve client value through integrated practices, require careful navigation when implementing collaborative agreements due to potential drawbacks such as legal uncertainties and substantial upfront investment without guaranteed returns (McAuley & Lefèbvre, 2019). While fostering joint problem-solving and risk-sharing, these investments necessitate meticulous planning to mitigate financial and operational risks (Mossman, 2009; Woodhead et al., 2023).

Furthermore, collaborative contracts that encourage concurrent engineering facilitate the Lean Construction principle of integrating design and construction phases. Yet, this approach demands managing complex acquisition rules and potential collaboration exhaustion, highlighting the critical need to effectively address multiple-party coordination challenges (Johansen & Walter, 2007; Woodhead et al., 2023).

In essence, while lean-oriented contracts promote cost savings and improved project outcomes by preventing inefficiencies (Sarhan & Fox, 2013), transitioning to collaborative contracts requires addressing inherent challenges, including attitude changes and the significant initial investments involved.

RESEARCH METHOD

This study utilizes a mixed-methodology approach, combining insights from a practical survey with an exploratory literature review. The authors applied the practical survey to evaluate the level of knowledge and perceptions regarding collaborative contracts within the Chilean construction industry. The survey was designed through a collaborative effort involving representatives from the Autonomous University of Chile, the Productivity Commission of the Chilean Chamber of Construction, and the Technological Development Corporation (CDT). The dissemination strategy involved a mass distribution to the CDT's comprehensive professional database, courtesy of the Chilean Chamber of Construction. This professional database included 1,400 individuals, yielding a response rate of approximately 6.14%, with 86 professionals providing their insights. This method achieved a substantial and varied industry representation, providing a robust analysis database.

The demographic and professional profiles of the survey respondents represented a comprehensive spectrum within the construction industry, encompassing a range of roles from architects and engineers to contractors and project managers. Among these, a notable 87% of participants hailed from the Metropolitan Region, with 45.5% serving in companies with a national reach and 40.9% working within firms with multi-regional coverage. The respondents also brought a significant breadth of experience; 56.5% had over 20 years in the construction sector, thereby enriching the study with seasoned insights.

Survey questions focused on participants' experiences, comprehension of collaborative contracts, and their perspectives on the associated benefits and challenges. The survey themes encompassed the utilization of collaborative contracts, the types of contracts employed, reasons for their selection, and the perceived pros and cons. Figure 1 shows the areas evaluated in the survey. The aspects investigated included the level of collaboration, collaboration barriers, quality improvements in projects, efficiency enhancements, and risk management tactics. Insights into the challenges encountered and lessons learned were also collected, alongside assessing the respondents' familiarity with collaborative contracts. The characterization of participants included detailed demographic and professional data, such as roles, experience, and company sectors.

An extensive literature review was subsequently undertaken to deepen the understanding of collaborative contracts and Lean Construction. The review utilized Google Scholar as a primary database, with searches centered on keywords such as 'Lean Construction,' 'Project Delivery Method,' 'Collaboration and Partnering,' and 'Collaborative Contract.' This examination aids in discerning the synergy between collaborative contracts and Lean Construction principles, significantly contributing to the study's main objectives, particularly regarding the benefits and challenges delineated in the survey.

Respondent Group	Evaluated Areas	Questions
Yes - Have used collaborative contracts	Collaborative Contracts	• What type of collaborative contract have you utilized in your projects? • Why did you choose this type of contract?
	Advantages and Disadvantages	• Have you been able to detect any advantages or disadvantages in your experience with Collaborative Contracts? • What are the significant differences and benefits you have experienced by using a collaborative contract compared to a traditional contract?
	Collaboration	• Have you managed to evaluate collaboration in relation to the use of collaborative contracts in your projects? • The level of communication and cooperation among the different project team members. • The effective collaboration among the different project team members. • The degree of trust and teamwork among the different project team members. • Have obstacles been encountered in the collaboration? Please evaluate from the project stage versus barriers • Has there been an improvement in collaboration thanks to the collaborative contract?
	Quality	• How do you perceive the quality of the projects in which collaborative contracts have been used has been measured? • Besides your perception, have key performance indicators (KPIs) been used to measure and evaluate the quality of projects with collaborative contracts?
	Efficiency	• Has there been an improvement in project efficiency thanks to the collaborative contract? • How has the efficiency of the projects with collaborative contracts been measured?
	Risks	• Have the project risks with collaborative contracts been managed? • How have the project risks with collaborative contracts been managed compared to a traditional contract? • Have there been any challenges or lessons learned in the implementation of a collaborative contract? What could be improved in future projects?
No - Have not used collaborative contracts	Level of Knowledge	• Are you familiar with collaborative contracts? • What do you believe would be the main challenges and lessons in implementing a collaborative contract?

Figure 1: Questions and evaluated areas in survey.

RESULTS

This section presents a comprehensive overview of the survey findings, delineating the discerned knowledge levels among participants concerning collaborative contracts. The section first explores the insights from industry professionals utilizing collaborative contracts, highlighting the advantages and disadvantages. Perspectives from those not engaged with collaborative contracts reveal their expectations and potential reservations. Finally, the section presents a comparative analysis, synthesizing these perspectives with the challenges and benefits identified, setting the stage for the subsequent section. Here, the authors examine how Lean principles and tools may address collaborative contracts' inherent attributes and synergies, considering aspects such as Trust and Transparency, Risk Management, Efficiency, Quality Improvement, Collaboration, Cultural Shifts, Work Structure, and the investment of initial resources. This intersection of survey results with an exploratory literature review encapsulates the current understanding and potential of collaborative contracts within the industry.

PARTICIPANT KNOWLEDGE LEVEL

The survey’s initial question inquired whether participants had implemented collaborative contracts in their projects. The findings indicate a low usage rate, with only 14% of respondents confirming their participation in such contracts. On the other hand, 86% of respondents reported that they had not used collaborative contracts. However, when these professionals were further questioned about their familiarity with collaborative contracts, 28% acknowledged having knowledge of them despite not utilizing them. This discrepancy highlights a substantial opportunity for growth and educational development in the sector.

In efforts to deepen the understanding of collaborative contracts within Chile’s Architecture, Engineering, and Construction (AEC) industry, it became apparent that there is a divergence in professional interpretations. For instance, one respondent mistakenly identified the Building Information Modeling (BIM) methodology as a collaborative contract. This example highlights the need for a clearer and more precise definition of collaborative contracts to ensure consistency across the industry.

Various contract types have been documented within the subset of construction professionals who have used collaborative contracts. However, no contracts that fully respond to the collaborative contract criteria have been identified. Despite implementing various contractual practices in the industry, there remains a gap in identifying contracts that fully meet the criteria for collaborative agreements. These criteria include effective team integration, shared risk management, and open communication. This underscores the need for a precise definition of collaborative contracts and an in-depth examination of their characteristics to foster true collaboration, going beyond the simple combination of services or methodologies.

PERSPECTIVES OF PROFESSIONALS WITH EXPERIENCE IN COLLABORATIVE CONTRACTS

Professionals who declared having used collaborative contracts select these contracts principally based on economic efficiency, risk and responsibility management, expertise and quality assurance, and operational excellence and client requirements.

Participants also emphasized 'Quality, Timeliness, and Conflict Reduction,' aiming to improve execution times and quality while mitigating conflicts and ancillary costs. 'Fair and Joint Costing' was noted as a benefit, allowing the parties to achieve a target price in a jointly developed project. The need for 'Process and Cost Optimization' was also a driving force, with the recognition that these contracts could optimize processes and costs, sometimes being the preferred contracting method for certain entities.

Finally, 'Client Requirements' also played a role in the contract type selection, highlighting the client's influence in the contractual decision-making process. This range of reasons reflects a nuanced understanding and appreciation of the strategic benefits of collaborative contracts among those who have implemented them in the Chilean construction industry.

Figure 2 shows a clear consensus in identifying both advantages and disadvantages when contrasted with traditional contracts. According to the survey results, a majority have identified benefits, with improved collaboration and communication among the involved parties being the most frequently noted advantage. This is closely followed by better risk management and prompt problem resolution, increased efficiency in project execution, greater transparency in decision-making, and enhanced satisfaction and trust among stakeholders.

Advantages		Disadvantages	
Enhanced collaboration and communication among the involved parties	23,26%	Requires a greater initial investment of time and resources to establish collaboration foundations.	33,33%
Improved risk management and early problem resolution	20,93%	Can be more difficult to implement in projects with multiple involved parties.	23,81%
Increased efficiency in project delivery	13,95%	May require a cultural and mindset change in the involved parties.	23,81%
Greater transparency in decision making	16,28%	Increased bureaucracy in decision making.	4,76%
Increased satisfaction and trust among the involved parties	16,28%	Essential fiduciary compliance of the parties, which is very difficult to achieve.	4,76%
Enhanced control of the project	2,33%	Assigns all risks to the developer.	4,76%
Increased technical capacity	2,33%	Possible increase in contract management complexity.	4,76%
Reduced environmental impact	2,33%		
Meeting cost objectives	2,33%		

Figure 2: Reasons cited by practitioners: Advantages and Disadvantages

Conversely, the disadvantages reflect concerns about the need for a greater initial investment of time and resources to establish the collaboration framework, a challenge echoed by the majority of respondents. Cultural and mindset changes of the involved parties were also cited as significant impediments, along with potential increases in bureaucracy and contract management complexity. One response highlighted the specific risk of developers assuming the burden of unforeseen conditions, such as archaeological findings, without recognizing the associated repercussions.

Therefore, the "Advantages and Disadvantages" section highlights a pragmatic recognition among industry professionals. While collaborative contracts foster a more synergistic and integrated approach to project execution, they also demand a considerable initial commitment and can introduce new complexities into the contractual landscape.

FAMILIARITY WITHOUT ADOPTION: INDUSTRY PERSPECTIVES ON COLLABORATIVE CONTRACTS

Respondents familiar with collaborative contracts but without actual use articulate several advantages such as increased trust and transparency, risk reduction, conflict minimization, improvements in efficiency and economy, early integration, alignment of objectives, and quality enhancements. These perceived benefits align with the fundamental principles of collaborative contracting, indicating an appreciation for the theoretical value these contracts can offer.

Conversely, the disadvantages cited by these respondents highlight cultural barriers, the need to foster teamwork through transparency and trust, concerns about the efficient structuring of work phases, knowledge and education gaps regarding the benefits of the contracts, and apprehensions about profitability. These perceptions reveal the perceived obstacles that could impede the adoption of collaborative contracts.

Figure 3 highlights a paradox wherein the recognized potential value of collaborative contracts contrasts with a reluctance stemming from cultural and practical concerns.

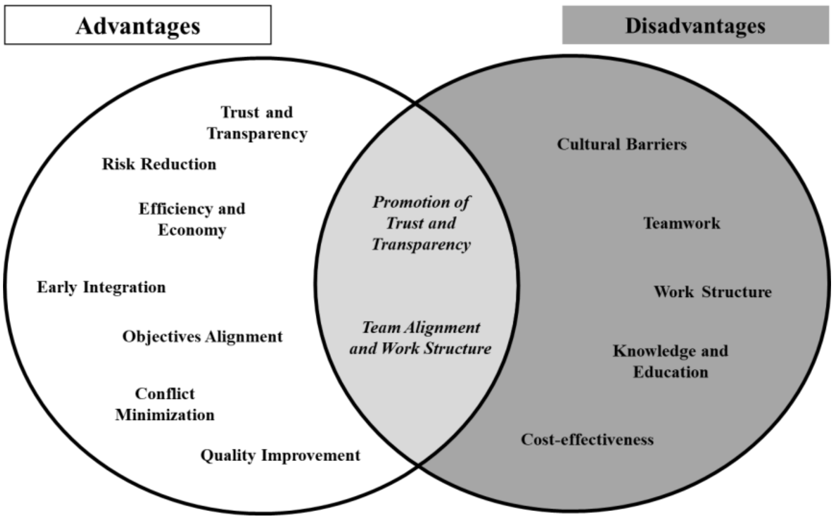

Figure 3: Intersection of Perceived Advantages and Disadvantages of those familiar but have not utilized these Collaborative Contracts.

ANALYSIS OF LEAN TOOLS AND PRINCIPLES IN ADDRESSING THE BENEFITS AND CHALLENGES OF COLLABORATIVE CONTRACTS

This section provides a focused analysis of select potential benefits and challenges of implementing collaborative contracts in the construction industry, as illuminated by Lean tools and principles. The scope is deliberately narrowed to those areas that have shown pronounced synergies with Lean methodologies and collaborative contract frameworks, thus highlighting the instrumental role of Lean Construction in enhancing the efficacy of collaborative agreements.

Experienced users, as well as those who are familiar with but have not utilized these contracts, recognize common benefits, including "Trust and Transparency," "Risk Reduction," "Efficiency and Economy," and "Improvement in Quality." Challenges such as "Cultural Barriers," "Change in Mindset," and "Work Structure" are also acknowledged by both groups, highlighting shared industry concerns.

However, differences arise between users' perspectives and those who are familiar with but have not utilized these. Users emphasize "Increased Collaboration and Communication" as a significant advantage. At the same time, they face the challenge of a "Higher Initial Investment of Time and Resources" and the complexity of "Projects with Multiple Parties." Those who are familiar with but have not utilized these may lack the direct experience to appreciate these nuances fully. Figure 4 presents an overview of the potential benefits and challenges.

Type	Detail	Lean Tool/Principle/Technique	Brief Description
Advantages	Trust and Transparency	Last Planner System® (LPS®)	Promotes transparency and trust through active planning and execution.
Advantages	Risk Reduction and Management	Kaizen	Continuous improvement to identify and eliminate risks and waste.
Advantages	Efficiency and Economy	Lean Production Practices	Reduces overburden and non-value-adding work to enhance efficiency.
Advantages	Quality Improvement	5S	Focuses on quality from design to execution, creating an efficient work environment.
Advantages	Greater Collaboration and Communication	Value Stream Mapping, LPS®, Building Information Modeling (BIM)	Enhances understanding of work flows and improves coordination.
Disavantages	Cultural Barriers and Mindset Change	Lean Training and Workshops, Respect for People	Shifts towards a more collaborative and team-centered approach.
Disavantages	Work Structure	Integrated Project Delivery (IPD), Value Stream Mapping (VSM)	Promotes integrated and efficient work from the project's inception.
Disavantages	Initial Time and Resource Investment	Training, Process Restructuring	Views initial investment as short-term cost for long-term benefits.
Disavantages	Difficulties in Multi-party Projects	IPD, LPS®, BIM	Manages complexity in projects involving multiple teams and disciplines.

Figure 4: Intersection with Lean Construction

Trust and Transparency. Trust and transparency are pivotal in collaborative contracts, a sentiment echoed by industry professionals in our survey and supported by Lean Tools. Integrating Lean tools like the Last Planner System (LPS) into project management practices enhances these elements by facilitating clearer communication and task visibility, as Ribeiro & Costa (2018) demonstrated. Their work underscores the significance of visual aids in presenting information straightforwardly, fostering improved stakeholder communication and collaborative planning. Chiu & Cousins (2020) further confirm that LPS's implementation can lead to better alignment within design teams and schedule adherence. Lühr et al. (2023) contribute a nuanced view, proposing that while transparency promotes a more accurate evaluation of partners' reliability, it does not automatically translate into trust—a reminder that transparency acts as a foundation for, but is not synonymous with, trust.

Risk Reduction and Risk Management. Survey respondents highlighted risk reduction and management as key benefits of collaborative contracts, which Lingard & Lin (2004) and Muchinsky (2006) substantiated through the lens of Lean Construction. With its focus on continuous improvement, the Kaizen principle has been pivotal in mitigating risks by fostering a constant process evaluation and enhancement cycle. Muchinsky (2006) notes the positive ripple effects of Kaizen on job satisfaction, leading to a more organized work setting and preemptive risk handling. Lingard & Lin (2004) concur, emphasizing how process standardization and a quality-centric approach from inception to completion enhance job satisfaction and bolster workers' dedication to their tasks. This collective emphasis on systematic improvement via Kaizen underpins a safer, more predictable project landscape.

Efficiency and Economy. The integration of Lean Construction principles, as identified by Cheng (2015), directly aligns with the efficiency and economic benefits highlighted in the survey regarding collaborative contracts. Lean practices, notably the elimination of non-value-adding activities, play a crucial role in enhancing project outcomes. Cheng emphasizes the importance of a continuous value flow, distinguishing between controllable aspects, like material and equipment management, and uncontrollable ones, such as supply chain and design information dynamics. This foundation of Lean Construction ensures a smoother, more efficient workflow, significantly reducing project costs and timelines, thereby boosting overall profitability and demonstrating the practical benefits of Lean methodologies in realizing the potential of collaborative contracts.

Improvement in Quality. The emphasis on quality improvement, as a recognized benefit of collaborative contracts from survey feedback, is mirrored in Lean Construction principles, notably through adopting the 5S methodology and visual management tools outlined by Bajjou et al. (2017). The 5S framework—Sort, Simplify, Sweep, Standardize, and Self-discipline—establishes an orderly and efficient environment, laying the groundwork for high-quality outcomes in every project phase. Additionally, visual management enhances transparency and safety, facilitating improved communication among project participants. This integrated approach ensures continuous quality improvement from design to execution, demonstrating the synergy between Lean Construction practices and the quality enhancement goals of collaborative contracts.

Greater Collaboration and Communication. Survey findings identify both the enhancement of collaboration and communication as pivotal benefits and challenges within the context of collaborative contracts. Lean Construction, with its focus on fostering a collaborative culture, leverages tools like Value Stream Mapping (VSM) and the Last Planner System (LPS), as detailed by Setiawan et al. (2021) and Mossman (2005), respectively. VSM helps team members visualize the project's workflow, encouraging a unified approach by elucidating each participant's role in enhancing efficiency and customer satisfaction. Similarly, LPS fosters alignment on project goals through regular, collaborative planning sessions, minimizing misunderstandings and ensuring coherent team efforts. Additionally, the integration of Building Information Modeling (BIM), as noted by Liu et al. (2017), offers a shared digital platform that further streamlines team coordination. Together, these methodologies underscore the crucial role of advanced planning and technology in bridging communication gaps and cultivating a cooperative project environment, reflecting the dual nature of collaboration and communication as both a benefit and a challenge in implementing collaborative contracts.

Cultural Barriers and Mindset Change. As reflected in survey responses, addressing cultural barriers and the necessity for a mindset shift has emerged as a notable challenge in the adoption of collaborative contracts. As Moradi and Sormunen (2023) articulate, Lean Construction requires more than adopting tools; it calls for a profound organizational culture shift toward collaboration and team orientation. Key to navigating these barriers is engaging all organizational tiers in Lean-oriented educational activities, which underscore the philosophy's collaborative and continuous improvement ethos. Such initiatives, coupled with senior management's commitment and the promotion of respect and teamwork, are essential in cultivating an environment conducive to embracing Lean methodologies. This strategy underscores the importance of a supportive and inclusive culture in facilitating the transition towards more efficient, collaborative construction practices.

Work Structure. The reconfiguration of work structures emerges as a key challenge respondents highlight regarding implementing collaborative contracts. Adopting Integrated Project Delivery (IPD) and tools like Value Stream Mapping (VSM), Lean Construction addresses this challenge by promoting a seamless, integrated approach to project delivery. IPD, as noted by Mesa et al. (2016) and Viana et al. (2020), fosters a collaborative environment from a project's inception, ensuring alignment of interests and facilitating efficient communication and teamwork. This approach enhances performance and distributes gains and risks more equitably among all stakeholders. Additionally, VSM's role in elucidating the construction process, as demonstrated by Paciarotti et al. (2011) and Serrano et al. (2008), helps pinpoint inefficiencies, thereby streamlining operations and elevating strategic capacity. This dual emphasis on IPD and VSM underlines the importance of structured, collaborative work environments in overcoming the inherent challenges posed by new contract models.

Initial Investment of Time and Resources. The necessity for an initial investment of time and resources has been identified as a challenge in adopting collaborative contracts. This upfront commitment includes extensive staff training, process reorganization, and integration of novel tools and technologies. Despite the initial costs, it is vital to recognize these expenditures as investments towards long-term gains. Nahmens and Ikuma (2012) support this view by showing that Lean Construction can significantly decrease material waste and production hours while enhancing safety, thereby promoting sustainability. This perspective underscores the importance of effectively communicating the value of this initial investment in Lean practices, highlighting its potential to boost project efficiency, quality, and overall financial performance.

Challenges in Projects with Multiple Parties. The challenge of managing construction projects with multiple parties was underscored in survey responses, highlighting the complexity of coordinating diverse teams and disciplines. Lean Construction principles, including adopting Integrated Project Delivery (IPD), are instrumental in addressing these challenges. IPD fosters a unified approach by aligning the interests of all stakeholders and promoting collaborative decision-making, essential in complex, multi-stakeholder projects. Ebrahimi & Dowlatabadi (2018) and Hamerski et al. (2019) emphasize the hurdles encountered in maintaining collaboration and operational efficiency, selecting competent teams, and implementing IPD effectively. Furthermore, tools like the Last Planner System (LPS) and Building Information Modeling (BIM) play pivotal roles in improving project management by enhancing planning and ensuring coherent communication across teams. This approach underlines the necessity of a cohesive strategy to efficiently manage the intricacies of projects involving numerous parties.

This literature review elucidates the congruence between Lean Construction principles, tools, or techniques and collaborative contracts, illustrating how Lean Construction tools can underscore the benefits highlighted in the survey on collaborative contracts. The parallelism between trust and transparency in collaborative contracts and the Last Planner System® (LPS®), or how the Value Stream Mapping (VSM) technique aligns with promoting integrated and efficient work, resonates with the challenges identified in collaborative contracts. Nonetheless, ascertaining the level of Lean Construction knowledge among professionals is paramount to ensure that the identified synergies can be harnessed in practice, thus amplifying advantages and overcoming any disadvantages or challenges.

CONCLUSIONS

The survey underscores a significant shortfall in the uptake of collaborative contracts within Chile's construction industry, with a mere 14% of professionals reporting their deployment. Additionally, only 27% familiarity with these contracts is noted among those not currently employing them. These results suggest fertile ground for incentivizing the use of collaborative contracts, initially through educational endeavors followed by demonstrating their merits in construction projects.

In summarizing the findings from the survey, it is imperative to elucidate the definition of collaborative contracts within the Chilean construction industry to foster their application. The survey indicates a substantial potential for enhancing the adoption rates of collaborative contracts among projects and professionals. However, it also signals the need to explore the underlying reasons for their underutilization.

Building upon the survey's insights, the perceived advantages of collaborative contracts come to the forefront, emphasizing their transformative potential in the construction sector. The professionals´perceptions indicate that these advantages include the establishment of trust and transparency between stakeholders, a cornerstone for any successful collaborative venture. Moreover, they facilitate a reduction and better management of risks, ensuring a more predictable and stable project environment. The survey also identifies efficiency and economy as key benefits, with collaborative contracts perceived to streamlining processes and cutting unnecessary costs, leading to an overall improvement in quality. Notably, these contracts are seen to enhance greater collaboration and communication, which are pivotal in achieving project objectives with aligned stakeholder interests.

Conversely, the survey sheds light on several disadvantages that impede the widespread adoption of collaborative contracts. Cultural barriers and the need for a mindset change present substantial challenges, as they require a shift from traditional practices to a more cooperative approach. Work structure emerges as another obstacle, with existing frameworks often ill-suited to collaborative contracts' flexible and integrative nature. The initial investment of time and resources is a deterrent, with a clear need to demonstrate the long-term value to overcome short-term reservations. Finally, the complexity of managing multi-party projects under collaborative contracts is highlighted as a significant hurdle, necessitating adept coordination and robust conflict-resolution mechanisms. These challenges demand a strategic focus to harness the full potential of collaborative contracts within the industry.

Reviewing the literature reveals a symbiotic relationship between Lean Construction methodologies and collaborative contracts, which proposes a dynamic framework to propel the construction industry forward. Lean Construction, with its core principles and techniques such as the Last Planner System® (LPS®), Kaizen, and Value Stream Mapping (VSM), provides a structured approach that bolsters transparency and trust, key tenets in collaborative contracts. The continuous improvement and risk management inherent in Kaizen and the efficiency ethos of Lean Production Practices directly buttress the fundamental attributes of collaborative contracts focused on efficiency and economic prudence.

Furthermore, Lean Construction's commitment to quality enhancement through the 5S methodology is in harmony with the collaborative contracts' pursuit of elevated standards and greater cooperation. The employment of Value Stream Mapping, LPS®, and Building Information Modeling (BIM) within Lean Construction facilitates an advanced understanding of workflow and communication, capabilities essential to overcoming the cultural barriers and mindset changes frequently perceived as drawbacks in the realm of collaborative contracts.

Lean Construction is committed to enhancing work structures through targeted training and workshops. By promoting respect for each individual and fostering a collaborative, team-centric approach, this methodology effectively addresses the challenges faced in work environments. The initial time and resource investments, often seen as constraints in collaborative contracts, are recontextualized within the Lean paradigm as strategic investments yielding long-term returns, thereby offering a counterbalance to the initial expenditures. Ultimately, the arsenal of Lean Construction tools adeptly manages the complexities inherent in multi-party projects, thus confronting a pivotal challenge of collaborative contracts. The Lean Construction toolbox complements and intensifies the advantages of collaborative contracts, simultaneously offering strategies to surmount their intrinsic disadvantages.

ACKNOWLEDGMENTS

We extend our heartfelt thanks to the individuals and organizations whose contributions were vital in developing this article. Special appreciation goes to the Corporación de Desarrollo Tecnológico (CDT) of the Cámara Chilena de la Construcción (CChC) for their invaluable support and insights, as well as the Comisión de Productividad of the CChC.

We also appreciate the academic support and collaboration of the Universidad Autónoma de Chile. We are particularly grateful to Mariela Muñoz, Leader of Human Capital and Academic at the CDT, and Jose Luis Jimenez, Leader of Productivity at the CDT, , as well as dedicated student Franco Lopez Nuñez.

The authors acknowledge the financial support from ANID via the FONDECYT Regular project No. 1210769, thank the Production Management Centre GEPUC at Pontificia

Universidad Católica de Chile for facilitating this study, and appreciate the support from ANID BASAL FB210015 CENAMAD.

TRADITIONAL TENDER VERSUS EARLY CONTRACTOR INVOLVEMENT (ECI): A COMPARATIVE ANALYSIS OF WORK HOURS

Lachlan Saunders[1], Kasun Wijayaratna[2] and Cecilia G. da Rocha[3]

ABSTRACT

The strategy of Early Contractor Involvement (ECI), wherein contractors participate in a project's design and planning stages, is seen as an effective approach to address inefficiencies and complex interpersonal dynamics of construction projects. These challenges arise from contracting and procurement systems that do not promote collaboration, leading to delays and increased costs. Tendering, marked by competition and unpredictability, mirrors the industry's fragmentation and waste. Contractors face issues such as scope ambiguity, flawed documentation, market volatility, strict deadlines, and probity. This paper conducts a comparative analysis of two infrastructure projects in Australia, involving a tier 1 Contractor. Each project underwent both a traditional tender and ECI, facilitating comparisons. The results indicate that ECI tends to extend the time and resources utilized by contractors, with Project 1 and Project 2 experiencing increases of 12 weeks and 10 weeks, respectively, along with additional work hours and personnel. Despite ECI increasing time and resources, it improves the tendering process by enhancing certainty, focus, and communication.

KEYWORDS

Collaboration, Tender, Workhours, Collaborative Project Delivery.

INTRODUCTION

Current practices in contracting and procurement contribute to financial waste and hinder collaborative initiatives (Farrell & Sunindijo, 2022). Projects, especially those that are intricate and dynamic, exhibit low productivity, delays, and frequently surpass budgetary limits (Kim et al., 2016). Within project, tendering is a specific stage in the construction industry burdened with inefficiencies, uncertainties, and challenges related to resource allocation. Primary contractors wrestle with the task of securing projects through competitive pricing while avoiding potential cost overruns (Urquhart & Whyte, 2020). Addressing these inefficiencies not only promises clients and contractors increased certainty in tender outcomes but also facilitates smoother handovers to site teams and empowers contractors to trim business expenses or bid for additional work.

The incorporation of the lean philosophy into construction management seeks to maximize value while minimizing waste. A key aspect of this philosophy is the collaborative nature with anticipated engagement of relevant stakeholders. This includes Early Contractor Involvement

(ECI), which entails the early introduction of the contractor into a project's lifecycle. Typically, ECI involves the contractor providing design, pricing, and scheduling inputs before the primary contract is awarded (Rahman & Alhassan, 2012). This practice generally fosters improved relationships between clients and contractors, enhances constructability, and promotes shared risk. Indeed, innovative project delivery approach (e.g. Integrated Project Delivery, Strategic Partnerships, etc) have been shown to improve overall projects performance (e.g. Paulsen et al. 2023, Hanna et al 2023, Mavik et 2021).

ECI is perceived as valuable for contractors, enhancing productivity during construction (Pheng et al. 2015, Rahman and Alhassan 2012). However, the impact of ECI on the internal operations of contractors remains unexplored, specifically at the tendering stage. Furthermore, there is a lack of consensus in the limited literature concerning its influence on resourcing. While Gransberg (2013) and Pheng et al. (2015) argue that contractor design inputs and concurrent planning can expedite the preparation phase, reducing it by 30-40% according to Mosey (2009), Malvik et al. (2021) present case study evidence suggesting that ECI may extend procurement timelines. Differently, Sødal et al. (2014) observed an increase in time and resources during the design and preparation phases. Additionally, Greenhalgh (2013) emphasised a heightened presence of senior staff during the early stages due to ECI.

This research aims to investigate the effects of ECI on the tendering process and assess the value it may offer. Specifically, it seeks address the following question: (i) What effects does ECI have on the length and resource use (staff numbers, hours, and disciplines) for contractors compared to Traditional tender? This paper is based on the final year undergraduate thesis developed by the first author of this manuscript.

COLLABORATIVE PROJECT DELIVERY MODELS

Non-traditional or collaborative project delivery models (e.g. Integrated Project Delivery - IPD, Strategic Partnerships, etc) are believed to increase the quality of constructing products, while lowering overall costs, and expediting completion times. Indeed, a number of studies set out to assess the performance such models and/or compare these against their traditional counterparts, notably Design-Build (DB) or Design-Bid-Build (DBB) (e.g. Suttie 2013, Assainar and El Asmar 2014, Ibrahim and Hanna 2019, Kulkarni et al. 2012). Kulkarni et al. (2012) examined two proxies for IPD and DBB, respectively, CM-at-Risk (CMR) and Competitive Sealed Proposal (CSP). It was found that the overall cost is more reliable for CMR projects and that reducible changes for error, omissions and design modifications is also lower. Ibrahim and Hanna (2019) examined a data set of 109 projects delivered using DB, DBB, CMR, or IPD and found statistically significant differences among these models in five performance areas (cost, schedule, quality, communication, and change management). The pairwise of comparison of the models also showed that DBB performs noticeably worse than the others, in particular IPD. Assainar and El Asmar (2014) examined the two non-traditional collaborative approaches: (i) Contractor and Subcontractor's involvement in the design phase, and (2) Architect or Engineer (A/E)'s involvement in the construction phase. Statistical tests using performance scores for 30 construction projects complete in the US show that non-traditional approaches are significantly linked to improvement in project quality.

Such studies attest the benefits attained with the integration and collaboration of all stakeholders in early stages of a project. This includes ECI, however, thus new model does alter Contractor's traditional ways of working, particularly during the early non-construction stage. Indeed, the impact of Early Contractor Involvement (ECI) on tendering and its effect in the contractor resourcing is less explored. According to Pheng et al. (2015), ECI typically involves a "two-stage tendering" approach, where, in the initial contract, contractors provide design advice, address key risks, and work towards a target price before the main construction contract is awarded (Pheng et al. 2015). By adopting this initial appointment approach, contractors can differentiate themselves based on experience and capability, moving away from a sole reliance on price (Love et al., 2014). Love et al. (2014) further contend that, even if not all contractors are proficient in ECI, it could still be applied in situations where competitive tendering is limited. Malvik et al. (2021) explored projects with extended procurement phases involving collaboration and negotiation with multiple contractors to establish competitive pricing. For ECIs where contractors contribute to design, this involvement leads to an increase in time and resources during the project's early stages (Sødal et al. 2014). On the other hand, the simultaneous development of project aspects can reduce preparation time (Pheng et al. 2015), a notion supported by Mosey (2009), who quantifies time savings of up to 30-40%.

Gransberg (2013) suggests that procurement times can be reduced through contracting procedures and aggressive deadlines rather than relying on ECI alone. However, contractors' inputs can expedite the design process (Gransberg 2013). Both contractors and clients commonly allocate senior staff to play more substantial and prolonged roles in the early stages of a project, characterized by potential reimbursement of costs but relatively low profit margins (Greenhalgh 2013). Furthermore, project teams, including seasoned project engineers, may be extensively engaged for tasks such as estimating, scheduling, and procurement, as emphasized by Migliaccio and Holm (2018). Long-term benefits in tender resourcing are also recognized by various researchers, such as the reduction of arbitrary tendering highlighted by Love et al. (2014) and the generation of more consistent work streams suggested by Song et al. (2009). Mosey (2009) contends that, even in cases where upfront costs do not necessarily decrease, the initial investment is anticipated to yield enduring advantages.

RESEARCH METHOD

This study focuses on the Tender Process, encompassing the development and submission of pricing, programs, and necessary documentation to compete for project awards, along with associated negotiations and planning, prior to contract execution. Traditional Tendering is operationally defined as the contractor's unpaid development of a tender submission in response to a Request for Tender (RFT) to vie for a project. Early Contractor Involvement (ECI) is conceptualized as a process wherein a contractor is engaged by a client, typically for a fee, at an earlier project stage, offering various services involving design inputs, scope definition, and budget pricing. The tender process, involving pricing development and persuading clients to award contracts, is inherently integrated into this ECI phase. Notably, both examined projects were tendered under both traditional and ECI models.

PROJECTS 1 AND 2

'Project 1' entailed remediation of control systems and valves for a state-owned corporation, denoted as 'Principal 1' (Figure 1a). Having unsuccessfully bid for a Design and Construct (D&C) contract in late 2019 (referred to as 'Traditional'), the Contractor was later appointed as one of two delivery partners in 2021 by Principal 1. The project underwent partial completion, and in 2023, following an Expression of Interest (EOI) directed at the two delivery partners, the Contractor was chosen to enter an Early Contractor Involvement (ECI) stage to evaluate and formulate a scope, subcontracts, pricing, and a program (referred to as 'ECI'). Subsequently, the Contractor secured the Construct-Only contract for the remaining works. 'Project 2' entailed a D&C contract for enhancements and additional filtration facilities at a major water treatment plant for a council, designated as 'Principal 2' (Figure 1b). After being shortlisted following an Expression of Interest, the Contractor submitted a tender proposal in 2021 ('Traditional'). The project experienced a 12-month hiatus before the Contractor was exclusively engaged to undergo an ECI process in 2023 ('ECI'), ultimately securing and executing the contract.

DATA COLLECTION AND ANALYSIS

The data collection involved quantitative data, namely, timesheets for the two projects examined for the traditional and the ECI tender periods, with a further analysis of workhours per discipline for Project 2 (data which is not available for Project 1). Qualitative data was also gathered in the form of six semi-structured interviews involving key pre-contracts and delivery personnel, including a general manager, construction manager, planning manager, and several estimators. A thematic analysis of interviews (Braun and Clarke 2006) method was carried out, in which the transcripts were coded through manual annotation and note-taking, then grouped by theme. This enable uncover distinctive perspectives on the contextual nuances of each project, discern staff perceptions regarding the impact of Early Contractor Involvement (ECI) on tendering, and factors beyond ECI that might have impacted tendering efficiency to be uncovered.

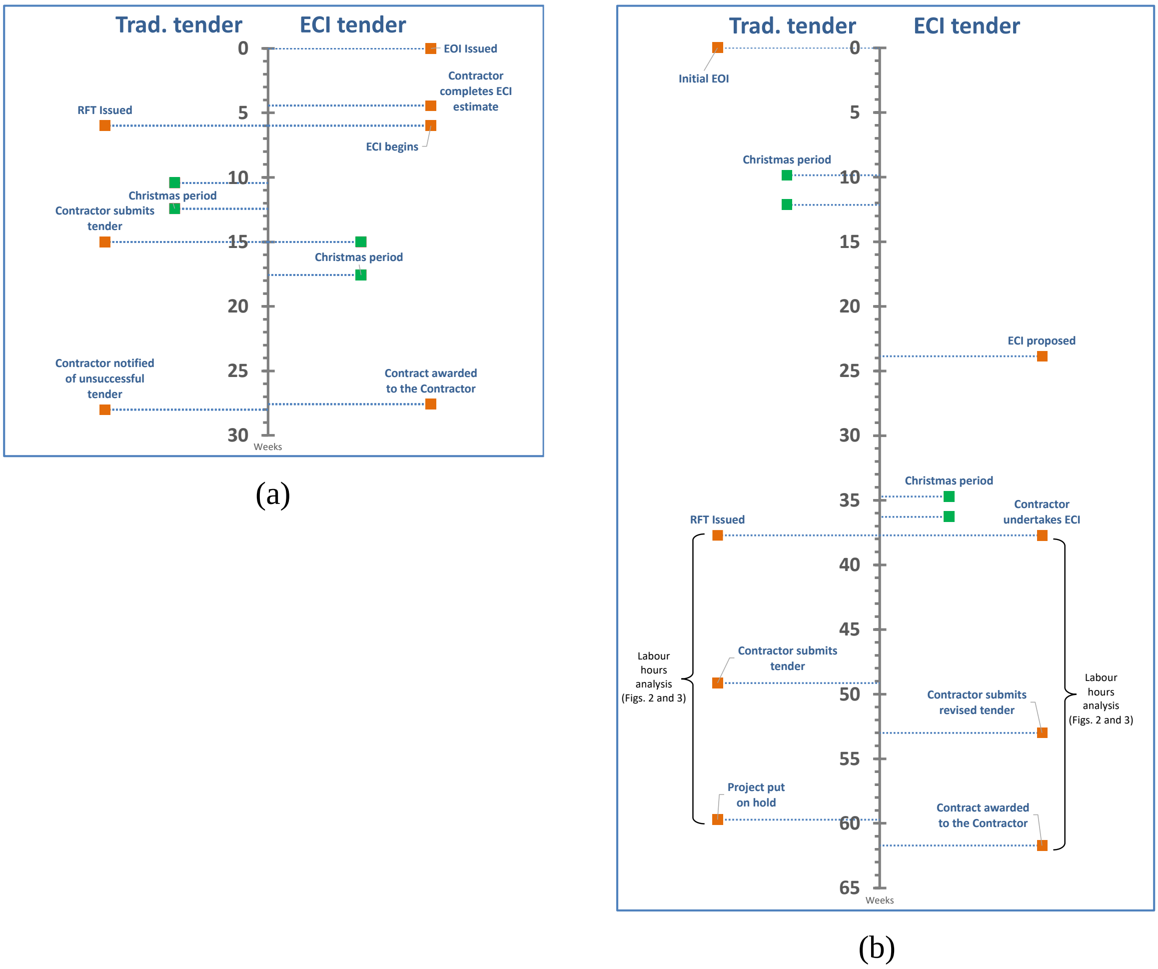

Figure 1: Timelines for Project 1 (a) and Project (2)

RESULTS

PROJECT 1

Length of the Tender Process

The Request for Tender (RFT) for the Traditional stage was released in Week 6 and concluded on Week 15, spanning a total of 9 weeks, as illustrated in Figure 2. Although the plan aimed for contract award in Week 20, the Contractor received notification of their unsuccessful submission only in Week 28, a delay of 22 weeks post-RFT release. Accounting for a two-week

Christmas shutdown period between weeks 11 and 13, the entire process of developing and submitting the tender extended over 7 weeks, with an additional 13 weeks dedicated to awaiting a response, as depicted in Figure 2. This timeline aligns with insights from an interviewee who highlighted the historical duration of tenders, ranging from 4 to 8 weeks, with some recent instances extending up to 16 weeks.

Preceding the ECI stage, an Expression of Interest (EOI) was initiated in Week 0, with the Contractor submitting their proposal in Week 1, as depicted in Figure 2. One interviewee argued that the EOI could be perceived as a business development activity, similar to the efforts of business development staff in ensuring the Contractor's shortlisting for other tenders. Consequently, the time span between the release of the Request for Tender (RFT) and contract award (Weeks 6 to 28) remained consistent for the ECI, mirroring the timeline observed in the Traditional tender, although the duration of active involvement was notably lengthier. Initial discussions and the preparation of an ECI estimate occurred during Week 5, followed by the commencement of the ECI in the subsequent week. While the contract award was initially slated for Week 13, an interviewee pointed out that the allocated timeframe "*was never going to be enough.*" After several months of additional meetings, presentations, and negotiations, the contract was eventually awarded in Week 28.

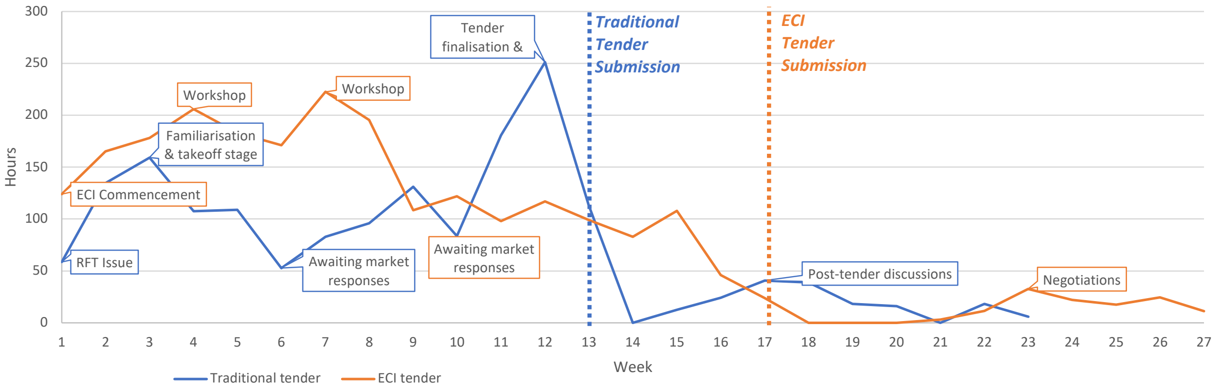

Figure 2: Work Hours Per Week (Project 2)

Views on ECI Impact on Tender Length

Respondents exhibited divergent perspectives on the impact of Early Contractor Involvement (ECI) on tendering duration, reflecting inconsistencies in the existing literature, as observed in the contrast between studies by Sødal et al. (2014) and Pheng et al. (2015). One interviewee asserted an unequivocal extension of the process, with acknowledgment that ECI could have been even lengthier if not for leveraging groundwork from the Traditional tender during the ECI. In contrast, another interviewee emphasized ECI's potential to streamline efforts, allowing the Contractor to approach the market sooner, obtain real-time responses, and expedite the tender process. Project 1 exemplified ECI's capacity to foster collaboration and establish common objectives.

The ECI model was identified as a crucial factor in enhancing efficiency, aligning with insights from Gransberg (2013) on the influence of contracting procedures. Another interviewee concurred, noting that the ECI was approximately four weeks shorter than a typical tender, facilitated by a deeper understanding of subcontractor capabilities and contacts through access to client personnel. Initial concerns about tight timeframes imposed by Principal 1 were addressed, with discussions highlighting scheduled shutdowns and contractual negotiations imposing a hard deadline for the ECI process. Despite varied perspectives on the ECI period's definition, one interviewee revealed a prolonged ECI process marked by extensive project reviews over three months before final pricing, underscoring the lack of consensus in defining the ECI duration.

Overall Resource Usage

One interviewee highlighted the predominant involvement of a single estimator during the Traditional tender, with additional support from undergraduates and site supervisors. In contrast, the ECI witnessed increased participation, encompassing a site team concurrently engaged in another project. Several participants disclosed heightened engagement of construction personnel during the ECI enabling more thorough scrutiny of provided information, provision of advice to estimators, and participation in workshops with Principal 1. The dynamic nature of resourcing during Early Contractor Involvement (ECI) was emphasized, characterized by an initial intensity that could be subsequently increased or reduced based on encountered challenges. The significance of client-funded staffing for the Contractor was underscored, enabling access to vital resources that would otherwise be financially prohibitive. However, the complexity of maintaining the right personnel available for tenders (when projects constitute the primary income source for the Contractor) was highlighted as challenge. Conversely, another interviewee perceived the ECI as a streamlined process primarily orchestrated by management staff—a perspective in alignment with Greenhalgh's (2013) view that such staff plays a more substantial role in ECI tenders compared to traditional ones. Despite the potential similarity in total work hours with the Traditional tender, this interviewee emphasized a more concentrated effort during the ECI, contributing to its perceived brevity.

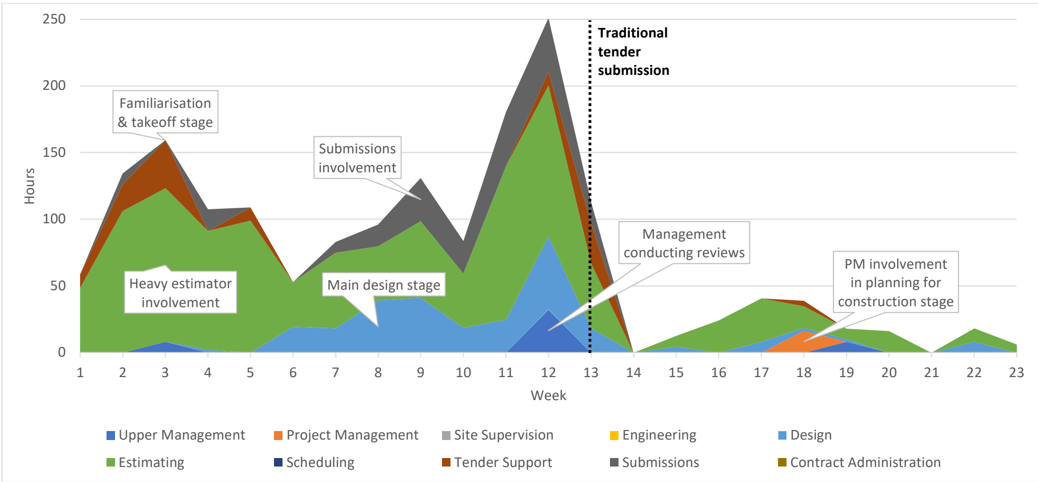
PROJECT 2

Length of the Tender Process

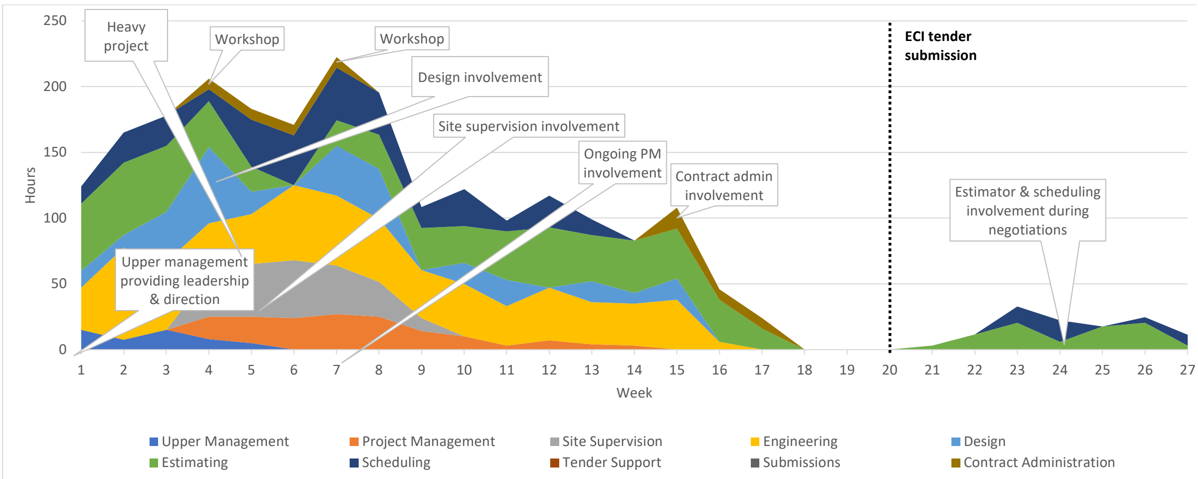
The Traditional tender, characterized as "normal" and akin to typical tenders, extended over 23 weeks, as depicted in Figure 1. The Request for Tender (RFT) process spanned 13 weeks, initiated in Week 38 and concluding in Week 50, aligning with a conventional 16-week Design and Construct (D&C) tender timeframe noted by an interviewee. Figure 1 illustrates an ensuing 10-week period of discussions and negotiations concluding on Week 60. In contrast, consistent with Sødal et al.'s (2014) emphasis on contractor involvement in design, the ECI tender unfolded over 38 weeks, commencing preliminary Early Contractor Involvement (ECI) discussions in October 2022 (Week 24) and culminating in the final contract review on Week 62 (Figure 2). Participants cited increased design inputs and the identification of unforeseen issues as contributors to the extended tender period, enhancing pricing certainty but lengthening the process. Accounting for a two-week Christmas break and a three-week lull post-ECI, a total of 33 working weeks transpired. The ECI stage itself spanned 16 weeks, with the Contractor submitting the revised tender in Week 53. One interviewee highlighted the advanced starting point for the ECI after a two- or three-month traditional tender but suggested minimal impact on the overall process duration. Challenges in obtaining pricing from the supply chain extended the timeline, with one interviewee noting a month spent acquiring competitive market pricing: *"That five months was extended due to some... issues. Responses from the supply chain (were) probably the main issue... (we spent) up to a month getting decent pricing back from the market"*. Additionally, extended pricing negotiations ensued due to hyper-escalation, as observed by a second and third interviewee.

Overall Resource Usage

Figure 2 illustrates the weekly work hours for the Traditional and ECI tenders over time. In the Traditional stage, the total work hours amounted to 1735, distributed among 16 staff members, averaging 108.4 hours per person and 4.7 hours per week. During the RFT stage (weeks 1 to 13), 1560 hours were expended, averaging 5.4 hours per person weekly. Notably, a peak exceeding 150 hours in week 3 (familiarization & take-off stage) was clarified by interviewees as a period involving meetings, document familiarization, and preparation of tender packages for subcontractors and suppliers (Figure 3a). Subsequently, a trough (weeks 5 to 10) occurred while awaiting market responses, succeeded by a peak of 251 hours in week 12 (tender finalization & review) just before tender submission. This peak was succeeded by a substantial decline in work hours, coinciding with post-tender discussions between the Contractor and Principal 2, as noted by one interviewee (Figure 3a).



(a)



(b)

Figure 3: Work Hours Per Discipline in Project 2: Traditional (a) and ECI (b) tenders

In the ECI, a total of 2880 work hours were expended by 19 individuals, including 4 or 5 full-time staff according to one interviewee. The average total hours per person were 151.6, with a weekly average of 4.6 hours. Work hours prior to ECI tender submission reached 2251, with staff averaging 12.8 hours per week each. The initial 8 weeks were particularly labour-intensive, peaking over 200 hours per week twice. Notably, the ECI involved extensive discussions in the first four weeks regarding the possibility and details of ECI, requiring approximately 100 hours per week from staff before tapering off before the Christmas period. This contrasted starkly with the traditional tender, where discussions on the tender process were unnecessary, and the RFT was issued to shortlisted tenderers. The ECI phase included an average of three client meetings per week, unlike the two key meetings in the Traditional tender – a briefing and a site visit. Peaks during this period, such as those in Weeks 4 and 7 in Figure 3b, can be attributed to key workshops. After the ECI submission, several weeks were dedicated to commercial and contractual negotiations, requiring significantly less time from the Contractor's tendering team.

Interdisciplinary & Interdepartmental Resource Distribution

The timesheet data reveals a significant increase in delivery personnel involvement in the ECI compared to the Traditional stage, including five site supervision staff and two project engineers, while none from either discipline were engaged in the Traditional tender. This observation aligns with insights from multiple interviewees emphasizing the intensive participation of delivery personnel in ECI, often in full-time roles, deviating from the traditional approach of assisting with tenders while concurrently working on-site on other projects. This supports Migliaccio and Holm's (2018) perspective that project teams are more likely to be extensively involved in ECI. Additionally, one interviewee highlighted a related phenomenon: in traditional tenders, on-site staff often work on tenders in their spare time, potentially on weekends, leading to their working hours being predominantly allocated to the concurrent on-site project, which might not be considered a cost of the tender by the business. While it is evident that the implementation of ECI resulted in a substantial increase in the number of hours project staff dedicated to Project 2, the data also underscores a second effect of ECI: more accurate logging of staff hours, partly driven by the requirement to submit payment claims to the client based on staff timesheets.

In the traditional tender process, interviewees highlighted the necessity of a submissions coordinator responsible for organizing site meetings, managing client correspondence, compiling non-price criteria, and creating a polished final submission. In contrast, the ECI process did not require a submissions team, likely attributed to the iterative nature of ECI rather than a single submission event. Additionally, the ECI process involved a contract administrator to handle cost-reimbursable aspects, a role not necessary in the Traditional stage. The discipline with the highest involvement in the Traditional tender was estimating, accumulating a total of 1085 work hours with an average of 270 hours per person, followed by the design and submissions teams with totals of 262 and 203 hours, respectively. Estimators and undergraduates exhibited heavy initial involvement, combining for 534 hours in the first 5 weeks, peaking in week 3 (familiarization & takeoff stage). This aligns with activities such as document review, quantity take-offs, and distribution of tender packages. Design team involvement grew subsequently as the Contractor's design consultants-initiated work on a tender design. The peak involvement per person for design staff (averaging 40.25 hours per person per week) occurred between Weeks 8 and 9, presumed to be the primary design stage before the final pricing review and submission. Steady involvement from the submissions team paralleled the work of design personnel.

The paid nature of the ECI, a feature not guaranteed in all cases, significantly influenced increased participation from construction personnel and consultants. An interviewee emphasized that the involvement of design consultants in the ECI process would not have been possible without payment from the Principal, aligning with the concerns expressed by Malvik et al. (2021) and Mosey (2009) regarding contractors' reluctance to engage in unpaid ECI work. Estimating remained the most engaged discipline in the ECI, mirroring the total hours in the Traditional tender (1081 hours), while project engineers assumed a more substantial role during the ECI process. This supports Migliaccio and Holm's (2018) assertions regarding the utilization of experienced project engineers for ECI tenders. The peak during initial discussions (between weeks 2 and 4 in Figure 6) involved extensive estimating efforts (439 hours), 4 hours of senior management input, 8 hours of scheduling contributions to formulate an ECI program, and 56 hours of engineering support.

DISCUSSION

Several interviewees stated that ECI is most suited to complex projects where there is significant uncertainty, such as operational treatment plants like the one in Project 2. Scope definition was one challenge identified, with ECI providing better awareness and understanding of the scope. ECI also reportedly allows the contractor to work with the client to resolve issues due to poor documentation. According to one interviewee, "*the main challenge is (that) we're trying to get the right price*", which is predicated on having the correct information from the client and site. As identified by Tower & Bacarini (2012), this is a fundamentally inexact process. Risks and unknown elements are typically reflected in added risk pricing or tender qualifications. Multiple participants noted that the increased transparency between client and contractor and the additional time spent exploring issues during ECI allow risks to be identified, allocated appropriately, and priced accordingly. One asserted that "*the less uncertainty we have, the more certain we can be on the pricing and the more comfort we can give our senior management that we understand the project*", highlighting the means by which ECI can facilitate more astute business decision-making. For example, in Project 1, past operational issues were identified by the client.

In Project 2, the Contractor owned the design, and interacted with Principal 2 to address them. One interviewee also stated that commercial risks can be better understood, permitting less aggressive contracting. They also argued that the success of an ECI lies in the right resourcing, which provides comfort to all parties that they are receiving the correct information. One participant also remarked that the increase in price typically associated with greater knowledge of risks can be detrimental to a contractor's competitiveness if the tender goes to open market post-ECI. Multiple responses also acknowledged the major challenge of securing engagement from the market – subcontractors and suppliers – to provide pricing, particularly since COVID. However, it was noted that through ECI, the Contractor was able to go to the market with a better understanding of market capabilities, greater confidence they would be awarded the project, and with the ability – and willingness – to be transparent with subcontractors, improving the likelihood of market interest. Subcontractors were reportedly brought to site and into discussions with the client, providing an additional layer of confidence and further mitigating subcontractor-related risks.

Interviewees also clearly identified understanding client expectations and market price escalation as challenges of tendering. One participant stated that the ECI process is reflective of increasingly collaborative construction contracting, with the ability to tap into an engaged client through open forums. Rahman and Alhassan's (2012) study, which revealed the prominence of relationship-related benefits of ECI, confirms this view. Another interview revealed that during the ECI tender Project 2, operators of the treatment plant could be brought in to verify information and identify potential solutions. Yet another interview exposed similar advantages with the ECI tender for Project 1, where the Contractor was able to utilise Principal 1's knowledge of existing issues and risks. That same interviewee noted that same transparency allowed risks associated with escalation pricing during Project 2 to be addressed by the client. An issue that became apparent as interviewees discussed the effects of ECI on the efficiency of tendering was probity, which acts as a barrier to information flow and problem-solving. In a traditional RFT process, the client must provide their answer to one tenderer's question to all tenderers. Interviewees noted that this is typically a lengthy process, with answers often lacking detail. By contrast, they revealed that greater access to the client and the involvement of only one tenderer "does streamline the whole question and answers elements", allowing the contractor to raise ideas, receive feedback, and address potential difficulties without a prolonged request for information (RFI) process.

CONCLUSIONS

This paper examined the impact of ECI during tender on a Contractor's resourcing, and more specifically on staff workhours. Projects 1 and 2, which had both traditional and ECI tender processes (for stages A and B, respectively) were examined in terms of quantitative and qualitative data (respectively, time sheets and semi-structured interviews). The comparative analysis of traditional and ECI tenders suggest that the latter streamlines certain aspects but tends to result in a more prolonged and resource-intensive procedure. ECI in Project 2 did not merely extend the work involved in the tender process across a longer period, resulting in a substantially greater total number of hours spent on the pre-construction phase. Also, the weekly average hours per person more than doubled during the actual tendering period. Tenders involving ECI also showed increased engagement from delivery personnel, including site supervisors, project and site engineers, and project managers, attributed in part to the Contractor being reimbursed for their time in ECI tenders. Despite the extended and more involved tendering process associated with ECI, the qualitative data demonstrated that it offers significant value by addressing challenges like unclear scope, poor documentation, probity, lack of market responses, tight timeframes, and price escalation through enhanced certainty, focus, and communication.

This investigation provides a different angle to existing studies (e.g Suttie 2013, Assainar and El Asmar 2014, Ibrahim and Hanna 2019, Kulkarni et al. 2012) by uncovering the changes in the staff workload in pre-construction phases. Prior research suggests that such additional effort and workhours upfront are paid off by enhancements in the overall project performance. It is nonetheless key to map and outline these changes as done here so stakeholders (e.g. Contractor) can be prepared and plan accordingly. Lastly, it is also important to acknowledge the limitations of this study. It is clear from the qualitative results that factors such as project complexity, client relationships, internal resource capabilities, and the contractual model likely limited the generalization of results. Due to availability of staff, the qualitative data provided by the Contractor only consisted of six interviews with management and estimating personnel. Furthermore, conclusions from the Project 1 were hindered by incomplete timesheet data (i.e. no discipline breakdowns). Also, this paper has only examined the impact of ECI on specific projects and has not given consideration to whether bidding decision-making or tender success is affected by ECI, so the impact of ECI on the total resources used by the organisation for tendering has not been addressed. Furthermore, further to the literary consensus that ECI's primary advantages are attained during delivery, one interviewee suggested that the success of a project would be an indicator of tender success, however this factor could not be examined here due to time limitations.

ACKNOWLEDGMENTS

The authors would like to thank the Contractor involved in the case study reported here for supporting this research.

COMPETITIVE NEGOTIATED PROCEDURE: EXPERIENCES FROM RV. 555 THE SOTRA CONNECTION

Faustin M Machozi [1], Ola Lædre [2] and Paulos Wondimu [3]

ABSTRACT

To reduce the number of conflicts in their projects, the Norwegian Public Roads Administration has implemented procurement procedures which allow dialogue and negotiation before the signing of contracts. One of these procedures is the Competitive Negotiated Procedure (CNP). The literature that addresses the implementation and experiences of CNP is limited, despite it has existed for several years. The purpose of this paper is to explore how the CNP can be improved for future use. The study has been carried out as a literature review and a case study. The case study investigated the infrastructure project Rv. 555 Sotra Connection and consisted of a document study and fourteen semi-structured interviews with representatives from the client and the qualified suppliers. The implementation of the procedure was divided into five phases. There were challenges with the procedure. Both the client and the suppliers encountered challenges with the zoning plan, which limited the supplier's ability to implement cost-saving alternatives. The suppliers experienced challenges regarding the client's evaluation of the most economically advantageous tender (MEAT). Both the client and the suppliers highlight that the CNP is demanding, but it allows clarification of ambiguities and risks before contract signing. This reduces the risk of future conflicts.

Lean Construction, Competitive Negotiated Procedure (CNP), Procurement, Collaboration, Most Economically Advantageous Tender (MEAT)

INTRODUCTION

Norway implemented a new Public Procurement Regulation on the 1st of January 2017 to efficiently use the resources of society and provide competition in public procurement. The new legislation superseded the previous regulation from 2006. Norway's procurement law is largely based on EU directives, which Norway must implement under the EEA – agreement (Wondimu 2019). The regulation applies to all state authorities, county and municipal authorities, and public law bodies and associations affiliated with them. The Norwegian Public Roads Administration (NPRA) is an administrative body subordinated to the Ministry of Transport and is obliged to comply with the law of public procurement. This involves following the basic principles of non-discrimination, equal treatment, transparency, proportionality and mutual recognition (Lennerfors 2007). For public procurement, the EU directive identifies procurement

procedures such as open and restricted procedure, competitive negotiated procedure (CNP), competitive dialogue and innovation partnership (Wondimu 2019). The selection of the procurement procedure should depend upon the scope and complexity of the project (Hansen 2019). The law of public procurement creates several barriers for public clients, but involving contractors earlier in projects than today is still recommended (Wondimu et al. 2018a). There is however a lack of research in the IGLC community in the area of public procurement (Wondimu et al. 2018b). There is also a lack of research on the application of LC concepts in the preconstruction phase (Reginato and Alves 2012).

There has been a high level of conflict between NPRA and their suppliers in NPRAs bigger projects, resulting in additional expenses for both parties. Causes of conflict have been errors and deficiencies in the tender specification, interpretation of the contract, and due to use of the lowest price as the sole criterion for awarding the contract (Sabri et al. 2019). To reduce conflicts and thereby reduce waste, NPRA has shifted focus from mere price competition to procurement methods more in line with the principles of LC. The purpose of this shift is to establish an equal understanding of the contract's contents. One of the procedures that allows for dialogue before contract signing is the CNP. This procedure has been allowed by public authorities for several years. The literature review did not reveal much literature that addresses practical implementation or experiences from using this procedure. By looking at an infrastructure project in Norway, this paper aims to fill the knowledge gap. The paper answers the following research questions:

RQ1: How was the competitive negotiated procedure implemented?

RQ2: What are the experiences from the competitive negotiated procedure?

RQ3: How can the competitive negotiated procedure be improved for future use?

This study is limited to a Norwegian infrastructure project and explores the experiences of the client and the three qualified consortiums that made a bid on the project. After a presentation of the theoretical framework and the applied research methods, the findings from 14 interviews are discussed.

THEORETICAL FRAMEWORK

COMPETITIVE NEGOTIATED PROCEDURE

CNP is a procurement procedure that allows the contracting authority to negotiate with the suppliers. The procedure can be used in the following circumstances: a) The needs of the contracting authority cannot be met without adaptation of readily available solutions; b) They include design or innovative solutions; c) The contract cannot be awarded without prior negotiations because of specific circumstances related to the nature, the complexity or the legal and financial makeup or because of the risks attaching to them; d) The technical specifications cannot be established with sufficient precision by the contracting authority concerning a standard, European Technical Assessment, common technical specification or technical reference; e) In response to an open or a restricted procedure, only irregular or unacceptable tenders were submitted (Burnett 2015).

CNP is a two-stage tendering procedure where interested suppliers can request to participate in the qualification stage. The goal of the qualification stage is to select an appropriate number of qualified suppliers that can participate in the negotiation stage. The contracting authority may limit the number of suppliers invited to submit tenders, but the minimum number of suppliers is three in CNP (Telles and Butler 2014). If the number of suppliers interested exceeds the number of suppliers the contracting authority intends to negotiate with, the contracting authority may select suppliers based on predetermined selection criteria. Several selection criteria are used to evaluate and select the suppliers. These criteria must be objective and non-discriminatory (Doloi 2009). The selected suppliers are invited to participate in the negotiations.

Except from the generic principles of public procurement, there are no specific requirements for how to conduct the negotiations. The contracting authority may negotiate all aspects of the tender and the supplier's proposal, but is restricted from negotiating the award criteria and absolute requirements set in the tender documents (Burnett 2015).

While not required to explicitly highlight any weaknesses in the offers, the contracting authority must inform the suppliers of factors that will be given significant or decisive importance in evaluating the bids. The principle of equal treatment requires that the contracting authority should treat all suppliers impartially during the negotiations. Equal treatment of suppliers ensures that all suppliers are given equal opportunities to improve their proposals (Šostar and Marukić 2017). When the contracting authority highlights the strengths and weaknesses of an offer to one supplier, it must also disclose the strong and weak aspects of other offers. This ensures that all suppliers have equal information to improve their offers.

Negotiations can be conducted in multiple stages, with a gradual reduction of suppliers at each stage (Burnett 2015). The reduction will occur through the evaluation and ranking of the revised bids based on the specified award criteria and minimum requirements. The contracting authority is responsible for ensuring that an adequate number of offers remain in the final phase of negotiations to maintain competitiveness. Negotiations are concluded by establishing a deadline for the remaining suppliers to submit their final bids.

AWARD CRITERIA

The EU procurement directives specify two distinct criteria for awarding public contracts; either based on the lowest price or the most economically advantageous tender (MEAT) (Bochenek 2014). If the sole award criteria is the lowest price, the contract will be awarded to the supplier with the lowest price (Lædre 2009; Parikka-Alhola et al. 2006). According to Tavares (2019) contracting authorities often opt for the lowest price as the award criterion due to its simplicity and to avoid any suspicion regarding the evaluation of the various bids. When a contract is awarded by using MEAT as an award criterion, it involves emphasizing the weight of different aspects of a product or service that adds value to a project. It ensures that factors beyond price, such as quality, environment, and social aspects, will be taken into account as part of the selection process (Marcarelli and Nappi 2019; Wondimu et al. 2020).

The award criteria and their corresponding weight shall be established beforehand and made known to the suppliers. The objective of establishing and formally disclosing the award criteria is to achieve the following objectives: a) Enable tenderers to prepare their tenders in a manner that aligns with the contracting authority's stated priorities. b) Ensure that the evaluation of tenders is conducted by the contracting authority in a transparent, reliable, and objective manner. c) Allow relevant stakeholders, such as review bodies, other government entities, or economic operators, to oversee the process and prevent the use of discriminatory or unauthorised award criteria (OECD 2011). Identifying the most economically advantageous tender poses a challenge due to the lack of explicit guidelines in the regulations on how it should be executed (Sebastian et al. 2013; Wondimu et al. 2018c).

According to Ottemo et al. (2018), a point, ratio or price correction system can be used to evaluate MEAT. The point system converts all aspects of the tender into points based on an objective calculation reference. The supplier with the highest number of points is awarded the contract. In the ratio system, each criterion in the tenders gets a basic monetary value if satisfying the minimum tender requirements. When a supplier exceeds the minimum requirements, the added value is added to the basic monetary value. The supplier who achieves the highest value is awarded the contract (Sebastian et al. 2013). By using a price correction system each criterion – except the price – is assigned a fictional monetary value. This monetary value is subtracted from the bid price. The supplier with the lowest corrected bid price is awarded the contract (Chiappinelli and Zipperer 2017). Bergman and Lundberg (2013) suggest that to identify the MEAT, the client must assign a monetary value to the quality. All in all, it is not a good idea to mix cost with value (Schöttle et al. 2015).

LEAN AND COMPETITIVE NEGOTIATED PROCEDURE

Multiple research studies conducted on productivity within the construction industry have shown the potential for an increase of 10-20 % in productivity. This increase can be achieved by improved interaction among stakeholders (Hansen 2019; Wondimu et al. 2017). Lean Construction (LC) aims to maximize value and minimize waste (Bertelsen 2002; Emmitt et al. 2005). It draws its principles from the success of the lean philosophy in the manufacturing industry (Young et al. 2017). The goal is to reduce costs, shorten production times, and increase quality throughout the entire construction lifecycle, from planning and design to completion and operation (Alves and Tsao 2007). In addition, the LC community agrees upon that the goal of projects is to deliver value (Drevland and Lohne 2015). LC is about optimising production systems aimed at delivering value (Drevland and Tillmann 2018). Clients can use CNP to act according to LC principles, i.e. improve processes and project outcomes.

As stated before, CNP allows for negotiations between the contracting authority and the suppliers before contract signing. This allows collaboration with the suppliers to identify uncertainties and potential challenges at an early stage (Kantola 2015). CNP allows for greater flexibility in project planning, design, and execution by facilitating open communication and collaboration among project participants. This flexibility enables the contracting authority to discuss terms of contracts before contract signing, for example making adjustments to the project scope as needed to optimize project outcomes and deliver value to the client (Burnett 2015). Negotiations allow value engineering exercises to be conducted collaboratively among project stakeholders. Value engineering is an approach used to obtain the required component at the lowest total cost without reducing the necessary quality (Ilayaraja and Eqyaabal 2015). By incorporating value engineering into the negotiation process, the project team can identify and implement cost-effective solutions that align with project goals and client requirements.

METHODS

The research was conducted using a literature review and a single case study. To establish a theoretical foundation, a literature review of the relevant literature was conducted. A literature review serves multiple objectives. It can highlight results from previous studies in a research area, and it can provide a framework for comparing your findings with previous findings (Creswell and Creswell 2018; Hart 2001). The literature review used Arksey and O'Malley's framework for literature review. The framework has five steps: 1) uncover research questions, 2) find relevant literature, 3) select literature, 4) map data and 5) collect, summarize and report the results (Arksey and O'Malley 2005). To find relevant literature, an initial search on "Competitive Negotiated Procedure" was conducted in various databases such as Google Scholar, Web of Science, ASCE, Scopus and Science Direct. The search returned a few results across those databases, with some returning no results whatsoever. It became necessary to expand the search area by adding more keywords such as "Public Procurement" and "Award procedure". To identify more relevant literature, various approaches like "Backward Snowballing" and "Forward Snowballing" were used. "Backward snowballing" involves reviewing the list of sources cited in a relevant article, while "forward snowballing" involves reviewing articles that references the relevant article (Webster and Watson 2002). The literature review was used to describe the existing body of knowledge and to formulate the interview questions.

The case study was carried out based on the recommendations of Yin (2014). The project studied is the procurement of a large road infrastructure contract. The contract is the largest single contract entered into by the NPRA and the largest public-private partnership contract awarded in EU in 2021. The contract have a value of 1,98 billion euro (Statens vegvesen 2021). The case was studied through fourteen semi-structured interviews and a document study.

The interview objects consisted of participants from the client and all the joint groups that made a bid on the project. The interviewees were design consultants, legal advisors and a variety of participants in management positions. All the interviews except one were carried out via Teams. The interviews followed an interview guide. The interview guide began with introductory questions, allowing the informant to provide self-introduction. Following the introductory questions, the interview guide was organised based on the identified phases in Figure 1. For each phase, the three research questions were asked, beginning with RQ1, then RQ2 and finally RQ3. The interviews lasted from one to three hours, with some of the participants displaying great interest towards the research. With the respondents' consent, the interviews were recorded, transcribed, and sent as a summary for their approval.

The document study was carried out in a two-stage process. The initial stage of the document study involved acquiring fundamental information regarding the project. The tender document and documents that were created during the tender process such as the evaluation report, were among the case-specific documents studied. The second stage of the document study was conducted after the interviews to identify any inconsistencies between the documents and the interview data.

FINDINGS AND DISCUSSION

The first section in this chapter starts with introducing the practical implementation of CNP, answering the RQ1. The section follows the phase model in Figure 1.

IMPLEMENTATION OF COMPETITIVE NEGOTIATED PROCEDURE

During the study, five phases of the CNP were discovered. The five phases consisted of Preparation, Qualification, Clarification, Negotiation, and Evaluation. Figure 1 depicts the phases, important activities and decision gates throughout the tender process.

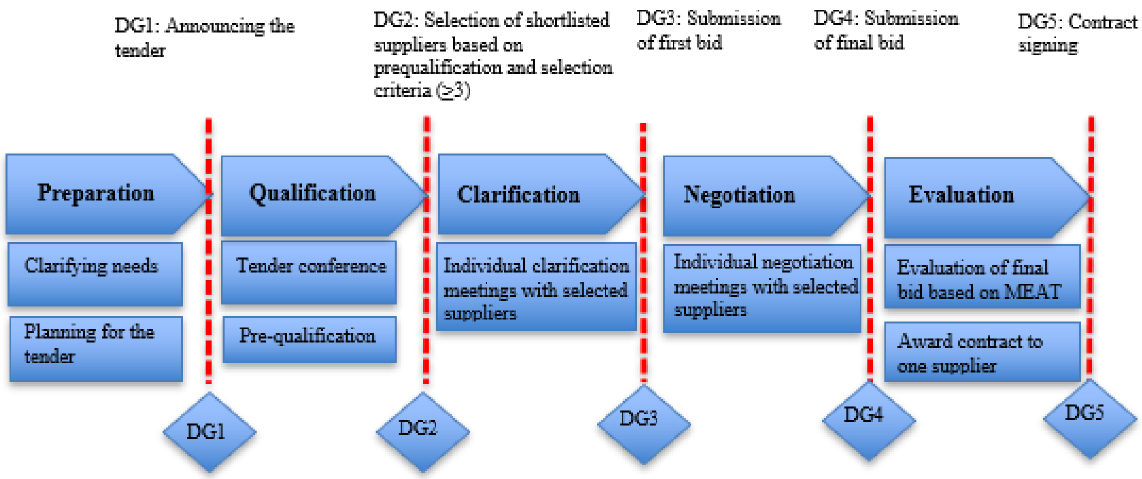

Figure 1: Implementation of Competitive Negotiated Procedure: Phases, main activities and decision gates (DG). Based on findings from the study.

The preparation phase began with the client clarifying the project's needs and how they could be met. Subsequently, the preparation continued by planning for the tender. This included developing tender documents, establishing a negotiation strategy and engaging in marked dialogue with the supplier market. Multiple market and information meetings were held during the process of creation of the tender documents. It was crucial to maintain contact with the supplier market during this phase. This was to prevent the client from creating a tender that the potential bidders did not want. During the meetings, the suppliers had the opportunity to provide feedback to the client on qualification and award criteria. **The qualification phase** began with a tender conference, during which the client invited the industry to an informative meeting, followed by a site visit. During the information meeting, the client presented the project with the main deliverables, contract structure, qualification requirements and the description of the tender process. During the qualification phase, the goal was to select three qualified suppliers who would be invited to submit bids. Following the expiration of the deadline for requests to participate in the competition, the client had four interested suppliers. Out of the four suppliers who submitted a request, only one failed to meet the requirements. During the **Clarification phase**, a total of four clarification meetings were held with each qualified supplier. In the first clarification meeting the client presented the tender documents. The theme for the second clarification meeting was the contract and a review of the works to be performed. The third clarification meeting focused on the financial aspects of the contract. The final clarification meeting focused on questions and clarifications that had emerged from discussions at the previous meetings. Following the clarification phase, the suppliers were to submit their first bid. The first offer represented the beginning of the **Negotiation phase**. The client had planned a total of three negotiation meetings. The first negotiation meeting did concern the supplier’s response concerning award criteria 1: Bid price. The second negotiation meeting did concern the supplier’s response regarding award criteria T2-T5. The final negotiation meeting was a two-day meeting. The submission of the supplier's final bid represented the beginning of the **Evaluation phase**. During this phase, the client had to determine the most economically advantageous tender by evaluating the bids using the award criteria as a basis. The following were the competition’s award criteria:

- T1 Award criterion 1 – Bid Price
- T2 Award criterion 2 – Plan for organisation and execution / 60 million euro
- T3 Award criterion 3 – Traffic management / 50 million euro
- T4 Award criterion 4 – Quality of the infrastructure project / 30 million euro
- T5 Award criterion 5 – Climate and HSE / 50 million euro

The value of T2-T5 represented a potential reduction in the bid price that suppliers could receive. During the bid evaluation, the client would evaluate and determine the competitive price of each supplier. The competitive price was determined using the following method: Competition price = T1 (Bid price) – (T2+T3+T4+T5). When a supplier's solution exceeds the award criteria requirements, it receives a fictional deduction, resulting in a reduced competitive price. To evaluate the different bids, five evaluation teams were formed, each assigned to a reward criterion. The teams were a combination of people who had taken part in the negotiations and others who had not been involved. The contract is then awarded to the supplier with the lowest competitive price as it’s the most economically advantageous tender.

EXPERIENCES WITH COMPETITIVE NEGOTIATED PROCEDURE AND FUTURE IMPROVEMENTS

This section addresses the experiences with the procedure and suggests possible improvements for future CNP projects, answering RQ2 and RQ3. The discussion and suggested improvements are based on the authors’ interpretation of the data from the case study.

Preparation phase

Zoning plan

During **The preparation phase** the client and the suppliers agreed that the zoning plan restricted the possibilities for an optimised production. The zoning plan restricted the possibility of making changes as one of the responsible municipalities stated that making any changes to the zoning plan would lead to a significant delay of several years. This frustrated the suppliers as they meant the client was unwilling to discuss cost-saving proposals that challenged the zoning plan.

The zoning plan offers guidelines to the suppliers regarding choices they can make in design. A zoning plan with a low degree of freedom may constrain the project's ability to incorporate new elements that appear after the zoning plan has been approved. At the same time, such a zoning plan will make the evaluation of the suppliers' solutions easier as the solutions will be more comparable. A zoning plan with a high degree of freedom might complicate the evaluation of solutions, as it can allow solutions that are difficult to compare. A suggested approach is to consider the relationship between the contract strategy and the degree of freedom in the zoning plan. If the planned contract strategy provides suppliers with significant opportunities for influence, then the zoning plan should have sufficient levels of freedom to accommodate this. If a contract strategy is designed to minimise the contractors' influence, it may be beneficial to have a more restrictive zoning plan with limited flexibility.

Lack of continuity in the project organization

One experience mentioned by the client was the lack of continuity in the project organization. Optimising the construction process according to the LC principles is difficult when there is a lack of continuity. Different people were involved in the phases from choice of concept to operation. Decisions restricting future opportunities were made in the early stages. The client created experience reports throughout the project, but an informant from the client noted that the reports did not contain all the information about the experiences that were made. NPRA view each phase of a road project as a separate subproject, each having its project organisations. When transitioning to a new phase of the project, the entire project organisation might be completely replaced. This may be explained by the fact that different phases require different skills and competencies within the project organisation. Lack of continuity might limit the project organization's ability to have a full grasp of the entire project, as individuals may only possess detailed knowledge of the specific phase they were involved in.

The project ought to have mechanisms that guarantee continuity during the transition to a new phase. It might be beneficial to have the project manager, along with key personnel, oversee the project across multiple phases. Ensuring project continuity through personnel can be a formidable task, as it might take several years from the initial planning to the start of construction. Another way to ensure project continuity might be through detailed experience reports containing the five Ws (Who, What, When, Where, and Why) for each experience. These reports can serve as a valuable resource for new team members joining the project at different phases. By documenting key information and lessons learned, the project can maintain consistency and efficiency throughout its lifecycle.

Qualification phase

Qualification criteria

Both the client and the suppliers agreed that the client had chosen the correct qualification criteria during the **Qualification phase**. In the creation of the qualification requirements, the client used both the insights from the Quality assurance 2 report and from previous projects where too many suppliers were qualified. The informants from the client' believed that the qualification requirements were appropriate for the project, as they received a total of four interested bidders and three qualified suppliers.

Based on the findings from the case study (n=1), the respondents agreed that the tender qualification criteria were appropriate. This was achieved by having early marked dialogue and involving suppliers to determine the qualification requirements. As a result, the client got the desired number of qualified suppliers without using selection criteria.

Clarification Phase

Risk distribution

Upon evaluating the tender documents, it became evident to the suppliers that they had to take on too much risk. The supplier noted that the tender document and contract framework originated from past PPP projects and perceived this as a mistake. The previous PPP projects were of a scale that allowed the involvement of Norwegian contractors. The informants from the suppliers held the belief that this project relied on international financing as the project was too big for the Norwegian industry. Initially, the client required the project to be financed in Norwegian kroner. To secure favourable financing conditions, it became necessary to use the international market instead of restricting the financing currency to Norwegian kroner. This measure reduced the supplier’s risk and resulted in a cost reduction for the contracting authority.

The case study (n=1) findings indicate that when the client transfers too much risk to suppliers, the suppliers will add a risk premium that increases the project's overall cost. This is done to ensure that they have sufficient resources to handle this risk effectively. Through the clarification and negotiation meetings, the client and the suppliers can determine the specific risks that each party can assume. The risk should always be allocated to the party with the highest capability to manage it. By effectively allocating risks based on each party's capabilities, the project can proceed smoothly with minimized costs and delays. It is crucial for both parties to have open communication and a clear understanding of their responsibilities in managing risks throughout the project lifecycle.

Road construction guidelines and handbooks

An interesting experience is that participants have different perceptions of the national road construction guidelines and handbooks. Consultants who were interviewed perceive the guidelines and handbooks as positive, they show what regulations to follow. Contractors perceived the regulations to be good for guidance, but that guidelines and handbooks are made for Design-Bid-Build (DBB) projects where the client is responsible for design, i.e. drawings, descriptions, and calculations. At times, contractors perceive regulations as restrictive, as these impose excessive control over how they should execute their tasks. NPRA has primarily used DBB in their projects. This contract type requires a high level of detail from the client since he holds the risk for errors and flaws in the design. This has led to NPRA's internal processes, guidelines, and handbooks being tailored to the needs of DBB. NPRA wants to increase the use of Design-Build (DB) contracts in their projects, but a challenge arises from the fact that the same standards, guidelines, and process codes are utilised in DB contracts.

Based on the findings it can be argued that current guidelines and handbooks need to be revised as they are designed for DBB contracts and restrict the room for manoeuvre that is needed in other contract types.

Negotiation Phase

Quality of the feedback on suppliers’ solutions

During the meetings, the client faced a dilemma between the need to provide counsel, the concept of treating all parties equally, and the obligation to maintain confidentiality. The client is obliged to provide identical information to all suppliers simultaneously. Some informants found it challenging to track the information and comments provided to suppliers to prevent any supplier from gaining a competitive edge. The suppliers had difficulty comprehending the client's feedback and felt that it did not provide valuable insights for evaluating the strengths and weaknesses of their offer. The suppliers regarded the feedback as a hindrance, which reduced the quality of the final product obtained by the client. With more feedback, suppliers meant they could have prioritised value-adding solutions and improved the customer's project.

Feedback from public clients can help suppliers to improve their proposals. To improve their proposals, the feedback must be clear and specific, highlighting the proposals' strengths and weaknesses. In the feedback, the client can emphasize how the supplier's proposal is aligned with or deviated from the minimum requirements and award criteria outlined in the tender document. As the feedback must be based in the award criteria and the minimum requirement in the tender document, the quality of the feedback will significantly influence the proposals received by the client. If the suppliers receive vague feedback, it might be seen as not helpful for suppliers seeking to improve their proposals to add more value for the customer. Workshops and training for feedback givers can also improve feedback quality. This includes advice on common mistakes, best practices, and how to align feedback to client's needs. If the client lacks knowledge of the process of providing feedback, it may cause public clients to adopt a passive approach to ensure compliance with the Public Procurement Act. This can result in their failure to make use of the full range of available actions in providing feedback.

Evaluation Phase

MEAT-Evaluation

The informants representing the client had varied experiences throughout the evaluation of the final bid, but they unanimously agreed that the final bid was evaluated accurately. The evaluation teams performed both an individual assessment and a collaborative assessment to compare the results. The evaluation team found this process to be challenging. Despite the suppliers' evaluation being focused on their solution; the evaluation was required to be conducted simultaneously for all suppliers. The reasoning for this was that if any negative attributes were uncovered in one solution, the remaining solutions had to be examined for the same attributes to prevent favouring one supplier. This made it difficult for the representatives of the evaluation team to evaluate the solutions without comparing them. Another aspect, which was also challenging in the evaluation, was to define added value. The suppliers had varying experiences with the evaluation of the final bid. Upon reviewing the evaluation report, a supplier informant found no difficulties in accepting the evaluation provided by the client. Simultaneously, some members of the winning consortia felt that they ultimately did not know how they were evaluated. Other informants thought the evaluation to solely focus on the aspect of price. If the price was acceptable, the evaluation became also better on the technical side.

The evaluation teams for the final bid the evaluation teams consisted of members who participated in the negotiations and members who did not participate in the negotiations. Having members who have participated in the negotiations during the evaluation process has the benefit of displaying the impact of clarifications and negotiation meetings in the evaluations. The challenge is that unconsciously formed relationships during negotiations can affect evaluation. The evaluation can lose its objectivity and may favour one supplier. Another challenge that was addressed is the possibility that the evaluation could be influenced by the bid price. An approach to solve this is for the suppliers to submit their proposals using a two-envelope system. One envelope would contain the bid price, while the other would contain the response to the award criteria unrelated to the price. A limited number of evaluation members should have access to both envelopes to ensure that the price does not affect the other award criteria.

***Compensation for approved final bid*:**

A notable experience was the level of compensation that the suppliers were granted for an approved final bid. The suppliers, along with the client, perceived the compensation to be insufficient project and suggested that it should have been increased. The compensation was insufficient to cover suppliers' costs towards their subcontractors. It was a big challenge for the client to determine the size of compensation for the suppliers. If too low, it might discourage competition participation. If too high, it might attract suppliers more interested in the compensation rather than the project.

There should be a fair proportion between the expenses incurred by the suppliers and the compensation that is provided for an approved final bid. One possible method for determining the compensation amount is to consider the external expenses that suppliers pay to their consultants and subcontractors during the process of tender preparation and submission.

Demanding process

All representatives from the client and the suppliers acknowledged that CNP was demanding, but they agreed that the appropriate procedure was chosen for the project. According to one of the informants from the client, there has been a high number of conflicts in major projects due to the sole use of DBB and price competition as procurement procedures. When the cost exceeds 200 million euro, the contract is difficult to manage and monitor. This led to disagreements, which in turn resulted in increased expenses for both parties involved. The client states that the suppliers need to comprehend the scope of the project and the specifics of the contract, including the allocation of responsibilities and risks between the involved parties before contract signing. The suppliers had also a demanding process, requiring significant use of both internal and external resources. It is not just the tender process that consumes resources. Winning would require a significant apparatus to support the project.

The initiative to have clarification and negotiation meetings proactively addressed uncertainty and risk conditions that would often come later in a traditional project. Clear communication and a shared knowledge of the project scope and terms before signing the contract give the suppliers valuable insight into the project. The client was also convinced that they achieved a more precise price for the project through negotiating. Although negotiations and clarifications can reduce risks, overall cost, and the likelihood of future conflicts, competitive negotiation is a demanding procurement procedure that may not be suitable for smaller and less complex projects due to the significant amount of resources it demands from both the client and suppliers.

CONCLUSION

This paper shows how clients can use CNP to act according to LC principles during the tendering process by answering three research questions, namely RQ1: “How was the Competitive Negotiated Procedure implemented?”, RQ2: “What are the experiences with Competitive Negotiated Procedure?”, and RQ3: “How can Competitive Negotiated Procedure be improved for future use?”.

The paper has both theoretical and practical contributions. In terms of theoretical contributions, the paper documents the practical implementation of CNP and the experiences from the tender process in a Norwegian infrastructure project. Figure 1 illustrates in what phases the main activities and decision gates of CNP were implemented. The supplier and client experienced better collaboration than they were used to. The clarification and negotiation meetings before contract signing resolved concerns that could have caused problems later. However, the collaboration could have resulted in even more cost-saving solutions if the zoning plan was more flexible. In total, CNP mitigates waste by reducing the likelihood of conflicts.

In terms of practical contributions, this paper contributes to the IGLC Community by explaining a procurement process that allows public clients to implement lean principles in public procurement. The paper suggests improvements for future projects and can act as a managerial checklist for public clients seeking to incorporate lean elements in procurement.

There has been a shift from mere price competition to procurement methods more in line with the principles of Lean, and the consequences should be documented. Therefore, experiences from other recent infrastructure projects that have used CNP should be documented.

STRATEGIC PARTNERSHIPS BETWEEN PROJECT CLIENT AND CLIENT'S AGENT

Johan Christie Ørke[1], Atle Engebø[2] and Ola Lædre[3]

ABSTRACT

Strategic partnership is an emerging project delivery method characterized by long-term collaboration in multiple projects. In this paper, we seek to increase the knowledge about strategic partnerships. From a lean perspective, strategic partnerships could be a potential measure towards mitigating inefficiency caused by lacking continuity and previous relationships. Our purpose is to reveal aspects that can help clients and client's agents organize better strategic partnerships. The client's agent is the contracted adviser who takes care of all the functions which the client's project management cannot handle. A literature review and a case study were conducted, where the case study included eight semi-structured interviews. The findings identify several benefits regarding soft factors in a strategic partnership. However, some challenges are also identified, especially by the client. Based on the findings, four measures are suggested to improve strategic partnerships between client and client's agent: Mutually helping the other part get new projects, ensuring competence development, ensuring availability of demanded qualifications, and more focus on the long-term and future perspective of the strategic partnership.

KEYWORDS

Lean construction, contract and cost management, strategic partnerships, client's agent.

INTRODUCTION

Integration, collaboration, and continuity are highlighted in the Lean Construction literature. This is expressed already in the fundamental literature of the field: Koskela (2000) claimed that projects where the actors have no previous relation will be less efficient by definition. Further, Ballard (2008) claimed that contracts based on relation will increase the likelihood of project success, in theory also decreasing the need for contingency reserves.

While the importance of integration, collaboration, and continuity is clearly stated in the literature, there is still a discrepancy between theory and practice. Even though the conflicting interests of stakeholders in conventional construction projects have been on the agenda for years, the subject is still relevant (Lahdenperä, 2012) and traditional contracts are often a source of opportunism and distrust between the actors (Kadefors, 2004). The profit of one actor, either measured in value or monetary terms, often comes at the expense of another actor's profit.

To face this challenge, new project delivery methods intending to increase the collaboration and integration between the actors have emerged. Commonly known examples of such project delivery methods are alliancing, integrated project delivery, early contractor involvement, and

different approaches to partnering (Engebø et al., 2020b; Paulsen et al., 2022). A key characteristic of relation-based project delivery methods is that they are based on trust (Lahdenperä, 2012) and mutual commitment between the actors (Walker & Lloyd-Walker, 2012).

A particular collaborative project delivery method that could be used to achieve integration, collaboration, continuity, and, importantly, long-term relations between actors, is strategic partnerships. Strategic partnerships can be defined as "a long-term collaboration between a client and a delivery team on a collective project portfolio." (Jensen, 2021). This implies that strategic partnerships seek to utilize the benefits from both the collaboration in partnering and the long-term perspective of framework agreements. Koolwijk et al. (2022) used a similar definition, emphasizing that the term "strategic" brings a long-term perspective. Strategic partnerships are practiced either through a contract for multiple projects, a contract for a given period, or an agreement where success in one project will lead to new partnering projects (Koolwijk et al., 2022; Paulsen et al., 2023).

Koolwijk et al. (2022) noted that despite the potential of strategic partnerships in the construction industry, this project delivery method has not been adopted in the same magnitude as in other industries. They call for more case studies of the dynamics within strategic partnerships to obtain more generalizable results. Our searches indicate that most literature concerns strategic partnerships between clients and contractors, and that there is a need for more generalizable knowledge. Ferstad et al. (2023) concluded that more research is needed on strategic partnerships in other relations than between client and contractors. Bygballe et al. (2010) similarly concluded that there is a need for studies "from the view of different actors over time". Paulsen et al. (2023) also pointed to a demand for more research regarding strategic partnerships, especially case studies investigating the effects: "There is still a lack of proof of how well strategic partnership is working in practice. […] Therefore, more case studies and interdisciplinary research are needed to further clarify improvements."

This paper builds on the above-mentioned literature by scrutinizing a particular strategic partnership between a client and a contracted client's agent. These actors were chosen as client's agent should have different interests and business model than a contractor (Berg et al., 2021). Further, no previous research on this specific relation was identified. The term client's agent describes a contracted adviser who takes care of functions which the client's project management does not have the capacity to carry out. In Norway, this role is often denoted as *byggherreombud* (Rådgivende Ingeniørers Forening, 2018). The client's agent is henceforth referred to as agent.

The study was conducted to increase the knowledge about strategic partnerships, and hopefully contribute to a broader understanding, which in turn may contribute to establishment of more generalizable knowledge about the subject. The purpose of the paper is to reveal aspects that can help clients and client's agents organize better strategic partnerships, contributing to the delivery of more efficient and effective projects. The purpose was investigated through the following two research questions:

- RQ1: How does strategic partnership affect the relationship between client and client's agent?
- RQ2: What are the resulting effects of this relationship?

STRATEGIC PARTNERSHIPS IN LITERATURE

Collaborative project delivery models are emerging in the construction industry due to their many advantages (Lahdenperä, 2012). There are however plenty of collaborative project delivery methods used in the industry: Tadayon et al. (2018) mentioned 15 different definitions, while Engebø et al. (2020a) mentioned ten different approaches before basing the article on five umbrella terms. Engebø et al. (2020a) also underlined that collaborative project delivery methods cannot be discretely categorized: The magnitude of, and approach to, collaboration in different project delivery methods rather represents a continuous spectre. Ørke et al. (2023) found that the perception of value, and the motivation of value generation, depends on perspective. Engebø et al. (2020b) highlighted that alignment of these factors is crucial for both trust and good collaboration in a construction project.

Even though partnering is a frequently used term, there is no unified definition of partnering, or what such project delivery methods involve (Nyström, 2005). There seems to be a pool of approaches that may be used, meaning that two partnering projects may be quite different, though both are defined as partnering projects. This challenge was addressed by Nyström (2005), who used Wittgenstein's family-resemblance concept to state that even though there are not necessarily any defining common features between the different partnering approaches, they have overlapping similarities. The lacking unified definitions is a weakness of the literature: Varying terms and variations within the same term complicates comparison and linking knowledge from different sources.

In the lean construction literature, collaborative project delivery models are often referred to as either integrated project delivery (IPD) or Lean Project Delivery System (LPDS). Mesa et al. (2019) made a comprehensive review of IPD and LPDS and found that they utilize many of the same perspectives with regard to project organization. To achieve integration among key project participants, both project delivery methods seek to involve key participants in the early stages and form an integrated project team that works together in an environment of collaboration, open communication, and mutual respect and trust.

A common denominator for many collaborative project delivery models is that they are project-specific and not concerned with a long-term perspective. As stated by Beach et al. (2005); most collaboration efforts never reach the strategic level but are sustained for the specific project and focused on short-term benefits. The strategic perspective implies a long-term commitment between organizations across several projects. In their review, Bygballe et al. (2010) highlighted both the importance of a long-term orientation and the difficulties that this poses in practice. Furthermore, Sundquist et al. (2018) stated that succeeding in relationship development and adopting a strategic perspective, rather than a project perspective, requires a shift from competitive bidding in single projects to collaboration across a series of projects. Further, decentralization of authority to the project level needs to be supplemented with increased centralized decision-making to achieve strategic perspective. It is however a weakness within the literature that interpretations of the term strategic seem to differ slightly.

In scrutiny of the limited occurrence of strategic partnerships, Sundquist et al. (2018) found that existing literature pointed to two causes: One being implementation challenges, and the other being lacking knowledge of how strategic partnerships come into being. Berg et al. (2021), on the other hand, concluded that the archetypical roles in the industry cause friction when they are to collaborate in strategic partnerships, due to conflicting business models.

PHASES

In the construction industry, projects are often divided into phases, where the phases depend on the project and the project model of the client (Volden & Andersen, 2018). Samset and Volden (2014), among others, separate between two phases: front-end phase and implementation phase. The cost of changes is lowest in the front-end, continuously increasing as the project develops. Oppositely, the flexibility for changes is at its highest in the front-end, continuously decreasing throughout the project (Olsson & Magnussen, 2007; Samset, 2010).

For this paper, it will only be relevant to separate projects into the front-end phase and the implementation phase, as these are the two phases the interviewees relate to, from their industry perspective. Separating into more phases would not reflect the interviewees' perception of the construction process.

TRUST

According to Lahdenperä (2012), trust is the basis for every relation-based contract. This is supported by Zaheer and Harris (2005), who claimed that across fields of study, there is a common belief that project delivery methods based on relation are dependent on trust. They also claim that trust, especially on organizational level, improves both performance and behaviour. Importantly, Zaheer and Harris (2005) also noted that trust has a time perspective: The benefit from building or showing trust will be gained at some unknown point of time in the future.

KNOWLEDGE GAP

We have found a relatively limited amount of literature on strategic partnerships in construction industry compared to other industries and compared to other collaborative project delivery methods. When searching for "strategic partnership", the vast majority of literature originated from other industries. The identified literature from the construction industry is asking for further research (Bygballe et al., 2010). Strategic partnerships may be practiced between different actors, and much of current literature focuses on partnering between client and contractor (Bygballe et al., 2010). Through the literature review, there has not been identified literature about strategic partnerships focusing on such partnerships between client and client's agent. By examining such a case, we intend to fill this knowledge gap and contribute to a broader understanding of strategic partnerships.

METHOD

The study has been conducted with a bilateral approach. A literature review was executed to get an overview of the existing literature and to reveal knowledge gaps. Fellows and Liu (2022) highlight literature review as appropriate for getting an overview, while Wee and Bannister (2016) support that a literature review is a suitable method for revealing knowledge gaps. To obtain empirical insights into strategic partnerships between client and client's agent, one in-depth case study was conducted. Fellows and Liu (2022) confirm the suitability of case studies, and Flyvbjerg (2006) claims that even if such studies are highly specific, they are of great value for scientific development. Further, he emphasizes that the importance of cases as exemplars should not be underestimated.

LITERATURE REVIEW

The literature review was conducted with two approaches: database search and backward snowballing. The database search was conducted in Scopus and with no defined time range. Searches included a range of terms considered somehow similar. For example, (TITLE-ABS-KEY)-string with "strategic partnership" has, using "AND", been combined with terms such as "sponsor", "owners' delegate", "client's agent", and similar. These searches returned no literature. However, "strategic partnership" AND "trust" returned nine articles within subject of Construction. The relevance of these nine were evaluated based on the abstract. Two articles were considered relevant and included in the study. The database search was supplemented with snowballing based on the results from the database search and literature the authors knew from before. Jalali and Wohlin (2012) support snowballing as a legitimate method, concluding that snowballing gives the same conclusions and answers as structured literature searches.

CASE STUDY

The case chosen is the company Stafr Consulting AS, henceforth referred to as Stafr. Stafr is an affiliated company in the company group Base Gruppen AS. The examined strategic partnership is between Stafr and two other affiliated companies under Base Gruppen AS: Base

Bolig AS and Base Property AS, henceforth referred to as Base. As Base Bolig and Property are real estate developers, Stafr works as the client's agent in projects where Base is the client.

To study the case, a document study and semi-structured interviews was conducted. Table 1 displays the key characteristics of the two methods.

Table 1: Overview of methods for case study.

	Document study	Semi-structured interviews
Available data	Project archives and invoicing system	8 interviewees
Source	Contracts, minutes, and project descriptions	Project managers, 4 from Base and 4 from Stafr
Purpose	Overall insight	In-depth insight

Semi-structured interviews

Semi-structured interviews were conducted to answer the research questions. An interview guide was developed where questions were categorized into three categories. As the paper builds on the work by Ferstad et al. (2023) and Paulsen et al. (2022), the interview guide used the same categories as them: Contract, organization, and relationship. The categories chosen were perceived to represent three major themes of project delivery methods. The duration of the interviews was between 45 and 90 minutes. Five interviews were conducted in person, while three interviews were conducted using Microsoft Teams due to the localization or availability of the interviewee. The interviewees were chosen based on a judgement of which individuals in the case that could share knowledge. Client's project managers and client's agents were, in number, equally represented. Combined with the different roles of the interviewees, this was done to pursue a balanced perspective. These considerations were supplemented and confirmed by the question in the interviews that asked for relevant interviewees: All of the interviewees either proposed interviewees within this sample or confirmed the suitability of the sample. All interviews were recorded and automatically transcribed. Interviews were then analyzed to extract relevant findings that answered the research questions.

FINDINGS

Here we present the findings concerning the case study. The findings focus on how the relationship between client and client's agent is affected by strategic partnerships and the potential effects of this. The results are sorted using the categories from the interviews: Contract, organization, and relationship.

HOW THE STRATEGIC PARTNERSHIP IS PRACTICED

Contract

The interviewees describe an informal contracting process, where the agent is involved in the project in the front-end phase. Due to the close relationship, Base often mentions possible projects to Stafr before they are even decided, and Stafr assists Base in their due diligence and decision process. When Base decides on the project, the collaboration is formalized through a standard contract. However, a characteristic of this strategic partnership was that the contract was given little importance: Some of the interviewees stated no knowledge about the contracts. It is reported that both companies use the same contracts within the strategic partnership as they use with other actors. The interviewees from the client side also emphasize the importance of Stafr being competitive regarding price and competence.

Another characteristic concerned decision-making and authority. Beyond the definitions in the contract, referring to Norwegian Standard (Standard Norge, 2008, 2011), the roles and responsibilities are mostly defined based on relation on project level, or through continuing the practice, i.e. common understanding, from previous common projects. There is no formal decision mandate or threshold value for what decisions the agent can decide: In some cases, the agent knows his authority by experience from the relation, but in most cases, the client and agent collaborate so closely that the client is involved in every decision, eliminating the need for specifying the agent's mandate.

Organization

Compared to a conventional agent, the interviewees report that Stafr is involved in front-end phase, even before the acquisition or in the consideration of a new project, and that their tasks often are extended. All the interviewees categorically answered that it is beneficial that Stafr is involved as early as possible. In addition, the interviewees express that in the strategic partnership, the agents often exceed their defined role, both in time and assignments, in a manner that benefits the project and relieves the client.

Stafr's performance is not measured using any parameters or indicators: Base is rather evaluating their own satisfaction via gut feeling. The organization and cooperation are annually formally evaluated, however, this evaluation reportedly only involves the companies' managing individuals, while other employees, i.e. project managers, are reportedly not present in these evaluation meetings. Beyond the annual evaluation, there seems to be a consensus that issues are being addressed when they pop up, and this is reported as a satisfying practice. However, some report that the feedback given within the strategic partnership is of the same character as would be given to any supplier or contractor.

Relation

The interviewees seem unable to decide whether the relations are mostly on a personal or organizational level, but some express that they believe it would be beneficial if the relations were more organizational, so that the strategic partnership was less reliant on personal relations.

The responses are also lacking direction when it comes to individual preferences: All interviewees emphasize the importance of competence and experience, but many also emphasize that personal relation is crucial too. It however seems like relation is a benefit, while competence is a must.

Spontaneous and informal meetings or settings are also an aspect of the strategic partnership, forming for instance if the employees meet in the hallway, or have an informal chat before or after a meeting. In such settings, where there is no agenda, other subjects are brought up, both personal and work-related.

POSITIVE EFFECTS

In the interviews, several positive effects of strategic partnerships between client and agent are reported.

Firstly, when the client and client's agent have a relation from previous projects, the interviewees experience that the agent has a better basis for acting according to the client's wishes and interests. As a result, the agent is also sometimes given increased freedom to do so.

The importance of continuity is emphasized. It is described that the early involvement of the agent that is practiced in the strategic partnership is highly beneficial: Not only does the agent's competence and experience benefit the project from the start, but the agent also does a better job when it knows the history of the project. For Stafr, early involvement is also an efficient way to secure new projects, on which their business depends.

The performance of the agents is not systematically measured. This allows the agents to allocate their efforts to where they find it most beneficial for the project, rather than chasing good performance according to a score on specific indicators.

Regarding spontaneous and informal meetings, the interviewees have varied experiences Some signify this as an essential part of the collaboration, while others feel that there is little time for such settings. However, all of those who recognize the existence of spontaneous and informal meetings, seem to agree that these benefit the project. Bringing up subjects when there is no agenda increases the mutual overall insight in the projects, and offers a setting for discussing matters that are precepted not sufficiently important or mature for formal, planned meetings. In addition, the informal chats are reported to be more personal, improving the relationship and extending the mutual knowledge of non-work-related subjects.

Except for annual evaluation meetings among the managements of the companies, little formal evaluation of the collaboration in the strategic partnership is reported. However, informal feedback is continuously being exchanged throughout the projects. In order to pursue optimal collaboration, the interviewees emphasize the importance of being able to both give and receive constructive feedback. Further, some of the interviewees explain that since the collaboration can be improved from project to project, learning from previous collaboration, collaboration is better within the strategic partnership than in single project relations.

Another positive effect for both client and agent, is the strategic partnership's effect on work efficiency. Due to the interorganizational relation, there are direct decision and communication lines. This is not only beneficial for the individual's time use, but also for the time the organization uses to process the decision, so that the decision may be carried out faster. Further, when the same employees work together on several parallel projects due to the strategic partnership, some describe that they have status meetings for multiple projects, saving time compared to having separate status meetings for every project. Working together on parallel projects also increases the overall interaction, benefitting communication about the project: If the client makes a phone call asking a question about one project, the agent may use the opportunity to inform about a matter on another project. As a result, time is saved, and information is transferred faster. Lastly, communication is simplified, and efficiency is increased due to the shared history: Challenges and problems can more easily be explained and handled when referring to similar cases in preceding common projects.

NEGATIVE EFFECTS

The role of the interviewee seems to highly correlate with which negative effects of the strategic partnerships that are highlighted.

For Stafr, there is one significant drawback: Due to their commonly known close relation with Base, other real estate developers that consider Base as a competitor, have expressed scepticism regarding using Stafr. Some have explicitly expressed that they will not use Stafr because of the relation, whilst others have demanded proof of a Chinese wall between Stafr and Base. This scepticism is reportedly due to: 1) fear that a contribution to Stafr's revenues will benefit Base, or 2) that information will flow towards Base, to Base's benefit.

The interviewees from the client side however describe several challenges regarding strategic partnerships. Firstly, the client's project managers feel that they lose the flexibility to freely choose agent. They express dissatisfaction with not being able to freely choose the most qualified agent in the market, as the management in Base Gruppen to some extent demands the use of Stafr. As a result, several of the interviewees describe the strategic partnership as a "forced marriage".

Secondly, a lot of strategic partnerships and framework agreements complicate collaboration projects with other companies, i.e. multiple owner projects, for the client. This challenge is emphasized by one interviewee, who had thorough considerations regarding strategic partnerships. He states: "We can't drag a lot of framework agreements and strategic partnerships along if we are to develop projects together with others. Then, they won't choose us".

Thirdly, when Base ties closely to one company, i.e. the strategic partnership with Stafr, their network and range is restrained. When dealing with more companies, more and more diverse experience and competence is shared with Base than Stafr can supply. This effect is increased by Stafr's relatively small size. In addition, before the strategic partnership, companies delivering services to Base hinted Base about project opportunities, hoping that they would be hired if the project was initiated. The client interviewee reporting this problem did not experience that Stafr fulfilled this: He states that the strategic partnership gives Base "fewer tentacles". On the contrary, an interviewee from Stafr highlights this as an advantage of the strategic partnership: He claims that Base and Stafr mutually hint each other about projects, mutually increasing the market position of both companies. However, these two interviewees, reporting contrary perceptions, have not worked together. This last point indicates individual practices; there is no defined practice for this in the strategic partnership.

DISCUSSION

All interviewees, both from Base and Stafr, reported that though relation and trust between client and agent are important, the decisive factor is the individual's competence. The benefits regarding relation in strategic partnerships are well described. However, considering that competence is the decisive factor, the companies in the strategic partnership should probably not solely aim to benefit from the relation. If adequate competence is not present, well-developed trust and relations will not have significant value. As a result, the development of competence, and availability of demanded competence, should not be overlooked in the strategic partnership. It is also natural to assume that the right competence contributes to successful projects, and that individuals who have delivered successful projects together have a better basis for mutual trust and relation. Trusting an individual as an agent may consequently be a result of the individual's previously demonstrated competence.

There is without doubt different perspectives on both the positive and negative effects of strategic partnerships. However, in our study the clients seem to have more hesitations than the agents. A possible explanation is that the agent's increased safety for assignments directly comes at the expense of the client's flexibility to freely choose agent in the open market. The latter is the most emphasized drawback reported by the interviewees representing the client side.

The combination of a good relationship, and spontaneous and informal meetings, seems to lower the threshold for, and ease, communication, be it "stupid questions" or "bad gut feelings". Considering the increasing cost of changes and decreasing flexibility throughout a project (Olsson & Magnussen, 2007; Samset, 2010), one could assume that this lowered threshold for communication increases value and reduces cost, as opportunities and challenges are brought up at an earlier stage.

The early involvement increases the agent's understanding of the client's project value, both helping to develop this in the front-end phase, and looking after this in the implementation phase. This should enhance customer value and effectiveness. This is in accordance with fundamental principles of LPDS, as Ballard (2008), stated: "The job of the project delivery team is not only to provide what the customer wants, but to first help the customer decide what they want. Consequently, it is necessary to understand customer purpose and constraints." Further, this shifts the role of the client's agent in the project team away from the archetypical engineer role, as defined by Berg et al. (2021).

The divergent perceptions regarding whether the strategic partnership contributes to new projects, is an interesting finding. The interviewees reporting divergent perceptions, represent different groupings within the strategic partnership: One comes from Stafr/Base Bolig and one comes from Stafr/Base Property. The divergent reports may indicate that there are no overall guidelines aiming for the companies in the strategic partnership to mutually take advantage of each other in order to get new projects. Rather, it seems like it depends on the individuals collaborating whether this benefit is exploited. A concluding remark regarding this, is that one would assume that if Stafr positively contributed to new, profitable projects for Base, and vice versa, such a favour would also positively influence the relationship.

It seems that most of the interviewees recognize the positive effects resulting from having worked together in the past, in accordance with Koskela (2000), but have thought less of the possibilities of strategic partnerships regarding the future. This does not only appear from which benefits they emphasize: The client's project managers express that they at any point of time want the most competent agent. Only one mentions that this may come at the expense of the extending of competence for the employees in Stafr, and this interviewee also expresses that the agent's competence in each project is more important than developing competence in Stafr. An interviewed agent in Stafr also remarks that it seems like Base struggles to see the importance and benefits of developing Stafr's competence: Base is most concerned with what competence is available in the present. These reflections could be considered in relation to the utterance of one of the project managers in Base: Base' evaluation of Stafr does not differ from the evaluation of other companies. This is counter-intuitive, as one would expect that the long-term aspect of strategic partnerships would influence evaluation.

The relatively low use of strategic partnerships in the construction industry, may have several causes. Firstly, it might be perceived risky to try new project delivery methods, shifting away from the well-known and archetypical roles described by Berg et al. (2021). Secondly, companies lacking a common ownership, like the one in the studied case, might not get the push to enter such a relationship. This supports the statement of Sundquist et al. (2018), that the initiation of partnerships are not sufficiently illuminated. Lastly, the disadvantages, listed in Table 3, may discourage especially clients from initiating strategic partnerships. However, the four recommendations in bullet points in Conclusions, might mitigate this reluctance.

Implementing these recommendations should require little use of resources and no substantial changes, and hence be very feasible. These recommendations may also, importantly, be implemented without increasing the perception that Base and Stafr is the same organization.

The findings regarding the benefit of the soft factors are congruent with the lean literature. For instance, continuity enhances efficiency and facilitates for continuous improvement., in accordance with Koskela (2000). Thus does this paper not only support the current knowledge, but it confirms its application also for strategic partnerships. However, by also pointing out disadvantages following the increased relationship and continuity, the paper contributes to the nuance of the existing knowledge.

CONCLUSIONS

This paper set out to increase the knowledge about strategic partnerships. The two research questions, and the most important findings are displayed in Table 2 and Table 3, respectively.

Table 2: Main findings for RQ1

RQ1: How does strategic partnership affect the relationship between client and client's agent?	
Simple and insignificant contracts	No formal mandate
Early involvement	No measuring using indicators
Evaluation: Running informal and annual formal	Both personal and organizational level relation
Competence is crucial	Spontaneous and informal meetings

Table 3: Main findings for RQ2. C indicates client, whilst CA indicates client's agent.

RQ2: What are the resulting effects of this relationship?	
Positive effects	**Negative effects**
Better mutual understanding, especially regarding interests and purposes	CA: Lost assignments due to too close a relation
Increased continuity	C: Lost flexibility when choosing client's agent
Increased efficiency regarding time and communication	C: Complicating multiple owner projects
Lowered threshold for communication	C: Restrained network/range
Taking advantage of CA's competence in the front-end phase	
CA's extended mandate and role relieves C	

The overall purpose of answering the research questions was trying to reveal aspects that could be improved, and thereby contribute to better strategic partnerships between client and client's agent in the future. Based on our findings and the following discussion, we suggest the following actionable and practical recommendations:

- **Mutually helping the other part get new projects:** Being on the lookout for new projects for the other part, both within the strategic partnership, and also outside. This would involve that Base suggests using Stafr to for instance tenants and other estate developers, while Stafr hints Base when project opportunities occur, for instance, possible plots or partners for multiple owner projects.
- **Ensuring competence development:** Ensuring mutual sharing of competence and experience, compensating for the decreased network for input.
- **Ensuring availability of demanded qualifications:** Clear dialogue between the companies regarding what competence the client demands, in order to counter the lost possibility to freely choose the most qualified actor in the market.
- **More focus on the long-term and future perspective of the strategic partnership:** More effort to enhance the strategic partnership, focusing on the future. The companies should aim not only to take advantage of the past-part of the long-term relationship. One of the main factors of strategic partnerships is the knowledge that the parts are to work together in the future, hence they should accommodate for taking advantages in the future. This also implies that evaluation within the strategic partnership should differ from evaluation with other actors.

The study is limited to only one case, with eight interviewees, all in the same strategic partnership. As a result, little can be said about the generalizability of the results. Strategic partnerships between actors with different roles, or where there is no common owner, may experience different positive and negative effects. However, the benefits concerning relation, trust, continuity, etc. mirror the findings in the literature, especially within the field of lean construction. In a lean perspective, strategic partnerships might be one approach to enhance or ensure such soft factors.

Strategic partnerships with different actors or ownership structures should be researched further. Quantitative information about the effect would also be highly valuable.

ACKNOWLEDGEMENTS

We would like to express our gratitude towards Stafr, Base, and the eight interviewees for their cooperation and eagerness to contribute.

STRUCTURING APPROACH AND CURRENT STATUS OF INTEGRATED PROJECT DELIVERY (IPD) IN GERMANY

Marc Weinmann[1], Carolin Baier[2], Ana Schilling Miguel[3] and Shervin Haghsheno[4]

ABSTRACT

The construction industry has been striving for some time to find efficient ways to ensure the successful delivery of project goals for all project participants and stakeholders, while at the same time improving the quality of collaboration and overall productivity. In addition to the use of collaborative methods and tools, Integrated Project Delivery (IPD), developed in the early 2000s, represents an innovative approach to deliver construction projects. Due to the positive results of initial pilot projects, IPD is increasingly attracting international interest. Since 2018, IPD approaches have also been used in pilot projects in Germany. This article presents the current state of research on the development of IPD in Germany and highlights the status of its practical application. Twenty IPD projects in Germany are identified, documented, and analyzed based on various criteria. For the first time, this paper creates transparency on an international level about the five-year development of IPD in Germany. It also provides a basis for more in-depth analysis, particularly regarding the qualitative aspects of the IPD pilot projects carried out in Germany.

KEYWORDS

Integrated Project Delivery (IPD), Germany, structuring approach, framework, implementation, collaboration.

INTRODUCTION

Integrated Project Delivery (IPD) is a project delivery approach that emphasizes increased integration and collaboration among construction project participants. The goal is to minimize waste and maximize efficiency in all project phases. (The American Institute of Architects, 2007) The term IPD was first introduced in the United States in the early 2000s (Lahdenperä, 2012). Due to the limitations of traditional contractual structures, construction and design firms have developed a new approach to align the interests, objectives, and practices of project participants. This approach facilitated better coordination, cooperation, innovation, and optimization in construction projects. (Matthews & Howell, 2005) Initial studies demonstrate that project objectives were achieved significantly better compared to traditional project delivery approaches (American Institute of Architects [AIA], 2012; Cohen, 2010).

Since the early 2000s, IPD has developed in various directions, influenced for example by collaborative approaches from Australia and the UK (Lahdenperä, 2012). The evolution of IPD can be described using the characteristic feature of a multi-party agreement in international practice. This includes project delivery approaches such as 'Project Alliancing' and 'Integrated Project Delivery' (IPD) as well as approaches from the UK such as the 'Project Partnering Contract' (PPC2000). (Haghsheno et al., 2022)

In recent years, there has been significant research on the implementation of IPD in various countries. The studies address the challenges and opportunities associated with the global spread of IPD. Several studies have examined the implementation of IPD in different regions. For example, Rached et al. (2014) explored the implementation and challenges of IPD in the Middle East, while Forero et al. (2015) investigated the perception and disposition towards IPD in Colombia. The studies by Li and Ma (2017), Aslesen et al. (2018), Erazo et al. (2020), and Dargham et al. (2019) examine the barriers and challenges to implementing IPD in China, Norway, Peru, and Lebanon, respectively. Additionally, Attouri et al. (2023) investigated the legal feasibility of IPD implementation in France.

Examples of German academic research on Integrated Project Delivery (IPD) in an international context include studies on trust in IPD, as presented by Haghsheno et al. (2021), the development of an simulation demonstrating the functioning of IPD elements, published by Russmann et al. (2022), and analyses of the implementation of co-locations in IPD projects, as presented by Szyperski et al. (2023).

RESEARCH DESIGN

A systematic literature review on IPD in Germany was conducted in the first part of this paper. The review examines the development of IPD in Germany in theory and the current state of research. Relevant theoretical studies in English and German were identified.

The analysis of current IPD projects in Germany was conducted using a multi-layered research methodology. To achieve a comprehensive market analysis, various sources of information and types of interaction were combined. A thorough review and evaluation of available information and data from secondary sources was undertaken through comprehensive open-source research. The evaluation process involved analyzing scientific publications, industry analyses, company announcements, and documents and presentations from conferences, seminars, and market information events. Public tenders were also considered. Additionally, targeted bilateral discussions were conducted with market participants to gather additional data, especially data that is not publicly available. Excerpts from the analysis results have already been published in the annual IPD report at the German IPD conference.

DEVELOPMENT OF IPD IN GERMANY AND CURRENT STATUS OF RESEARCH

The construction industry in Germany is facing numerous challenges. Conventional project management is characterized by a lack of integration between project participants, inadequate risk management, a lack of partnership-based cooperation and insufficient conflict resolution mechanisms. In addition, many projects experience cost increases due to errors in cost calculation or tendering, changes by the client or price increases. (Kochendörfer et al., 2021)

Between 2000 and 2015, over 40% of federal building construction projects exceeded their budget and more than 35% did not meet their deadline targets (Bundesministerium für Umwelt, Naturschutz, Bau und Reaktorsicherheit [BMUB], 2016). This is also reflected in the sector's productivity. While productivity in the German manufacturing industry rose by 27.1% between 2006 and 2016, the construction industry only recorded growth of 4.1%. (Schober et al., 2016)

To address these issues, optimization and innovation potential should be utilized throughout all stages of building creation. This requires collaboration and integration among various service providers and clients. (Girmscheid, 2016)

In 2016, a federal construction reform identified nine areas for action. One of these areas is the implementation of partnership-based contract models to address the lack of sustainable, long-term, and trusting cooperation between project participants. The reform aims to achieve this through early integration of contractors, increased use of risk and rewards regulations, transparent calculation documents, and partnership-based pilot projects. (BMUB, 2016)

Integrated project delivery has been implemented in initial pilot projects in the German construction industry since 2018. The term was initiated by the 'Initiative Teambuilding', which was founded in 2016 and consisted of about 40 organizations from practice and science, which examined approaches for better collaboration already established abroad for the German market. In 2018, a private client organization launched the first IPD pilot project, followed by a public sector pilot project in 2020. (Haghsheno et al., 2022)

The Initiative Teambuilding led to the founding of the 'IPA Zentrum' (The Competence Center for Integrated Project Delivery or IPD Center). The IPD Center is a central platform to enable stakeholders in the construction industry to successfully implement complex construction projects through the use of IPD models in Germany. It significantly contributes to the demand-oriented and resource-efficient construction and maintenance of built infrastructure. The main goal is to create an inclusive networking platform that facilitates the sharing of knowledge and experience, thus promoting the implementation of IPD models in the construction sector. The IPD Center is comprised of more than 80 carrier organizations from across the construction industry. An advisory board, consisting of representatives from eight universities and over 20 professional and trade associations in Germany and Austria, provides strategic guidance to the leadership and incorporates perspectives from politics, professional associations, and academia. Volunteer experts from the IPD community collaborate in various working groups to develop concepts and publications. (IPA Zentrum, 2023)

IPD – A Structuring Approach from Research

The 'House of Integrated Project Delivery' is a structuring approach that was published in 2022 by Haghsheno et al. As illustrated in Figure 1, the structure consists of four pillars based on a foundation. The approach is based on previous work to structure the model of IPD such as Darrington et al. (2009) or Lichtig (2005). The structuring approach includes framework conditions, requirements, and experiences from German IPD projects. In this structured approach, IPD is based on values and a multi-party agreement. The values define fundamental principles of cooperation, while the multi-party agreement provides the legal framework and sets out common rules for cooperation.

Structuring Elements

IPD is based on a multi-party agreement as a legal framework with common rules and values as the basic principles of cooperation. Building on this foundation, the structuring approach consists of four pillars: culture, organization, economy, and methods. The culture pillar describes approaches for establishing shared values. In order to fully exploit the advantages of the model, a change in the project culture and the behavior of the team members is required. Developing a shared understanding of values and creating a sense of belonging are lengthy and complex processes. Various tools can be used as part of project management, such as the development of a project charter, team building, onboarding activities, and structured team reflections.

The organizational pillar refers to integrated structures for communication and decision-making. Efficient decision-making and flat hierarchies require an integrated and interdisciplinary organizational structure to react quickly to changing conditions. In terms of economics, value-based financial incentives are set, and risks are allocated. IPD is most effective when the economic incentives of the partners align with the project goals. Positive economic incentives replace penalties such as liability or contractual penalties. The methods pillar outlines processes for promoting transparency, collaboration, and efficiency. Therefore, Lean Management is a crucial component of IPD, especially the ideals and principles of Lean Management which help in implementing IPD and establishing the right project culture. Methods such as the Last Planner System, Target Value Design, Building Information Modeling, or Choosing by Advantages are utilized. All four pillars are important for the stability of the project and therefore are critical to its success.

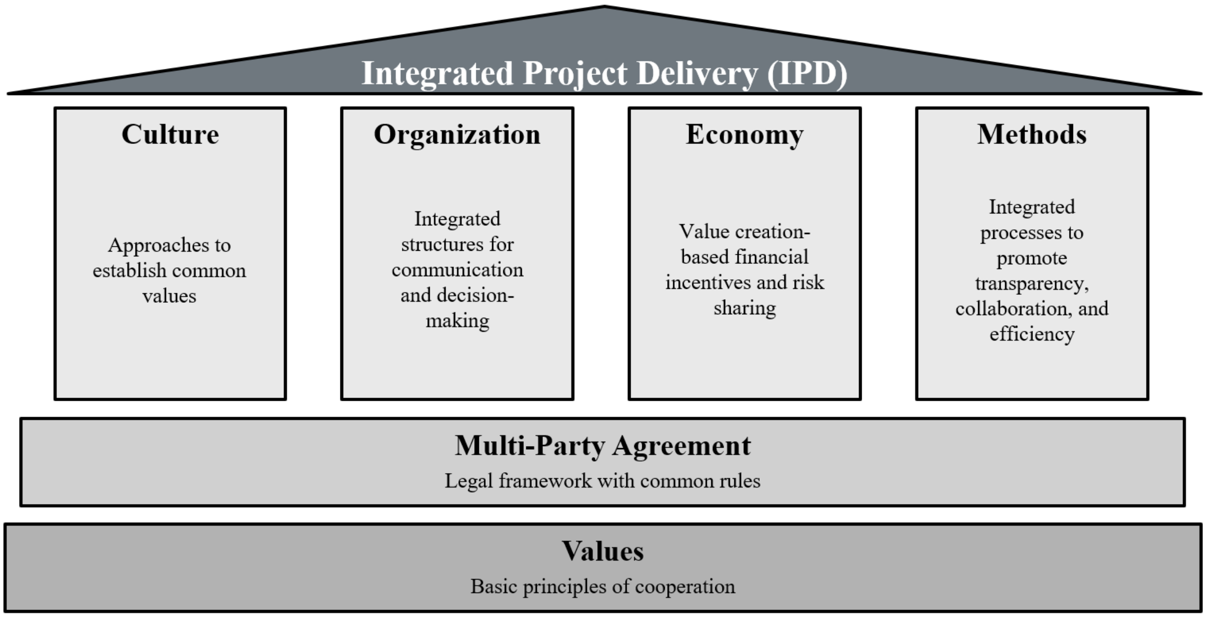

Figure 1: House of Integrated Project Delivery (Haghsheno et al., 2022)

Elements are assigned to the categories of the House of Integrated Project Delivery as sub-items. These elements enable the precise characterization of specific models of integrated project delivery and the classification of projects, considering the implemented elements.

IPD – A Structuring Approach from Practice

Also in 2022, the IPD Center initiated a conceptual framework for the German Integrated Project Delivery model. The characteristics and model components were developed based on initial experience gained from the implementation of IPD in Germany by experts from science and practice. The framework was developed due to the observation that many projects were adopting the new project delivery approach and referring to themselves as 'IPD projects', despite significant differences between the projects. The framework was considered a necessary step to ensure a common understanding in the industry, to enable the identification of IPD projects, and to provide transparency on the underlying concepts.

IPD Characteristics and Model Components

Figure 2 displays the model, which comprises eight characteristics and 21 assigned components. To be classified as an IPD project, a project must cumulatively meet these relevant success factors. Therefore, all 21 model components must be utilized in the project.

One of the key characteristics of a successful collaboration is the establishment of a multi-party agreement in which at least three parties are involved in the rules of cooperation. The early involvement of key stakeholders through a competition of competencies is of significant importance. Besides competencies, skills related to effective teamwork, such as behaviors and attitudes, are also relevant. In addition to joint risk management, which involves identifying, evaluating, and managing project risks and opportunities at an early stage, there is also joint decision making based on shared responsibility for project goals.

The compensation model's incentive system aims to align participants' behavior with project goals. Collaborative working methods aim to enhance effective cooperation, transparency, and collaboration within the project team. This is achieved through the use of BIM and Lean Construction methods.

The framework treats conflicts as a potential for value creation and aims to resolve them as quickly and constructively as possible through solution-oriented conflict resolution. In a final step, understanding and aligning behavior with shared values, the cooperative attitude of the participants, is a mandatory prerequisite for the success of an IPD project. (IPA Zentrum, 2022)

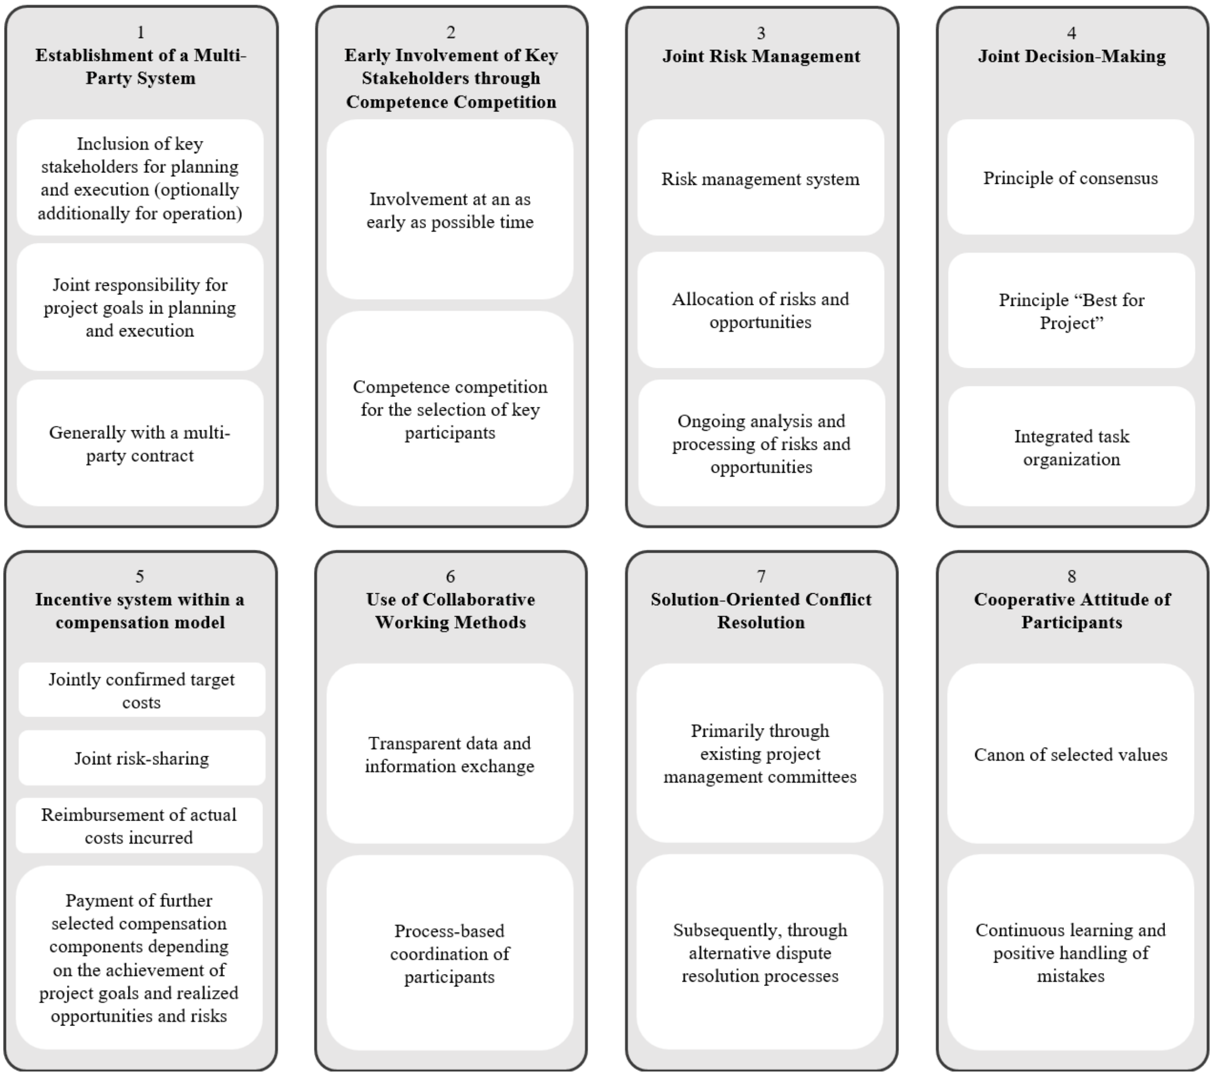

Figure 2: IPD characteristics and model components (IPA Zentrum, 2022)

The structuring approach of Haghsheno et al. (2022) and the framework of the IPD Center are not contradictory, but rather complimentary. Therefore, the essential contents of both approaches are comparable.

CURRENT STATUS OF IPD IN GERMANY: PROJECTS IN PRACTICE

The following section constitutes a comprehensive report, synthesizing pertinent details concerning projects executed through Integrated Project Delivery in Germany. The criteria for an IPD project to be listed are that the IPD characteristics as defined by the IPD Center are present or (foreseeable) and that at least the partner selection phase has begun. The data collected dates back to 2018, when the first IPD project started in Germany. Figure 3 provides an overview of the IPD projects in Germany. In addition to the project name, they are categorized according to project costs. The timeline displays the individual phases of the IPD projects at the respective points in time. As of 2023, there are a total of 20 IPD projects that have either been completed or are currently ongoing, at least in the partner selection phase. Out of the 20 projects, one has been completed, seven are currently under construction, and six are in the 'Integrated Planning' phase. One project is currently on hold, while five others are still in the 'Partner Selection' phase.

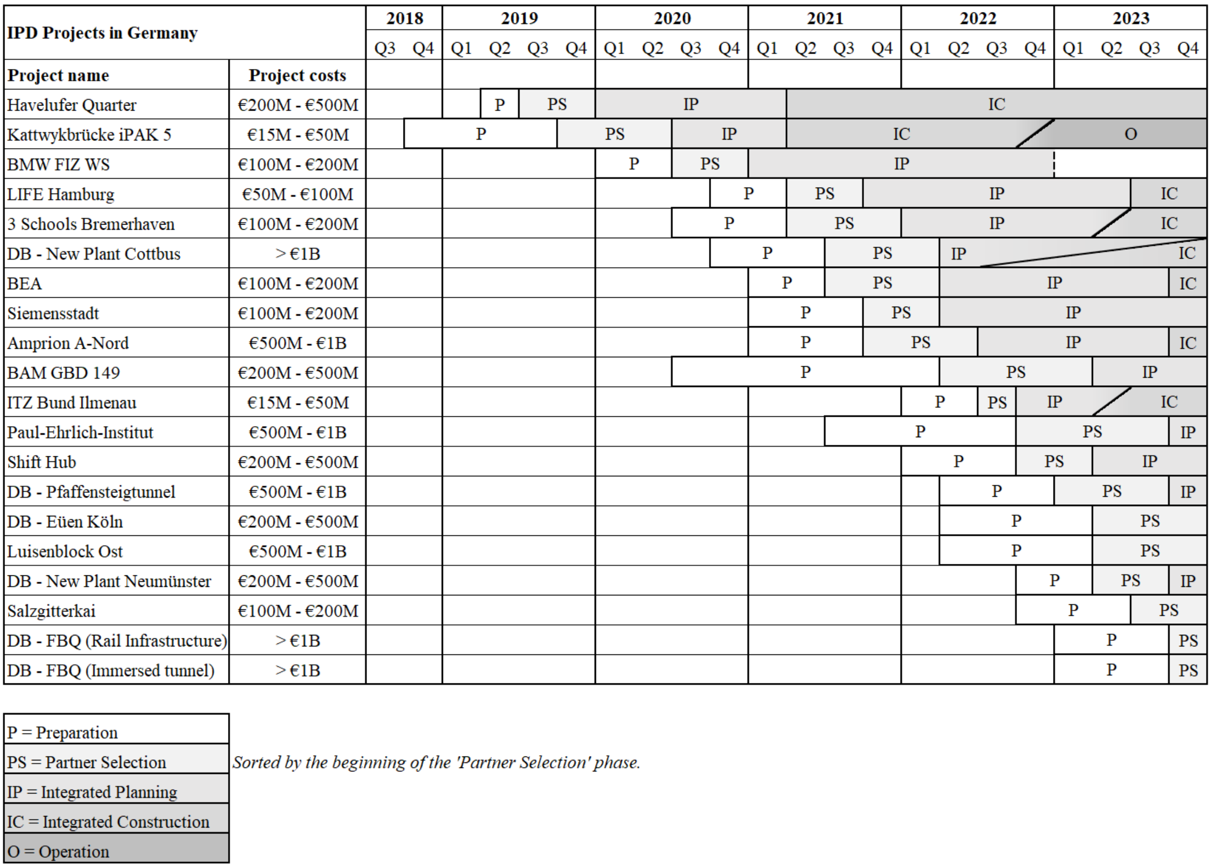

Figure 3: IPD Projects in Germany

In comparison to 2022, there have been two discontinued IPD projects due to a re-evaluation of investment activity in response to changed circumstances, which led to the projects being discontinued for economic reasons. During the period from mid-2022 to mid-2023, eight new IPD projects have been identified and are currently ongoing.

In addition to the IPD projects listed, for which at least the partner selection phase has started, seven other IPD projects are currently in preparation. These are projects for which it is known that a decision has been made in favor of IPD as the project delivery model. IPD is also being intensively discussed as a project delivery model for other projects. However, a final decision has not yet been made on these projects.

Project Costs and Client Structure

In Germany, the smallest IPD projects fall within the project size category of €15 - €50 million, as shown in Figure 4. Analysis of IPD project distribution reveals a preference for implementing the project delivery approach in larger projects. The reasons for this preference are varied. IPD is particularly well-suited for complex projects. Complexity can arise from various factors such as many participants, technical challenges, or large project sizes.

According to the definition provided by the IPD Center, an IPD project must fulfill eight characteristics and 21 associated model components to be classified as such. This may result in increased costs, especially during the initial phase of construction projects. For example, there may be extra expenses for the assessment center to choose partners or for team building activities. Ideally, the initial costs are offset by improved collaboration during the planning and construction phases of the project. For larger projects, the higher initial costs account for a comparatively smaller proportion.

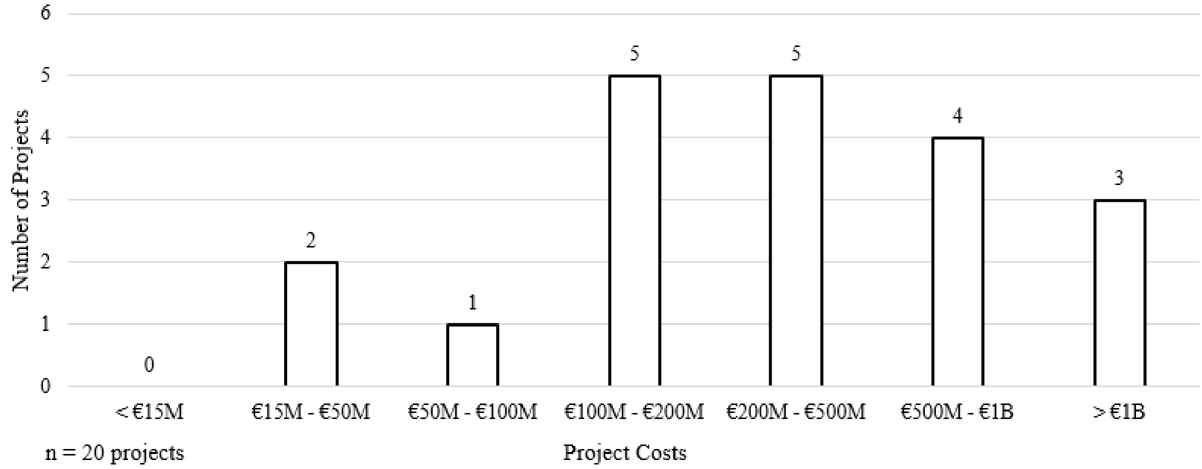

Figure 4: Project costs of IPD Projects in Germany

The distribution of IPD projects clearly shows that IPD is used primarily in larger projects. Out of 20 projects, 17 have a project volume exceeding €100 million. Due to the increase in IPD projects in the area of transport infrastructure, there is a trend towards larger projects. All three projects with a volume of over €1B are assigned to transport infrastructure.

In total, 14 of the IPD projects are being carried out by public clients, while six are being carried out by private clients. A comparison between 2023 and 2022 shows an increase in the proportion of IPD projects in the public sector. The Deutsche Bahn (German Railway) is making a significant contribution to this by driving forward an increasing number of pilot projects.

Type of Use

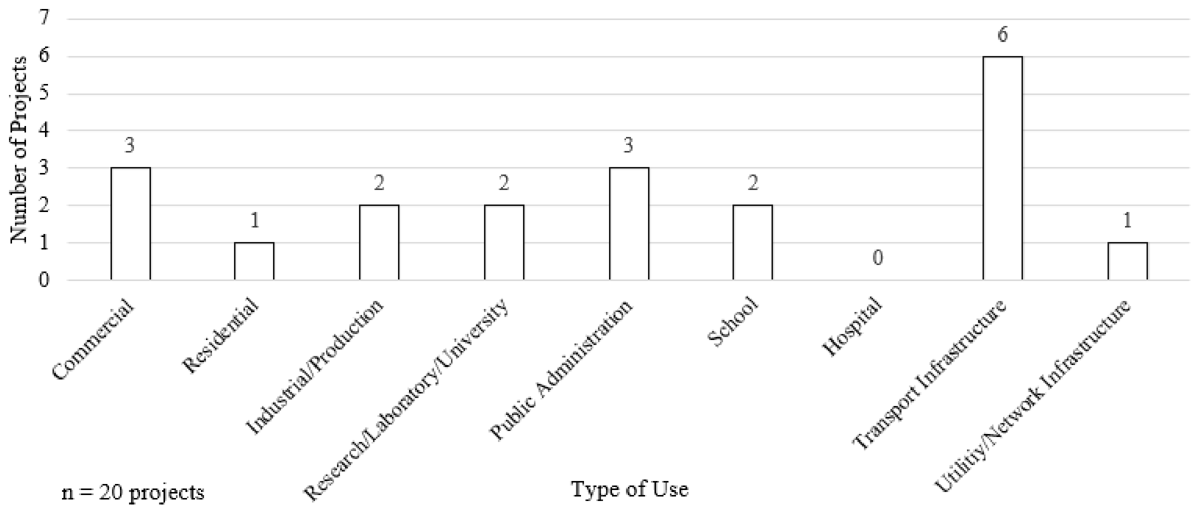

Figure 5: Types of use of IPD-Projects in Germany

Figure 5 displays the distribution of IPD projects by type of use, indicating that the projects can be assigned to a wide range of uses. Three of the analyzed projects can be assigned to the commercial construction sector, one to the residential construction sector, two to the industrial/production sector, and two to the research/laboratory/university sector. Additionally, three projects are intended for public administration use, two for educational purposes, and one for the utilities/network infrastructure sector. As stated in the previous section, six IPD projects were dedicated to transport infrastructure, which accounts for the largest share. The evaluation indicates that IPD is utilized in completing projects in both building construction and civil engineering.

A comparison of new and existing construction projects reveals that the majority of IPD projects concentrate on new construction activities. In cases where projects involve both new and existing construction components, the classification is based on the primary focus of the construction task. While 17 projects are classified as new construction projects, only three projects primarily relate to measures in existing buildings. Existing building measures are typically associated with increased uncertainty and specific requirements. It is to be seen whether the use of IPD for existing building measures will be increasingly preferred by building owners in the future. The benefits of IPD could arise in particular from the flexible management of risks.

Number of Contractual Partners

A further differentiation between the IPD projects is whether the team is put together through separate tender or selection procedures with individual applications or through team applications. 18 IPD projects use the concept of individual applications, while team applications have only been used in two IPD projects.

Figure 6 displays the distribution of IPD projects based on the number of contracting parties in multi-party agreements. The diagram depicts a single project with small dots, and two projects on the same axis with large dots. The IPD Center defines a multi-party agreement as having a minimum of three contractual partners: the client, the key planner, and the key contractor. Criteria for determining the necessary number of key partners generally include the scope of services, their influence on the project's success, their contribution to value creation, and the significance of their expertise for product development and process flows. (IPA Zentrum, 2022)

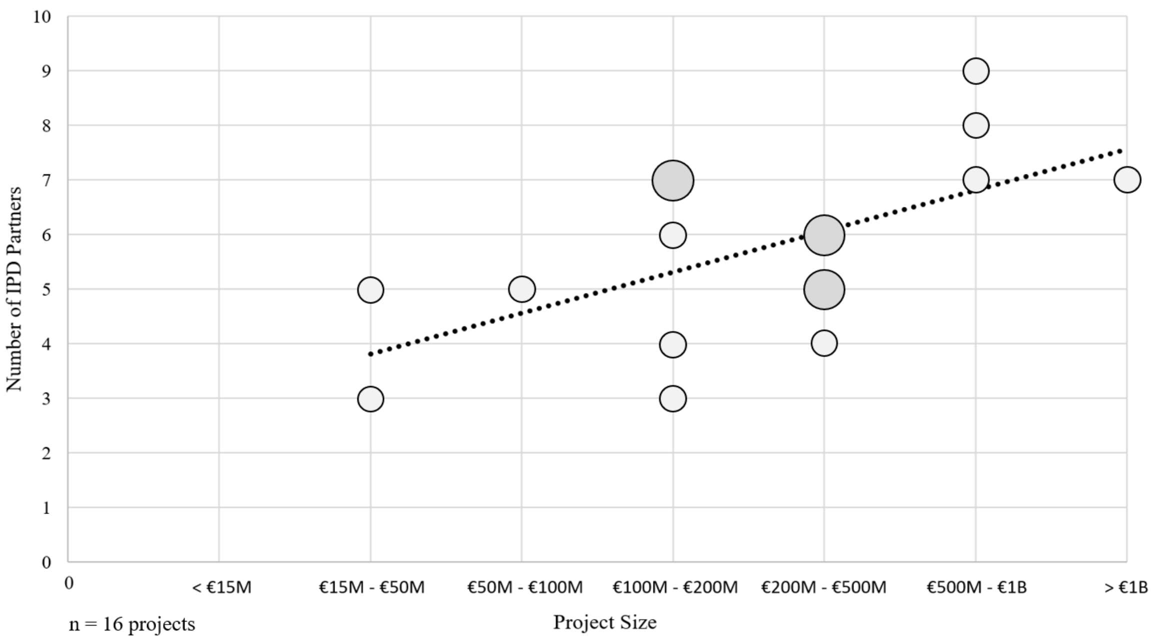

Figure 6: Number of IPD partners in comparison to the project size

The number of contractual partners is also determined by the construction task and the market structure of potential providers. The appropriate team size is being considered in relation to integrated organizational structures and decision-making in committees, without overburdening those involved. This is especially important as the parties involved are undergoing an intensive change process that is accompanied by the implementation of IPD.

The sample relates to 16 projects due to incomplete information on all projects. The distribution indicates that four projects have five contractual partners, while another four projects have seven contractual partners. Two projects have the minimum number of three contractual partners. With nine contract partners, one project has the maximum number of all projects in the sample. Beyond this survey, a trend towards the implementation of projects with even more contractual partners in the German IPD market can be observed in projects currently in the preparation phase. The linear trend line confirms the theoretical explanations that there is a tendency towards more contractual partners with higher project volumes. However, there is no clear correlation between the number of contractual partners and the type of use or other characteristics.

Experience in Completed and Advanced IPD Projects

Experience with IPD projects in Germany has been positive to date. The following section presents experiences from individual projects. For example, the 'Kattwykbrücke iPAK5' project, a lift bridge located in the port of Hamburg, was built to the desired quality and within the planned costs, but the construction time was significantly reduced compared to conventional project delivery. This was accomplished by prioritizing problem-solving over assigning blame when issues arose. The project claimed that Integrated Project Delivery represented a new paradigm of collaboration for them. (Hacker & Schulz, 2022)

The '3 Schools Bremerhaven' project, the parallel construction of 3 schools in Bremerhaven, is drawing positive effects as an interim conclusion, particularly from the earliest possible start of the alliance based on the results of the preparation phase and the client's conditions of satisfaction. In addition, IPD, particularly in combination with BIM and Lean, offers optimal framework conditions for achieving genuine collaboration and a focus on objectives in the project. (Hamel & Rodde, 2022)

The 'Siemensstadt' project in Berlin involves the construction of a high-rise and an atrium building. According to one of the construction companies involved, the risk/reward profile is balanced, and the worst-case scenario can be effectively managed through risk management. The fact that influence can be exerted early in the planning phase and that all partners work together as equals is also highlighted as a positive aspect. Challenges mentioned include complete transparency, i.e. the profit rates and overhead rates known to all, which may be new to the corporate cultures, and the lack of co-determination rights in the selection of other construction partners in the project. During the preparation and validation phase, success factors and advantages were identified, including a realistic client budget, early definition of key systems, and high levels of management support within the client organization. Additionally, the establishment of a project culture based on partnership was successful, and there was a high willingness to try out new processes and roles. The increased time and cost required for validation due to IPD was offset by significant savings in the planning phase and binding cost statements from the construction companies. (Clesius & Warlich, 2023)

Experience from various validation phases of IPD projects shows that a high level of personnel deployment and regular presence in the colocation is necessary. The new project delivery model requires experienced and well-trained personnel. Each contractual partner must have an authorized decision-maker. Project management should be a joint effort of the team and not underestimated. (Schedensack & Büchner, 2023)

CONCLUSION AND FUTURE WORK

Integrated Project Delivery has been utilized in Germany since 2018. An analysis of the theoretical work on this topic in Germany shows that there are two structuring approaches. One approach is the concept of the 'House of Integrated Project Delivery', while the other examines the characteristics and associated model components.

In practice, the authors' research shows that a total of 20 projects based on the definition of the IPD Center had been carried out in Germany by 2023. Most of these projects have a volume of over 100 million euros. The percentage of IPD projects executed by public client organizations is presently on the rise. The evaluation indicates that IPD projects are present in nearly all forms of use and construction. This highlights the potential of the IPD project delivery model for various segments of the construction industry. It is worth noting that the IPD partner selection process also allows for team applications in addition to the established individual application approach. The number of contractual partners in the multi-party contracts range from three to nine.

The analysis demonstrates that the momentum started in 2021 is continuing in terms of the number of IPD projects launched. Therefore, an increasing number of market participants can experience IPD through practical implementation, and initial findings can be evaluated for desired results. In addition to the analyzed projects, several other IPD projects are currently in the decision-making phase. The extent to which the positive development of IPD will continue remains to be seen and will require further monitoring.

In this article, a descriptive analysis was conducted on the gathered data. Research on the documentation of IPD projects in Germany has predominantly taken a descriptive approach, focusing on quantitative core information and framework conditions. However, to not only document but also comprehensively evaluate IPD projects in the future, a qualitative study is necessary. Design features that could be analyzed include compensation mechanisms, risk-sharing contributions, risk and rewards systems, tender criteria and their weighting, the timing of IPD team formation, target cost agreements (planning status), collaborative methods, decision-making rules, and alternative dispute resolution arrangements. This aims to provide additional insights and a more comprehensive understanding through supplementary parameters and qualitative data collection.

As part of a research project funded by the German Federal Ministry for Housing, Urban Development and Building, the authors aim to complement the existing descriptive approach with a qualitative and structured evaluation of information. The objective is to identify correlations between design elements and the processes and outcomes of an IPD project. The study aims to determine the extent to which different design elements influence the processes and outcomes, and what impact they have on the overall process and the achievement of the overall project goals, in order to derive specific recommendations for practice.

LEAN CONTRACT, COLLABORATIVE POWER: ACCELERATING DELIVERY IN UNDERGROUND METRO PROJECT

Prabhu P[1], Nalin M[2], Ashwetha U[3], Aravind V[4] and Jayarama H[5]

ABSTRACT

This paper examines the practical implementation of lean principles in the contract management and operations of the TU 02 underground metro project in Chennai City, India. The project, a crucial component of Chennai Metro Rail Limited's Phase 2 development spanning 116 km, stands out for its intricate collaboration with multiple contractors. Despite its scale and complexity, CMRL TU 02 project team has embraced lean management principles since its inception. The project encountered about 24-months of delay due to the unavailability of shafts for lowering and retrieving TBMs. This paper provides a detailed analysis of the lean principles applied in Contracts Management to reduce this delay from 24 months to 18 months. The collaborative approach to lean management with clients and General consultants not only mitigated the schedule delay but also minimized TBM idle time, a critical aspect with high risks. Additionally, process optimization techniques, such as Value Stream Mapping (VSM) in the precast yard and TBM lowering cycle time reduction at the project site, are explored, showcasing the effectiveness of lean concepts in complex construction projects.

KEYWORDS

Lean construction, Lean Contract Management, Enhancing project efficiency, Value Stream Mapping (VSM), Big Room Planning and Collaborative Planning.

INTRODUCTION

Chennai, the bustling capital city of Tamil Nadu state in India, is undergoing a transformative phase in Infrastructure upgradation with the ongoing expansion of its metro rail network through CMRL's Phase 2 corridors. The TU 02 project, a significant segment of this expansion, involves the construction of 12 kilometers of twin bored tunnels and key underground station structures critical for enhancing urban connectivity and reducing traffic congestion. It encompasses the construction of diaphragm walls and entry/exit structures for 4 key stations

namely Chetpet, Royapettah Government Hospital, Thiruvanmiyur, and Greenways Road. The scope of project is summarised in table 1.

Table 1: Scope of the project

Sl. No.	Description	UOM	Total Scope
1	Diaphragm wall	RM	2,757
2	Shaft Excavation	cum	70,352
3	Ring Casting & Erection	Nos	18,366
4	TBM Tunnelling	RM	25,000

The deployment of 8 state-of-the-art Tunnel Boring Machines (TBMs) underscores the project's technological advancement and its role in shaping the city's infrastructure landscape. However, like many mega construction projects, TU 02 faced challenges, including a notable 24-months delay in interface contracts, which necessitated innovative approaches rooted in lean principles for effective contract management and project operation.

COMPLEXITY IN PROJECT

A notable aspect of the CMRL TU 02 project is the execution of 4 launches for each of the 8 TBMs, totalling to 32 drives. The total of 32 launches and 32 retrievals needs to be taken up from total of 16 stations along the alignment. Out of the 32 shafts, 8 shafts are in the scope of Tunnelling Contractor. The balance 24 shafts are in the scope of Interface Station Contractor. The scope of Tunnelling and Station works are depicted in Figure 1.

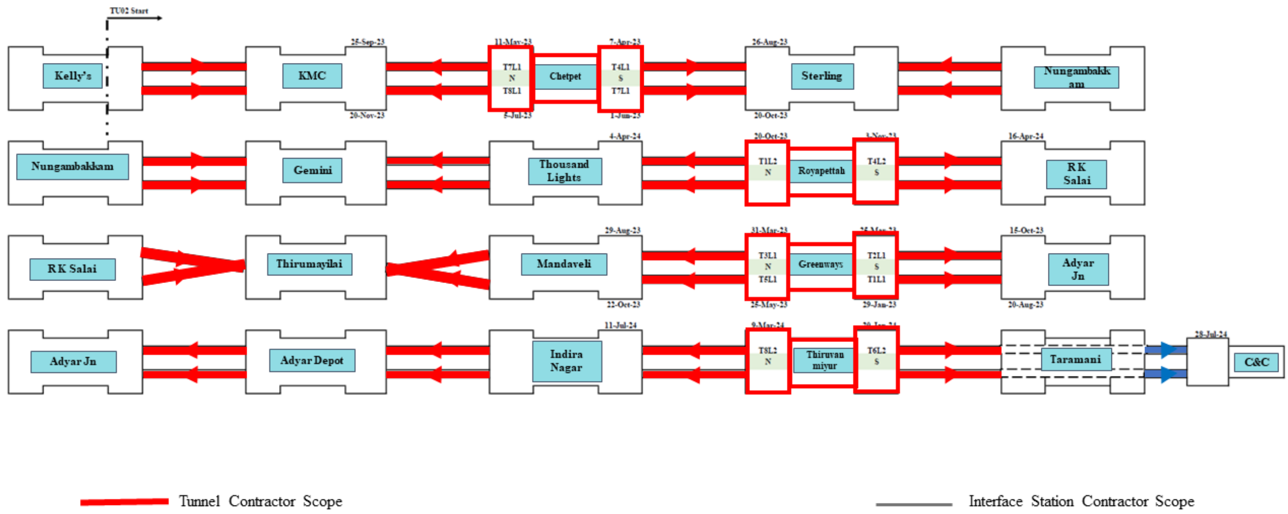

Figure 1: CMRL Phase 2 Corridor 3 – Kellys to Taramani Alignment

However, the complexity of the project was exacerbated by a 24-months impact on project schedule in the interface contract, stemming from various delays with the client. This delay posed a formidable challenge, leading to the postponement of TBM launches and a subsequent ripple effect on both cost and timelines.

To overcome these challenges and optimize project progress, lean initiatives were adopted, necessitating the resequencing of TBM launches and innovative approaches to contract management. This paper delves into the dynamic application of lean contract management principles in the context of CMRL TU 02, exploring strategies employed to minimize TBM idleness, renegotiate contracts, and propel the project forward. Our journey involves reshaping traditional approaches, resequencing TBMs, and converting setbacks into opportunities for efficiency enhancement and collaboration. The overarching goal is to not only highlight the practical solutions implemented but also to contribute valuable insights to the broader field of metro construction project management. Also, this paper explores the implementation of Value Stream Mapping in Precast Yard of the same project to reduce the cycle time of precasting of tunnel rings. As we embark on this exploration, the title encapsulates the essence of our endeavours. The paper describes the intricacies, challenges, and triumphs of CMRL TU 02, as we showcase how a lean approach can truly optimize progress in the dynamic landscape of underground metro construction.

NEED FOR LEAN IN CONTRACT MANAGEMENT

The complexities of modern construction projects, including tight schedules, fluctuating budgets, and multiple stakeholders, underscore the need for lean principles in contract management. Traditional approaches often fall short in meeting the dynamic demands of such projects, leading to inefficiencies, delays, and disputes. Contract documents for construction projects are traditionally prepared to manage conflicts rather than collaboration (Skinnarland and Yndesdal 2010). Lean principles offer a holistic approach to addressing these challenges by emphasizing continuous improvement, collaboration, and adaptability. By integrating lean principles into contract management processes, construction projects can achieve greater efficiency, transparency, and stakeholder satisfaction. Contracts can be structured to exploit the tremendous opportunities for performance improvement (Miles and Ballard 1997).

LEAN AWARENESS LEVEL IN PROJECT

CMRL TU02 is already a lean-managed project where a lean culture was inculcated into the root level of the team. Initiating a culture of lean practices within a construction site required a fundamental shift in mindset and a deep-rooted understanding of lean principles among the project team. At the heart of the project's lean journey was the recognition of the importance of motivating the project team to embrace lean practices. This motivation was cultivated by providing tangible evidence of the benefits of lean through data-driven insights from lean tools such as Work Sampling, Foreman Delay Survey (FDS), and Value Stream Mapping (VSM). Under the guidance of the project director, a dedicated lean implementation team was formed to spearhead the initiative, laying the groundwork for lean practices to permeate throughout the project, including contract management processes. The effectiveness of the lean tools was evident through the improved customer focus and eliminating waste (Refer to Mastroianni and Abdelhamid 2003).

IMPLEMENTATION

A structured approach was adopted to implement lean practices, starting with a focused drive to kickstart the journey. Below (Figure-2) is the Lean Organogram of the project framed to cultivate lean culture in project. Simulations help Lean learners evaluate from a flow- and efficiency- perspective how project team members are managing production system design and control (Tsao and Howell 2022) Lean culture was developed by organizing meetings and training sessions directly at the project site, providing an immersive learning experience for team members. Real-world case studies and interactive lean games (e.g., Airplane game) were utilized to impart hands-on knowledge of lean principles, ensuring that team members were equipped with the skills needed to embrace lean practices in their respective roles, including contract management. Training sessions were conducted extensively across various departments, equipping team members with the skills and knowledge needed to integrate lean principles into all aspects of project management, with a specific focus on contract management.

Approximately 80 team members underwent training, ensuring that lean principles were fully integrated into daily operations, including contract negotiation, execution, and evaluation.

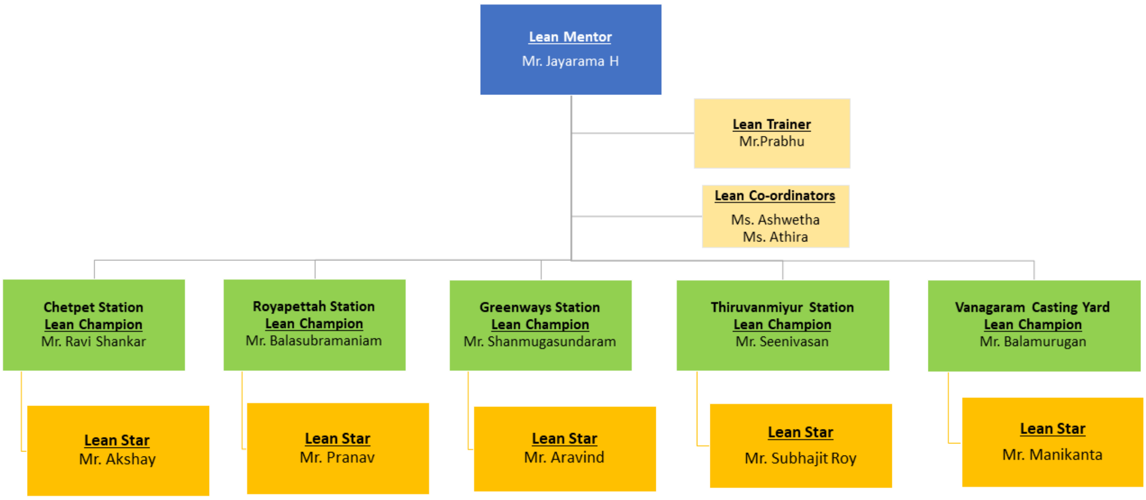

Figure 2: Project Lean Organogram

Consistent weekly review meetings played a crucial role in maintaining momentum and assessing progress. These meetings provided a platform for team members to review Planned Percentage Completion (PPC) achievements, identify constraints, and conduct root cause analysis, fostering a culture of continuous improvement and accountability in contract management processes.

PROBLEM STATEMENT

The project faced significant challenges during its implementation. One of the foremost obstacles was the 24-month delay in the interface contract, which had cascading effects on project timelines and costs. This delay led to the postponement of Tunnel Boring Machine (TBM) launches and subsequent disruptions in construction activities. The level of technical and commercial risk anticipated because of the delay was very high. Additionally, the complexity of the project, compounded by its underground nature and urban setting, posed unique challenges in resource management, stakeholder coordination, fulfilling the contractual requirement, collaborative work with the CMRL contractors, and risk mitigation.

STRATEGIES OF LEAN CONTRACT MANAGEMENT ADOPTED

Lean Contract Management was chosen as a tool to mitigate the challenges faced in the project in terms of delay in time and cost impact from same. Below are the step-by-step lean strategies adopted in the project.

1. Proactive delay notification
2. Establishing the Pull
3. Big Room Planning
   - Phase 1: Initial Level
   - Phase 2: Core Level
   - Phase 3: Senior Management Level
4. Incorporation of Results in Contract

PROACTIVE DELAY NOTIFICATION

Effective communication with the client is paramount in managing mega projects successfully. Letters, emails, and monthly reports uploaded in Project Management Interface System forms part of official communication of project as per contract. As a first step, the Tunnel Contractor prepared the project schedule incorporating the delays as on date and submitted the same to client. The baseline schedule of 54 months got extended by 24 months. The other interface contracts were not awarded to contractors from Client, and it created a huge impact in timeline of tunnelling contract. The technical risk arising out of idling of TBMs under the ground of 15-18m for months is also notified. By systematically documenting and communicating these potential delays, we ensured transparency and facilitated collaborative problem-solving with all stakeholders.

ESTABLISHING THE PULL

The tunnelling contractor established the Lean Concept of Pull in the System (PMI 2017) with Client by exercising on the Key Milestone Dates of Shaft Handover in Contract. The communication was submitted for seeking of Shaft Handover dates (especially retrieval shafts) from client. This established the pull and underscored the gravity of situation to act immediately.

BIG ROOM PLANNING

Lean principles of collaboration and risk assessment were integral in reducing delay. Upon aligning the Contractor, General Consultant and Client on the criticality of the delay, the Contractor implemented the Lean Practice of Big Room Planning. Big Room Planning is a tool that increases the joint work and ownership of all stakeholders and develops mutual trust and respect (Başağa et al. 2019). A Big Room Planning workshop was initiated with all stakeholders to collaboratively discuss and plan to find all measures to reduce the impact of delay. Big Room Planning was taken up at different phases to mitigate delay to the maximum extent. The different phases are explained in detail as below:

Phase 1: Initial level

As a first step, technical representatives from all stakeholders, namely Tunnelling contractor, General Consultant and Client were part of the Initial Big Room Planning. The Handover dates of shafts as per Contract were analyzed and the plan for revised Handover dates were devised. The plan for revised Handover dates were to be derived by resequencing the entire TBM drives, considering different geologies and machine types as the very fundamental factors.

Phase 2: Core level

The stakeholders engaged in rigorous Big Room Planning exercise for second time to finalize the TBM drives and the Hand over dates. Through rigorous permutation and combination calculations, different schedules were arrived and the optimum sequence with less number of idling time is chosen. In addition to resequencing, methodological changes were also proposed to reduce the time of construction. Table 1 describes the comparison of first and second drives of all 8 TBMs.

Phase 3: Senior Management Level

The senior management of all stakeholders sat down for final discussion in concluding the entire resequencing plan, thereby finalizing the schedule. This open collaborative discussion of Big Room Planning reduced the anticipated 24-months delay to 18 months, agreed upon by all stakeholders. This resequencing resulted in a 30% reduction in TBM idle time.

Addressing critical delays

Despite resequencing activities, inevitable delays were foreseen for 4 TBMs starting from 2 stations. To mitigate this, the contractor renegotiated to commence the execution of retrieval shafts in 2 locations, implementing effective risk mitigation measures in contract management. This measure not only reduced TBM idle time but also prevented losses to the contractor. By proactively addressing critical delays, we demonstrated our commitment to efficient project management and stakeholder satisfaction.

Table 2: TBM Mining as per contract vs revised.

TBM No	As per Contract		Revised Sequence	
	1st Drive	2nd Drive	1st Drive	2nd Drive
TBM 1	Chetpet metro to Sterling Road junction	Chetpet metro to KMC	Chetpet metro to Sterling Road junction	Royapettah Govt Hospital – Crossover – to Thousand lights
TBM 2	Chetpet metro to Sterling Road junction	Chetpet metro to KMC	Chetpet metro to Sterling Road junction	Nungambakkam to Gemini
TBM 3	Royapettah Govt Hospital – Crossover – to Thousand lights	Royapettah Govt Hospital – Crossover – to Thousand lights	Greenways road metro to Mandaiveli	Royapettah Govt Hospital to RK salai Jn
TBM 4	Royapettah Govt Hospital to RK salai Jn	Royapettah Govt Hospital to RK salai Jn	Greenways road metro to Mandaiveli	Nungambakkam to Sterling
TBM 5	Greenways road metro to Adyar Jn	Greenways road metro to Mandaiveli	Greenways road metro to Adyar Jn	Mandaiveli to Thirumayilai
TBM 6	Greenways road metro to Adyar Jn	Greenways road metro to Mandaiveli	Greenways road metro to Adyar Jn	Kellys to KMC
TBM 7	Thiruvanmiyur metro to Taramani Cut&Cover tunnel	Thiruvanmiyur metro to Taramani Cut&Cover tunnel	Chetpet metro to KMC	Thiruvanmiyur metro to Taramani Cut&Cover tunnel
TBM 8	Thiruvanmiyur metro to Indira nagar	Thiruvanmiyur metro to Indira nagar	Chetpet metro to KMC	Thiruvanmiyur metro to Indira nagar

INCORPORATION OF RESULTS IN CONTRACT

There were two major changes contractually because of Lean Strategy Implementation.

1. *Changes in the Interface Contract*: The mutually agreed sequence of construction with Tunnelling Contractor has been finally effected in the Interface Contract of other contractors and Client. Collaboration with senior management led to the modification of interface handover dates of underground station contractors to align with the resequenced dates, thereby revising the project's baseline schedule. The final revised TBM sequence is represented in figure 3 and in table 2.

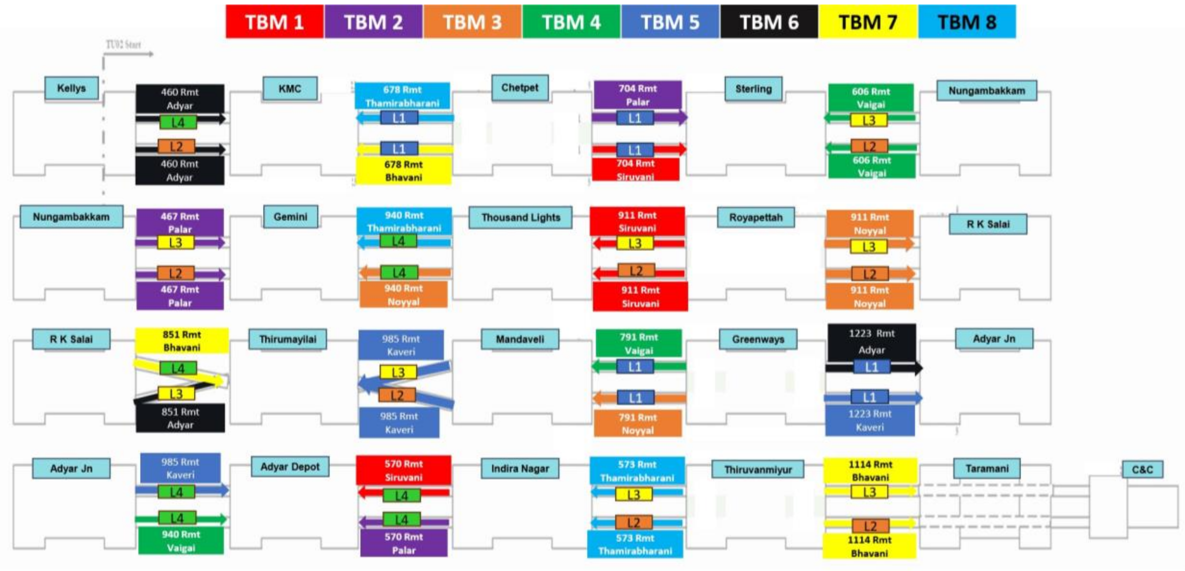

Figure 3: Revised TBM launching sequence.

Table 3: Results of Big Room planning Resequencing - Delay and Idle time reduction

S.no	Description	Project Start	Project End	Duration (In Days)	Duration (In Months)
1	Original Contract duration	09-06-2021	05-11-2025	1610	54
2	Revised duration without Resequencing	09-06-2021	16-10-2027	2320	77
3	Revised duration with Resequencing	09-06-2021	01-05-2027	2152	72

2. *Issuance of Variation Order*: Two number of critical shafts for retrieval were descoped from the Interface Contract and added to the scope of Tunnelling Contractor as a variation order in Contract. Also, it helped the tunnelling contractor to generate more revenue with the existing resources. Hence, the risk was converted into a revenue generating opportunity.

The collaborative nature of Big Room Planning taken up systematically ensured that diverse perspectives were considered, leading to innovative solutions and improved project outcomes.

CONTINUOUS IMPROVEMENT IN TIMELINE

Even after the underground contractors commenced execution at different stations, the contractor ensured further optimization of the schedule by rescheduling within the interface contractor's dates, further minimizing project idle time. This ongoing focus on continuous improvement underscores team’s dedication to maximizing project efficiency and delivering value to all stakeholders. Central to the success of TU 02 was the cultivation of a culture of continuous improvement. The project team encouraged feedback and suggestions from all stakeholders, fostering a collaborative environment where innovative ideas were welcomed and implemented. Regular review meetings and performance evaluations helped identify areas for improvement and drive ongoing enhancements in project execution.

IMPLEMENTATION OF VALUE STREAM MAPPING IN CASTING YARD

The precast yard for tunnel segment manufacturing is located at 20 km from project alignment. The project requires production of 18366 rings from the casting yard. The total cycle time of production of a ring was 16 hours 5 min.

To reduce the cycle time, Value Stream Mapping (VSM) was chosen as the lean tool to evaluate the present cycle time in detail and reduce the Lean Waste (Vilasini and Gamage 2010).

Initial State of VSM

The different activities in production of a tunnel ring are listed and the time taken for each activity is recorded for a continuous 12 days and the VSM is generated as per the figure-4 given below:

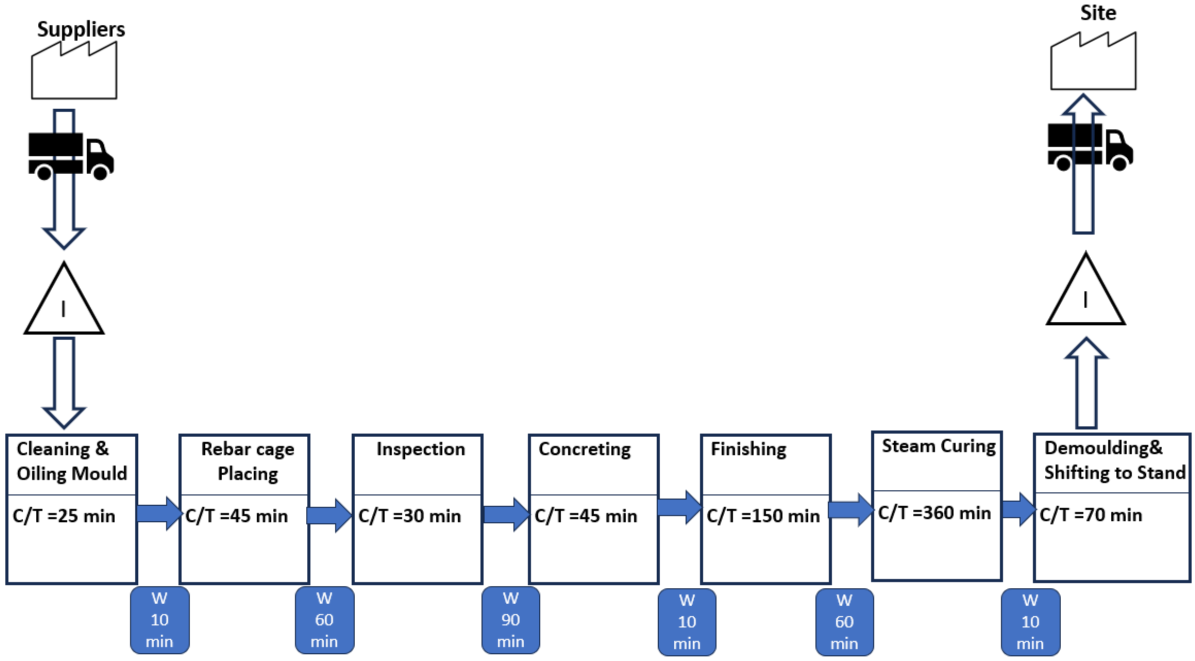

Figure 4: Segment Ring Casting VSM-Initial State.

The total cycle time is 16 hours 5 minutes with the bifurcation of Value Added -12 hours 5 minutes and Non-Value Added- 4 hours.

By collaborative discussion with construction managers, the below measures were taken at each step to reduce the Waiting and Idling time to completely reduce the Non Value-Added time to zero.

1. Increase of rebar crew from 10 to 15 numbers to remove the waiting time of 10 min.
2. Client approval was sought for each ring instead of 3-4 rings together to remove the waiting time of 60 min.
3. Ordering for concrete when the inspection is called for to reduce the 90 min of waiting of concrete.
4. Increase the crew size of finishing from 2 to 6 numbers to reduce the time of finishing from 150 min to 120 min.
5. Increase of one more stand to reduce waiting time for lifting of segment from mould by 10 min.

Below Figure 5 is the future state VSM that was envisaged and later achieved at site. The cycle time has been reduced to 11 hours 15 minutes.

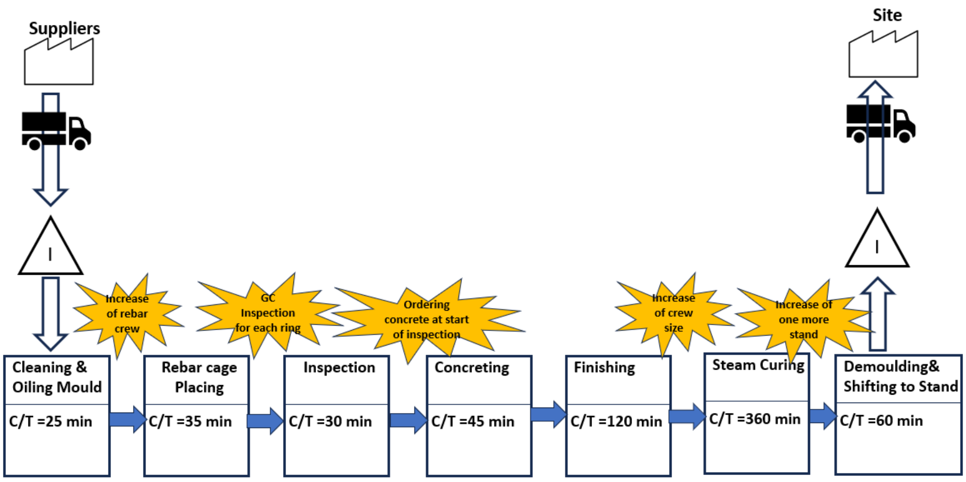

Figure 5: Segment Ring Casting VSM- Future State.

IMPLEMENTATION OF BIG ROOM PLANNING FOR TBM LOWERING ACTIVITY

In the context of tunnelling projects, particularly in densely populated urban areas, the process of TBM lowering and assembly emerges as a pivotal and intricate process. The spatial constraints inherent to urban settings necessitate meticulous planning and synchronization of various resources. It becomes imperative to organize the logistics, deployment of lifting machinery, and assembly teams in a manner that minimizes any downtime for these critical resources. Previously, the assembly of two TBM units consumed a substantial period, stretching over a duration of fourteen days. In response to this, a challenging internal target was set: the goal was to complete the lowering and assembly of two TBM units per shaft within ten days, ultimately achieving the ambitious milestone of four TBM assemblies within a span of twenty days. To accomplish this formidable task, it was imperative to foster collaboration (Rothman 2016) among a multitude of stakeholders.

The different teams involved in this highly critical activity include:

- Specialized Transporters
- Plant & Machinery department.
- Specialized Assembly Team
- Procurement team
- Safety team
- Quality Assurance team
- Administrative team
- General Chennai Corporation (GCC)
- Traffic Police Department
- General Consultant (GC) and
- Customer

The cohesive synergy between all teams was achieved through the implementation of Big Room planning. Within the Big Room planning exercise, a granular examination of the project was conducted. This entailed scrutinizing micro-level plans, proactively identifying potential constraints, and formulating precise action plans. It was during this collaborative process that several previously unrecognized, although crucial, minor activities came to light. The constraints identified and the action measures taken as output of Big Room Planning are summarized in Table 4.

Table 4: Constraints and Action Measures Implemented from Big Room Planning

S No	Constraint Identified	Action Taken
1	The shortage of Umbilical Hoses required for TBM Initial Drive has been identified as the same earlier planned quantity has been engaged in TBM 1 & 2	Immediate procurement order was finalized
2	Traffic Police Approval required from two different jurisdiction is identified	Admin team person in charge is allocated and both approvals were processed in parallel
3	Cutter Protection walls which were required in present shaft and not required in previous shafts was identified	Civil team has been engaged to take up this activity before TBM lowering
4	Crane Positioning: As per crane positioning and lifting sequence, the outrigger of 700T crane needs to be placed on D-wall panel. However, the same panel has been proposed for rectification measures already.	The entire micro schedule has been planned after completion of rectification of D wall
5	Route survey: The activity of joint route survey along with GC was missed in program	The same has been incorporated in program with duration of 2 days

The 700T and 300T cranes being the critical equipment driving the entire task of 7 days, rigorous microlevel planning was done to achieve the Just in Time lowering activity. To ensure the seamless execution of these preparatory tasks, resources such as boom lifts, specialized lifting tools, and scaffolding were meticulously organized and delivered promptly. These concerted efforts, guided by meticulous planning and precise execution, culminated in the remarkable achievement of completing the lowering and assembly of all four TBM units within a commendable twenty-day timeframe. This achievement underscores the effectiveness of a collaborative and detail-oriented approach to construction planning, demonstrating how meticulous coordination and proactive problem-solving can lead to significant gains in project efficiency and ultimately pave the way for the successful realization of complex construction objectives.

Figure-6: Big Room planning at TU02 project site.

RESULTS AND DISCUSSION

1. The adoption of lean principle – Big Room Planning in Contract Management in the CMRL TU 02 project yielded significant results, including:
    a. **Reduction in TBM Idle Time:** By resequencing TBM launches and implementing innovative contract management strategies, we were able to reduce TBM idle time by 30%, minimizing the impact of delays on project progress and cost.
    b. **Optimum Resource Utilization:** Collaborative planning and risk assessment enabled the efficient allocation of resources, ensuring optimal productivity and cost-effectiveness throughout the project lifecycle.
    c. **Timely Project Completion:** Despite the initial delay in the interface contract, the project has been rescheduled within 72 months, meeting client expectations and demonstrating our commitment to delivering quality infrastructure on time and within budget.
2. The adoption of lean principle - Value Stream Mapping in Casting Yard reduced the cycle time of precasting activity from 16 hours 5 minutes to 11 hours 15 minutes. Total time savings of 5.5 months. These improvements in the precast production also directly benefit construction projects by reducing expenses and increasing delivery. (Deffense and Cachadinha 2011)
3. The adoption of lean principle – Big Room Planning for critical activity of TBM Lowering enabled the project team to lift and lower 4 TBMs within a record time of 20 days and saving total of sixty days.

CONCLUSION

The CMRL TU 02 project serves as a compelling case study in the effective application of lean principles in underground metro construction. By embracing collaboration, proactive risk management, and continuous improvement, we were able to overcome significant challenges and deliver a successful project that enhances urban connectivity and fosters economic development. Our experience underscores the importance of lean practices in modern construction projects and highlights the value of collaborative problem-solving and stakeholder engagement in achieving project success. As the construction industry continues to evolve, the lessons learned from CMRL TU 02 will serve as valuable insights for future projects seeking to optimize efficiency, mitigate risks, and deliver sustainable infrastructure that meets the needs of communities around the world.

ACKNOWLEDGEMENTS

We express our sincere gratitude to all the project teams and stakeholders whose invaluable contributions made this research possible. Their dedication, collaboration, and commitment to embracing lean principles in contract management have been instrumental in shaping the insights presented in this paper. Their collective effort and unwavering support exemplify the spirit of continuous improvement and innovation in the construction industry. This acknowledgment serves as a tribute to their hard work and collaboration, which have contributed to advancing project efficiency, collaboration, and overall success. We are grateful for their partnership and the opportunity to showcase their exemplary work in this paper.

COST CONTROL IN MODULAR CONSTRUCTION: A TAXONOMY FOR EFFECTIVE COST MANAGEMENT

Margaret P. Keorapetse[1], Helena Utzig[2] and Carlos T. Formoso[3]

ABSTRACT

The cost effects of modular construction, which shares the same principles with lean construction, have been a subject of debate among researchers, with contrasting perspectives on how to control costs, compared to traditional construction cost management methods. Proponents of modular construction indicate that it can potentially be cost effective compared to traditional construction. As modular construction is gaining momentum in the construction industry, slowly replacing traditional on-site construction methods, there is a need for new cost control methods. The unique characteristics of modular construction create distinctive cost control difficulties. In this article, an attempt is made to showcase challenges and factors influencing costs in modular construction. The aim of the study is to propose a taxonomy of costs for modular construction processes. The study is ongoing and preliminary results presented in this article seek to understand the production process of modular construction, its associated costs and highlight potential cost control methods that align with the unique features of modular construction.

KEYWORDS

Modular construction, Cost control, Lean construction

INTRODUCTION

The construction industry is currently experiencing a substantial shift towards modular or off-site construction, steadily substituting traditional on-site construction methods in some market segments (Molavi & Barral, 2016). Modular construction utilizes building modules produced inside a controlled setting within manufacturing facilities to be conveyed and assembled on site. The concept of off-site construction has been known for a long time, but was not positively embraced until recently when the industry was subjected to pressure due to swelling labour costs and the need for sustainable buildings and processes (Zhang et al., 2016). In a study done by Assaad et al. (2022) in collaboration with the Construction Industry Institute (CII) in the USA, it was forecasted that off-site construction will grow from its current average percentage of 33.64% to an anticipated average of 54.9% in the future. This predicted increase will mark a substantial 4.33-fold industry growth in the USA over the coming decade. This significant increase indicates the acceptance and adoption of industrialized construction methods in the

building industry, thus reflecting its potential to transform and restructure the construction methodologies and practices.

Modular construction attracts extensive attention from the construction industry because of its enormous benefits over traditional construction methods. Gibb (1999) states that the least desirable location one would want to construct a building is on a building site. Construction sites are burdened with inefficiency and different types of waste. By contrast, modular construction is usually faster, safer, and more reliable than traditional construction, as well as has reduced on-site labour requirements, improved quality, less wastage, and a lower environmental impact (Nazir et al., 2020). These benefits add to the increasing belief that modular construction successfully deals with the industry's needs for efficiency, sustainability, and value generation (Tsz Wai et al., 2023). However, despite the potential advantages offered by off- site construction, traditional on-site construction methods are still prevalent (Liew et al., 2019).

Modular construction shares the same principles and aims of waste reduction and enhanced efficiency with lean construction. The two approaches can complement each other in setting the pace for improvements in the construction industry. The fast speed construction of modular construction provides time-related cost savings for items such as site supervision, plant and equipment (Zhang et al., 2016). However, the unique features of modular construction, such as off-site manufacturing, transportation logistics, and assembly processes, create distinctive cost control difficulties. These challenges require innovative cost control methods throughout the lifecycle of modular construction projects. The application of lean construction concepts and methods in modular construction can contribute to streamline processes and the fostering of a culture of continuous improvement. This ultimately results in better cost management and project execution. By contrast, there is an ongoing argument that whilst volumetric modules can decrease the labour costs, it may simultaneously increase transportation costs.

This perspective article argues that relying on traditional cost control strategies is inadequate for delivering modular construction successfully. The study proposes a taxonomy of costs for modular construction processes and advocates for cost control approaches that align with the unique characteristics of modular construction, supported by empirical evidence and scholarly insights.

This investigation addresses a gap in knowledge, as little attention has been given in the literature on effective cost control strategies in modular construction. The development of such approaches is essential to ensure the implementation and delivery of modular construction projects in a cost-effective manner.

LITERATURE REVIEW

CHALLENGES OF TRADITIONAL COST MANAGEMENT

Cost management in construction generally involves monitoring the actual performance in comparison to the cost estimates and finding variances (Kern & Formoso, 2004). A major challenge of traditional cost management has been identified as the lack of accurate cost estimating and cost control processes, insufficient information modelling, and the absence of integrating cost management techniques and production management systems (Aziz, 2013).

According to Forgues et al. (2012) the cost estimates are often carried out when the conceptual design is at an advanced level or even finished, making it too late for relevant stakeholders to make informed decisions. Therefore, cost management can play a key role not only in terms of reducing costs but also in the analysis of trade-offs that affect functionality, quality and the long term performance of the building.

Koskela (2000) criticizes most of the cost management methods utilized in the industry for following a standard cost method, strongly based on mass production ideas, which associates most cost items to a finished element derived from design drawings, for example, walls (m2) and windows (units). Koskela further contends that traditional cost management disregards the nature of the product and the production process in question due to its insufficiency of the conceptual base. Kaplan (1984) concurs that it is improbable that any cost accounting system can sufficiently summarize a company's manufacturing operation.

COST IMPLICATIONS OF MODULAR CONSTRUCTION

Previous studies have explored the cost performance of modular construction, discussing the cost effects from contrasting perspectives on the overall cost compared to traditional construction methods. Some of them have explored how some lean principles and methods can improve efficiency and cost effectiveness in modular construction.

Zhang et al. (2016) state that the cost of industrialized construction can exceed the cost of a building delivered through traditional methods. The high costs in modular construction are often attributed to the initial investment in equipment and land for module production, the complexity of the design and materials used (Nahmens & Ikuma, 2012). However, advocates of modular construction argue that while upfront costs may be substantial, they can be offset by reduced labour costs, waste and reduced overhead costs, and potential time savings.

The installation of ready-made module units on-site requires less labour, resulting in decreased labour costs compared to traditional construction, which heavily relies on labour-intensive techniques (Nazir et al., 2020). In this context the application of the concept of standardized work can result in the synchronization of work processes and in higher productivity of the workforce (Bataglin et al., 2020).

Modular construction contributes to improved environmental performance by incorporating lean principles such as reducing construction waste and improving energy efficiency resulting in optimized costs (Nahmens & Ikuma, 2012). Material recycling and inventory control that happen in controlled factory environments align with lean goals of value generation and waste minimisation.

Gibb (1999) suggests that cost reductions can also be achieved through factors such as on-site overhead reduction, stemming from potential time savings due to shorter durations and increased installation efficiency. Pull planning and value stream mapping can assist in identifying and discarding activities that do not add value while incorporating activities that add value like efficient utilisation of resources (Bataglin et al., 2020). This leads to improved project predictability and decreased overhead costs.

While there are no generalised figures on the improved performance of modular construction, some studies have found that modular construction can reduce overall waste weight by 83.2% in large structures and 81.3% in small structures (Loizou et al., 2021); 35% reduction for on-site labour and an overall cost benefit of 8.62% for a hospital development (Court et al., 2009); savings on rework costs that can be as high as 2% in conventional construction (Lawson et al., 2012); and produce 40% less greenhouse gases emission than conventional construction (Quale et al., 2012).

In overall, pull production and Just in Time (JIT) production play a key role in the integration between on-site and off-site processes in modular construction (Innella et al., 2019). Pull production is important for planning and controlling production in the manufacturing plant so it is possible to cope with variability in the project. Construction site production of modularity must pull the delivery of pre-fabricated components from the manufacturing plant to the site for assembly. JIT means production considers only what is necessary, when it is necessary and where it is necessary.

Tam et al. (2005) highlight that savings in modular and prefabrication can be fully realised when the construction process is fully mechanised, changing construction into an assembly industry, and using recycling materials for prefabricated components.

CHALLENGES AND FACTORS INFLUENCING COST CONTROL IN MODULARITY

The cost of transportation has emerged as a primary challenge in modular construction. The high cost emanates from transporting large volumetric modules to the site where they will be assembled (Shahtaheri et al., 2017). The transportation costs increase if the project site and manufacturing facility exist in different countries or far away from each other. Court et al. (2009) advocate for setting up an assembly workshop on the construction site if the space permits or setting up adjacent to the construction site for cost reduction. However, during the transportation and installation, risks related to breakage of modules may be encountered, thus leading to even higher costs (Shahtaheri et al., 2017).

The storage capacity of the manufacturing plants is usually limited and can give rise to costs related to inventories (Nazir et al., 2020). High inventory due to excessive production and non-movement of modules can have a financial bearing in the organisation as storage costs have to be paid. Therefore, a cost effective inventory control of work in progress (WIP) of modules is essential. The use of the JIT approach can potentially promote continuous flow of modules with the aim of precisely matching the demand of the modules with the supply as produced by the factory (Balkhi et al., 2022).

The factory's demand is another important factor for considering opportunity costs. Opportunity cost is related to production time and refers to the potential benefit lost due to one choice (or necessity/obligation) over another (Windheim et al., 2017). In instances of high demand of specific modules, a delay in production can mean increasing the cost associated with the production of certain modules and reducing the company profit. The opportunity to produce more modules is lost at the expense of finalising the required modules (in this case, not by choice, but by the emerging situation).

Another noteworthy challenge is the management of dimensional and geometric variability in modular construction (Shahtaheri et al., 2017). It is expensive to accommodate plant changes during design and construction.

Molavi & Barral (2016) state that there is a high scarcity of skilled workers in the production of modular and prefabricated components. Skilled workers are needed to carry out complex techniques, and intricate designs in the production and installation of components.

The design stage also plays a critical role in cost control. While the actual expenditures associated with the design may be small because each module require a small number of changes each instance, the level of influence on cost control is the greatest during this stage (Gilbert III et al., 2013). Thus, efforts to reduce and control costs should be reinforced at the design stage.

During the production stage, costs arise from materials, labour, and indirect costs of the manufacturing plant. Since production is done in a factory-controlled environment the production of waste is minimal hence reduced cost of production (Nazir et al., 2020). However, the literature does not provide information on the range of costs related to rebuilding components due to damages, transport costs, inventory costs, labour costs and factory costs in modular construction.

The literature review presented in this sub-section pointed out several opportunities to improve the way costs are modelled in modular construction, by considering the nature of the production processes. Therefore, some key cost categories emerge, and should be considered in the proposed taxonomy: logistics costs, opportunity costs, inventory, time-related costs, fixed costs, etc.

POTENTIAL STRATEGIES FOR COST MANAGEMENT IN MODULAR CONSTRUCTION

Clients always expect that the construction work should be done within the budgeted amount, specified quality and on time (Aziz, 2013). Therefore, modular construction requires cost control methods that can achieve the expectations and requirements of the customers.

LEAN CONSTRUCTION

Lean construction is rooted in the removal of wasteful activities from construction processes. Lean construction uses different methodologies and techniques like JIT, pull planning, target costing, value stream mapping among others for the removal of waste in processes. Therefore, it is important to have a cost management system that clearly identifies and highlights the cost of non-value adding activities. A study by Nahmens & Ikuma (2012) done in the USA which applied lean construction for the construction of industrialized housing, construction material waste was reduced by 64% and the production hours were reduced by 31%.

USE OF TECHNOLOGY

According to Sergei & Gennady (2016) the best technology for constructing modular buildings must be able to recognize and understand the factors and features that allow the reduction of the stated costs, labour inputs and work duration.

The support that Building Information Modelling (BIM) provides to off-site construction in managing design risks and improved documentation, has been well documented in the literature (Zhang et al., 2016). The visualisation capabilities of BIM allows early clash detection, speed and accuracy of cost estimation, and enhanced coordination. The use of 5D BIM model allows accurate materials quantities take offs. The benefits of virtual design and construction are evident and cannot be overstated (Zhang et al., 2016). However, the main shortcoming of 5D BIM is its inability to capture time-related costs which are not dependent on quantity take offs.

STANDARDIZATION AND MODULARITY

Standardization is a concept that involves the extensive use of components, methods with regularity and repetition (Viana et al., 2017). Standardization provides better conditions for implementing modular systems efficiently as modularity focuses on standard modules and standard processes. The central idea of modularity is the possibility of decomposing a product into manageable parts (modules) that have standardized forms of interactions (Gibb, 1999). Modularity has been pointed out as a key concept in modular construction, especially when there is a need to customize products according to customer requirements. It enables the development of flexible production systems and has shown to be effective in dealing with complexity in different types of systems (Viana et al., 2017). The literature further indicates that the adoption of modularity brings several benefits that are enhanced when this strategy is related to concepts of industrialized construction such as standardization.

METHODOLOGY

DESCRIPTION OF THE EMPIRICAL STUDY

The study adopted a Design Science Research (DSR) approach, which combines descriptive and prescriptive research to close the gap between practice and theory (Holmström et al., 2009). The objective of DSR is to develop solution concepts, also known as artefacts for classes of complex and relevant problems, considering a certain context, and, in general, have a multidisciplinary character (Voordijk, 2009). DSR was selected because it is oriented towards the creation of new knowledge through design and action rather than just description.

The main artefact to be developed in this investigation is a conceptual model, i.e. a taxonomy of costs for modular construction processes. This taxonomy can support the development of design propositions for the development of cost management systems for modular construction, which can be regarded as a recommendation for action to be taken in a specific circumstance with the aim of achieving a certain result (Voordijk, 2009).

This study has an exploratory nature that sought to get an in-depth understanding of the problem, which is the starting point for developing propositions. The investigation was focused on cost of manufacturing, transportation and the installation of prefabricated modules. The conventional construction activities, often involved in project delivery, were out of the scope of the investigation. The study was developed through three phases; problem definition and comprehension, development of the solution, and analyses and reflection. The three phases were broken into six stages as shown in Figure 1.

(i) Stage 1: sought to identify a gap in knowledge through an in-depth analysis of a practical problem and review of existing literature.

(ii) Stage 2: involved an in-depth theoretical exploration of the identified problem and its specific characteristics. During this stage there was a deep practical involvement with the aim to: understand the production process of the company; understand the flow of information related to costs; and understand how the company estimates and controls costs.

(iii) Stage 3: consisted of collecting and analysing data and understanding the nature of modular construction costs from documents and through observations.

(iv) Stage 4: involved discussions and validation of information with relevant managers. The research artefact was developed, which is the taxonomy of costs for modular construction based on understanding the phenomenon of production.

(v) Stage 5: involved presenting and discussing with company representatives the research products, analysis and diagnosis developed in the previous stages.

(vi) Stage 6: consisted of a qualitative analysis of the contributions of the main research products.

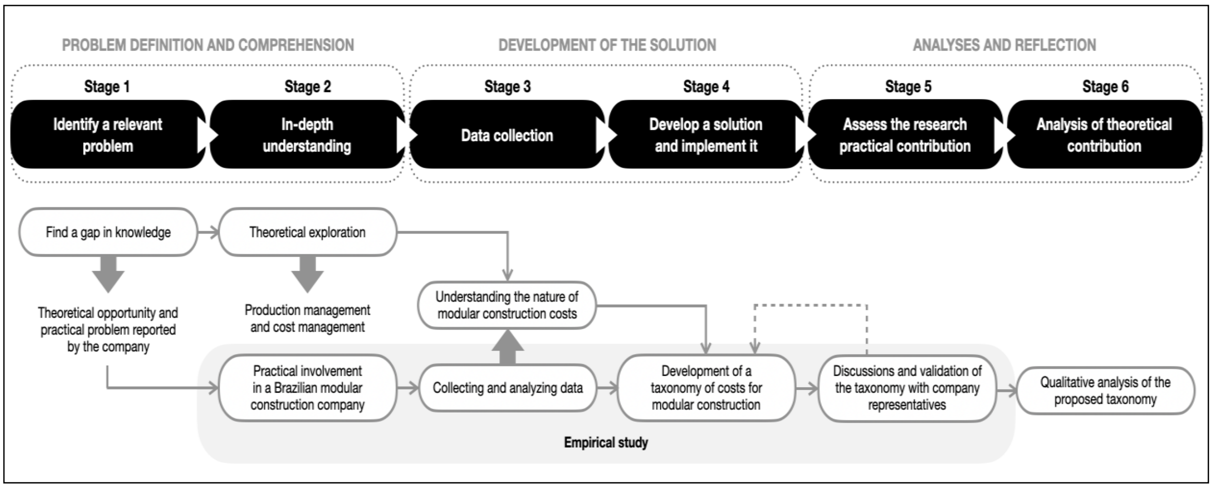

Figure 1: Stages of the Research Design and Development

The empirical study was developed in a Brazilian modular construction company, which develops and delivers complete modular components solutions for projects in different segments (e.g. education, security, residential). The company is responsible for all production, transportation and installation of volumetric modules, project development, execution of on-site installation and management of both factory production and construction work.

The company offers two volumetric modular solutions that differ in terms of the technology used and service to the business segments. This research focuses on the Y modular solution for the education market segment, whose volumetric unit has a standard dimension of 3x6x3m and is formed by a steel structure module (chassis) combined with slabs and external cladding (various types and number of panels). The modules were diverse and involved personal customization combined with pure customization. There was limited repetition of the same module. The structural module is delivered with finishing with hydro-sanitary and electrical installations and internal and external floor and wall finishings.

The family of modular products for schools consists of 46 standard products made up of several volumetric modules. Standard products are used for both new projects and expansions of existing schools.

The company was selected mainly because of its long experience and relevance in the Brazilian modular construction sector. The company was also involved in an improvement program based on the principles of Lean Production.

The strategy that was adopted in order to improve the reliability of the findings is triangulation. Triangulation allows the use of multiple data sources for a deeper comprehension of the subject of study (Farquhar et al., 2020). Data was collected through open-ended interviews, direct observation and the independent analysis of different drawings and documents. In total, more than 20 hours of interviews and meetings were held, 4 visits to two construction sites and approximately 13 hours of observations of the production process of the modules in the factories. Interviews were conducted with multiple company representatives. The study commenced in July 2022. The development of the taxonomy was based not only on the analysis of the data collected, but also on the literature review about cost management challenges in the context of modular construction (see literature review). Table 1 displays the sources of evidence utilized for the study for the respective phases and stages.

Table 1: Sources of Evidence

Phases	Stages	Main Activity	Details of activities	Sources of evidence
Problem Identification and Comprehension	Stage 1	Exploring gap opportunity	Understanding a relevant problem from practical and theory point of view	Literature review; Participant observation (planning meetings)
	Stage 2	In-depth exploration	Understanding the production process at the factory and modular products	Direct observation (manufacturing plant)
Development of the Solution	Stage 3	Collecting and analyzing data	Understanding the budgeting process and information flow; Analyzing factory production, cost control and challenges; Exploring logistics costs and factory costs with other sectors; In-depth understanding of the budget process for modular solution Y; Analysis of various budgets for modular solution Y, cost breakdown and material spreadsheets; Analysis of design drawings	Open ended interviews (cost management system); Document Analysis (cost estimates, design); Direct observation (manufacturing plant)
	Stage 4	Development of a taxonomy of costs	Discussion and validation of information	Open ended interviews (cost management system)
Analyses and Reflection	Stage 5	Presenting and discussing the product	Discussions with company representatives; Validation of the taxonomy	Participant feedback (cost management system)
	Stage 6	Qualitative analysis	Using literature and previous stages to qualitatively analyze the research product	Open ended interviews (cost management system) Literature review

RESULTS

This paper presents the preliminary results of this investigation. The company prepared a cost estimate by using a spreadsheet, in which the costs of each modular product was calculated, through accounting data and standard cost of raw materials and the standard time of production for each product or product family. The cost management system employed by the company can be classified as the traditional standard costing method. The changes were monitored by costing by apportionment of the transformation cost categories. The change in specification cost and the total hours for incorporating the changes in manufacturing the unit were recorded. The cost of different Y solution modules categorized according to their complexity, direct material cost and estimated production time with its own labour. Four categories were used for generating and controlling costs associated with different types of modular solution Y; (i) complex, (ii) medium complex, (iii) simple, and (iv) circulation or the most simple. The analysis of the estimated costs and production cost control suggested that cost estimates were developed with some form of logic aimed at aligning them closely to the production cost, especially indirect manufacturing cost. Some modules were stored in an open space at the manufacturing plant before being transported to their respective construction sites.

The nature of the production process led to the categorization of the main phenomena that generates costs. The taxonomy of cost categories followed five distinct key stages of manufacturing and assembling the modules as shown in Figure 2; (i) design process, (ii) production of volumetric units, (iii) logistics process at manufacturing plant, (iv) transportation process and, (v) assembly of pre-finished volumetric units.

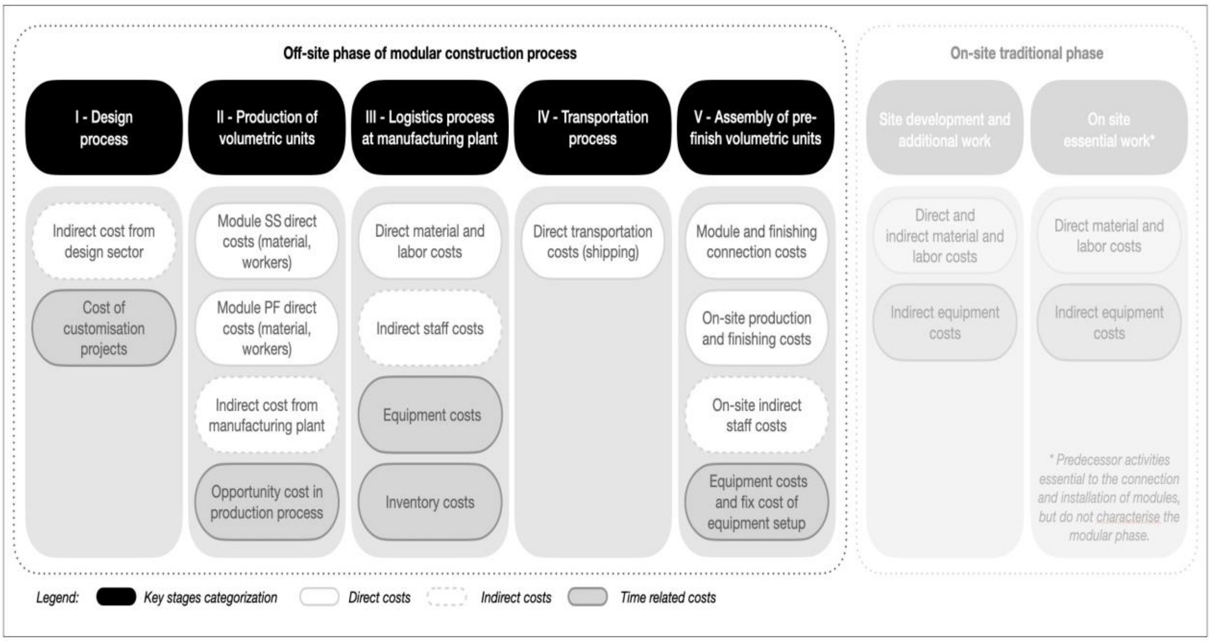

Figure 2: The Nature of Modular Construction Process and Associated Costs

Costs related to the design process can be divided into two main categories: indirect costs related to the design team, and project customization costs. During the production stage, costs arise from materials and labour of the structural shell (SS) and the pre-finished (PF) modules, indirect costs of the manufacturing plant, and opportunity costs in the manufacturing plant. Manufacturing indirect costs refer to transformation costs and other industrial costs such as indirect costs of energy, water, maintenance, rent and depreciation. The logistics process at the manufacturing plant incurs indirect and direct costs from the workers, equipment and inventory. The transportation process essentially includes the costs directly associated with freighting volumetric units and are estimated from the potential supplier or freighting company. The transportation costs depend on the number of modules and the distance to be travelled to the delivery point. The assembly of pre-finished volumetric units involves costs associated with materials used for connecting the modules, plant and equipment used during the assembly, and costs of the workforce.

DISCUSSIONS

The study has provided insights into the various stages of modular construction and the associated costs at each phase. It has shed light on the complexities of cost management in modular construction, emphasizing the need for innovative cost management solutions and the application of some lean methods to overcome the specific challenges posed by each stage of the process.

TAXONOMY OF MODULAR CONSTRUCTION PHASES

The reviewed literature does not provide an explicit description of the different stages that modular development goes through. Providing a taxonomy of the different phases of modular construction provides a point of departure for understanding different costs associated with modular construction. Taxonomy provides a good foundation for calculating operational costs for each category, which is usually disregarded when preparing cost estimates. Moreover, taxonomy provides a structured conceptualization and common language for communication among construction team members, aiding clarity. The structured conceptualisation makes it possible and easy to identify sources of cost deviations in case of cost overruns. Production planning can also be improved as the appropriate efforts and resources for cost control can be dispatched according to the requirements of any category.

REPETITION AND STANDARDIZATION OF COMPONENTS

Modularity allows repetition, which facilitates cost management. This repetition can lead to more accurate cost estimates and better cost control throughout project delivery. In addition, modularity provides opportunities for customization whilst maintaining cost effectiveness. The use of components that can be customized and combined in numerous ways provide opportunities to achieve cost advantages through repetition and standardization. This balance between repetition for cost efficiency and customization provides evidences of the potential positive impact of modular construction in improving project cost control.

There are some opportunities for improving cost estimating and control related to the use of digital technologies, such as the improvement of the existing cost database, and the use of 5D-BIM for quantity takes-offs. Through BIM, adjustments to the designs can be made at any given point in time and BIM can show real time changes and visual representation of cost data of different components of the modules. However, the impact of digital technologies tends to be very limited if traditional cost modelling, based on the standard cost method, is still used.

SYNCHRONIZATION OF ACTIVITIES

The management of inventories to avoid storage cost by the company is also a key change. The adoption of lean production techniques such as JIT and pull planning, are important for synchronising not only with the construction site but with the suppliers of materials for producing modules. As suggested by Bataglin et al. (2020), confirmation points (triggers) can be used as a mechanism for pulling components from manufacturing plants, according to the status of the system. Therefore, the implementation of lean techniques will reduce different types of waste as only necessary modules will be produced, workflows streamlined, as well as aligning on-site and off-site operations, ultimately reducing lead times and saving cost.

STRENGTHENED LOGISTICS SYSTEM

The transportation of modules from the manufacturing plant to different schools spread across the country may also impact the overall expenses of producing modules. Several strategies can be utilized to reduce those costs. Space utilization of the trucks used for transportation can be maximized through efficient loading processes, and leveraging economies of scale through bulk transportation and reducing the number of trips. The selection of transportation modes can also assist in controlling transport costs: an effective, adapted and strengthened logistics system is critical for cutting transportation costs incurred by the company (Hsu et al., 2017).

In overall, modular construction offers opportunities for reducing lead time, and consequently time-related costs, and also can improve reliability of cost estimates. The complexities associated with off-site manufacturing, transportation logistics, and on-site assembly require a re-evaluation of traditional cost control methods. The dynamic nature of modular construction projects needs proactive approaches that consider the intricacies of supply chain coordination, production scheduling, and site integration.

CONCLUSIONS

Modular construction is known for its efficiency and predictability. The streamlined processes of modular construction allows for waste reduction and shorter project lead times. Modularity also provides an opportunity for operational costs to be reduced as assembly line activities are much simpler. It allows for customisation while still maintaining cost effectiveness, making it possible to achieve cost advantages through standardization and the repeated use of components. This balance between repetition for cost efficiency and customization highlights the effectiveness of modular construction in managing costs in projects.

However, to a large extent, the unique characteristics of modular construction create distinctive cost control difficulties. The high costs in modular construction often stem from the initial investment in equipment and land for module production, the complexity of design and materials used. The primary cost drivers in modular construction emanate from transportation, warping and damage during transportation, and a shortage of specialised skilled workers. To address cost control in modular construction, it is crucial to use cost control methods that align with the unique features of modular construction.

The main conceptual contribution of this study is the development of a taxonomy outlining the different phases of modular construction. A structured framework for determining costs associated with each phase of modular development is provided through taxonomy, aiding better cost management custom-made to the requirements of each phase. The taxonomy of cost categories followed five distinct key stages of manufacturing and assembling the modules; (i) design process, (ii) production of volumetric units, (iii) logistics process at manufacturing plant, (iv) transportation process and, (v) assembly of pre-finished volumetric units. The development of this taxonomy is strongly related to some lean principles, such as elimination of the share of non-value adding activities, reduction of variability, pull production, synchronisation and takt time, and simplification by the reduction of the number of steps and parts.

Whilst this perspective paper sheds light on valuable insights and reflections on the current subject, there are a few notable limitations of the study that needs to be acknowledged. As this is an on-going study, the results of the study are partial thus limiting the depth of analysis of some aspects which have been explored comprehensively and in detail. Moreover, the lack of previously published information about the different stages of modular construction made it impossible to draw comparisons with prior studies thus making it difficult to build upon existing knowledge. Finally, there were some limitations related to the research method as the findings of the study are based on a specific company, and thus cannot be generalised to other situations because of the unique context and conditions.

Regarding future studies, the following suggestions emerged from this investigation: to develop additional prescriptive knowledge (e.g. principles and prescriptions) for designing cost management systems for modular construction, and to test the taxonomy of cost management categories by applying in the development or testing of cost management systems.

ABSTRACT

Despite the availability of advanced managerial tools and technologies for project planning and control, projects failing to meet schedules and budget targets remains a common phenomenon. We argue that a root cause for these failures is the absence of strategic planning. Optimized Cycle-time Flow (OCF) is a strategy developed by Intel Inc., that enables teams to plan portfolios of projects subject to resource constraints and the principles of flow, while avoiding the pitfalls of the planning fallacy and unnecessary time-extensions. This paper presents a thorough exploration of OCF through a case study in a typical installation project, one of the first OCF implementations. Practical applications of the principles of OCF are explored through analysis of construction plans and interviews with key personnel. The paper provides supplementary observations and validation of empirical findings regarding the effectiveness of OCF. The multi-project environment and the sense of urgency to reduce time-to-market are recognized as a catalyzer for OCF. The case study highlights the importance of critical production thinking as manifested in the first two OCF principles: "Plan and Integrate Strategically" and "Plan Tactical Targets".

Constraint Management, Design Science Research, Last Planner® System, Optimized Cycle-Time Flow (OCF), Production Control, Strategic Integration & Planning, Target Pull-Plan

INTRODUCTION

Significant progress has been made in recent years towards the realization of Lean Construction (LC) for installation projects in Intel Corporation (Gabai et al., 2023; Gabai & Sacks, 2020). First, an organizational learning process was carried out to assimilate the basic principles and tools of LC, including the Last Planner® System (LPS). Later, in light of growing awareness of waste and the need to enhance value in a predictable way, additional improvement attempts were made, leading towards the development of Optimized Cycle-time Flow (OCF) strategy.

The theories and tools expressed in OCF are diverse, including Transformation-Flow-Value (TFV) (Koskela, 2000), Portfolio, Process and Operations (PPO) (Sacks, 2016), Theory of Constraint (Goldratt 1997; Goldratt et al. 2004), and LPS (Ballard, 2000). Over the following years, OCF yielded significant results, including successful implementation of pull scheduling

at the organizational level, reductions in projects' cycle-times, and improved resource flow. Human capital played a central role, thanks to the commitment throughout the entire value chain, from production floor workers to senior managers. In addition, an international learning group was initiated, the "OCF Industry Tribe", with participants from a variety of AEC backgrounds and at different stages of OCF implementation at their projects and organizations.

OCF was developed in a unique production environment: a multi-project organization with a clear value proposition, portfolios of similar projects, urgent installations needed to enable factories to begin production, and a "clean room" environment requiring accuracy and cleanliness.

Previous papers on OCF (Gabai et al., 2023; Gabai & Sacks, 2020) reported remarkable empirical results, including significant cycle-time reduction and enhanced throughput (TH). This paper provides an exploratory investigation and analysis of the empirical results, aiming to improve understanding of how the principles of OCF work in practice, and so to set the stage for a discussion regarding the applicability of OCF to other construction domains, in the context of portfolio or single project management. A case study for OCF implementation on a typical installation project is presented, attempting to identify how the principles of OCF were expressed.

LITERATURE REVIEW

Optimized Cycle-Time Flow (OCF) is a strategy that was originated to benefit both project stakeholders and project implementation teams. The seven principles of OCF are derived from various proven theories and methodologies, that are reinforced and synergized as they are combined. OCF principles are composed of six planning principles and only one execution principle, which emphasizes the importance of up-front planning to achieve 50% cycle-time (CT) reduction, and to double the organizational TH.

Figure 1: The OCF flywheel (Credit: Intel Corporation).

The OCF flywheel (Figure 1) begins with Principle I - ***Plan and Integrate Strategically***, and Principle II – ***Plan Tactical Targets***. These two principles are based on the Strategic Project Leadership® (PSL) approach to project management (Shenhar, 2015), that emphasizes business and strategic thinking at the project level, and guides managers how to translate strategy into practical activities within their project. SPL optimizes business outcomes by deploying strategies that effectively address project complexity and rapid changes, ensuring alignment between project and organizational objectives. In the context of multiple project organizations, and based on the Portfolio, Process and Operations (PPO) model (Sacks, 2016), these two first principles address the flow of trades and operations upon portfolios of projects and target an organizational throughput improvement. This is reinforced once integrated with Transformation-Flow-Value (TFV) theory (Koskela, 2000), emphasizing value generation to the customer, and efficient production flow. At the outset of implementation of these principles, the stakeholders develop a Target Pull Plan per project that must align with the strategic plan for 50% CT reduction and optimized organizational TH.

Principle III – ***Collaborate*** – This principle also stems from PSL and emphasizes a cultural environment that must show respect and develop trust and integration within the project team. It is also related to LPS implementation (Ballard, 2000) and emphasizes the importance of collaborative planning to improve reliability and stability of the production system. In a multiple project environment, this collaboration also leads to formation of organic high-performance teams, composed of trades from several subcontractors, that flow from project to project (ensuring CT reduction and completing projects on time).

Principle IV – ***Resolve Constraints***, and Principle V – ***Restructure Resources*** – are based on the Theory of Constraints (Goldratt 1997; Goldratt et al. 2004) and aim to identify and alleviate potential bottlenecks in the system. These two principles reinforce the implementation of LPS as they enhance lookahead planning and the make ready process, focusing on either physical or informational constraints that limit the production system (Ballard and Tommelein 2016). In the context of project portfolio management, these principles are applied to ensure constraint removal on projects that are pulled for construction. In the construction phase, continuous efforts are made to identify and remove constraints that may evolve in real time. This requires full support from the back office (for design issues etc.), and enhanced involvement of senior management when ad-hoc decision making is required (including resource allocation) to enable smooth production flow.

Principle VI – ***Control Project Start*** – and Principle VII – ***Ensure Project Flow*** originate from the Toyota Production System (Liker, 2001) and include pulling project to production just-in-time and according to client needs. Only once everything is set in place, work can be performed without stopping until completion. Thus, projects are batched according to customers prioritization and their maturity level, enabling to level the Work in Progress (WIP), and the availability of resources to reduce cycle times (each OCF batch is reduced by 50% CT).

RESEARCH METHOD

As presented in previous studies (Gabai et al., 2023; Gabai & Sacks, 2020) and as demonstrated in the next section, empirical data indicates the effectiveness of OCF in terms of cycle time reduction. This case study provides a supplementary observation and validation of the empirical findings, enabling a deeper understanding of the working mechanisms of OCF at the individual project level. The case study approach was selected, as it "…allows the questions of why, what and how, to be answered with relatively full understanding of the nature and complexity of the complete phenomenon" (Voss, 2008). As OCF is an emergent practice, there is great importance to present detailed examples that may enable industry practitioners to evaluate the applicability of the method in their organizations and projects.

Information for the case study was gathered from two main sources.

1. Review and assessment of construction plans, in the format of excel spread sheets exported from Primavera P6, and documentation of target pull plan meetings in which the durations of each task were re-examined, and a revised plan was developed.
2. Semi-structured one-hour interviews were conducted with key personnel, including the project manager, the piping subcontractor, and the owner representative (the tool owner). The interviews included open questions regarding the application and influence of each of the seven OCF principles at the project and organization level. Additionally, interviewees were asked to elaborate on the assumptions and actions that enabled CT reduction.

DOUBLING THE THROUGHPUT

To provide context for the case study, this section presents preliminary empirical results from OCF implementation on over 1,700 projects to date. The case study applies a magnifying glass to one of these projects.

At the organizational level, OCF implementation was done in a pincer movement: from one side, reduction of CT at the single project level (as detailed in the case study), and from the other side WIP management via “OCF batching”, to ensure only ready and required projects enter the construction phase, considering the demonstrated capabilities of the production system. Figure 2 illustrates a non-feasible baseline plan (in red) with extreme peak points regarding WIP levels, compared to an OCF batching plan (in green) which provides stable WIP levels. Figure 3 presents a non-feasible baseline Gantt chart that illustrates the number of projects under construction at the same time, compared to an OCF batching plan, with 24 batches of projects. Once OCF batching is combined with targeted 50% CT reduction at the single project level, doubling the TH becomes feasible.

CASE STUDY: OCF IMPLEMENTATION ON AN INSTALLATION PROJECT

BACKGROUND

This case study focuses on OCF implementation on a typical tool installation project in one of Intel's fabrication factories. The factory, which is spread over thousands of square meters, includes over one thousand tools that must be installed at a millimeter tolerance level and must enable efficient space usage. In these projects, the factory in general and specifically each "tool owner" is referred to as the client, and value is measured through their lenses. Thus, a project that provides most value is one that is pulled according to production needs, meets specifications, and is carried out in minimal cycle times and disruptions to the production process.

The location breakdown structure of the project included three locations where work was performed: Level 1 – the Utility Level – contains electrical panels, utility pipes and ductwork that feed up to the sub fab; Level 2 – the Sub-Fab – contains pumps, transformers, power cabinets and other systems that support the clean room; Level 3 – the Fab or "clean room" – includes the tool itself and the interface with the products and workers on the production line. Figures 5 and 6 illustrate the three locations of the project, and Figure 7 illustrates workers at the clean room level (they wear "bunny suits" to maintain the sterile production environment). The construction scope herein is being done in all 3 levels mentioned above. Four main trades, from different subcontractors, took part in the project: Electrical, Piping, Ductwork, and Architecture-Carpenters. The trades worked in close coordination with the tool owner, who was also required to take actions at several steps in the process.

In general, the work breakdown structure of a typical tool installation project includes three main phases: Phase 1 – connection of the lateral lines at the sub fab to the clean room, according to the location of the tool to be installed ; Phase 2 – tool installation works at the clean room, that involve only non-dangerous gases and electrical charging; Phase 3 – tool installation works at the clean room, that involve dangerous gases.

CONSTRUCTION PLANS

The project was carried out using LPS and Pull scheduling, which were already implemented throughout the company's projects, and the teams were experienced in their operation. The preliminary plan, with a duration of 61 working days, is presented in Figure 8. During the application of OCF, a “Target Pull Plan” was collaboratively developed, to meet the company’s strategy to reduce installation projects cycle times. The Target Pull Plan, with a duration of 24 working days (CT reduction of 61%), is presented in Figure 9. Visual comparison between the plans highlights how the Target Pull Plan led a reduction in the duration and increased the work in parallel. It should be noted that the project was completed according to the plan, with a PPC above 90%.

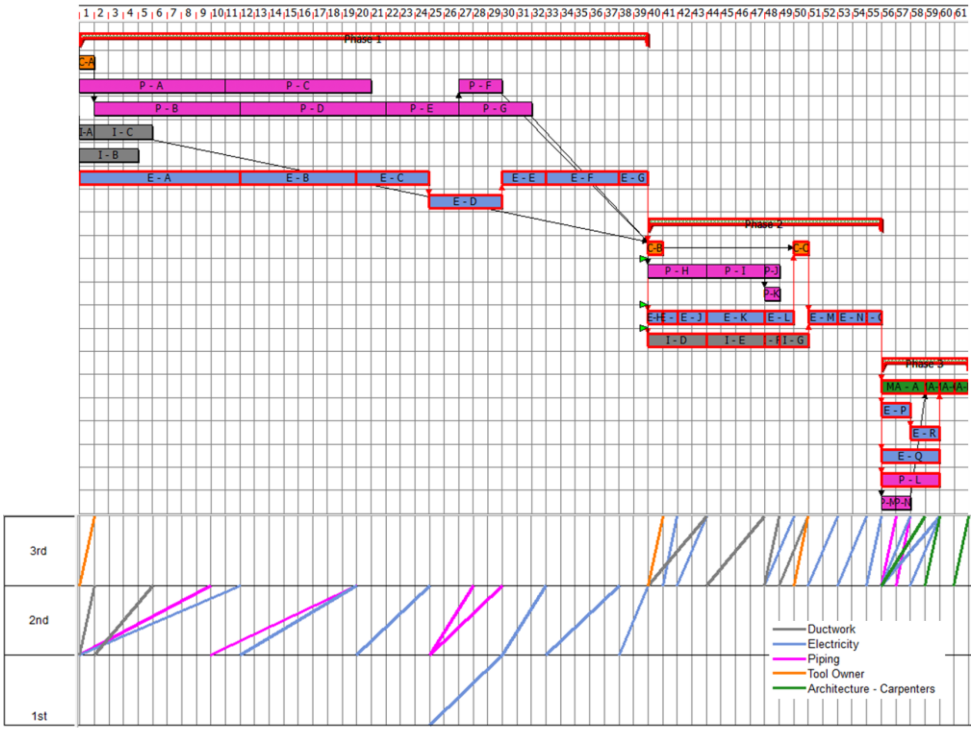

Figure 8: The preliminary baseline plan, before OCF implementation.

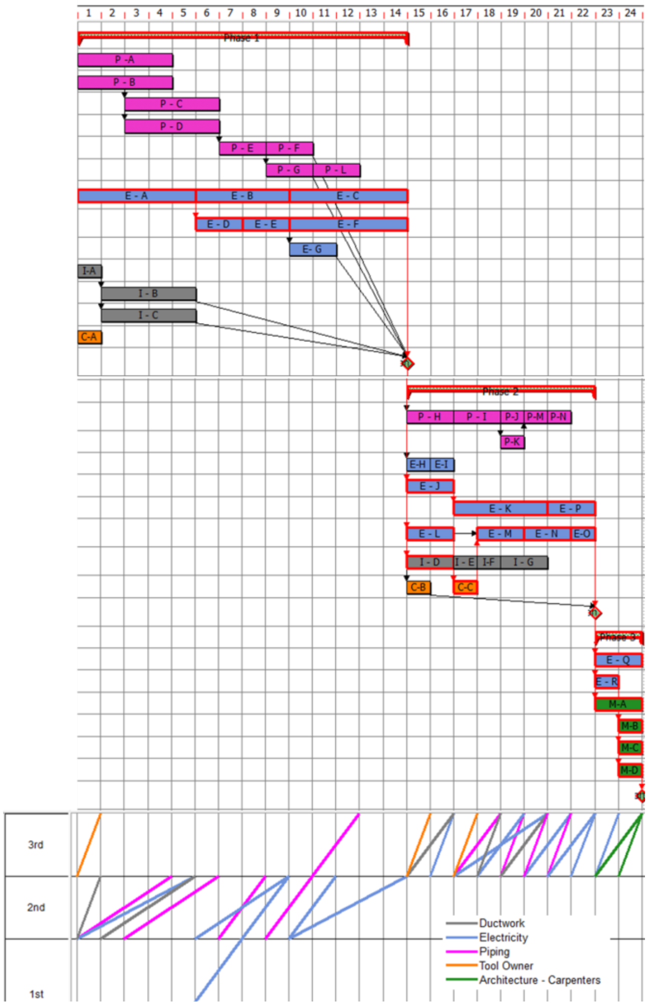

Figure 9: The 50% Target Pull Plan for OCF implementation.

IMPLEMENTATION OF THE SEVEN OCF PRINCIPLES

After the preliminary plan and the Target Pull Plan were compared, and illustrated the dramatic reduction in the project duration, semi-structured interviews were held with key personnel in the project to understand how the seven principles were implemented. The personnel interviewed included: the Project Manager (PM) from the construction division of the owner; the piping subcontractor (P-Sub), and the tool owner (the internal costumer). Interviewees were asked to elaborate on how each of the seven principles manifested at the project and organization level. In addition, they were asked to refer to the essential changes between the preliminary plan and the Target Pull Plan (Figures 8 and 9), and to describe how these changes were made possible. Highlights from the interviews, regarding each of the principles, are presented in the following sections.

Principle 1 - "Plan and Integrate Strategically": This refers to the organizational strategy to double the TH of completed installation projects, by OCF batching to control the WIP levels, and by setting 50% reduction target. Interviews highlighted that strategic planning was the core principle that initiated OCF implementation. The tool owner emphasized that completing the project with minimal CT, once all necessary preconditions are met, allowed early beginning of production in the Fab, thus increasing the competitive advantages of the organization.

The P-Sub admitted that at first, he thought this strategy would require investment of additional resources, but he took the leap of faith and "the results speak for themselves." In a pre-OCF environment, part of his business model relied on accelerations as projects were running late. With the long-term strategy, including OCF project batching (Figures 2 and 3), the piping company was able to maintain a stable, reliable cash flow, invest in well skilled trades, and undertake more projects per annum. He admits that "…with OCF and without accelerations, the profitability was improved and predictable".

All trades agreed that reducing the WIP enabled resources availability, and increased motivation to complete the project and move on to the next OCF batch. It also enabled them to generate greater value for the customer, who could start production earlier, and with minimal interruptions.

Principle 2 - "Plan Tactical Targets": The preliminary plan was revised, and a Target Pull Plan was collaboratively developed according to the strategy of doubling TH and reducing CT. As seen from the comparison of the preliminary plan and the target pull plan (Figures 8 and 9), a CT reduction of 61% was reached on this project. During the Target Pull Planning the trades were required to challenge the assumptions reflected in the preliminary plan, regarding both durations and feasibility to perform several tasks in parallel.

At the first stage, the team examined the feasibility that baseline duration estimates could be reduced if they could work on substantially fewer projects in parallel. Each trade was required to examine whether they could commit to shorten the durations by 33%, 50% or 80%. This approach led the trades to re-examine their work assumptions. In some cases, the answers were unequivocally negative. However, for a significant number of tasks, possibilities emerged as it became clear that long durations with inflated internal buffers were assumed in the preliminary plan.

At the second stage the logical connections between tasks were re-examined, possibilities for simultaneous work were considered, and an improved workflow sequence plan was developed. Once the trades let go of the limiting assumption that each trade must require a separate location for any work to be performed, the door was also opened for many opportunities to work in parallel. Thus, a "lean" production plan was established, relying on the targeted required durations, and sound logical connections. It should be noted that once the durations were reduced, some of the tasks gained a positive total slack, and buffer management became possible (Goldratt 1997; Goldratt et al. 2004). Additionally, production was shielded by limiting the number of concurrent projects (WIP) for each trade, allowing resource availability, enhanced motivation for early completion, and improved workflow for each trade, as well as earlier cash flows (because payments are approved upon completion of work).

Principle 3 - "Collaborate": This principle was brought up many times in interviews and in different contexts, highlighting its importance and lateral influence. Tight collaboration was shown by trades at the Gemba, senior management of the subcontracting companies, and by the tool owner. The PM demonstrated how trades coordinated their daily work at an hourly level of resolution, to enable a significant portion of work to be performed in parallel at the same location. Even lunch breaks were coordinated to enable trades to perform specific tasks that require the entire location, with minimal influence on other trades. Senior management collaboration was reflected by the back-office support, including agile ad-hoc design coordination when needed.

There were voices in the organization that questioned whether the extensive parallel work would align with the safety standards of the organization. However, as the P-Sub explained, the opposite was the case: the exposure to safety incidents decreased as the CT of the project was reduced; the collaborative approach led to an improved safety environment, as safety plans where tightened and coordinated; inputs were generated from the safety inspectors of each trade, enabling preventive actions ahead of time.

Collaboration was also the key for coordinating the work performed by the tool owner and the vendor, enabling them to perform their work in parallel to the installation team. The tool owner emphasized his presence and availability on site and his commitment to respond in real time to any constraint that may arise during the work (contrary to traditional RFI processes that may be untimely, sequential and cause work stoppages).

Principle 4 - "Resolve constraints": This principle integrates with the look-ahead plan and the make ready process in LPS. The P-Sub explained that traditionally each trade was required to provide its own working platform, that not only did not fit the needs of the other trades, but in most cases blocked their access. To resolve this constraint, the trades planned an integrative working platform, that would fit the needs of all trades and would enable them to work in parallel. As described regarding principle 3, the PM and the tool owner had substantial influence to resolve constraints in real time. This included providing design solutions at the Gemba, without triggering a cumbersome system of "design changes".

Principle 5 - "Restructure Resources": the preliminary plan clearly shows that the electrical works were on the critical path, and the electrical team was working at its full capacity, indicating the presence of a bottleneck. It was suggested to restructure the resources within the electrical team. The senior electrical team that worked on the project received a broader role, including mentoring of junior teams in a portfolio of projects, and a reinforced motivated junior team was assigned to the project enabling reduction of the bottleneck effect.

Principle 5 was also implemented by maximizing the potential for off-site pre-fabrications of the piping works, enabling dramatic reduction of the welding required on site. As a result, the piping trade was able to carry out more tasks in parallel, with improved safety and reduced disruptions to the other teams.

Principle 6 - "Control Project Start": In the pre-OCF environment, in general, tool owners would drive the system based on push strategy, meaning that projects would start as soon as possible, regardless of projects maturity levels, and even if the tool vendors' delivery dates were far off. In that situation, the project technically could not be completed, increasing the cycle times dramatically. Under OCF strategy, the tool owner shifted to a pull strategy that triggered the project only once it reached a suitable maturity level, and Just in Time regarding the vendor's delivery date. The tool owner explained that without this principle, "we may end up in situations where after installations are started, the trades can't complete their job and switch to start another installation, then when the prerequisites are met, the trades or the vendor are no longer available, and so on". Thus, the tool owner made sure to complete all prerequisites before the project was launched.

Principle 7 – "Ensure Project Flow": This principle refers mainly to the construction phase once the project is carried out. To ensure project flow, the entire supply chain must align with the project and provide full backup. This was achieved through the personal involvement of stakeholders, with direct communication to coordinate and resolve any issues that arose. The project was carried out with the "…touch the project once…" concept in mind of all trades, while fully focusing on the project, and without diverting attention to future or parallel projects.

DISCUSSION AND CONCLUSIONS

The case study demonstrates application of OCF at the single project level, detailing how it works through implementation of seven principles. The results reinforce the conclusions from empirical results that showed enhanced performance in over 1700 projects where OCF was applied.

Analysis of construction plans in the case study (Figures 8 and 9) revealed over 50% waste removal, in the form of inflated durations that were considered a cushion to absorb delays. We suggest that the presence of non-value adding times in such work scopes reflect planning failure, which leads to inflated internal buffers. It is likely that these types of waste can be found in many construction projects, even when planning is done using proven methods (e.g. LPS), as plans are ultimately based on motivations, constraints, and internal buffers of each individual trade. Thus, setting strategic and tactical goals to reduce durations, may initiate identification and removal of this type of waste. As detailed in the case study, work plans were coordinated on a half-day level of precision, with tight collaboration of the trades, to ensure optimal workflow and waste removal.

Critical production thinking manifests in OCF strategy through the first two principles: "Plan and Integrate Strategically" and "Plan Tactical Targets". These principles are the pillars of OCF and are a necessary condition to OCF strategy success. Once the first two pillars are set and an organization aims to double its throughput, the other principles of OCF should pave the way to the desired results. As presented in the literature review, the principles are deeply rooted in previous LC work, and thus enhance implementation of other methods as well (e.g. LPS).

The interviews highlighted the importance of vertical integration of all parties in the project. This was reflected as senior managers were present in the Gemba, emphasizing their personal commitment, and providing real-time solutions to remove constraints. This integration was reinforced once the WIP levels were controlled, allowing the focus required on the individual project.

The multi-project environment was recognized as a catalyzer for OCF. The trades adopted a macro perspective that enabled them to level the WIP and reduce the CT, and to enable continuous flow from one project to the other. This was also reflected by the relinquishment of the traditional reward mechanisms (e.g. accelerations), preferring stable cash flow, that allows investment in long term resources and human capital fed with continuous work (as reflected from the OCF batching strategy presented in Figures 2 and 3). We argue that a multi-project environment is not a "given condition", but rather a perspective that arises from critical production thinking, and a clear product and value proposition. Therefore, it may apply to a variety of construction environments. For example, a residential building can be examined as a multi-project environment, with each apartment being a sub-project with a different customer (Sacks & Goldin, 2007). Thus, reduction of CT and increasing TH will reflect completed apartments delivered to customers.

This study was limited to the context of OCF implementation on an installation project in a manufacturing plant environment. Further studies are required to test and evaluate the working mechanisms of OCF outside the factory walls and on non-repetitive projects.

REDUCTION OF FLOOR CYCLE TIME VARIABILITY IN HIGH-RISE BUILDING CONSTRUCTION

Bernardo de Cossio[1], Danny Murguia[2], Jorge Gonzalez de Cossio[3], and Jorge Antonio Gonzalez de Cossio[4]

ABSTRACT

High-rise building construction projects, characterized by their inherent complexity and susceptibility to unpredictable variations such as complex logistics, weather, and resource availability, often face challenges in maintaining schedule reliability. Despite the potential for optimization due to the repetitive nature of high-rise structures, traditional planning methods struggle to address the cascading effects of variability, resulting in long cycle times for completed floors and frequent shifts in estimated completion dates. This paper presents the outcomes of implementing a Last Planner System (LPS)-based strategy for the structural frame of two high-rise buildings. Key performance metrics such as cycle time, production rates, and labor productivity were chosen to evaluate the impact. The findings demonstrate that detailed operational planning and interventions to support continuous improvement reduce the floor cycle time and its variability. Furthermore, the results offer tangible evidence of actual performance, providing practitioners with the necessary data to create more realistic master plans. This approach enhances the operational efficiency of high-rise construction projects and contributes to the broader understanding of effective strategies for managing schedule variability.

KEYWORDS

Phase scheduling, flow, variability, continuous improvement, standardization.

INTRODUCTION

The Last Planner System (LPS) is widely recognized for its effectiveness in improving production planning and control, steering projects toward their goals (Ballard & Tommelein, 2021). Despite decades of lean research and industry practice, many construction firms still rely on traditional methods like Gantt Charts and a transformational view of construction (Bølviken & Koskela, 2016). Previous research has investigated high-rise building construction, with a particular focus on the production planning of control for interior finishing work (Sacks et al., 2005), façade installation (Friblick et al., 2009), and formwork technologies (Abou Ibrahim & Hamzeh, 2015). Moreover, some studies in high-rise construction have explored the effect of learning curves on specific activities such as interior wall installation (Lee et al., 2015), formwork installation, and rebar fabrication and installation (Nguyen & Nguyen, 2013). Despite these efforts, there appears to be a notable gap in prior research concerning the

assessment of floor cycle time performance for structural frames in high-rise construction and its association with overall project performance, including floor-level production rates and labor productivity (Murguia et al., 2022). Understanding the relationship between cycle times and project performance serves as evidence to advance the adoption of lean construction techniques in the sector further.

High-rise building structures face challenges such as resource availability, supply chain issues, complex logistics, and weather, leading to unpredictable cycle times and significant delays. To address these challenges, an LPS-based implementation strategy involving daily work planning, design of operations, and continuous improvement was implemented in this research during the structural phase of high-rise building construction. Two high-rise buildings in Mexico City using in-situ reinforced concrete structures with post-tensioned slabs were investigated as case studies. The structural frame contractor confronted the challenge of accelerating concrete structure delivery due to unforeseen delays, presenting an opportunity to introduce optimization tools to minimize cycle times and bridge the gap between plans and actuals. The paper details the specific tools implemented in the case studies, such as collaborative operation analysis, crew balance charts, and time-motion studies. The primary objectives were to manage variability in floor cycle time and quantify project performance metrics, including floor-level production rates and labor productivity. The results address current gaps in project planning and control for the structural frame in high-rise building construction. Furthermore, the findings contribute to planning more precise (and realistic) master schedules for clients, cost consultants, and contractors in agreeing upon project milestones. This research seeks to provide evidence of performance improvement and illustrate the possibilities when production planning and control are coupled with meaningful project control metrics.

RESEARCH BACKGROUND

Cycle time variability is prevalent in construction projects and necessitates effective management. Reducing and coping with variability is a key concept in lean construction (Thomas, 2002). The LPS was developed to protect construction operations from upstream flow variability (Ballard & Tommelein, 2021). However, variations in production systems can be reduced but never eliminated. Therefore, an LPS-based implementation strategy, including detailed work planning and design of operations, are required to absorb those variations and shield-protect targets. In addition, effective performance evaluation metrics are needed to assess the effectiveness of interventions.

CYCLE TIME AND VARIABILITY

Cycle time is defined as the cumulative duration of activities minus overlaps between activities plus the sum of waiting times (i.e. work discontinuities). Consequently, cycle times can be reduced by reducing waiting times and activity durations and increasing overlapping activities (Ballard, 2001). Gabai & Sacks (2020) provided strong evidence of cycle time reduction of up to 48% by implementing a lean-based method called "optimized installation flow" in industrial infrastructure installation in the semiconductor industry. In structural frame construction, the floor cycle time is the time elapsed between installing the first vertical element on a floor (start date) and the last slab concrete pour on that floor (finish date).

DAILY WORK PLANNING AND DESIGN OF OPERATIONS

A wealth of evidence, both in research and practice, supports the implementation of weekly work planning within the LPS. However, one of the least implemented components of the LPS is the design of operations at the daily planning level (Ballard & Tommelein, 2021). The design of operations entails collaborative planning among Last Planners (foremen or front-line supervisors) and craft workers responsible for executing the tasks. Operations encompass the steps to be carried out by one or multiple workers, specifying the steps, durations, sequence, individuals responsible for each step, and the pathways for workers, equipment, and materials (Ballard & Tommelein, 2021). Previous research has investigated productivity enhancement through detailed production planning, involving eliminating non-contributory work and increasing the Percent Plan Complete (PPC) (Ghio, 1997). The findings underscored the need for daily work planning to effectively manage change orders and devise efficient task completion strategies without escalating the workforce size. However, there is still insufficient evidence of the relationship between daily work planning and project performance metrics.

PROJECT PERFORMANCE METRICS

The expanding body of literature reveals a growing understanding of the relationship between production planning and control within the LPS, and its impact on project performance. Pérez et al. (2022) delved into key LPS metrics to evaluate project performance in high-rise buildings. Analyzing a dataset of 71 projects in Chile, they correlated production planning and control metrics, namely Percent Plan Complete (PPC) and constraint removal time (CRT), with output metrics such as the schedule performance index (SPI) at the planned completion point. The results indicated moderate correlations (between 0.3 and 0.4) between PPC, CRT, and SPI. Similarly, Liu & Ballard (2009) demonstrated the need for daily planning to enhance workflow reliability and labor productivity. Analyzing data from 592 working days, they found moderate associations between labor productivity and PPC with commitment plans and favorable weather conditions (correlations between 0.34 and 0.42). Arumugam & Varghese (2014) proposed a method to characterize flow in the reinforced concrete structure of high-rise apartment buildings, noting a floor cycle time of 6 to 8 days. However, as the floor area per level was not reported, benchmarking a floor-level production rate was not feasible. In contrast, Veran-Leigh et al. (2022) provided benchmark values for production rates of structural works of 63 m²/day and 73 m²/day but did not correlate PPC metrics with performance values.

RESEARCH METHOD

This research selected the case study approach to investigate the phenomenon (i.e., the case) in depth and within its context (Yin, 2014). Several sources of data were collected to achieve the research objectives: project documents (contractual programs, daily plans, design of operations), quantitative data (concrete pours, crew size, number of worker-hours), and qualitative data (on-site research observations) during the structural frame construction. Data were screened to ensure quality and analyzed using statistical tools. Based on Murguia et al. (2023), the following performance metrics were established: cycle time (days), production rate (m^2/day), and labor productivity (m^2/worker-hour). These metrics align with the research aim, which is to provide evidence-based project performance due to the implementation of daily work planning and continuous improvement strategies.

CASE STUDY DESCRIPTION

Project U, a 60-story residential development in downtown Mexico City, features 18 basement levels, a Total Gross Floor Area (TGFA) of 48,745 m² and a total height of 207 m. The typical floor has 847 m² of Gross Floor Area (GFA). Figure 1 shows the typical floor plan. The structural frame is a reinforced concrete structure with post-tensioned slabs and an average rebar density of 88 kg/m². Construction commenced in May 2021, and a single tower crane was part of the construction strategy. Project P, a 31-story luxury hotel project in a high-end residential neighborhood with a total height of 106 m, boasts a TGFA of 27,432 m², with floors averaging 945 m². Each floor was divided into two slab pouring events to accelerate the schedule (Figure 1 shows the typical floor plan with the division considered). Unlike Project U, the main structure had an average rebar density of 107 kg/m², reflecting higher structural safety standards demanded by the client. For both projects, the typical activities within the floor cycle included setting out, vertical rebar (columns and shear walls), vertical formwork, concrete pour of vertical elements, beam formwork, beam rebar, slab falsework and formwork, slab rebar and slab pours.

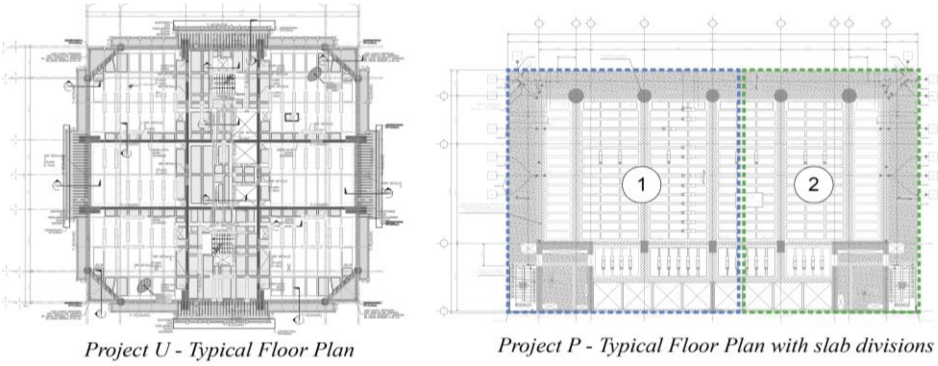

Figure 1: Project U and Project P's typical floor plans

LPS-BASED IMPLEMENTATION STRATEGY

Both projects implemented a lean-based approach led by the contractor's top management and an external lean consultant. Field engineers and crew leaders actively led daily work planning sessions, conducted collaborative operation analyses, and monitored crew balance charts. Figure 2 illustrates the key steps of the LPS-based implementation strategy.

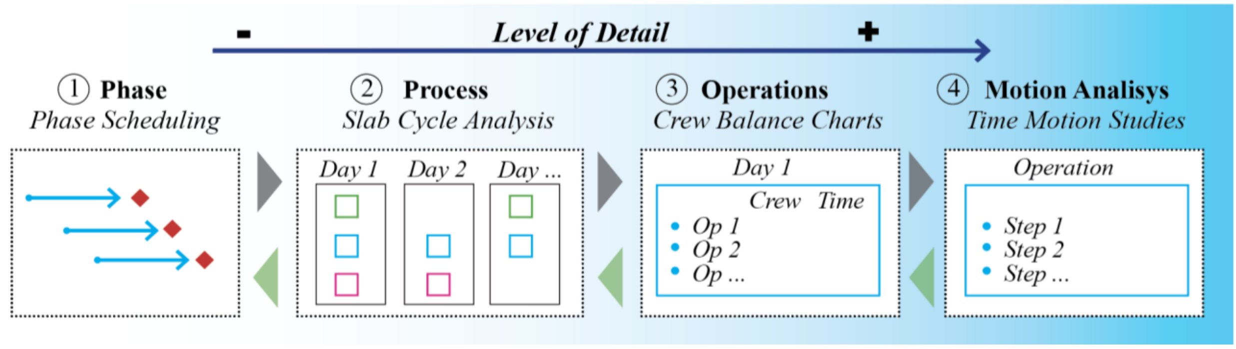

Figure 2: LPS-based implementation strategy

1. *Develop a phase schedule*: A collaborative schedule was developed by field engineers and project managers, incorporating milestones agreed upon with the developer. This step provided a robust framework for sequencing and monitoring progress.
2. *Slab cycle analysis – Daily operations by crew*: Through workshops with crew leaders, a collaborative approach was used to define the entire slab cycle for carpenters, steel fixers and concrete gangs. This ensured buy-in and alignment from all participants.
3. *Implementation and evaluation - Crew Balance Charts:* Operations listed on the corresponding day of the slab cycle analysis were handed to each crew using Crew Balance Charts and evaluated at the end of the day.
4. *Time-Motion Studies*: All the operations in the slab cycle, starting with the most repetitive, were analyzed using Time-Motion Studies. This allowed for a better understanding of all the steps involved in the operations and included suggestions from workers and field engineers.

RESULTS

The strategy was implemented from level 25 onwards on Project U and after level 3 on Project P, leading to different outcomes. In Project U, the structural frame reached the 25th floor with delays exceeding the contractual timeline. Further complicating matters, Project U experienced highly variable slab cycle times ranging from a swift 10 days to a staggering 54 days, primarily due to unforeseen disruptions caused by overlooked activities in the program, such as rebar bending or tower crane availability. On the other hand, the developer in Project P requested faster delivery times. However, Project P faced unique challenges, including the developer's control over the tower crane, which limited material availability for the contractor, especially rebar and falsework movement. Furthermore, Project P's spatial constraints needed off-site rebar cutting and bending, impacting additional processes such as pre-ordering and increasing inventory management efforts owing to large batches for reduced shipping costs. Moreover, the implementation strategy encountered significant organizational challenges, such as limited engagement from both crew and engineers, undefined roles, overlapping responsibilities, and communication problems. These issues required resolution before the implementation of the strategy, underscoring the critical role of robust on-site management in ensuring planning at the operational level and project success.

(1) Phase Scheduling

A collaborative planning session was conducted in line with pre-established milestones agreed upon with the owner's project managers, superintendents, and field engineers. This session brought together structural engineers with the construction team to thoroughly understand project constraints and determine the feasible number of slab partitions considering the structural design. In Project P, this analysis concluded that two pouring events were possible, while Project U could only accommodate one. This crucial definition directly informs the overall schedule and subsequent strategic decisions.

Additionally, these sessions established the general sequence and order of activities based on the specific site context. Factors considered included tower crane placement, personnel access, and material supply. This collaborative approach ensured optimal planning tailored to the unique conditions of each project.

(2) Slab Cycle Analysis: Daily Operations per Crew

At the outset of the implementation strategy, superintendents, field engineers, and crew leaders collaborated to develop detailed slab construction cycles for both projects. Project P achieved a 9-day cycle, while Project U required a 10-day cycle. These cycles outlined daily operations and responsibilities for carpenters, steel fixers, and concrete crews, highlighting critical interactions and potential constraints faced by each team (e.g., crane availability, dependencies on previous tasks, material availability, and post-tensioning requirements).

These slab cycles served as a starting point and were revised throughout the project lifecycle. Bi-weekly on-site reviews, led by the superintendent and lean consultant, incorporated lessons learned from time-motion studies and addressed execution challenges, such as overlapping activities and material handling issues.

Marked-up floor plans served as crucial visual aids in this process. Crews used these plans to map out the daily operation sequence, specifying required work hours, work quantities (kg, m2, m3), and specific locations for each task. Figure 3 exemplifies this concept for Day #3 of the slab cycle in Project U, focusing on rebar installation. It illustrates the operational sequence, labor resource allocation, and a color-coded layout to facilitate spatial coordination. This detailed planning process enhanced crew coordination and minimized unforeseen disruptions during construction.

(3) CREW BALANCE CHARTS

At the end of each workday, and based on the corresponding slab cycle plan, field engineers and crew leaders convened to develop Crew Balance Charts (CBC) to assign activities to carpenters, steel fixers and concrete finishers. These CBCs were handed to each crew member, detailing the operations expected for the following day, specifying the allocated worker-hours, time of day, crew identification, material quantities, and its location within the slab (Figure 4). During these on-site meetings, field engineers evaluated the operations performed during the day and any challenges encountered. Based on this evaluation, the team adjusted the CBC for the following day, incorporating mitigation plans when necessary.

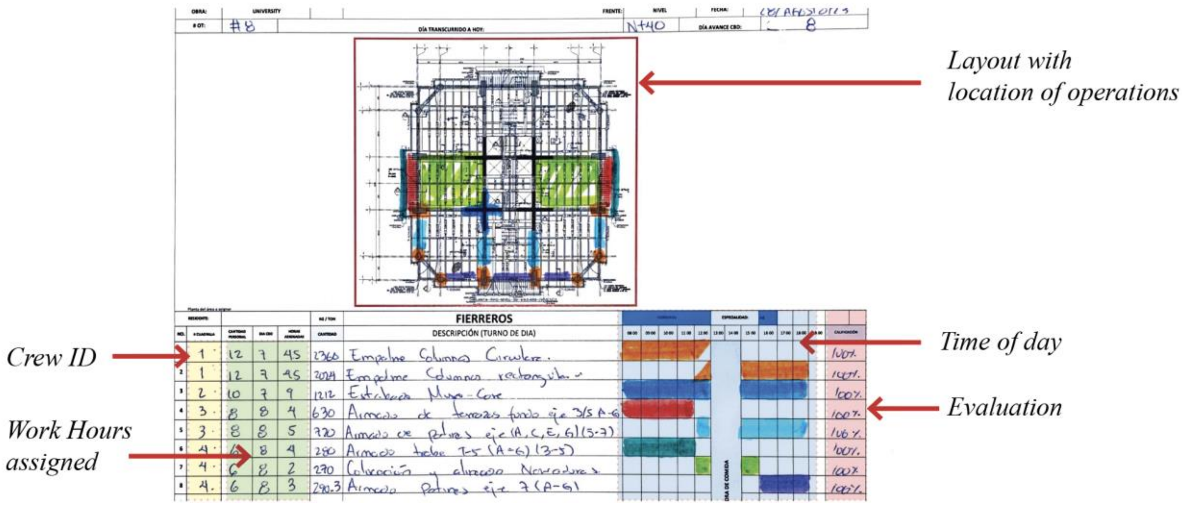

Figure 4: Crew Balance Chart for steel fixers

(4) TIME-MOTION STUDIES

To further refine the process and to validate the time considered in the slab cycle, time-motion studies were conducted by the lean consultants on most operations, starting with repetitive operations constituting up to 80% of the slab cycle, such as standard columns, shear walls and main beams. An illustration of one such study is depicted in Figure 5, focusing on rebar installation within a shear wall. The study outlined all necessary steps for completing the shear wall and the allocated time for each step, accompanied by a concise description, visual aids, and observations regarding potential improvements.

This approach fostered a collaborative environment by actively incorporating crew members and field engineers to suggest improvements for individual steps within each operation, ultimately enhancing overall slab construction performance. These studies not only validated execution times for future slab cycles but also highlighted opportunities for improvement, prompting targeted problem-solving efforts. Additionally, they served as valuable resources for training new crews on-site and standardizing procedures across all existing teams.

PROJECT PERFORMANCE

To visualize project performance, the master-level flowlines, as described in Murguia et al. (2023), were used to compare plans and actuals for both projects. Furthermore, production rates and labor productivity were estimated from the labor and concrete pour data. The flowlines in Figures 7a and 7b show that both projects missed the contractual completion dates for the structural frame. However, the strategy described in this paper was implemented from the 25th floor onwards on Project U. As shown in Figure 7a, this led to a noticeable acceleration in the cycle time, represented by the steeper slope of the actual line after that level. Had this strategy not been implemented, the project would have likely overrun the contractual deadline even further. The review of the actual performance results showed that the contractual dates for Project P were unrealistic because planners during the tender stage considered weekends or holidays within the contractual cycle times. These observations were evident in the unreasonably short timeframes, such as 7 days for completing 945 m^2 of work, creating a pace of 135 m^2/day, not very common in the industry for in-situ reinforced concrete frames with a single crane.

The boxplots in Figure 8 summarize the cycle time data. During the first stage of Project U (Floors 7- 25), the minimum cycle time was 10 days, whilst the maximum was 24 days (some outliers up to 54 are outside the boxplot). The median was 15 days. Additionally, the first and third quartiles were estimated at 12 and 17 days, respectively, suggesting an interquartile range of 5 days. During the second stage of Project U (Floors 26-50), the minimum cycle time was recorded at 9 days, whilst the maximum was 14 days. The median cycle time was 11 days. Furthermore, the first and third quartiles were estimated at 10 and 12 days, respectively, suggesting an interquartile range of 2 days. Therefore, substantially less variability was achieved. Finally, the minimum cycle time for Project P was recorded at 9 days, whilst the maximum was 19 days. The median cycle time was 14.5 days. Moreover, the first and third quartiles were estimated at 13 and 16 days, respectively, suggesting an interquartile range of 3 days, suggesting less variability.

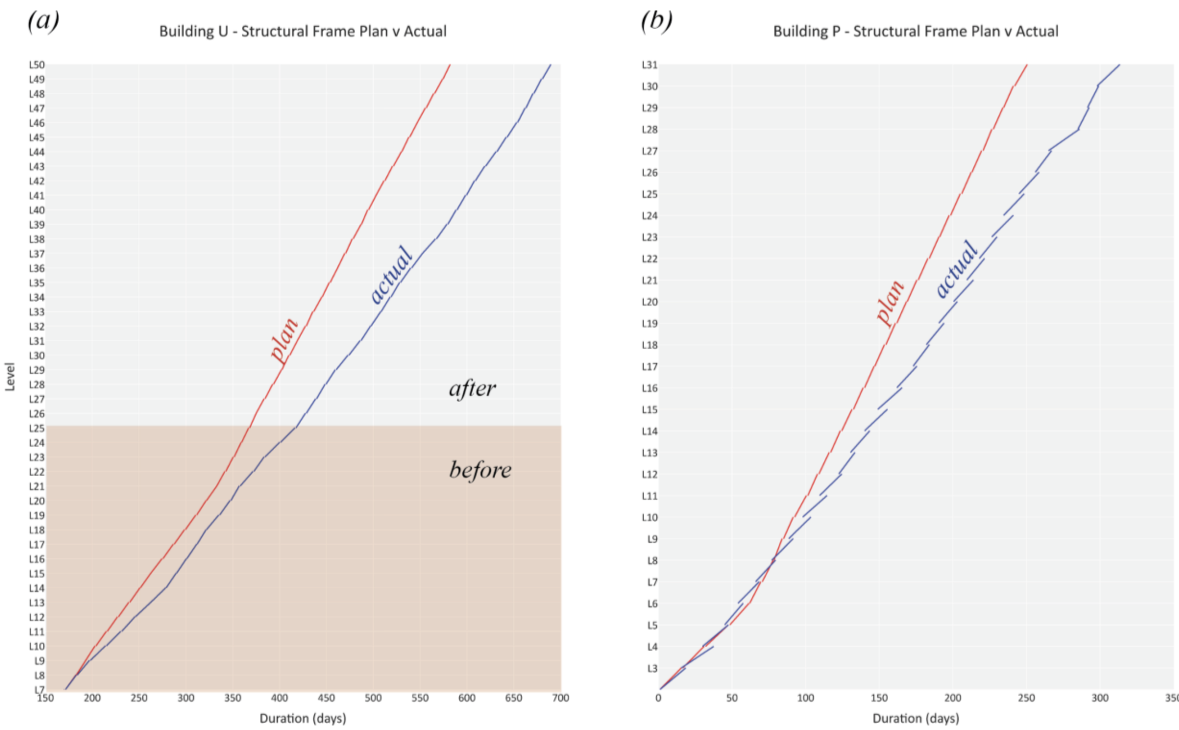

Figure 7a and Figure 7b: Flowlines (plan v actual) for Projects U and P

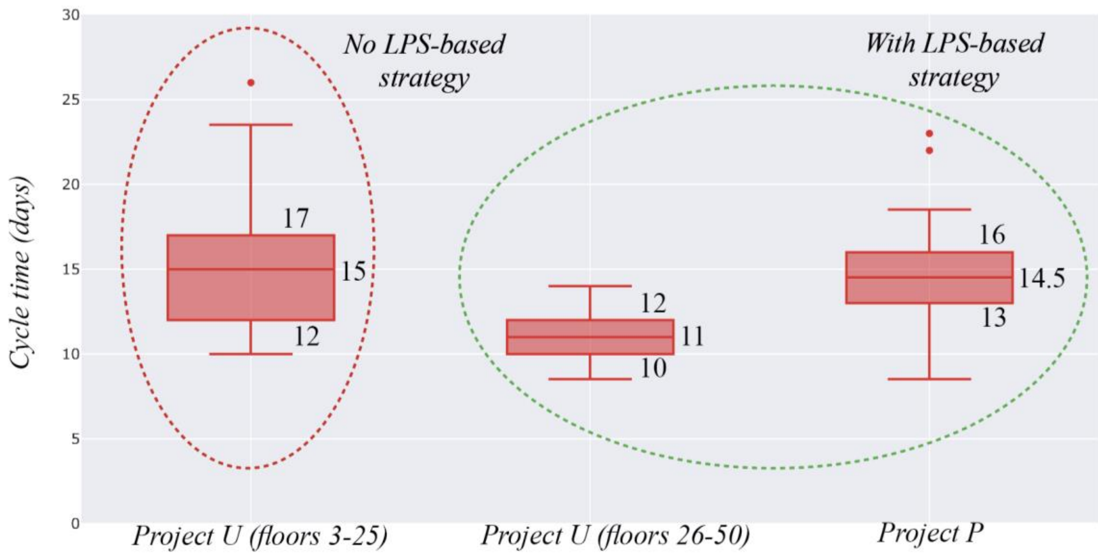

Figure 8: Cycle Time Boxplots for Projects P and U

TIME COMPRESSION AND WORKFORCE REDUCTION

Both projects experienced a significant acceleration in construction speed due to increased production rates, measured in square meters of GFA delivered per day. Notably, this was achieved while simultaneously reducing the number of workers required to complete each floor. For Project U (see Figure 9), the production rate before implementing the described LPS-based strategy (floors 7-25) was an average of 53 m²/day. In comparison, after implementing the LPS-based strategy (floors 25+), the average production soared to 79 m²/day, representing a **49% increase**, whilst **the number of workers had a reduction of 30%**. Overall, comparing phase 1 (levels 7-25) to phase 2 (levels 26-49), productivity increased from 3.5 m^2/100 worker-hours to 13.1 m^2/100 worker-hours, an astounding **274% increase**. In the case of Project P (see Figure 10), the production rate started at 67 m²/day and finished at 145 m²/day, marking a remarkable **116% increase**. In terms of the number of workers, there was a **29% reduction**.

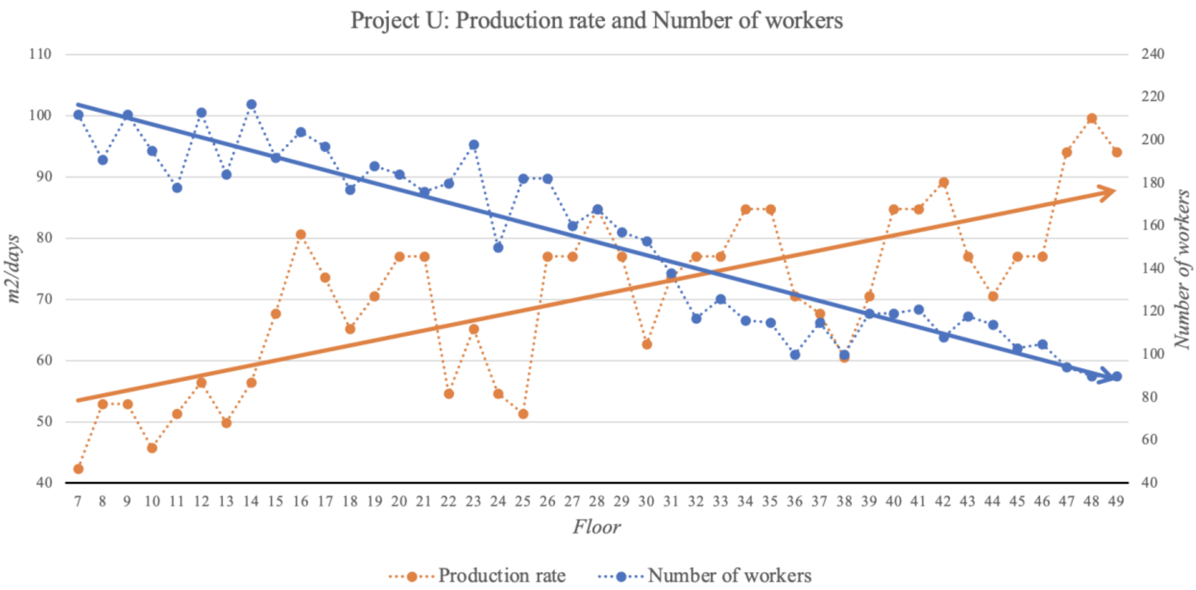

Figure 9: Productivity Metrics Project U

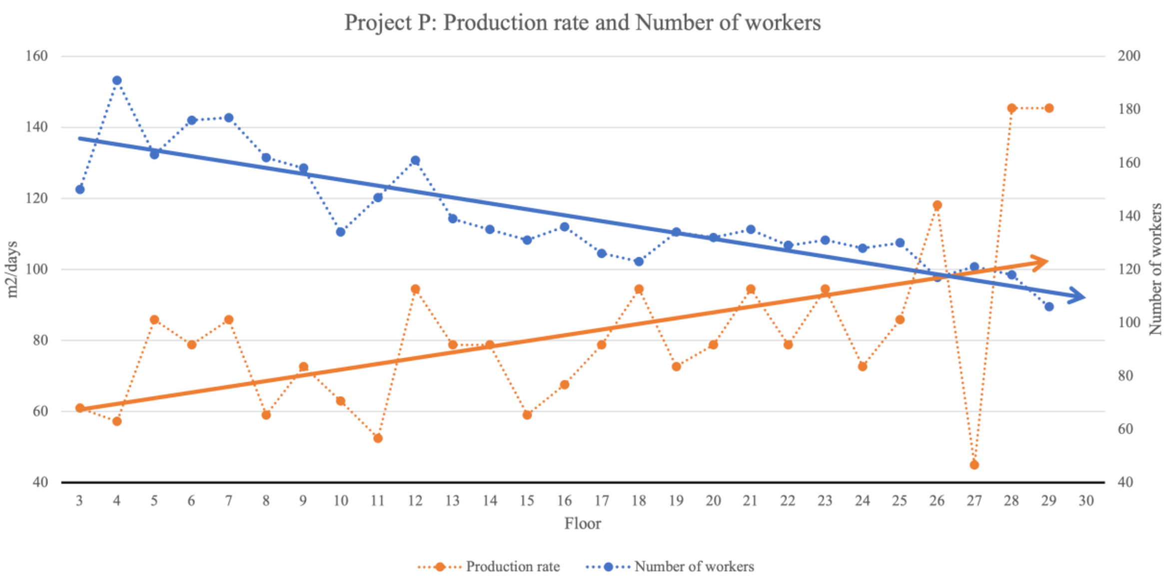

Figure 10: Productivity Metrics Project P

BEYOND PRODUCTIVITY: ADDITIONAL OUTCOMES

Building upon the productivity gains, both projects experienced **significant reductions in worker turnover.** Before the LPS-based implementation strategy, both projects faced substantial monthly worker rotation, averaging *41% for Project U and 43% for Project P*. These figures decreased to 18% and 24% on average for Projects U and P, respectively. The turnover decrease proved crucial for successfully implementing the LPS-based strategy by minimizing knowledge loss and the need for constant training of new workers. While a baseline level of worker turnover persisted, around 20% on average, on-site workers reported improved overall satisfaction. The initiatives described in this paper, including a 22% salary increase, likely contributed substantially to this positive shift in morale and commitment to continuous improvement.

DISCUSSION

UNREALISTIC CONTRACTUAL PHASE SCHEDULE

Despite operating in distinct contexts, both projects experienced significant benefits from the LPS-based strategy but did not meet the original contractual dates (Figures 7a & 7b). The contractor's planners developed these programs within the tendering team years before construction. It is worth noting that planners at the tender stage are typically unfamiliar with actual performance data or may inadequately consider the project context. Moreover, to secure contracts, a touch of optimism bias is introduced into the master plan. A data-driven, forward-thinking client would be prepared to procure projects that align more closely with actual performance. This approach to procurement would be crucial to avoiding misalignment between planned and actual timelines and, consequently, better predicting the overall duration of the structural frame.

WIN-WIN-WIN IMPACT AND FUTURE POTENTIAL

The LPS-based implementation strategy benefited all stakeholders: developers through reduced schedule variability, contractors through cost reductions, and the workforce through increased wages. Moreover, the incentive program is based on productivity gains, using CBCs and time-motion studies, effectively motivating crews and field engineers, demonstrating its potential for early adoption in future projects. Applying this strategy to subsequent trades such as façade, services, and fit-out in high-rise buildings holds immense promise. This could prevent gains in the structural phase from being negated by later trade bottlenecks, leading to overall project efficiency optimization. Further research exploring this application could pave the way for a more streamlined and cost-effective future for high-rise construction.

CONCLUSIONS

This study presented an LPS-based implementation strategy to support variability reduction of floor cycle time in the construction of high-rise building structures. The strategy included a master phase schedule, daily work planning, crew balance charts, and time and motion studies. The strategy was implemented in two live projects in Mexico City. The results showed a significant reduction in cycle time and its variability, leading to significant performance improvement for both production rate and workforce reduction. The significant gaps between plans (client's expectations) and actual (what is possible) need to be more aligned through a data-driven performance culture. This research uniquely presents performance data that can be used for benchmarking in future studies. This study has some limitations. PPC was not captured to correlate PPC performance and cycle time variability. Furthermore, the effect of learning curves was not considered in this study. Finally, future studies can examine other work packages, such as façade and interior work, along with the integration of lean and BIM.

NO SINGLE TAKT PLANNING METHOD FITS ALL PROJECTS

Iris D. Tommelein[1], Rafael V. Coelho[2], Carlos T. Formoso[3], Karina B. Barth[4], and Fabrício Berger de Vargas[5]

ABSTRACT

Takt planning methods have been used to plan and control production of a variety of construction projects that have been delivered in various contexts. Recognizing that projects vary by type based on different product- and process designs as well as contextual characteristics of relevance to project production, not one but several takt planning methods have therefore emerged. This paper presents the objectives pursued in takt planning and describes projects by type and context, based on their complexity, in relation to these objectives. It outlines several takt planning methods and then matches those methods to project types and contexts. It is clear that no single takt planning method fits all projects and also that takt planning may not be a suitable method to plan some projects. This paper aims to shed light on available takt planning methods and on choosing which one to use when considering the complexity of a given project and its context.

KEYWORDS

Takt planning, takt production, work structuring, complexity, uncertainty, variability, slack.

INTRODUCTION

Projects are complex socio-technical systems. Their complexity stems in part from the fact that they comprise a large number of elements that are interconnected in various ways and to various degrees (e.g., people, materials, equipment, activities, processes, economic conditions, and legal requirements). Complexity is exacerbated by expected and unexpected variability arising from internal processes (e.g., decision-making processes or production processes) and external factors. Articulating and managing project complexity is crucial for effective project planning.

Here we focus specifically on takt planning. Takt planning methods have been used to plan and control production of a variety of construction projects that have been delivered in various contexts. Recognizing projects by type based on different product- and process designs as well as contextual characteristics of relevance to project production, various takt planning methods have therefore emerged. Our aim is to shed light on available takt planning methods and on choosing which one to use while considering the complexity of a given project type and context.

This paper is structured as follows. We first offer a literature review on takt planning, project- and contextual complexity, and slack. Next, we introduce takt planning, present its objectives, and describe project characteristics relevant to takt planning. We then characterize and compare five projects, using data from case studies documented in the Lean Construction literature, based on their complexity and in relation to the aforementioned takt planning objectives. Subsequently, we outline four takt planning methods and match those methods to project types and contexts. We conclude the paper with recommendations for follow-on research.

LITERATURE

TAKT PLANNING

Takt planning methods set a regular "beat" for production so that work can flow in time and space, in order to match customer demand. The application of takt production in manufacturing dates to at least the early 1900s (Baudin 2012b), however the application of takt in construction has become more widespread only in this millennium. Takt planning can be applied to an entire construction project, but it is likely that different parts of a project will each have their own takt, as is the case in manufacturing where different assembly lines typically have different takts.

Quite a few instances of takted projects have been reported in the Lean Construction literature. These reports show that takt planning can be applied to projects of various types across the construction industry. Among relatively recent examples, Fiallo and Howell (2012) described the application of takt in designing the production system for an infrastructure project. Frandson et al. (2013) described the use of takt planning for the installation of a hospital's exterior cladding system, and Linnik et al. (2013) described how takt planning was used on the same project to plan non-repetitive interior work. Heinonen and Seppänen (2016) described the use of takt planning for the refurbishment of cruise ship cabins. Dlouhy et al. (2016 and 2018) applied their "three-level method of takt planning and takt control" to plan the construction of two automotive manufacturing plants. Vatne and Drevland (2016) described how takt was used to plan interior construction of a student housing complex, whereas Lehtovaara et al. (2019) used takt to plan interior construction of a residential building.

Although these reports mention the use of takt, not all takt planning methods are the same. In fact, takt planning describes a broad category of location-based planning methods, and therefore comparison with other methods in this category is warranted. Frandson et al. (2015) compared and contrasted the underlying assumptions of the Location-based Management System (LBMS) with takt planning. They identified key differences in how these methods make use of capacity-, space-, and time buffers. Formoso et al. (2022) presented a location-based approach for using takt on linear infrastructure projects, allowing for flexibility in choosing when to start work in any one of several planned work zones. Tommelein (2022) presented the Work Density Method (WDM) for takt planning, a method based on the work density concept to determine work locations and set a time limit for the completion of activities. Tommelein and Lerche (2023) compared the use of takt planning methods on projects of two different types: (1) a wind farm infrastructure project and (2) a healthcare facility project, the first paced by rather unique and expensive equipment, the second more flexible in throttling up-or-down the number of resources involved. These applications and methods may be viewed according to characteristics relevant in this production-planning context, as will be described in this paper.

Because takt can be used to plan the construction of products in different contexts—i.e., to deliver projects and phases of projects of various scope and size—the methods used on any given project may vary with time as needed to result in an efficient and effective plan. This aligns with Shenhar's (2001) assertion that "one size does not fit all projects."

Questions that come to mind are: (1) What are the essential conditions to implement takt time successfully in construction projects? (2) When all these essential conditions are met, is it still possible to fail in applying the fundamental principles of takt and find no solution? (3) When is it not appropriate to takt a process? (4) When does takt planning [and control] fail and what alternative methods can then be used?" These questions were inspired by Casey Ng's questions on LinkedIn, as quoted in Baudin (2012a). In this short paper, we begin to address these questions, but we cannot provide extensive answers.

A study of project- and contextual characteristics that affect the suitability of using takt planning and the choice of method is in order. In the following section we present such characteristics that we think are fundamental to assessing the applicability of takt planning. These characteristics may be grouped into concept categories pertaining to project- and contextual complexity and the availability of slack as a coping mechanism.

PROJECT- AND CONTEXTUAL COMPLEXITY

As it is said that construction projects are becoming more complex over time, and Baccarini (1996) stated that complexity makes a difference in the management of projects, we must first define complexity. Then we can ask: How can knowledge of what makes a particular project more (or less) complex than others be used to plan and deliver that project using takt planning?

Complexity, as defined by the Cambridge Dictionary (n.d.), is "the state of having many parts and being difficult to understand or find an answer to." The degree of complexity of an entity (e.g., a project) is, according to Klir (1985), "associated with the number of recognized parts as well as the extent of their interrelationship; in addition, complexity is […] related to the ability to understand or cope with the thing under consideration." Williams (1999) argued that in the context of project management, complexity manifests in two dimensions: (1) structural complexity and (2) uncertainty. Whereas structural complexity relates to the number of distinct elements in a project and the degree of interrelatedness between them, uncertainty relates to how well-defined the goals are and the means to achieve them.

Geraldi et al. (2011) systematically reviewed project complexities and presented a timeline of the historical development of complexity frameworks since the 1990s, showing when new understandings emerged in the literature. They identified five so-called "dimensions of complexity" in projects, namely (1) structural complexity, (2) uncertainty, (3) dynamic [complexity], (4) pace [complexity], and (5) socio-political [complexity]. In the framework presented in this paper we include an additional dimension, namely organizational complexity. Although these dimensions appear to not be mutually exclusive, we use this framework—with adjustments tailored to the context of construction and takt planning—to expand on the nature of project- and contextual complexity. Using example projects delivered with takt planning and mapping them to the complexity framework, we illustrate that some takt planning methods may be better suited for certain project types than for others.

1. Structural Complexity: 1.1. Product Complexity and 1.2. Supply Chain Complexity

Projects with a variety of numerous, interrelated elements give rise to structural complexity. Structural complexity may be attributed to product complexity and supply chain complexity. Product complexity is determined by the number of systems and their constituent elements, and the interrelationships between those systems and elements. These interrelationships can involve various degrees of tight- or loose coupling (Howell et al. 1993). In the construction context, interrelationships refer to how elements within a system fit together, and how changes in the design of one system affect the design of other systems. Supply chain complexity is determined by the quantity and variety of products, people, and organizations, and their interrelationships. Whereas Williams (2005) lumps both organizational- and supply chain complexity together under the umbrella of structural complexity, here we lump product- and supply chain complexity together and we treat organizational complexity separately. The articulation of complexity dimensions is itself rather complex and not generally agreed upon.

2. Uncertainty

The prediction and control of system performance is particularly challenging in the presence of uncertainty (Böhle et al. 2016). Uncertainty defines a state where individuals have incomplete knowledge of a situation (Saunders et al. 2015), e.g., due to measurement errors or a limited understanding of cause-and-effect relationships. Uncertainty may be viewed as "unexpected variability" (Saurin and Werle 2017). It may arise from human and social influences or organizational conditions, and it can be influenced by both internal and external factors.

3. Dynamic Complexity

Dynamic complexity refers to changes over time, so it indicates a certain kind of variability. Hopp and Spearman (2011) characterized variability as the attribute of non-uniformity within a class of entities. Process variability emerges from variations and randomness in work procedures, setups, random interruptions, and quality issues. Flow variability results from the way in which work is released to the system or transferred between locations.

4. Pace Complexity, i.e., Pace of Project Delivery

Pace is related to speed and urgency associated with performance and completion of project activities, reflecting deadlines and pressure to deliver results (Geraldi et al. 2011). "Fast" projects require numerous resources and overlapping activities (i.e., work taking place in many locations simultaneously), increasing activity interdependence and making them more tightly coupled, and consequently increasing the complexity related to planning. Lindkvist et al. (1998) suggested that the use of deadlines, milestones, and other time-based controls not only helps to pace projects in relation to overall time limits, but also supports parallel (simultaneous) work by encouraging communication and reflection. Takt time is a time-based method of control (Hall 1998) that helps to pace projects and indeed provides such support.

5. Socio-political Complexity

Socio-political complexity pertains to the network of interactions between people, power dynamics, stakeholder relationships, and political influences within and around the project environment (Geraldi et al. 2011). This dimension of complexity is related to the alignment of interests among stakeholders and their negotiation of project objectives.

6. Organizational Complexity

Organizational complexity encompasses technical elements (e.g., skill- and tool specialization) and human elements such as decision making, interactions among individuals (employees) at different levels of the organizational hierarchy (e.g., teams, departments, and divisions), as well as factors such as organizational size, culture, expertise, and risk tolerance (Peñaloza et al. 2020). In contrast to supply chain complexity that relates to elements and interactions between companies, and socio-political complexity that relates to elements and interactions both within and around a project, organizational complexity focuses on internal project team dynamics.

Takt planners, and planners in general, will recognize these dimensions of complexity in their projects and the contexts in which their projects unfold. To manage complexity, they can use certain coping mechanisms, which we present next under the broad category called "slack."

SLACK

Slack refers to the use of resources in a planned or opportunistic way to cope with complexity (Formoso et al. 2021, Saurin et al. 2021). Here, resources refer to not only people, materials, tools, and equipment, but also time, information, production strategies and, more generally, the flexibility people have in devising new approaches and creative solutions. Slack does not necessarily imply the use of extra or idle resources: existing resources can be readapted in order to protect systems from uncertainty and variability. Bourgeois (1981) described three roles for slack: (1) spare resources to prevent ruptures in the face of a surge of activity; (2) resources that allow an organization to adjust to external changes; and (3) resources that allow an organization to experiment with new products or innovations in management.

Formoso et al. (2021) and Saurin et al. (2021) advocated for two uses of slack in construction: (1) to have enough resources for fulfilling demands or carrying our strategic actions, and (2) to manage complexity as projects are complex socio-technical systems. Although it is (generally) desirable to reduce complexity rather than manage it, it is prudent to devise management strategies—e.g., strategically plan the use of slack—to cope with existing complexity that is difficult to remove or reduce. Slack resources should be planned and deployed judiciously so as to add flexibility or redundancy to systems while ensuring that they will have positive impacts. These impacts can be measured in terms of system resilience, reliability, robustness, innovativeness, and output flexibility. When the use of slack is mostly opportunistic or not well-defined, it can impact the system negatively and generate waste.

The provision and use of slack resources in the context of takt planning can be realized through various approaches. One approach is to develop alternative takt plans, so that the most suitable one can be used when uncertainties in the project diminish. Another approach is to determine what aspects of the work (e.g., work zones, work instructions, process sequence) should be standardized in a takt plan and what should be left for qualified workers to figure out. This poses strategic questions: (1) What level of specificity is appropriate for takt plans at different levels of planning? and (2) How detailed should takt plans be at various points of a project's construction timeline?

PROJECT CHARACTERISTICS RELEVANT TO TAKT PLANNING

With this understanding of takt planning, characteristics of project complexity, and slack as a means for coping with complexity, we now focus on project characteristics relevant to identifying a suitable takt planning method. The success of applying a takt planning method depends on the ability of the planner (i.e., the person or team responsible for developing and maintaining plans) to structure the work of a project, or a phase of a project. Here, "ability" encompasses not only personal- and team competence, but also the degree of flexibility granted to the planner. This flexibility can arise from the manifestation of resilience of the planning method, when the method enables the planner to define and fine-tune various production system design elements to their desire. The following are examples of "throttles" or "adjusting mechanisms" (Binninger et al. 2017) that can be manipulated to shape a takt plan.

1. Use alternative breakdowns of the scope of work.

One throttle is to study alternative breakdowns of the scope of work. Takt planning requires a breakdown of work into "chunks" that can be done concurrently, creating process modularity, allowing for fast feedback, and ultimately aiming to reduce lead time. Work breakdown relates to product complexity, i.e., how tightly- or loosely coupled project physical elements (building elements, assemblies thereof, and systems) are. On the one hand, when they are loosely coupled, planners have more flexibility, e.g., to structure work into small (in scope and duration) process steps and divide work space into more zones to reduce cycle time. On the other hand, when projects are less flexible, i.e., when elements and systems are tightly coupled and process steps are larger (in scope and duration), planners may not be able to divide work space into so many zones but instead have to rely on other takt planning throttles to realize shorter cycle times.

2. Re-sequence work or add/remove work from a process step.

A second throttle involves the possibility of re-sequencing work or shifting work content from one process step to another, essentially redistributing the workload between steps in order to achieve more evenness (workload leveling or “heijunka”). This helps to reduce cycle time and work fragmentation, and it results in a reduction in the workload of one process step and possibly a corresponding increase in another process step. The feasibility of resequencing work or shifting work content may depend on trade jurisdictions (e.g., whether a trade contractor can perform the work initially assigned to another trade), specialty equipment requirements, personnel training needs, etc.

3. Define the resources that can be assigned to perform work.

A third throttle is to adjust resources in terms of their type, quantity, or capacity (e.g., augmenting capacity by providing skill training). When all constraints for a task have been removed, the pace at which work happens is dictated by the nature of the resources involved.

For example, operations such as percussive- and rotary drilling are equipment-paced, i.e., the operation is inherently tied to the capability of the equipment being used. Reducing cycle time would require allocating additional- or alternative equipment, i.e., equipment that gets work done faster. However, such equipment can be expensive, difficult to obtain, and logistically challenging to mobilize on site. Furthermore, even when under ideal conditions a certain level of predictability in equipment performance may be anticipated, that performance will be impacted by uncertainties stemming from the surrounding environment—known unknowns.

In contrast, for example, operations such as those involving interior work (e.g., painting, tile installation, window installation) are worker-paced. Provided that there is some kind of slack (e.g., capacity buffers, multi-skilled labor, or financial resources to hire additional workers), it is relatively speaking more straightforward and affordable to adjust the number of workers. Although the pace of work is dictated mainly by worker skills and speed of construction, the surrounding context can also introduce uncertainty. For example, retrofit work tends to have more known unknowns compared to new construction (e.g., “Does the ceiling have asbestos or not?”), in which case the additional complexity must be considered during planning.

4. Exploit flexibility in the use of space.

Spatial features and flexibility in the use of space influence the flexibility afforded to planners. In some projects, most of the work must be performed in situ, and this need for location-specific work may limit how much work can be scheduled concurrently using takt planning while avoiding trade stacking. Conversely, other projects may allow some or several elements or assemblies to be produced ex situ, with only the final installation taking place in situ. The possibility of working ex situ provides planners with flexibility in structuring in-situ work. By reducing the time needed to perform in-situ work (i.e., reducing the work density), the corresponding process cycle times can be reduced, ultimately shortening the overall project duration. Furthermore, defining larger zones for takted work can allow several crews to work shoulder-to-shoulder, requiring them to figure out who works where and when, while at the same time offering the flexibility of choice.

5. Acknowledge the distinction between operable takt vs. customer takt.

Projects must be delivered to meet the customer’s takt, but approval processes and externalities can introduce uncertainty into the delivery process. For example, projects situated in seismically active areas require rigorous inspections of both structural- and non-structural elements during construction. Takt plans must make explicit the handoffs from upstream- to downstream process steps, including those required for inspections, and include decoupling buffers where needed. Slack can be used to mitigate some variability, e.g., from delays in inspections or rework resulting from failed inspections. Other projects, such as those in the realm of infrastructure, may encounter unknown underground and site access conditions. A takt plan can help to delineate different zones where work can take place simultaneously, limiting the propagation of variability (Formoso et al. 2022).

The flexibility to adjust these throttles derives from the characteristics and constraints of each project. Understanding the general characteristics of the type of project being evaluated can guide the identification of the most suitable takt planning method(s). For example, planning the construction of a multi-family building or a hotel may be simpler in some regards than in others when compared to planning the construction of an offshore wind farm.

SELECTION OF PROJECTS FOR COMPARISON

To compare construction projects in terms of their dimensions of complexity and rationalize the takt planning methods used to deliver them, we looked at data from five case studies documented in the Lean Construction literature. These case studies—some of which conducted by the authors of this paper—describe a variety of projects, namely:

[1] Multi-family residential building (Barth et al. 2020)
[2] Cruise ship cabin refurbishment (Heinonen & Seppänen 2016, Makinen 2021)
[3] Overhead MEP work in a healthcare facility (Frandson & Tommelein 2014a, 2014b)
[4] Offshore wind farm construction (Lerche 2020, Tommelein & Lerche 2023)
[5] Underground linear infrastructure projects (e.g., sewer lines, fiber-optic cables) (Yassine et al. 2014, Formoso et al. 2022)

PROJECTS COMPARED ALONG DIMENSIONS OF COMPLEXITY

By adapting Geraldi et al.'s (2011) framework to the context of construction—here specifically takt planning—we illustrate how one might evaluate projects based on their complexity. Although their framework presented five dimensions of complexity, we present seven as we not only added organizational complexity but we also split structural complexity into product- and supply chain complexity.

Based on group discussions among the authors and our expertise in takt planning, we scored each project along each dimension of complexity, assigning the full range of integer values from 1 to 5 (Table 1). Admittedly this is a very crude way of assessing complexity but, as we were wondering if an approach like this might be promising in any way, it offered an initial attempt at categorization. To add: scores assigned to complexity in one dimension are not to be summed up with scores assigned to complexity in another dimension, as these dimensions are qualitatively rather different and overlap to some degree, as previously mentioned. Clearly, follow-on research must include selection of an assessment method that is more fit-for-purpose, comprehensive, and superior to what is presented here. Methods matter! For choice problems, for example, we have argued that Choosing by Advantages (CBA) is superior to Weighting-Rating-Calculating (WRC) and to the Analytic Hierarchy Process (AHP) (Arroyo et al. 2014a, 2014b).

Table 1: Projects Scored According to their Dimensions of Complexity

Type of Project	PRODUCT	SUPPLY CHAIN	UNCERTAINTY	DYNAMIC	PACE	SOCIO-POLITICAL	ORGANIZA-TIONAL
[1] Multi-family building	4	3	1	3	1	2	2
[2] Cruise ship cabin refurbishment	3	2	2	1	2	1	1
[3] Hospital overhead MEP work	5	4	3	5	4	4	5
[4] Offshore wind farm	2	5	5	2	5	3	4
[5] Linear infrastructure	1	1	4	4	3	5	3

Product complexity assesses the interconnectivity of physical elements (e.g., building elements, assemblies thereof, and systems). A score of 1 indicates low complexity due to loose interconnectivity, whereas a score of 5 indicates high complexity due to tight interconnectivity. We scored case [5] the lowest, considering that it has relatively few, simple parts, connected one-to-one linearly and therefore is the least complex of all 5 cases, and we scored case [3] the highest, considering that many parts of different shapes and sizes make up the mechanical, electrical, and plumbing (MEP) systems, all routed and tightly packed in the same overhead space. Table 1 reflects these scores and the scores given to the three other cases, but due to the 12-page restriction of this paper we could not spell out all our rationale in this write-up.

Supply chain complexity gauges the level of customization of construction materials. A score of 1 represents a project using mostly made-to-stock materials (not customized, simple, and readily available), whereas a score of 5 represents use of engineered-to-order materials (highly customized, complex, and procured with long lead times). We scored case [5] the lowest, considering that many of its parts are commodities and made-to-stock, and we scored case [4] the highest, considering that its parts are engineered-to-order to reflect the latest technological advancements, and that they are being supplied by geographically dispersed companies.

Uncertainty here measures, for example, the unpredictable nature of approval processes (e.g., permitting) and workers' ability to ascertain where (work locations) work can be performed in the short term (e.g., influenced by weather or other unforeseen subsurface conditions). A score of 1 indicates the least amount of uncertainty, whereas a score of 5 indicates the highest amount of uncertainty. We scored case [1] the lowest, considering the more routine nature of the work involved, and we scored case [4] the highest, considering the potential impact of weather and sea conditions on the project.

Dynamic complexity (often tied to uncertainty) relates to the flexibility planners have—based on project characteristics—to break down work into smaller chunks, divide work space into zones, and rearrange process steps. A score of 1 indicates planners have a high degree of flexibility in work structuring, whereas a score of 5 indicates minimal to no such flexibility. We scored case [2] the lowest, considering that work zones (cruise cabins) are independent from one another, and process steps can be rearranged to some extent, and we scored case [3] the highest, considering the interconnectedness and density of parts in MEP systems, which impose limits on how work can be broken down and what zones can be defined.

Pace (or speed) complexity evaluates the difficulty of adjusting the number of resources in a project, considering factors such as cost, availability, and required worker skills or equipment capabilities. A score of 1 indicates that it is relatively easy to adjust the number of resources, whereas a score of 5 indicates that it is challenging to do so. We scored case [1] the lowest and case [4] the highest.

Socio-political complexity refers to the context and environment surrounding the project, characterized by the influence of the voices of stakeholders and power dynamics among them, that ultimately impact the project. A score of 1 indicates a weak impact, whereas a score of 5 indicates a strong influence of stakeholders on the project and strong stakeholder interactions. We scored case [2] the lowest and case [5] the highest.

Organizational complexity measures the experience, skills, behaviors, and knowledge levels required for performing work within organizations involved in the project team. A score of 1 implies that work is relatively straightforward, whereas a score of 5 indicates that work requires more experience, skills, behaviors, and knowledge, as well as specialized processes and tools or equipment as needed to perform more demanding work. We scored case [2] the lowest and case [3] the highest.

Of note is that our discussions that resulted in these scores were based on comparing specifics of individual projects, rather than only their project type. Being specific is important because numerous flavors of complexity can be discerned among projects, even among those of the same project type.

To visually capture the assigned scores and use the complexity framework, we drew a radar diagram (Figure 1). The aim is to provide planners with insights into the diverse complexity profiles of different projects, informing the selection of what may be the most appropriate takt planning method for their project.

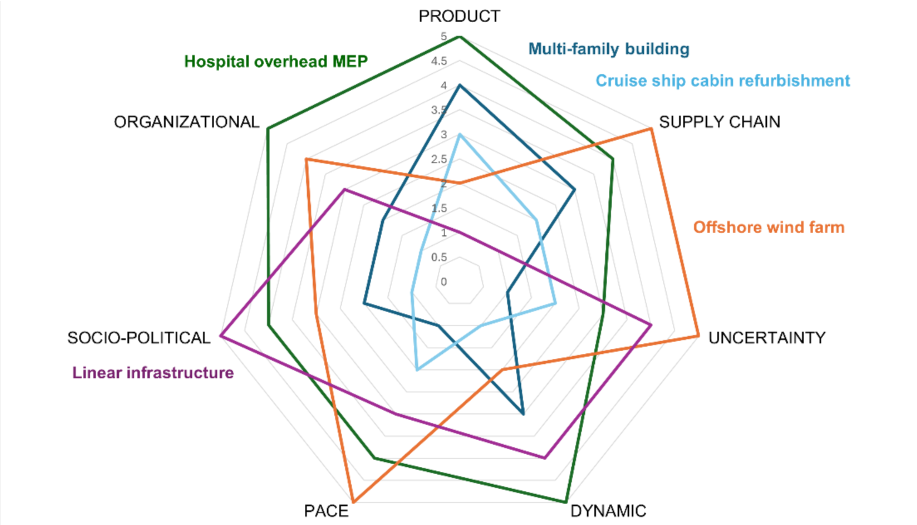

Figure 1: Radar Diagram Depicting Projects by their Dimensions of Complexity

TAKT PLANNING METHODS

The takt planning methods in use on projects around the world may be categorized as Methods A, B, C, and D. Method A is to define sequences of process steps and work zones a priori (i.e., before hiring trade specialists), typically based on some repetition in the physical product (e.g., rooms), and then use existing production data to compute the takt. An early promoter of a version of this method was Porsche Consulting (Gardarsson et al. 2019); Dlouhy et al. (2016, 2018) and Binninger et al. (2017) describe their own versions. This method of managing variability at the highest level of planning by creating a takt plan and then freezing it, while managing adaptations as needed at lower planning levels, applies to cases [1] and [2].

Method B is the Work Density Method (WDM) (Tommelein 2022). The method is to consider alternative work structures and develop work density maps showing how much time will be needed to perform certain scopes of work in different areas on site. It requires collaboration of the trades involved to decide on process steps, sequencing, and then zoning based on leveling of workloads (cumulative work density). This method applies to case [3].

Method C is to specify takt(s) and zones, but to defer deciding when to work in each zone until certain project uncertainties get resolved. This method is to define a hierarchy of locations, and exercise certain project control at each hierarchical level. It applies to case [5].

Method D stems from recognizing that certain resources have capacity constraints, i.e., they are bottleneck(s) in the system. The method therefore is to maximize the bottleneck's utilization and pace other work based on that (as is done in the Theory of Constraints). The other work can then be structured with its own takt (perhaps using one of the other methods mentioned), informed by the required pace. This method applies to case [4].

Looking at cases [1] and [2] in Figure 1 we see patterns of complexity that appear to be similar and we note that both projects used some version of Method A. This is also the method that we (based on our considerable expertise in takt planning) would recommend using for these projects. Similar analyses were conducted for Methods B, C, and D.

DISCUSSION

Takt planning enforces clarity and simplicity by defining small chunks of work, clearly delineating what is to be done where, when, and by whom and what the expectations are for the handoff to the next trade. However, different methods achieve these objectives in different ways. Based on our scoring of five projects using seven dimensions of complexity and the four takt planning methods as described, we see alignment between a project's scores according to these dimensions of complexity and the takt planning method selected.

Our findings are highly speculative at this time. However, further research may indicate that the proposed characterization of project attributes, thought to be relevant to takt planning according to certain dimensions of complexity, may help choose which takt planning method to deploy for a particular project or phase of a project. It may also become clearer in which circumstances it is appropriate to use location-based planning and control, yet not takt planning in full, or when takt planning is not a suitable method at all.

CONCLUSIONS

Various takt planning methods can be identified in the Lean Construction literature. No single method appears to be universally applicable to all projects. Our premise was that deciding which method to use requires consideration of the complexity and context of the project to be planned with takt. This paper started by describing the objectives pursued in takt planning and it listed references to illustrate the use of takt to plan projects of various types. The section that followed shed light on different dimensions of project- and contextual complexity, and outlined various project characteristics that are relevant to takt planning.

The extension of Geraldi et al.'s (2011) complexity framework to the context of construction- and takt planning offered a practical approach to assess project complexity based on seven dimensions. The authors scored different projects based on their product- and supply chain complexity, uncertainty, dynamic complexity, pace complexity, socio-political complexity, and organizational complexity. The scores depicted in a radar diagram indicated differences between projects that helped to rationalize why one takt planning method or another might have been used on a certain project. This rationalization can inform planners when choosing a suitable takt planning method, considering the unique characteristics and challenges posed by each project. Follow-on research will describe each project in more detail regarding its dimensions of complexity and how the takt planning method was formulated, so that the matching of complexity with the appropriate takt planning method can be refined.

ABSTRACT

The construction industry is a critical sector in the economy of countries; however, it has low productivity and is associated with errors and rework. In response, poka yoke or mistake-proofing devices have been developed to avoid errors or reduce the possibility of committing them. Their application has been documented in manufacturing and, to a lesser extent, in the construction sector, where the literature on this subject is scarce. Therefore, the following article aims to develop a literature review of poka yoke in the construction sector. To this end, a literature review was conducted using PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis). Twenty-five articles related to poka yoke were analyzed. From the literature review, it was obtained that the main poka yoke found corresponds to the principle of facilitation; the main benefits reported were improvement of quality and performance and reduction of errors, and the main barrier is the lack of training on the subject. The following article will contribute to professionals and researchers in the construction sector to have a better understanding of the applications of poka yoke.

KEYWORDS

Poka yoke, mistake-proofing, Lean Construction, PRISMA

INTRODUCTION

The construction industry is critical for economic strengthening and unemployment reduction (Bajjou et al., 2017). However, it faces significant challenges due to low productivity (Widjajanto et al., 2020), cost overruns, and low quality (Ramírez et al., 2021), among others. Challenges in the construction industry are often caused by errors during construction, making construction defects the main concern (Hosseini et al., 2012). Errors in the construction industry

manifest themselves at various project stages, from planning to maintenance, affecting financial, safety, and human life aspects (García et al., 2015). These errors can be related to higher levels of the organization, such as problems in design, poor specifications, inadequate control and supervision, and a lack of specialization or training in the workforce (Peralta & Serpell, 1991). Others may be associated with operational work, such as incorrect proportions of water in mortar preparation (Dos Santos & Powell, 1999) and failures in construction machinery (Bashir et al., 2011).

To counteract errors, a technique called mistake-proofing or poka yoke generated in Japan was developed to help reduce errors in the manufacturing industry through devices (Shingo, 1986), and has been successfully applied in other industries, including the Architecture-Engineering-Construction industry (Tommelein, 2019) and has been shown to have multiple benefits in this industry, such as variability reduction, quality improvement, work safety (Baijjou et al., 2017), reduction of rework, production of more added value, improved productivity and increased customer satisfaction (Zavichi et al., 2010). Despite the benefits shown in the literature, no previous literature review study on poka yoke in the construction industry has been recorded. That is why the following article aims to review articles recorded in the literature and evaluate the types of poka yoke and the benefits and barriers to construction projects.

BACKGROUND

POKAYOKE IN CONSTRUCTION

Although poka yoke has its origins in the manufacturing industry, its use in construction is also possible (Tommelein, 2019). Koskela (1992), is one of the pioneers in mentioning the term poka yoke in the construction industry, where he proposes poka yoke as an alternative to reduce variability and thus avoid performing activities that do not generate value. Then, Dos Santos & Powell (1999) show its application in 6 construction projects in England and Brazil, showing benefits such as: reduction of variability and improvement in the quality of the final result. Also, Tommelein (2008) mentions the application of poka yoke in the design stage, which consists of using different colors for the walls of a design plan, to denote that they are different and thus avoiding a mistake at the time of construction.

In addition, in Chile, Zavichi et. al (2010) propose a poka yoke device for the transport of materials between floors of buildings to reduce accidents. One of the guides that proposes many poka yoke devices is the one developed by Tommelein and Demirkesen (2018), where different poka yokes applied in the construction industry are compiled. Also, Tommelein and Yiu (2022) present several examples of poka yoke devices that seek to solve problems such as manual welding and measurement errors.

POKAYOKE PRINCIPLES

Tommelein (2019) states that the error-proofing methodology, known as Poka Yoke, is based on six principles: eliminate, prevent, replace, facilitate, detect and mitigate. These principles are organized according to the degree of desirability of error correction, from the most preferable to the least desirable, but no less valuable. When scheduling an operation before its initiation, the risks associated with the steps that make up the operation and their possible consequences are identified. Subsequently, their possible occurrence is "designed" to avoid them altogether.

The 6 types of poka yoke set out in Tommelein and Demirkesen (2018) will be explained below:

1. Eliminate: Eliminate involves eradicating the probability of an error occurring in a specific task, step, or sequence of operations by reconfiguring the product or operation so that the task (or associated part of the product) is no longer required. Zavichi et. al (2010) exemplify the removal of scaffolding in the construction industry, proposing the use of elevators with appropriate protective measures instead of scaffolding to ensure worker safety.
2. Prevent: Preventing involves designing and engineering the product or operation in such a way that no individual can make mistakes. Tommelein and Demirkesen (2018) present an example related to junction boxes in electrical installations, expressing concern about the possibility of faulty connections and the risks associated with the work at the height required to wire luminaires. As a poka yoke measure, they propose the installation of clips on each luminaire during the wiring process in a workshop environment. These clips, being designed to fit in only one way (asymmetry), ensure that the cables are always connected correctly. This practice significantly reduces the time required for overhead installation by electricians.
3. Replace: Replacing consists of substituting a task with a more reliable alternative to improve consistency. Tezel et al. (2010) give as an example a device that can virtually eliminate the need for statistical process control. They allow self-inspection in repetitive tasks by the line operator (which requires some vigilance and memory) by preventing errors using relatively simple and inexpensive mechanical, electrical and visual mechanisms.
4. Facilitate: Facilitate implies the use of resources to simplify the execution of a task, making it more affordable. Bajjou et al. (2017) provide a representative example of how water addition is commonly performed manually during mortar production without any strict control, which affects mortar quality, thus proposing strict monitoring of the added measurement as poka yoke.
5. Detect: Detect involves the quick identification of an error to correct it before it becomes a defect. Tezel and Aziz (2017) propose sensors in work helmets that vibrate or emit a sound to alert the worker of a work hazard.
6. Mitigate: Mitigate consists of using resources to minimize the impact of an error, especially in critical construction projects. Hosseini et al. (2012) provides an illustrative case where one of the critical errors in reinforcement operations involves improper delivery, cutting or bending of reinforcing bars. To prevent such errors, they propose a poka yoke method that involves coloring the ends of the tied bars, thus reducing the possibility of misuse.

METHODOLOGY

In the following research, a literature review was conducted on the application of the Poka Yoke method in construction projects using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology. The PRISMA method has been used previously in Lean Construction literature reviews such as the study conducted by Erazo et al. (2023) in which after collecting data under the PRISMA method they conducted their research on the benefits of applying Lean Construction, during the pandemic era. In addition, Lee et al. (2022) mention that this type of review facilitates the authors to become familiar with the primary knowledge retrieved in the selected articles thus developing a research model through a solid approach, thus exploring future research directions with greater precision.

For the literature review, a search for publications related to the application of Poka Yoke in construction was conducted using Scopus, the IGLC database and the Web of Science database. This because Scopus is one of the databases with a wide domain in research on the topic of construction compared to other databases (Galaz et al., 2021); IGLC hosts most publications on the application of Lean Construction worldwide (Daniel et al., 2015); and Web of Science because it is one of the most recognized international multidisciplinary references (De Filippo, 2013).

In the first identification phase, the search was performed using 9 keywords from year 1998 to 2024, because the first paper that addresses poka yoke in construction is (Dos Santos et al., 1998). The keywords and their combinations are shown in Figure 1. Likewise, 112 results were obtained based on all the keywords. For the next phase of eligibility, after having the combinations of articles found from I to XXIV, 61 duplicate publications were eliminated from the reviewed articles and relevant articles were filtered for evaluation. A total of 33 articles were excluded through title and abstract review, articles were excluded because they were considered not to refer to the application of Poka Yoke in construction projects or were far from the topic in question. A total of 18 articles were left, which, in the next phase of exclusion, were filtered again through a complete reading, thus excluding 6 articles that did not meet the criteria to be considered in this study: They do not mention at least one application of any of the 6 types of Poka Yoke in construction projects, and 13 articles belonging to snowball were added because they were centrated in the topic showing at least one application of Poka yoke in construction, leaving a total of 25 articles that were considered for this research.

The above steps are described in Figure 1.

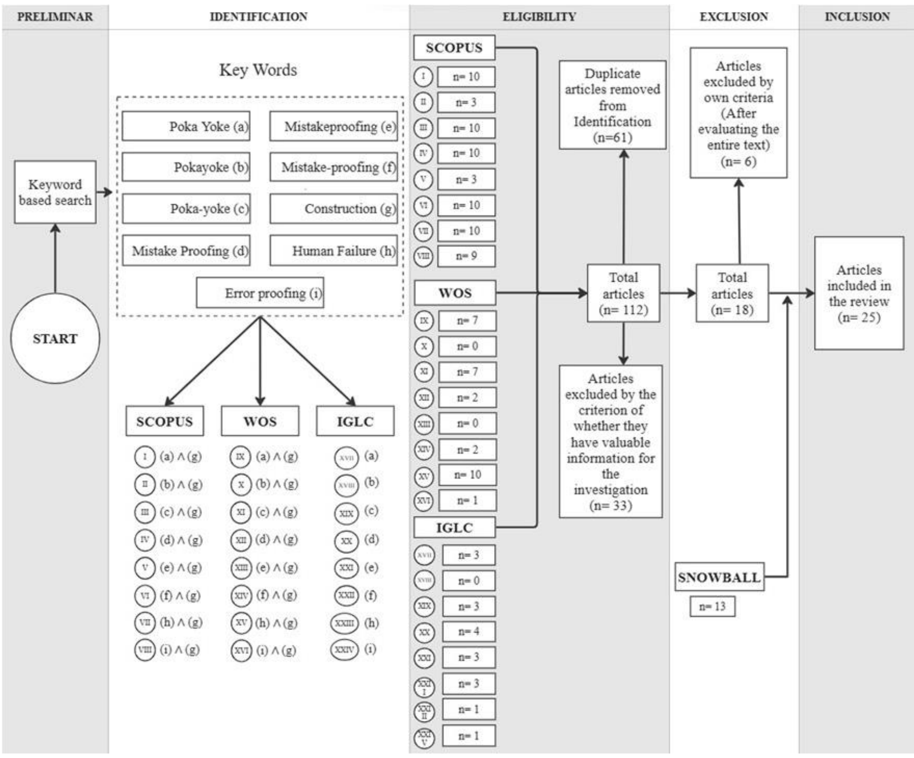

Figure 1. PRISMA flow diagram for the systematic review.

RESULTS AND DISCUSSION

PUBLICATIONS BY YEAR

In this section, the publications by year were divided into two graphs in Figure 2, an initial one where the number of articles per year is shown, and another one with the accumulated graph of poka yoke publications over time.

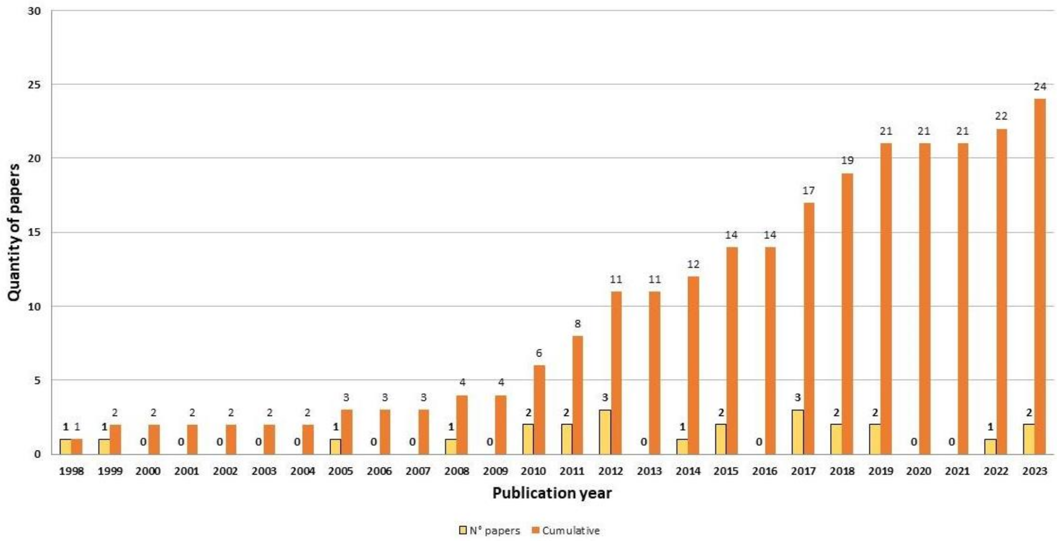

Figure 2. Number of poka yoke application papers in construction and their cumulative quantity vs year of publication.

From Figure 2, the first article dedicated to poka yoke, according to the review, was prepared by Dos Santos et al. (1998). This article explores the concept of Poka Yoke in the implementation of the principle of transparency in the construction sector. In this context, the use of an elevator control board is described as it prevents the elevator from moving if the door is open, thus constituting a PREVENT type of poka yoke. Later, in the following year, Dos Santos & Powell (1999) published an additional article, focusing exclusively on Poka Yoke devices under construction, being pioneers in addressing this topic in depth in this industry.

Between the years 2000 and 2009, there was little research on the topic, since only two articles were registered in that period: the research by Marosszeky et al. (2005) focusing on the use of quality control mechanisms to improve workflow reliability, and the article by Tommelein (2008) detailing the application of poka yoke in the manufacturing industry construction, providing a variety of examples and detailing different poka yoke devices. This work generated an increase in the production of research related to poka yoke, as reflected in the graph.

From 2010 onwards, a greater number of publications related to poka yoke in construction have been observed, addressing different topics such as: improving productivity in construction (Sadri et al., 2011), total quality management (Laguna et al., 2014), its relationship with Six Sigma (Vinod et al., 2015), safety (Bajjou et al., 2017), variation reduction in construction projects (Uhanovita et al., 2023b), among others.

Although the publications have been analyzed by year, Figure 2 also shows the cumulative analysis of publications. It is observed that until 2010, publications have been limited to slow growth. However, in the period from 2010 to 2020, there has been a significant increase in publications, going from 6 articles to 21 articles in 2020. This increase is attributed to the contributions of Tommelein (2008) and Zavichi (2010), who exhaustively explored the benefits of using Poka Yoke in the construction industry and provided various examples in their articles.

Likewise, as of 2020, 5 articles have been registered. In that sense, from the graph we can notice that there is a growing interest in the application of poka yoke and poka yoke principles in construction projects.

CLASSIFICATION OF POKA YOKE TYPES

In Table 1, the reviewed articles have been classified according to the 6 types of poka yoke presented in Tommelein & Demirkesen (2018):

Table 1: Number of examples of poka yoke principles found in the review.

Id	Principles	Examples in literature	Number of references	References*
P1	ELIMINATE	15	6	1, 3, 4, 5, 9, 11,16
P2	PREVENT	20	17	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 15, 16, 18, 22, 23, 24
P3	REPLACE	12	8	2, 3, 4, 6, 11, 16, 19, 23
P4	FACILITE	30	13	1, 2, 3, 4, 5, 7, 11, 14, 15, 16, 20, 23, 24
P5	DETECT	17	12	1, 2, 5, 6, 7, 11, 12, 15, 16, 17, 21, 24
P6	MITIGATE	14	8	4, 5, 11, 13, 16, 19, 24, 25

*1. (Zavichi et al., 2010), 2. (Tommelein, 2008), 3. (Uhanovita et al., 2023a), 4. (Tommelein & Yiu, 2022), 5. (Tommelein, 2019), 6. (Rubio et al., 2019), 7. (Bajjou et al., 2017), 8. (Schmidt, 2013), 9. (Dos Santos & Powell, 1999), 10. (Dos Santos et al., 1998), 11. (Tommelein & Demirkesen S., 2018), 12. (Bajjou et al., 2017), 13. (Bashir et al., 2011), 14. (Hosseini et al., 2012), 15. (Laguna et al., 2014), 16. (Marosszeky et al., 2005), 17. (Mollo et al., 2018), 18. (Saurin et al., 2012), 19. (Tezel et al., 2010), 20. (Tezel & Aziz, 2015), 21. (Tezel & Aziz, 2017), 22. (Vinod et al., 2015), 23. (Sadri et al., 2011), 24. (Uhanovita et al., 2023b), 25. (Mollo et al., 2019)

From Table 1, the poka yoke principle most frequently cited in the literature for its application in the construction sector is the FACILITE (P4) principle, which was found in 13 articles and 30 examples of this type of poka yoke. Tommelein (2019) mentions that this principle is one that AEC practitioners tend to use the most because it is not a principle that consists of poka yokes designed to avoid errors. For example, Tommelein (2008) addresses design quality in construction systems and mentions examples of FACILITE type poka yoke, such as color coding for different types of walls on plans. Hosseini et al. (2012) discuss the implementation of Lean Construction in the Waste Management of construction processes and provides an example of FACILITE type poka yoke, which consists of coloring the end of grouped bars to prevent improper cutting or bending.

In second place in terms of mentions is the PREVENT (P2) type principle, where 17 related articles and 20 examples of this type of poka yoke were found. Tommelein (2008) provides two examples that belong to the PREVENT type, thus representing most of the examples identified in the present study. Examples of PREVENT type presented include the use of a connection plug to ensure proper wiring and the use of a sealant and return leg to ensure proper performance of the ceiling panels. Furthermore, Tommelein and Yiu (2022) point out an additional example of the PREVENT type, where CIVIL 3D software is used to link a 3D model with a 2D plan and prevent design mismatches and errors. On the other hand, Rubio et al. (2019) mention a specific example of the application of poka yoke, which consists of the use of safety railings to prevent falls from heights, also being an example of the PREVENT type.

The DETECT (P6) principle is documented in 12 references in the literature and 17 examples were identified in the analyzed articles. One of these examples consists of the implementation of an RFID detection system, which activates an alarm when an unauthorized worker accesses a dangerous area (Rubio et al., 2019). Additionally, another example is illustrated that involves the use of a dynamic information panel, which workers update in case of errors to alert their colleagues. Likewise, the use of understandable Squirter DTIs washers is mentioned, which indicates when a bolt reaches its target tension and becomes functional (Tommelein, 2019).

From Poka yoke principle of ELIMINATE (P1), 15 examples were found in 6 references. For example, Zavichi et. al (2010) provide as an example the change from the traditional work method (use of scaffolding) to a safer and more efficient alternative (use of an elevator with sufficient protection), this eliminates the possibility of errors or accidents associated with the use of scaffolding. and improves worker safety. Uhanovita et al. (2023b) illustrate some examples of ELIMINATE type poka yoke, among which is ensuring that the detailed designs provided to bidders are clear, precise and complete, as this would help avoid misunderstandings and errors during the pricing process and tender. Dos Santos and Powell (1999) illustrate an example of ELIMINATE by proposing an implementation of electronic and mechanical devices to avoid errors in the manual addition of water during mortar production, guaranteeing quality and efficiency on the job.

The MITIGATE (P6) principle was the second with the fewest examples that the literature provided, with only 14 examples in the literature in 8 references. Examples include the use of PPE to reduce the impact in the event of accidents that occur on site (Bashir et al., 2011), the use of SawStop saws which detect the moment in which human skin comes into contact with blade making it instantly hidden and thus causing the least possible damage to the user (Tommelein, 2019), the creation of protrusions with some nails on the heads of the tubes for a more precise installation, thus mitigating the possibility of incorrect installation (Tezel et al., 2010).

The REPLACE principle was the one with the fewest examples found, with only 12 examples in 8 references. Tezel et al. (2010) suggest an example of REPLACE-type poka-yoke, which is manifested through the implementation of adjustable metal struts designed to hold the benches in place during the construction process, replacing traditional struts to improve precision, safety and productivity in the work environment. Tommelein and Demirkesen (2018) propose a REPLACE-type poka-yoke to address the concern of potential worker falls from the edge of the roof. The solution involves installing a parapet along the perimeter as part of the permanent structure. This measure not only improves safety by mitigating the risk of falls, but it also replaces temporary protection, generating economic benefits throughout the life cycle of the building. Rubio et al. (2019) suggest dynamic information panels such as poka-yoke to improve static signs on construction sites, providing updated safety information and allowing remote updates by workers and the safety manager.

There are also potential poka yokes that are based on a combination of principles. For example, Tommelein (2008) mentions that design specialists use a color code as a type of pokayoke that facilitates and prevents. It prevents in the sense that they use it for their specific work and phase of a project to avoid confusion. And, it facilitates because color coding can be used to distinguish various types of walls, which makes it easier to clarify and categorize specified design requirements and helps better organize planning and cost.

BENEFITS AND BARRIERS OF ITS ADOPTION

In this section, the barriers and benefits that poka yoke generates in construction projects are described, which is why two summary tables have been developed: Table 2, where the benefits of poka yoke are seen, and Table 3, with the barriers found in the literature.

Table 2: Benefits of poka yoke in construction.

Id	Benefits	Absolute frequency	Relative frequency (n=45)	References*
B1	Improves quality and performance	8	17.78%	1,2,3,4,5,6,7,8
B2	Reduction of errors	8	17.78%	2,7,9,10,11,12, 13,14
B3	Reduction of rework	5	11.11%	6,9,10,15,16
B4	Reduction of time	3	6.67%	3,9,17
B5	Improves efficiency and minimizes resource usage	3	6.67%	3,13,20
B6	Continuous flow	3	6.67%	18
B7	Better customer satisfaction	2	4.44%	7,18
B8	Low investment cost	2	4.44%	10,18
B9	Reduction of variability	2	4.44%	3,8
B10	Reduction of interference	2	4.44%	7,19
B11	Improves profitability	2	4.44%	11,15
B12	User-friendly	2	4.44%	8,11
B13	Personnel reduction	1	2.22%	1
B14	Reduction of incompatibilities	1	2.22%	1
B15	Improves safety	1	2.22%	3

*1 (Tommelein & Yiu, 2022), 2 (Tommelein, 2019), 3 (Bajjou et al., 2017), 4 (Marosszeky et al., 2005), 5 (Tezel & Aziz, 2017), (Sadri et al., 2011), 7 .(Burlikowska & Szewieczek, 2009), 8 (Dos Santos & Powell, 1999), 9. (Zavichi et al., 2010), 10. (Tommelein, 2008), 11. (Bashir et al., 2011), 12 (Hosseini et al., 2012), 13. (Tezel & Aziz, 2015), 14 (Tezel et al., 2010), 15 (Laguna et al., 2014), 16 .(Li & Liu, 2016), 17 .(Bajjou et al., 2011), 18 .(Uhanovita et al., 2023a), 19 .(Dos Santos et al., 1998), 20 .(Saurin et al., 2012).

From Table 2, 15 benefits were identified from the literature, where the two main benefits were found with a frequency of 8 articles, which are “improvement of quality and performance” (B1) and “reduction of errors” (B2). Benefit B1 refers to the improvement in worker performance and processes. Uhanovita et al. (2023a) mentioned that Poka Yoke provides the opportunity to increase your ability to carry out a quality construction process, reducing variations that allow the parties to work collaboratively and help increase productivity and project success. Likewise, they also recommend that before starting the design stage, the requirements of the end users must be identified through the Poka-Yoke principles, and after that, the projects can be completed without variations in the stage. construction increasing productivity.

Benefit B2 is equally often about “reduction of errors” (B2), maintaining the idea that errors decrease thanks to the timely detection of their cause and in some cases preventing them from occurring. The goal of error reduction is to achieve a better system by avoiding more defects in the product and process by eliminating waste, trying to reduce variation, and not tolerating poor quality (Tommelein & Demirkesen S., 2018). For example, Marosszeky et al. (2005) mentioned that thanks to the implementation of Poka Yoke, the possibility of changes in requirements can be prevented in the design stage since the client must be given a complete idea about the design and once the client realizes Depending on the form, type and functions of the construction project, design changes and identified requirements will not arise during the construction phase.

The third most cited benefit is the “reduction in rework” benefit (B3), which has a positive effect since it prevents the error from getting worse. Through poka yoke, unnecessary use of personnel to correct an error can be avoided, which has the benefit of a “reduction of time” (B4), a “continuous flow” (B6) and a “personnel reduction” (B13). By avoiding the production of a defect in the product with a better one with no defect and in a shorter time, it produces “Better customer satisfaction” (B7). Moreover, the implementation and development of these mechanisms have a “low investment cost” (B8).

The use of these mechanisms produces a “reduction in variability” (B9) and a “reduction in interference” (B10). The reduction in errors, time, rework, interference and variability produces “improves efficiency and minimizes resource usage” (B5) which produces “improved profitability” (B11). Furthermore, poka yoke mechanisms often are “user-friendly” (B12).

On the other hand, Table 3 shows the 9 barriers obtained from the literary review of poka yoke.

Table 3: Poka yoke barriers in construction.

Id	Barriers	Absolute frequency	Relative frequency (n=10)	References*
C1	Lack of training	2	20%	5,6
C2	Uncertainty in the nature of construction	1	10%	3
C3	Tool immaturity	1	10%	5
C4	Resistance to change	1	10%	5
C5	Difficulty in identification	1	10%	1
C6	Lack of consensus	1	10%	2
C7	High investment cost	1	10%	5
C8	On-site work pressure	1	10%	5
C9	Limited research	1	10%	4

*1. (Tommelein & Yiu, 2022), 2. (Tommelein, 2019), 3. (Rubio et al., 2019), 4 .(Dos Santos et al., 1998), 5. (Uhanovita et al., 2023a), 6. (Tezel & Aziz, 2017)

The literature on barriers to implementing poka yoke in construction is sparse compared to the manufacturing industry, where detailed studies have been conducted, such as (Lazarevic et al., 2019), which identified obstacles such as high costs and lack of training. In construction, the review shows that most of the barriers are derived from the study of Uhanovita et al. (2023a) on the construction industry in Sri Lanka.

The most cited barrier is "Lack of Training" (C1), indicating that there is little knowledge about poka yoke and its benefits in the works. Tezel and Aziz (2017) highlighted the importance of management being well-trained for successful implementation. Given the uncertain nature of construction, identified as the "most uncertain industry" (C2) due to its unique characteristics (Ilyas & Ullah, 2019), it becomes a barrier as it implies a continuous change in the conditions of risks and defects in construction (Rubio et al., 2019).

The barrier "Lack of maturity of the tool" (C3) refers to the professionals' perception that poka yoke is a new tool, generating fear of not obtaining good results (Uhanovita et al., 2023a). "Resistance to change" (C4) is also observed, as in other lean tools such as LPS (Alarcón et al., 2002), indicating that professionals are reluctant to abandon traditional work practices.

CONCLUSIONS

From the present research, it was noted that the literature regarding poka yoke has increased in the last 10 years, due to greater research and interest in the topic of reducing errors. Likewise, it has been observed that one of the most used principles is facilitate, followed by prevent, and noticing few applications in mitigate and replace. Furthermore, the main benefits of using poka yoke devices have been improvement of quality and performance, and reduction of errors; and also, barriers to its use have been observed such as: lack of training, construction uncertainty, immaturity of the tool, among others. The authors recommend exploring the adoption of new technologies such as poka yoke devices and conducting workplace studies that will identify a greater number of poka yoke devices, identify the benefits observed in the field, and explore the barriers associated with their implementation on site. of construction.

ABOUT TIME-COST TRADE-OFFS IN TAKT PLANNING

Iris D. Tommelein[1]

ABSTRACT

Time-cost trade-off problems in construction scheduling are well known and described in the literature, but time-cost trade-off problems pertaining specifically to takt planning have received little attention to date. Previous papers have introduced concepts and applications of takt planning (aka. takt production) in construction. They addressed production systems design questions and presented various takt planning methods. Quite a few of those papers also mentioned how takt planning helps cope with variability that is known at the time of planning and with the manifestation of variability when it is encountered during plan execution. Coping methods include the use of capacity- (people and their means of production), materials- (inventory), space-, and time buffers. These buffers—and of course money too (financial buffers or contingencies)—come at a cost. This paper explores various costs to be considered in the takt planning process and it presents trade-offs that can be made to meet selected objectives. The goal is to initiate discussion on this topic and help spur further quantification of the advantages of using takt when designing project production systems.

KEYWORDS

Takt planning, buffers, slack, direct cost, indirect cost, fixed cost, variable cost, cost management, buffer management.

INTRODUCTION

While time-cost trade-off problems in construction scheduling have been studied extensively for many decades, time-cost trade-off problems pertaining specifically to takt planning have received little attention to date. To investigate the latter, this paper revisits the assumptions that underlie basic time-cost trade-off formulations and then scrutinizes those assumptions in light of the application of the lean concept "takt" used in the development and control of construction schedules. Note that the terms planning and scheduling are used interchangeably in this paper.

This conference paper is not a formal literature-review or research-based paper but rather a white paper reflecting the author's thoughts on time-cost trade-offs in takt planning. Essential parts of a formal study (e.g., an in-depth literature review) are therefore not included here but deferred until a later time. A white paper is meant to be thought provoking.

This paper is structured as follows. First, the literature section describes the basic formulation of the time-cost trade-off problem in construction scheduling. It then describes key concepts pertaining to takt planning in construction. The body of the paper elaborates on tangible and intangible time-cost benefits of takt planning. This is followed by a discussion on time-cost trade-off considerations, and conclusions with recommendations for further research.

LITERATURE

TIME-COST TRADE-OFFS IN CONSTRUCTION SCHEDULING

The time-cost trade-off problem in construction scheduling has been studied since the early days of the critical path method (CPM) (e.g., Kelley 1961) and has become a fundamental topic in project management textbooks (e.g., Ch. 10 in Harris 1978, Ch. 11.4 in Hendrickson et al., 2024). Numerous variations of this problem have since been formulated, based on different assumptions with resource- and other constraints added, and using various mathematical programming- or heuristic optimization methods.

The problem is formulated by means of activities networked using precedence relationships (e.g., finish-to-start links) to make up a construction schedule (essentially a directed graph). Each activity is given a duration (e.g., modelled using a deterministic value). Each activity comes at a cost (e.g., also a deterministic value) in function of what it takes to perform the associated work using a certain resource allocation (workers with tools, equipment, materials, etc.) so that the activity can be completed within the specified duration with reasonable certainty. By definition, direct costs of an activity are costs that would not be incurred if the activity were removed from the schedule. A (piecewise) linear relationship is assumed between the so-called normal duration at the normal cost of an activity and its crashed duration (shorter than the normal) at the crashed cost (higher than the normal).

Given the network's precedence relationships and activity data, the project's direct cost and duration defined by the so-called critical path(s) can then be computed. An activity is said to be on the critical path—it is a so-called critical activity—when, if delayed in finish time, the entire project would be delayed. A critical activity has no float.

Starting from the normal duration and normal cost for each activity, the project duration can be shortened while its direct cost will increase. A heuristic method for doing so is to stepwise shorten the duration of the critical activity (or several critical activities in parallel) that is the least costly to shorten. For example, the order in which to crash activities shown in Table 1 is F, C, C, B and C, A, and finally B and C.

Table 1: Example activity network with time- and cost data (Tommelein 2023)

Activity	Finish-to-Start Predecessor	Normal Duration [days]	Normal Cost [$]	Additional Cost/Day Shortened [$/day]	Minimum Duration [days]
A	-	3 days	$1,800	$800/day	2 days
B	A	4 days	$2,000	$200/day	2 days
C	A	5 days	$1,000	$150/day	1 day
D	C	1 day	$400	--	1 day
E	A	3 days	$1,500	$500/day	1 day
F	B, D, E	2 days	$700	$100/day	1 day

In addition to direct costs, projects also incur indirect costs. Sometimes called general conditions costs, these are not straightforward to attribute to only one or a few activities, but instead are more related to the project as a whole (e.g., the costs of project supervision, gate access and fencing around the site, provision of temporary utilities). They tend to accrue in direct relation to the duration of the project and are typically modelled as a linear function of time, expressed as cost per time unit (e.g., $300/day). Accordingly, they decrease (or increase) with the decrease (or increase) of the project duration. A project's total cost is the sum of its direct- and indirect costs.

Figure 1 depicts the direct- and indirect costs for different durations of the project. It shows that the plot of the project's total cost vs. time—called the time-cost trade-off curve—may exhibit a minimum rather than steadily increase or decrease. That minimum total cost point is the optimum duration for the project (indicated on Figure 1 at 8 days and $10,200) in the sense that the project will cost more when scheduled to be of any other duration, longer or shorter.

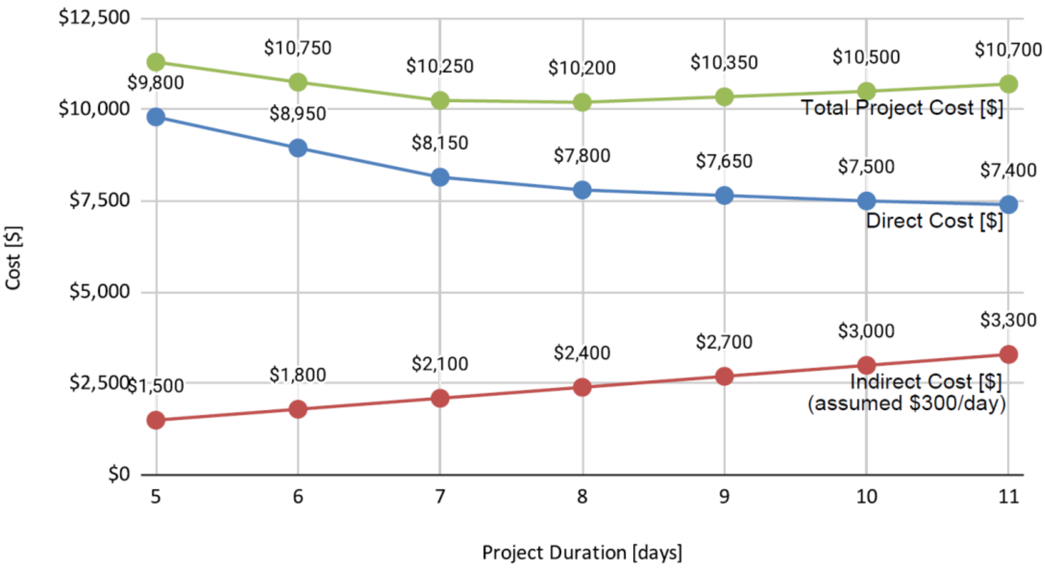

Figure 1: Time-cost trade-off in CPM scheduling (Tommelein 2023)

Note that the classification of a cost as direct or indirect depends on one's point of view and choices informed by the commercial terms of a project, including the cost accounting system in use. Figure 2 illustrates contributors to a company's and its projects' direct- and indirect costs. General and administrative (G&A) expenses are direct costs for the company, i.e., if the company did not exist, these costs would not be incurred. As they must be paid for in some way, they may be treated as indirect costs by accounting for them as an overhead charge on each project the company performs (e.g., as a percentage of a project's direct- plus indirect costs).

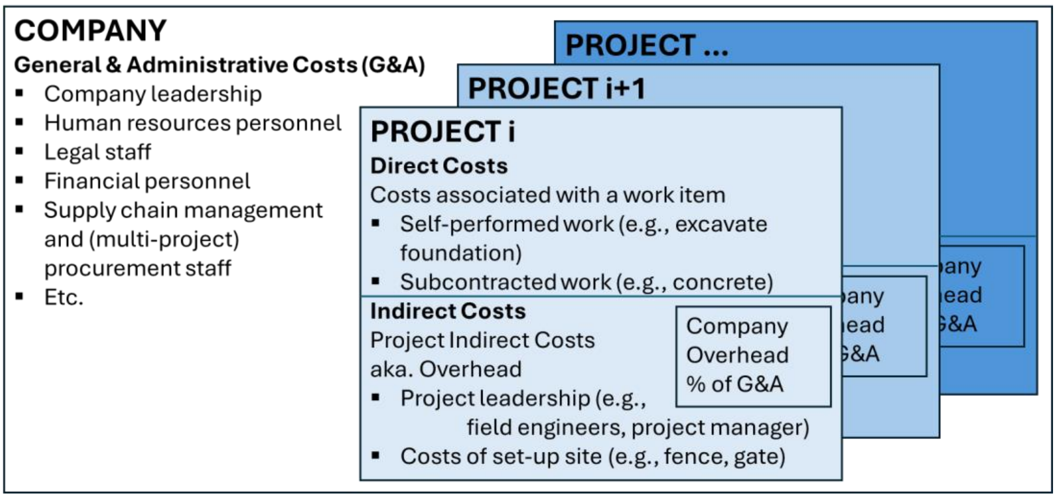

Figure 2: Contributors to direct- and indirect costs for companies and their projects (Tommelein 2023)

With this basic description of the time-cost trade-off problem and cost-related definitions pertaining to construction schedules in general, we next focus on takt planning, before we get into time-cost trade-offs related to takt plans (aka. takt schedules), a specific type of construction schedules.

TAKT PLANNING (AKA. TAKT PRODUCTION)

Practitioners and scholars alike have taken interest in defining a takt when planning construction processes (e.g., Frandson et al., 2013; Linnik et al., 2013; Heinonen & Seppänen 2016; Dlouhy et al., 2016, 2018; Binninger et al., 2017; and Lehtovaara et al., 2019). Despite this interest and the occasional mention of cost in takt-related papers (e.g., Vatne & Drevland, 2016), time-cost trade-offs problems pertaining specifically to takt planning have received little attention to date. In fact, a search for “time-cost” in papers posted on IGLC.net identified only a single one (O'Brien et al., 1997). It pointed out that the basic time-cost trade-off problem formulation ignores capacity constraints (e.g., resource availability, resource utilization, and site conditions) encountered when a schedule gets accelerated or delayed. We were unable to locate any prior studies on the specific topic of time-cost as it relates to takt planning.

In takt planning, the work to complete an entire construction project or a phase thereof is broken down into processes, with each process comprising steps arranged finish-to-start in linear order. The scope and sequence of these steps is decided while considering where work is to be done and avoiding trade stacking. Then the work space is divided into zones so that each step can be completed in each zone within the same, fixed amount of time, defined based on the duration needed to meet customer demand (T), aka. the “customer takt”. The work is structured so that only a single trade is working in any one zone at any given time while aiming to achieve continuous flow (e.g., Formoso et al., 2022).

Flow (i.e., a smooth progression of something, said to be “continuous” when there are no interruptions) manifests itself in multiple ways (Tommelein et al., 2022) which can be measured (e.g., Singh et al., 2020; Singh and Tommelein, 2023a, 2023b), e.g., (1) When a step is completed in one zone, the succeeding step of the same process can start there, and (2) At the same time, the trade that completed their work moves to start work in the next zone, etc. Thus, trades flow from one location to the next (Tommelein et al., 2022 called this “trade location flow”) and work in each zone gets done in the process order of successive steps (“process location flow”).

By creating concurrency of steps, the project can be completed faster than it would be otherwise (Figure 3). The cost for shortening the schedule duration will be a function of the trade location flow, process location flow, and many other metrics, and their costs. Using these, takt planners can then make trade-offs as needed to balance the degree to which they can meet their objectives.

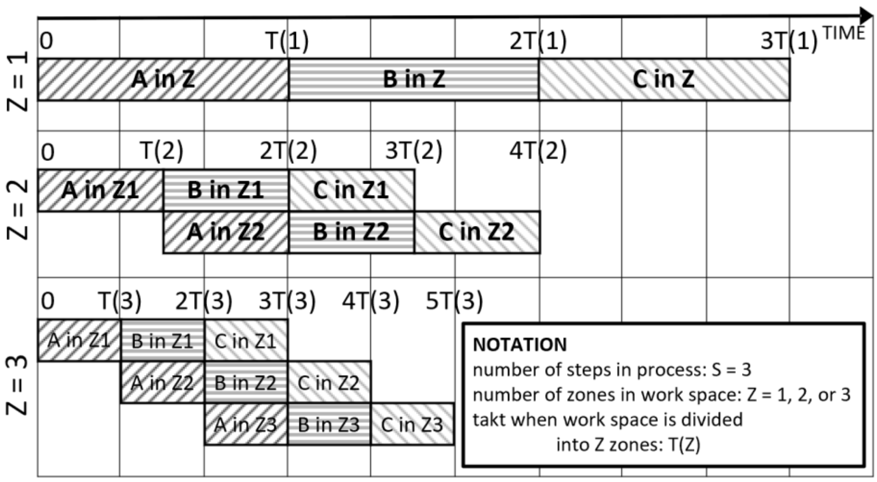

Figure 3: Duration of 3-step process (steps A, B, and C) when the work area

is divided into respectively 1, 2, and 3 zones Z (after Figure 1 in Jabbari et al., 2020)

Because workloads will exhibit some variability, any individual workload (i.e., the actual time needed by a trade to complete a certain scope of their work in a given zone) should be less than the time T allotted. How much less is a function of a workload's variability: trades must reasonably ensure that each step-worth of work will be completed by time T. This ensurance is obtained by underloading resources and thereby creating a capacity buffer, i.e., by scheduling resources to work below 100% utilization. The use of right-sized capacity buffers makes it possible to achieve plan reliability (Frandson et al., 2015).

In any case, at least one trade will have a workload greater than everyone else's and that is called the workload peak, aka. the "operational takt." The workload peak must be smaller than or at most equal to the time T allotted or the customer demand will not be met. As this workload peak is a function of the way zones are defined, it is labelled T(Z), with Z referring to a specific zoning of the space where work is to take place. Thus, the zoning and takt plan must be structured so that $T(Z) \leq T$.

Once the workload peak (possibly with an allowance to account for variability) of a process is known for a certain zoning of the work space, the shortest duration D of that takted process can be computed mathematically:

$$D = (S + Z - 1) \times T(Z) \quad \text{(Equation 1)}$$

where S is the number of process steps, Z the number of zones, and T(Z) the workload peak. An increase in the number of zones Z typically results in a decrease in the duration D, as zones get smaller in area and T(Z) tends to go down (up to a point, as noted in Jabbari et al., 2020).

Several methods exist to zone a work space. For example, as a tool to support the use of the Work Density Method (Tommelein 2017, 2022), Jabbari et al. (2020) described a mathematical algorithm, the Workload Leveling and Zoning algorithm aka. WoLZo. WoLZo uses a given distribution of workloads for each trade in the work space and the number of zones dividing the work space, to calculate the optimal boundaries for zones (constrained to be either rectangular or L-shaped), i.e., the zoning that results in the minimum operational takt T(Z).

Given this brief review of the literature on the time-cost trade-off problem and on takt planning, the following section opens the discussion about time-cost trade-offs in takt planning.

TIME-COST TRADE-OFF CONSIDERATIONS IN TAKT PLANNING

Float in a Takt Plan?

Now return to the basic description of the time-cost trade-off problem with solution methods that stepwise reduce the duration of one or several critical activities. Note that all steps in a takted process follow each other sequentially as in a Parade of Trades and they all are given an equal duration (Tommelein et al. 1999; Tommelein, 2020). Unless an explicit time buffer is incorporated in the process (e.g., a 1-takt delay, perhaps to allow for make-up work), there is no float from start-to-end of a process: all steps are critical. Time-cost optimization methods must therefore be rethought.

Indirect Cost when Shortening the Duration of a Process or Project

The argument may still hold, given the previously stated assumptions about overhead rates, that shortening the duration of a project will result in less indirect cost. Whether shortening the duration of a process (presumably one of several processes in a project) will also shorten the duration of the project depends on how that process fits into the project network.

We can extend the notion of criticality of an activity and identify critical processes in a project. However, it is common practice in takt planning to strategically include time buffers not only within- but also between processes to prevent any delays from reverberating through the schedule (Binninger et al., 2017). Teams pursuing takt planning must proactively manage their work to prevent a Parade of Delays (Dahlberg and Drevland, 2021) and should be cognizant of slack in their production system available to help them cope with unforeseen circumstances (Formoso et al., 2021). The practice of adding time buffers to a takt plan is similar in spirit to adding feeding- or project buffers to a schedule when using the Theory of Constraints (TOC) (Goldratt, 1990), or to adding a schedule contingency before the project completion date. When time buffers are added, then all processes have float.

Revisiting the assumption about the overhead rate, note that shortening a project or process by creating more concurrency in the schedule increases the schedule density (schedule density is a term used in construction claims; see for example Finke, 2000 or Ottesen and Hoshino, 2014). Otteson's (2019) thesis is that an increase in schedule density is a predictor for productivity loss. More activities underway in multiple locations at the same time and greater interdependence between them may result in greater complexity that in turn may require more managerial attention. Consequently, an increase in the need for managers could warrant an increase in the overhead rate.

However, the structure of the schedule, in and of its own, captures only a small part of the reality of a project. Team engagement and managerial practices play a role in project delivery! On takted projects, the shared understanding developed among trades during the takt planning process, and the visual- and structural clarity of the takted schedule (e.g., Figure 3) could be such that no additional managerial attention will be required when the schedule density increases. We speculate that research might even indicate that successful execution of a takt plan demands less managerial attention.

Cost of Shortening the Duration of a Process

The duration D of a process can be shortened in several ways, as indicated by the terms in Equation 1, namely by:

- Reducing the number of steps S in the process. This may be possible by moving work from one step to other steps (or combining steps) in the same process, by moving work to another activity or process step elsewhere in the project schedule, or by taking scope out from the on-site work and moving it off-site. A reduction of D in this way can either increase or decrease the project cost depending on capacity constraints (e.g., O'Brien et al., 1997), network characteristics, and the related economics.
- Increasing the number of zones Z to allow for more concurrency, if doing so indeed reduces T(Z) and has the effect of lowering D. The indirect cost implications in this case already were discussed in the previous subsection. As for the direct cost implications, in a first-order approximation, shortening the duration may be cost neutral as each trade's total amount of work and resources stay the same. In a second-order approximation, however, consideration must be given to costs stemming from work interruption or remobilization penalties. These are discussed later, in the subsection Cost of Logistics.
- Reducing work densities (e.g., by adding more resources) to lower the workload peak in a process, so that T(Z) can be lowered either in and of its own or by rezoning. Adding resources clearly comes at a cost. However, knowing which process step(s) essentially determine the workload peak also reveals which trade(s) in which zone(s) have a much smaller workload than others. These trades can use the process workload data to identify when and where they can slow down without jeopardizing the duration of the process. By assigning fewer resources, they can lower their cost while increasing their work density (not to exceed the workload peak) in certain or all zones. In combination, such cost changes due to increases and decreases in resources can have a positive or negative impact on the cost of the process.

When the workloads of all steps in a process are more-or-less balanced across trades and zones, resources presumably are used efficiently, and a near-continuous trade location flow and process location flow will be achieved.

Cost of Capacity Buffers (Underloading)

Whereas all steps in a takted process are critical, looking closer at the workload for each step in each zone it is noted that resources are underloaded. This is so by construction. Indeed, the intentional use of capacity buffers is what sets takt planning apart from other planning methods such as the Location Based Management System (Frandson et al., 2015). Underloading means that resources have a modest amount of extra capacity to do more work if needed, e.g., due to the manifestation of variability, and still finish each step on time. The whole point of takting a process (underloading resources at each step) is to allow handoffs to occur like clockwork, so as to prevent delays from occurring and impacting follow-on work.

Underloading comes at an increase in cost directly tied to a process step. Arguably, paying for intentional underloading is the greatest challenge to overcome when introducing takt planning to a team that is narrowly focused on productivity. Underloading brings benefits to the schedule, such as robustness, by creating slack time for trades to respond to disturbances encountered during plan execution.

Cost of Time Buffers within and between Processes

As was mentioned in the section on shortening the duration of a process or project, time buffers can be added anywhere in a takt plan, e.g., in or towards the end of a process, or in-between processes. Whereas all steps in a process are critical (they must be done within the takt), the process itself can be decoupled from preceding or subsequent processes by means of a buffer, and thus at that level have float.

While the use of a time buffer itself may appear to be free (a no-cost option), the buffer may extend the project duration and therefore result in an increase in indirect costs. Time buffers can also cause resources to be idle, having to wait for work, resulting in increased direct- or indirect costs depending on how the accounting is done. Trades involved in takt planning must duly consider how to use their time on site waiting until the next zone becomes available, e.g., by judiciously creating learning opportunities or workable backlog, in order to avoid otherwise unproductive wait times.

Cost of Space Buffers

Like time buffers, space buffers may appear to be free (a no-cost option), but that is not the case. They indicate a wasted opportunity to complete a process faster as work is waiting on workers. The availability of open spaces may tempt people to use them and as a result, materials handling and work practices may not be as well thought-out as they could be. Moreover, space buffers may not be free even when left open, e.g., when completed work requires protection or conditioning.

Cost of Logistics

Concern about the cost of logistics is often expressed when people hear about just-in-time production with its frequent deliveries of small batches of products—highly relevant to takt planning, especially when a work space is divided into many zones—because their minds are set on efficiencies of scale when producing and transporting large batches of products. It is also brought up in the context of kitting—likewise highly relevant to takt planning (e.g., Tetik et al., 2019, 2021; Gschwendtner et al., 2021). The concerns are valid when new practices are being contemplated. Lean practices such as those mentioned require engagement early on in a project and an up-front financial investment for their implementation. Cost accounting for logistics is complicated, and even more so when logistics is interpreted broadly (e.g., Mossman, 2007, Seppänen & Peltokorpi, 2016).

To illustrate, Figure 4 offers an example of a lean logistics cart used by a mechanical and plumbing contractor. This contractor invested in the development of this mobile, adjustable rack, that will serve not only the current project it is used on, but also future projects. The cost of this rack may be charged to the project for example on a per-use basis. Gschwendtner et al. (2021) accounted for such costs in their study of supply- and reverse logistics to support a takt plan, however they failed to obtain data describing the efficiencies gained by the installation crews that were supplied with kitted materials. Logistics costs are incurred by one group of people and the benefits reaped by others; when too narrowly accounted for, they will not pen out. This is where accounting (e.g., Horngren et al., 2012) and lean accounting systems have a role to play (e.g., Cunningham et al., 2003; Maskell & Baggaley, 2006; Maskell & Kennedy, 2007; and Maskell et al., 2011), to take a broad view on the production system and attribute costs appropriately, as needed here in the context of takt planning.

DISCUSSION

Taking a step back from these time-cost considerations, it will be clear to the reader that the intuition they may have developed about basic time-cost trade-offs in CPM-type scheduling does not exactly hold for takt planning.

The time-cost trade-off problem was originally formulated in the context of CPM, which is used at the master level of scheduling (using the terminology of the Last Planner® System (Ballard & Tommelein, 2021)). The time-cost trade-off problem as discussed in this paper, however, pertains to takt planning, which affects planning at multiple levels in the Last Planner® System, from master level scheduling all the way down to execution and control. Takt planning is production focused and therefore demands consideration of various kinds of variability in the system given its context, dedicated and shared resources, capacity utilization and allocation, production throttles that can be adjusted in the planning process, etc. All of these affect the cost of the takt plan and may thus be relevant to time-cost trade-offs.

In an effort to instil regularity in a takt plan (e.g., by means of defining process steps and balancing workloads) and aiming to achieve reliability in the execution of each and every step, some costs will have to be incurred (e.g., underloading of resources). This notwithstanding, such investments are expected to pay off and, if not immediately, then certainly in the long term reduce cost. Reliability and visual clarity in the takt plan create the possibility for project participants to tune their resource allocation to systemic needs, rather than exclusively to their own resource availability and company optimization strategy. Furthermore, the clarity in a takt plan's definition creates the stability that makes it possible for team participants to learn and improve their work over time in the course of a single project (e.g., Vatne and Drevland (2016) mentioned that crews were able to reduce their crew size as they speeded up), but also going from one project to the next one (e.g., increase their process capability) (e.g., Tommelein, 2020).

Further study is in order of existing algorithms for time-cost trade-offs—there are so many! It may be possible to use some parts of existing problem formulations (e.g., Feng et al., 2000, Al Haj & El-Sayegh, 2015) to study time-cost trade-offs in takt planning, and it certainly is possible to develop fit-for-purpose computer-based simulation models to allow for experimentation with alternative plans (e.g., Tommelein, 2020; Gschwendtner et al., 2021). Whatever problem formulations and algorithms exist, they will require extensions, e.g., to model various resource types, variability, work density, and other concepts specific to takt planning.

Besides the need to develop new algorithms and computer-based support tools to help takt planners make time-cost trade-offs, more fundamental is the development of lean construction cost accounting systems. This topic is worthy of greater study in our IGLC community, informed by publications on lean cost accounting as it is used in manufacturing and elsewhere.

CONCLUSIONS

Starting from the recognition that problems pertaining to time-cost trade-offs specifically in takt planning have received little attention in the scholarly literature to date, this paper explored various costs that are to be considered in the takt planning process. It raised a number of concerns and recognized a lack of knowledge; knowledge that will be needed to make informed time-cost trade-offs to meet selected objectives.

Only a few of the specifics related to time-cost trade-offs were presented in this paper. An in-depth study of the literature is needed, and formal cost models should be developed to support takt planners, e.g., using lean accounting methods. Our hope is that this paper's exposition of theoretical concepts related to the time-cost trade-off problem in takt planning will initiate discussion on this topic and help spur further quantification of the advantages of using takt in project production systems.

ACKNOWLEDGMENTS

RIGOROUS 2-HOUR TAKT REVEALS UPSTREAM UNDERPERFORMANCE

ABSTRACT

The primary purpose of this study is to demonstrate that rigorous production control requires high quality and flawlessness in the upstream production process. The research approach is a quantitative case study. One-piece flow forms the theoretical framework combined with the "sea of inventories" logic. The empirical material is collected from the case company's renovation projects' data, documentation, meeting minutes, and training material.

The definition, modelling, and analysis of the production system are fundamental to continuous improvement in construction. Systematic analysis, documentation, quality control, and quality assurance enable fact-based improvement and control of the production system. Our study, following the logic of continuously tightening requirements for control variables in the production flow, reveals upstream underperformance and drives the elimination of the problems, thus improving efficiency. In our case, company evidence shortening the takt from 4 hours to 2 hours reveals hidden problems in upstream flow, resulting in continuous improvement in production quality. Overall, our study provides evidence of the applicability of one-piece flow in construction.

KEYWORDS

One-piece flow, Toyota Production System, JIT, Takt

INTRODUCTION

The construction industry has used the Toyota Production System (TPS) and Lean methods since the 1990s. Still, results in increased productivity have not been rooted in the industry despite numerous successful Lean interventions (Pekuri et al., 2011; Da Rocha et al., 2022). Lately, Riekki et al. (2023) suggested that takt production could work as a ground-up driver towards implementing a Lean-based production system for construction.

Research has shifted to takt production and flow to increase the construction industry's productivity. At least four schools of thought can be distinguished from takt production: Takt Time Planning (e.g., Tommelein and Emdanat, 2022), Takt Planning and Takt Control (TPTC) (e.g., Binniger et al., 2017), Takt Time Planning (Gardarsson et al. 2019) and "hourly takt", takt production based on one-piece flow (e.g., Riekki et al., 2023). Research has tried hard to define the construction physics (Bertelsen et al., 2007) and flow of construction (Sacks 2016). Still, it has ended up where so many things flow that there is no unambiguous name or definition for

all identified flows (Tommelein et al., 2022), or the flow is just not flowing in the construction industry (Rocha et al., 2022).

In addition to the inability to formulate a theory for a holistic approach to a lean construction production system (Riekki et al., 2023), the research in the construction industry has not recognised products (different types of buildings), upstream processes or their importance as part of the production system. In contrast to TPS in the automotive industry, product development plays a minor role in the construction industry (Pekuri et al., 2014). Instead, construction companies typically outsource product development to subcontractors without realising that the construction and the assembly phases are some of the most critical stakeholders in setting the product requirements for industrial manufacturing (Stevenson, 2021, p. 165; Hopp and Spearman, 2011, p. 4; Fujimoto, 1999, pp 112-113). Without systematic product development, there is no systematic production capability creation, which would result in systematic production development (Annunen and Haapasalo, 2022; Annunen and Haapasalo, 2023). This underlines the observation that craftsman production (Womack et al., 2007, pp.19-24) is the predominant product design and production form in the current construction industry ("prototype production"). The focus of productivity development in the construction industry should be to transfer the design and construction from artisanal production first to the beginning of the industrial era. Then, we can take it further step-by-step and not, as is currently the case, transfer the characteristics of highly developed production methods in companies to a system based on craft production.

Based on the above, this article examines the basis of a construction production system and the enhancement of the production system in a case company, which brings previously hidden problems to the fore and their root causes. Thus, the main goal of this article is to show that rigorous control of production requires flawlessness of the upstream production process and thus causes a continuous improvement in the production quality as the more stringent control is moved. This goal is pursued through the following research questions:

1. RQ1: How is the one-piece flow used in the 2-hour takt case project to reveal the problems of the production system when compared to the previous 4-hour takt project?
2. RQ2: What are the problems and the root causes in upstream flow revealed by shortening the takt (4h takt to 2h takt)?

In this paper, we first review the literature to understand the relation between one-piece flow and eliminating disruptions (poor design, procurement, prefabrication, logistics, quality), resulting in quality and productivity improvement. Second, we describe our case study production system and analyse how the change from 4-hour takt to 2-hour takt has revealed more detailed failures. Also, we identify their respective failure mechanisms in the upstream process, leading to improved performance in the production system. We deliver case evidence on the applicability of one-piece flow in construction when carefully applied.

LITERATURE REVIEW

ONE-PIECE FLOW

The just-in-time (JIT) concept is part of TPS which creates a pull flow to the production, which forces the previous part of the process to do what the next part of the process (customer) needs. Part of the JIT is one-peace flow which brings the problems to the surface if implemented meticulously. The benefits of one-piece flow are undeniable: it builds in quality, creates natural flexibility due to shortening lead times and creates higher productivity since it reduces the cost of inventory and unleashes people's creativity. Simultaneously, it improves safety and morale (Liker, 2020, 71-73). If a problem surfaces, the entire production line is forced to shut down. This, in turn, forces everyone to stop and fix the problem so production can continue. This way, the crew and the process evolve. The one-piece flow with a short lead time enables higher quality because there is no large buffer of faulty parts when the defect surfaces. Also, part of the one-piece flow is that the next part of the process acts as an inspector for the previous part, and the defects are quickly found (Liker, 2020, pp. 61-76).

SHOP FLOOR CONTROL AND PRODUCTION SYSTEM

Hopp and Spearman (2011, p. 481) define Shop Floor Control (SPF) as the point where production planning interfaces with processes. They suggest that production control works best under stable conditions, which is precisely what TPS aims for. Unfortunately, creating such an environment can conflict with business requirements. As a result, in industrial production, part of the production is carried out in production systems, where some of the methods highlighted in Toyota's TPS research either do not fit well or do not fit at all (Irani, p. 36, Table 2.2). When classifying production systems and assessing their usability, one must understand the product being produced, its volume, and its variation—i.e., how many articles of the same product are intended to be manufactured. This product volume (Low vs High Volume) – product variation (Low vs High Mix) forms a product-process matrix. A low-volume, high-variation (LVHM) product can be considered more demanding to manufacture than a product with high volume and low variation (HVLM). Therefore, every Toyota facility is engaged in improving with Lean the productivity of HVLM assembly lines, which are very inflexible production systems (Irani, 2020, pp. 26-34; Chryssolouris, 2006, pp. 332-334; Hopp and Spearman, 2011, pp. 6-11).

The Bill of Materials is an essential part of the information maintained and processed by Manufacturing Resource Planning (MRP) for managing material flows in industrial production (Hopp and Spearman, 2008, pp.116-119). During the design phase, the designed parts, materials, subassemblies, and other objects combined with their part hierarchy can produce the Engineering Bill of Materials (E-BOM). Actual manufacturing requires the Bill of Materials at the purchasable part number (Manufacturing BOM or M-BOM) level and the corresponding article hierarchy (Sheng-Hung et al., 1997, Stevenson pp. 562-564).

The smaller the batch size, the more flexible the production system must be. As Lean focuses on cost reduction through waste elimination, the Theory of Constraints (TOC) provides a competing manufacturing strategy (Irani, 2020, p. 25) as its goal is to maximise flow through the entire system by identifying bottlenecks, balancing the flow and eliminating constraints (Stevenson, 2021, p. 715). Yet another production strategy is controlling the production system via Work in Progress (WIP). A pull system can be implemented with Kanban, but it is far easier to limit the amount of WIP to a constant level and use a Constant WIP (CONWIP) production system for pull production (Hopp and Spearman, 2011, pp. 363-368). All these strategies can be used for implementing a production system, and the question arises of which would be compatible with construction.

RESEARCH APPROACH AND LOGIC OF THE PAPER

Our research follows a case study approach, defined by Yin (2009), aiming to utilise the research material of one company. The target company of the case study was chosen because it has been developing production efficiency in two business units simultaneously using the same method, i.e., one-piece flow. The study chose between two business units and their different applications of one-piece flow based on the management and maturity of the manufacturing process. In the project selected for the study, 1) the manufacturing process was more comprehensive and 2) described in greater detail at the task level for workers. Also, the manufacturing process 3) utilised more prefabricated components and 4) employed a documented and trained management system for daily and weekly management. In other words, the selection criteria for the study were the extent of systemic change in product, design, procurement methods, contract models, the extent of one-piece flow usage, management of the manufacturing process, and team management. The research team also considered the significance of the takt duration for the study. It concluded that a 2-hour takt (implemented three times a day, leaving 2 hours as a daily buffer) is more significant than a 4-hour takt, where, based on observations, the wagons had more built-in buffer than in the selected project.

This research also shows how the one-piece flow principle of the TPS applies in the construction process, where effort is put into controlling variation in the production. This, in turn, has required and will require significant improvement in the quality of the upstream process in the studied business unit. Here, we apply the logic from the "sea of inventories" to more rigorous time control of the system. The empirical part is two-phased, based on first the description of the case project and details of the 2-hour takt. The quantitative study focuses on which deviations emerge after moving from a 4-hour to a 2-hour takt. The system's capacity can be utilised comprehensively only by analysing and eliminating the causes of disruptions, and therefore, design, procurement, design for the prefabricated parts and elements, off-site prefabrication, delivery, site-logistics and the construction process itself are studied as a production system.

The focus of the empirical analysis has been the implementation of our case company's refurbishment process of bathrooms. The model of the 2-hour production system was created together with the production team as they prepared for their next project, and the documents and organisational instructions were used as a reference. Our data was collected from the backlog of the previous 4-hour and 2-hour projects (contracts, planned and performed schedule), financial final accounts and deviation accounting maintained during the implementation phase of the projects, as well as defect/deficiency lists made in the projects and approvals of implemented repairs from the quality management system. The research team also accessed the project organisation's schedule analysis after the 2-hour project concluded. The most critical part of the study was the event data on deviations produced by the day-to-day management model of the last two projects, which the research team used as the starting point for quantitative analysis. This event data was classified and supplemented using WhatsApp records and analyses produced by three lean interventions on the implementation problems of one-piece flow. As a result, a comparison of the deviations in the 4-hour and 2-hour production systems was obtained and categorised data from the 2-hour project was integrated into the production system model. Using this framework, the aim was to formulate improvement suggestions to utilise one-piece flow and reduce production variability more effectively.

DEVELOPMENT AND DESCRIPTION OF THE PRODUCTION SYSTEM – CASE STUDY

The researched business unit primarily renovates residential buildings constructed in the 1960s and 1970s using a concrete element frame system. These renovations typically involve replacing water, sewage (occasionally also heating), and electrical systems, necessitating the dismantling of bathrooms and toilets down to the concrete framework in the apartments. Also, projects include the dismantling and renewing of the corresponding systems in the basement and the required connections to the municipal water, sewer and heating systems at the plot. Therefore, renovations vary depending on the surrounding city infrastructure, the size of the residential complex (number and type/size of buildings), and the geological conditions of the site. The organisation aims to achieve a lasting competitive advantage in the HVLM market by industrialising its production system and portfolio-based business model as described in Portfolio/Process/Operations-model (PPO, Korb et al. 2017, pp.165-167).

From Theory of Constraints (ToC) to Takt Production

The pipeline renovation business unit encompasses two distinct business models based on one-piece flow and subcontracted work. The studied organisation has systematically developed its production system to manage manufacturing. The organisation initiated the transformation from the traditional subcontracting method to partnering. Initially, the projects were subdivided, and subdivisions were tendered, repeatedly purchasing them as cheaply as possible from ever-changing subcontractors (black-box tendering) using the customer's design for HVAC.

The first step of the business unit towards developing an industrial production system was establishing a production Alliance. This objective was to standardise the production method by maintaining a consistent team and striving for longer-term collaboration with trades, employing the Alliance project delivery method starting in 2015 (Korb et al. 2017). However, the recurring problem on sites was the persistent variation, which led to applying ToC to identify and address workflow bottlenecks. Nonetheless, poorly designed details make the renovation process susceptible to variation. In the Design-Bid-Build (DBB) project delivery method, which the clients widely use in the Finnish bathroom refurbishment market, the main contractor is not adding value to HVAC designs. Instead, the main contractor uses the exact customer-originated 2D drawings in tendering for separate trades. As a result, the subcontractors are responsible for creating the implementation design and selecting the parts and materials, often while the work progresses. The Alliance method proved to be ineffective in solving various production-related problems. The project manager summarised that the production bottlenecks shifted faster than they could be identified and controlled. In 2019, the team moved to use the CONWIP model to gain control over the design and production processes to standardise products and work in some form. At the same time, the organisation transitioned to a partnership model with selected subcontractors, conducting business together based on the open-book principle.

The use of CONWIP as a core of the production system shifted the responsibility for completing plans, products, and materials, as well as understanding the execution of work, to the main contractor's organisation. Gradually, the organisation's ability to create and manage the housing manufacturing process as a whole grew to an exceptional level for a leading contractor in the market. Moving from a zero-sum game business to partnering enabled the transition to takt production, initially implemented with 4-hour takt and takt logistics. Project by project, the organisation improved its manufacturing planning expertise towards an LD400 level in each wagon. This led to more precise parts lists (M-BOMs) for procurement and logistics while simultaneously refining the standard product and standard work (manufacturing process). Continuous ambition to refine design towards the LoD400 level, increased design precision to form M-BOMs for each wagon, and the ensuing opportunity to meticulously plan and execute the production process down to the minute raised the maturity of the production system to its current level. During the last three projects, the organisation has systematically transferred material processing and assembly to a separate production facility, a "factory", causing the prefabrication level to increase drastically.

The continuously improved takt production system aims to execute construction using a one-piece flow. Because the renovation projects vary across the market area, each project is divided into two parts: the process and the project part. The process uses takt production, and its design is refined to LoD400. The project part is executed using a traditional management model influenced by the LPS. From the manufacturing industry production systems perspective, the unit has separated the recurring renovation of similar residences into a one-piece flow based on product and process standardisation, referred to as the HVLM production system. Over six years, the production system has been developed to increase production flow from 150 apartments in 2018 to 330 apartments. Meanwhile, the organisation and direct costs have grown by approximately 15% during the same period.

THE PRODUCTION SYSTEM IN THE CASE PROJECT

The core of the production system is the manufacturing process and its management. The organisation believes managing the manufacturing process necessitates control over the products (apartments) and their production. Consequently, the organisation of the business unit focuses on two principal tasks: 1) product design and 2) manufacturing planning. Since changes in the product invariably affect manufacturing, and alterations in manufacturing methods impact the product, the studied organisation has formed a single, cohesive and interactive team to implement their production system without hierarchical or organisational boundaries. The objective of designing the production system is the capability to plan all necessary materials and then required tasks from the beginning of manufacturing (a bathroom dismantled to concrete) to the finished product (a zero-defect delivered apartment). The studied organisation has set itself the goal of transitioning to industrial production, where the organisation is responsible for the product, all its materials, parts, tasks, work techniques, tools and procedures from design to installation. The responsibility also includes transitioning to hourly work, using the employer's unilateral right of supervision, and superseding subcontracting.

The project was implemented using the DBB method, where the client commissioned what is incorrectly known in the market as a feasible 2D design. The business unit had won the tender based on price. During contract negotiations, the implementation organisation developed the design so that the project could use as many established solutions and materials as possible that are known to be compatible with a one-piece flow production. Hence, the production system consisted of three segments: A) product/manufacturing process design and procurement, B) apartment manufacturing process and C) off-site prefabrication and supply chains. The production system is depicted in Figure 1. The design was an iterative process, and it consisted of the following subprocesses: 1) product design, i.e. apartment HVAC design; 2) pre-fabrication design; and 3) manufacturing process planning: creating M-BOM per apartment type, work breakdown structuring and formulating task lists per apartment type and staging and levelling the wagons. Since the design created and maintained M-BOMs, it also controlled the 4) procurement and takt logistics. The apartment manufacturing process was separated from the project on-site management, and the 5) daily operations and management included daily huddles for team members (TMs) and team leader (TL). The group leader (GL) met daily with TLs following the standard management procedure and problem-solving process. These meetings were also attended by design, prefabrication, procurement and project management. TLs and GL managed 6) logistics on-site and took care of 7) call-offs for JiT deliveries for both prefabricates and materials.

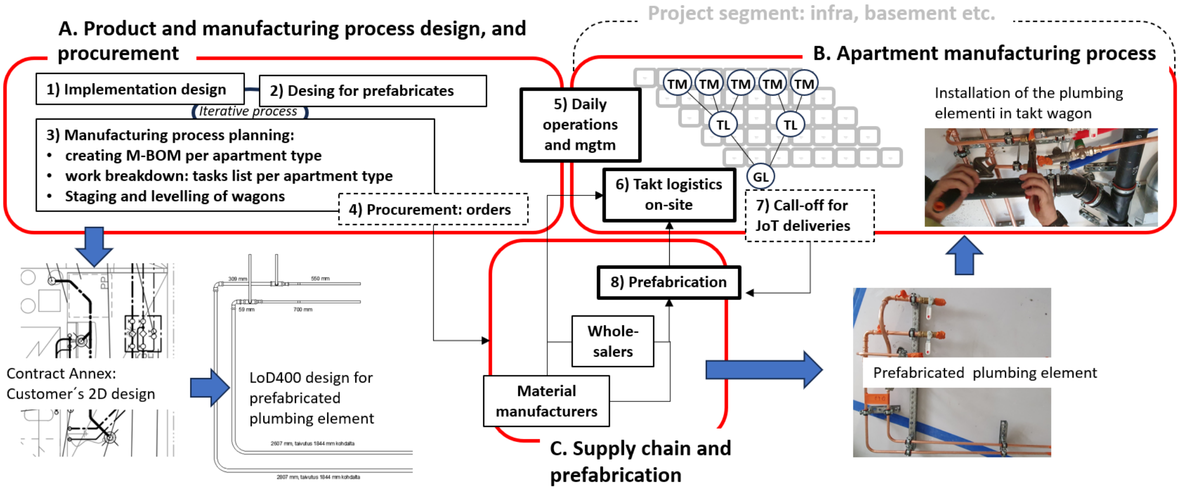

Figure 1: The modelled production system, which uses one-piece flow as a core

Timewise, the project was divided into two main phases: the production preparation phase and the production phase. The production preparation phase focused on prefabrication design, material selections, procurement planning and JiT-logistics. The prefabrications were designed to be millimetre precise for manufacturing, and simultaneously, M-BOM was formed for each apartment. Depending on the apartment type, the number of items in the M-BOM varied between 280 and 300 separate articles. The prefabrications reduced the number of parts and material items delivered to and built on-site by about 50-70 items per apartment. The apartment-specific parts and prefabrication list were the basis for planning takt-logistics, scheduling, and placing orders. It was also used to update the manufacturing process task list, which the organisation aims to shorten and specify with each project. There were 246 defined tasks in the studied project, for which duration estimates at the minute level and worker competency requirements were empirically defined. Using the task list created with the help of the plans and the M-BOM, a 2-hour takt train was formed, in which tasks were distributed and levelled across the wagons based on estimated task durations. The design principle was to leave a 15 – 30-minute buffer depending on the expected variation in each wagon and the daily 2-hour buffer. In levelling, the aim was to manage and balance execution time at a minute level, concentrate on specific tasks according to competency requirements, and consider staff capabilities. For prefabrications, the decision criterion in product design was the smoothness of the 2-hour takt and the reduction of throughput time. The manufacturing time of prefabricated components was not considered in the decision-making process, as there was insufficient data on actual manufacturing times.

The formation of the takt train created the prerequisites for resource allocation and the formation of teams for implementation. The structure and organisation of the production system were arranged by dividing the manufacturing process (adjacent wagons) into three teams: demolition and installation of vertical HVAC lines (wagons 1-3), casting, installation of horizontal HVAC lines, and tiling (4-11), and installation of fixed furnishings and finishing works (12-21). In each team, a team leader was responsible for team members implementing their wagons, daily supervision of workers, problem-solving and escalation, and work safety.

RESULTS AND DISCUSSION

The two-layer daily management model, which was adopted from TPS, was designed based on experiences from the 4-hour takt to control the manufacturing process and resolve problems arising in manufacturing. Based on interviews with management, the goal was for the team members of the three teams to be at the top of the hierarchy. Other levels of the organisation, team leaders, group leader, planning, procurement, and prefabrication, were supposed to support the team members, the actual operators implementing the manufacturing process. The project shifted to a 2-hour takt, similar to previous projects that used a 4-hour takt, prefabricates, standardised parts and materials, and established daily management practices. The team members were mainly the same as in the 4-hour takt, but the task contents were changed while the degree of prefabrication was increased. The product was expected to become more straightforward regarding prefabricated components, which resulted in a shortening of the manufacturing process and throughput time. In numbers, the shift from a 4-hour takt to a 2-hour takt changed the execution so that instead of the previous 40 units in a 4-hour wagon, the manufacturing process aimed to be implemented in 37 units of 2-hour wagons, of which 15 units had one or more prefabricates. Consequently, the throughput time for an apartment was reduced from 160 hours to 74 hours. Each day included an empty wagon as a buffer, so the calendar time for apartment throughput was decreased from 20 weekdays to 12,4 weekdays. The hours spent on factory work were not tracked for the prefabrication part, except for individual trial installations, which showed a time saving of 30-70%.

The project personnel conducted a more detailed internal evaluation based on the actual takt schedule for the part of the project they deemed most important (the C and D staircases, with 24 apartments, which they considered too large batch size after analysis). According to this assessment, there were start delays of 2 working days and completion delays of 5 working days, which meant that the throughput time for this project batch was extended to 17 working days. The same analysis also revealed that reducing the batch size could shorten the throughput time for the entire staircase by 4-5 working days. By moving the vertical HVAC installations out of the bathroom to the staircase, the throughput time for the bathrooms could be reduced by 4 working days when looking at the entire batch of apartments produced. However, the schedule review did not reveal any continuous deviations or the root causes of delays, so alongside the traditional schedule review, a quantitative analysis of deviation information produced by day-to-day management was included in this study.

How is the one-piece flow used in the case project to reveal the problems of the production system? (RQ1)

In the researched case, the implementation of 2-hour Takt production based on a LoD400-level plan specific to each apartment type, which 1) standardised materials into pre-cut parts, 2) defined prefabricated components, and 3) fixed the predefined number of parts and materials to be installed according to the M-BOM per location, revealed the weaknesses of upstream processes. This is because, in a 2-hour takt, there is no time for a redesign, acquiring additional parts or materials from the off-site factory or hardware store, or fabricating suitable parts from materials, as was possible in a more stable 4-hour takt in the previous case. Additionally, the precise dimensioning of the prefabricated components and the solutions chosen for tolerance management were not sufficient for all apartments. As a result, workers had to modify and alter prefabricated elements. This led to deviations in dimensions exceeding the tolerances, resulting in either a shortage of parts or materials in that specific takt wagon or a later wagon(s). The skills or available time of the team leaders did not allow for error detection, leading to a build-up of problems. Incorrect decisions made by the workers were caused by a lack of training, lack of printed instructions, and/or design errors due to mistakes made in the upstream processes.

Additionally, there were more takt wagons and workers at the site simultaneously during the project than in the previous one. Each worker had to implement a wagon in three locations equipped with prefabricated elements, parts, and materials. With three 2-hour daily cycles, the worker had to switch workstations (apartments) three times instead of two, as in the previous case. As a result, the team leaders encountered more errors in a day than before. The potential number of errors was also increased due to changes in personnel, alterations to prefabricated elements, partial changes in individual workers' wagons, reorganisation of team leadership, and the addition of new personnel to the order process, as well as the necessity of creating project-specific plans for installations, orders, and prefabrication.

The hierarchy of team leaders, group leader and support organisations were supposed to solve quickly escalated problems. However, the records from the meetings showed that problems began to accumulate from the start of the project, and the root causes of these issues were not resolved; instead, they began to recur. In other words, the one-piece flow highlighted problems. Still, the management arrangement could not conduct adequate root cause analysis or allocate sufficient resources to solve the root cause. The arrangement could only find a temporary solution to the problem and enable work to continue.

Another clear challenge in implementing a one-piece flow was that the latent interdependencies went unnoticed by team members and leaders. This became particularly evident when installing prefabricates, as incorrect installations were made in several apartments before the error was later discovered. A practical example involved installing water pipes in the ceiling, which were implemented as prefabricates. From the ceiling, the pipes continued as surface installations to fixtures such as shower taps, and the error was not detected until wagon 27. However, the incorrect installation was made in wagon 11. In the meantime, 15 incorrect installations have been completed. Various errors forced the project to undertake three Lean interventions. In the first two, the prefabricate installation method was thoroughly reviewed, and team members were defined and trained with precise instructions. In the third, a method for reporting defects was established, and problem sources were identified to make the WhatsApp channel more effective in communicating and resolving defect reports. The first two interventions impacted the number of defects, whereas the third did not appear beneficial, with defect numbers remaining the same despite the intervention.

What are the problems and the root causes in upstream flow revealed by shortening the takt (4h takt to 2h takt)? (RQ2)

The quantitative analysis of the day-to-day management log file revealed that the transition from a 4-hour takt to a 2-hour takt did not go smoothly, with the defect frequency (calculated as the ratio of deviations to the number of takts carried out during the review period) rising from 1,3 defects per takt to 1,9. The categorisation of deviations in the 2-hour takt project is presented in Figure 2. When examining the distribution of deviations, the shift to a 2-hour takt increased the number of product shortages (from 57 to 79 pcs), work errors (54 to 76), and design errors (13 to 20). Still, at the same time, resource allocation (11 to 8) and process errors (42 to 22) decreased. The shorter review period explains the reduction in deviations caused by absences.

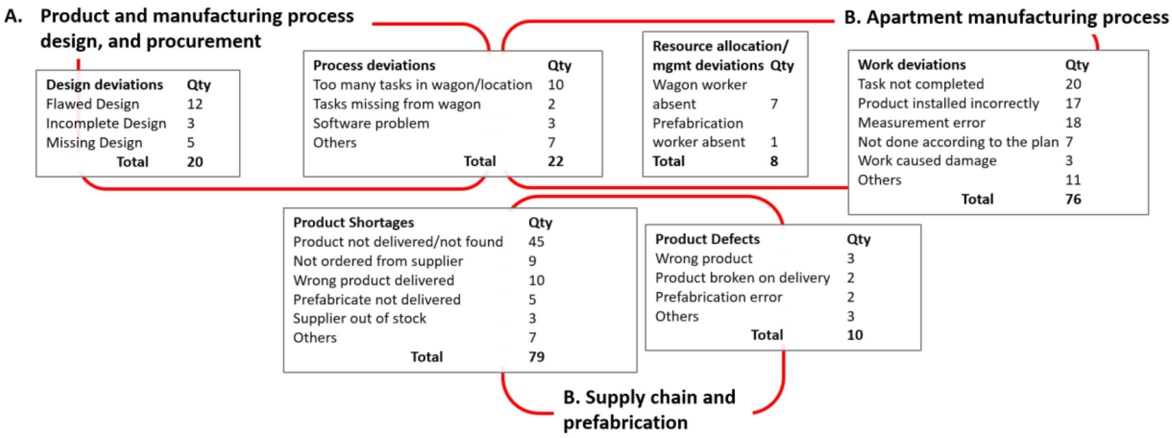

Figure 2: The results from quantitative analysis in the framework of the modelled production system

Process errors decreased because the manufacturing process was shortened in terms of the number of wagons and tasks as prefabrication increased. In other words, the design assumption that the manufacturing process would simplify due to the increased prefabrication seems correct. This is supported by the observation that the majority of process deviations were caused by an excessive number of tasks in individual wagons (levelling failure).

The primary root causes of work-related upstream underperformance can be divided into two categories based on the quantitative analysis of deviations. Work deviations stem from two leading causes: either the work standardisation is inadequate, the guidance is incomplete, or the guidance has not reached the worker responsible for the implementation in the wagon. In such cases, the team member is unaware of the installation instructions, their skill level is insufficient to follow and carry out the installation, or they have decided not to follow the instructions and instead carry out the installation as they consider best.

The supply chain was the weakest part of the production system in terms of the errors that were analysed. The reason is that parties involved in the supply chain lack communication, situational awareness, and verification opportunities in the studied project. Fundamentally, the material is missing because it has been 1) left undelivered to the correct apartment, 2) the wrong material has been delivered instead of the correct one, 3) not ordered or an ordering error has been made, 4) missing because the measurements of the apartment's bathroom exceed the planned tolerance, or 5) the material has already been used elsewhere.

The root cause of design errors is that the 2D drawings are inherently unfeasible, meaning the wagon has been misdesigned. The design may become unviable if a previous wagon has deviated from the implementation plan. Additionally, the drawing may be unfeasible because a measurement deviation in a particular apartment exceeds the established tolerance limits.

When examining process deviations, the most significant factor was the variation in task durations caused by different locations (bathrooms of various sizes). This resulted in what seemed like random overloading of specific wagons. Another reason was that the person did not follow the installation method or could not perform the tasks. At the start of the project, it became apparent that some of the wagon's tasks had been incorrectly planned or were unrecognised and unscheduled. These issues were partially corrected during the commissioning phase of the train by relevelling the wagons.

Based on the root cause analysis, the two most valuable improvements to the production system are transparent management of the supply chain and training team members for their installation tasks. In practice, managing the supply chain means managing the MBOM at the apartment and wagon level, from planned parts through procurement to final installation. For training purposes, the team leaders must study each wagon and its installation tasks themselves to train their team members for wagon-specific implementation and, especially, to lead the work and solve problems effectively. The third area for development is the prefabricates, whose installability must be ensured as part of the training. Since training is challenging to conduct before production starts, the training phase in a 2-hour takt system (i.e., the project start, where the train is brought into a new site) must be resolved either by implementing it at a slower takt, such as a 4-hour takt, or by over-resourcing the teams with additional trainers in the initial phase. The fourth area of development is takt logistics: Just-in-Time (JiT) deliveries divided the shipments into too small batches to track them manually or digitally. Batch size of deliveries should be increased and visual management added to detect deficiencies in delivery contents.

CONCLUSIONS

The primary purpose of this study is to show that rigorous production control requires high quality and flawlessness of the upstream production process. Through a literature review and case study, we formed a one-piece flow production system model from an example project.

The empirical material collected from the case company's renovation projects reveals that modelling the production system made visible the logical components of the production system. Similarly, it made visible the functions associated with these components, the implementation of these functions as processes, and the required and produced information, preconditions for systematic continuous development. This allows the identification of errors and their root causes, whether they need to adjust the product development, the operational model (necessitating correction of the production system), or the dysfunction of the model (necessitating staff training).

In our case study, implementing a 2-hour Takt production from a 4-hour takt revealed a list of new challenges to be eliminated. Therefore, it is validated that the logic of the "sea of inventories", continuously tightening the requirements for the control variable in the production flow, reveals upstream underperformance and drives the elimination of the problems, thus improving efficiency. Overall, our study provides evidence of the applicability of one-piece flow in construction. However, we have only studied a few renovation projects, and further studies need more cases to validate our findings fully. In this context, it is essential to note that the studied business unit and its organisation, which utilises a one-piece flow, is focused solely on executing repetitive projects that inherently involve a lot of repetition. The organisation refers to implementing a one-piece flow as a "housing factory" that flows through projects. Since the one-piece flow is a production system for HVLM products, its applicability to different construction business units is a fundamental topic for further research. Also, various construction project delivery methods must be studied to strengthen the external validity.

SHORT TAKT IN CONSTRUCTION: A SYSTEMATIC LITERATURE REVIEW

Malin Furuli Munkvold[1] and Frode Drevland[2]

ABSTRACT

Over the past decade, Takt planning has steadily gained ground as a production system design scheme in construction projects. The approach entails organising trades as wagons in a train and running that train through a set of designated work areas in a building, with the train making regular stops and the wagons spending a fixed amount of time – the takt – in each area. The most common takt in construction projects is weekly takt. While using a shorter takt in combination with smaller work areas yields a shorter overall execution time, there is limited research on the actual consequences and feasibility of reducing takt time in practice. This paper conducts a systematic literature review on using short takt in construction projects, seeking to consolidate existing knowledge and suggest avenues for future research. From searches in the Scopus and IGLC.net databases, the paper identifies 13 articles related to using short takt in construction projects. The articles are analysed using thematic coding, revealing seven themes: maturity, planning and preparation, production monitoring, visual management,mock-ups, logistics, and collaboration. Key insights include the importance of rigorous follow-up during production and the advantage of experience in managing short takt times. The paper concludes that the sum of existing knowledge on short takt times in construction is limited, offering minimal practical guidance for implementation. This identifies an urgent need for further research to fill this significant gap.

Lean construction, production system design, takt, short takt

INTRODUCTION

The construction industry has evolved significantly in the past few decades, with an increased focus on enhancing efficiency. This shift has seen the adoption of Lean principles to reduce waste and deliver better value. Recognised for their vital role in modernising construction processes, lean methods contribute to achieving superior outcomes (Kuenzel et al., 2016; Lohne et al., 2022). Over the past decade, one method that has gained particular traction is takt planning (Andreassen & Drevland, 2023; Halttula & Seppänen, 2022).

Takt planning is a method for planning and executing projects, strongly influenced by Lean and the Toyota Production System (TPS) (Linnik et al., 2013). Key principles in Lean and TPS include continuous improvement, elimination of waste, and optimal workflow (Power et al., 2023). Takt time is a central part of the Just In Time principle in TPS, which focuses on producing the product at the right time (Linnik et al., 2013).

A train metaphor often illustrates Takt planning (Dahlberg & Drevland, 2021; Haghsheno et al., 2016). A train comprises several wagons, each representing a trade's work (for example,

1 M.Sc. Graduate, Norwegian University of Science and Technology (NTNU), Trondheim, Norway.

2 Associate Professor, Norwegian University of Science and Technology (NTNU), Trondheim, Norway, frode.drevland@ntnu.no, orcid.org/0000-0002-4596-1564

electrical, HVAC, carpentry). In a construction project, the building is divided into work zones with an equal amount of work for each zone. The train moves through the building and stops in each zone at a specified rhythm – the takt. The most common takt time in construction projects is weekly (Binninger et al., 2018), meaning the train wagons stay in each zone for a whole week before moving on to the next zone. This cycle is repeated until all wagons have visited all zones.

By adjusting the size of work zones, it is feasible to significantly shorten the execution timeline of a takt (Binninger et al., 2018; Jabbari et al., 2020). Smaller zones necessitate reduced workloads within each, thereby permitting a decrease in takt time. This strategy can potentially lower both production times and project costs substantially. However, it also introduces new challenges, necessitating adjustments in logistics, coordination, and the frequency of work zone turnovers.

There is limited research on the actual consequences of reducing takt time in practice. Some smaller projects with limited scope have conducted such tests (Apgar et al., 2022; Binninger et al., 2018), as well as some larger construction projects (Apgar & Smith, 2023; Keskiniva et al., 2021; Riekki et al., 2023). However, the literature in this area is relatively limited, and there is a need for further research to gain more knowledge on how shorter takt time affects the practical execution of projects.

Adjusting the size of work zones offers a strategic means to significantly reduce project timelines, as smaller zones require less work per segment, thus allowing for shorter takt times. This approach can lead to notable reductions in both production times and costs, albeit introducing challenges related to logistics, coordination, and the management of work zone transitions (Binninger et al., 2018; Jabbari et al., 2020). Despite its potential benefits, there is a notable scarcity of research exploring the practical implications of reducing takt time, with limited studies focusing on both small-scale experiments and larger construction endeavours (Apgar et al., 2022; Apgar & Smith, 2023; Binninger et al., 2018; Keskiniva et al., 2021; Riekki et al., 2023). This gap highlights the necessity of exploring the impact of shorter takt times on project execution in real-world settings. Consequently, further research is essential to deepen our understanding of the effects of shorter takt times on the practical implementation of projects and to identify strategies for ensuring the successful execution of projects with short takt durations.

This paper presents the findings from a systematic literature review focused on the use of short takt in construction projects. The review served as a preliminary step to an empirical case study examining the implementation of 1-day takt. The aim was to consolidate current knowledge and identify potential avenues for future research.

The paper starts by outlining the methodology for selecting and analysing pertinent literature, leading to the identification of twelve studies that shed light on the implementation of short takt times. The thematic analysis reveals seven themes relevant to projects with shortened takt times: maturity, planning and preparation, production monitoring, visual management,mock-ups, logistics, and collaboration. Notable findings highlight the necessity of diligent follow-up during production and the benefits of experience in short takt management. The review finds that the sum of existing documented knowledge on short takt times in construction is minimal, with little practical guidance available for implementing short takt in projects – underscoring the pressing need for additional research to address this substantial knowledge gap.

METHOD

To identify literature, Scopus and IGLC.net were selected for their extensive coverage of relevant research. Scopus provides a broad range of curated peer-reviewed literature across disciplines, including construction, offering access to journals, books, and conference papers. The IGLC.net database contains all papers published at the IGLC's annual conferences.

The search used "takt" and "construction" to encompass the literature on takt planning. Searches conducted on Scopus and IGLC.net yielded 110 and 97 hits, respectively. Scopus searches included "construction" to narrow down the scope to construction-specific literature. In contrast, IGLC.net searches used only "takt" due to its focus on the construction industry.

The article selection process, illustrated in Figure 1, involved removing duplicates and excluding articles unrelated to takt planning with shorter takt durations. This process resulted in the final selection of 12 relevant articles, primarily case studies.

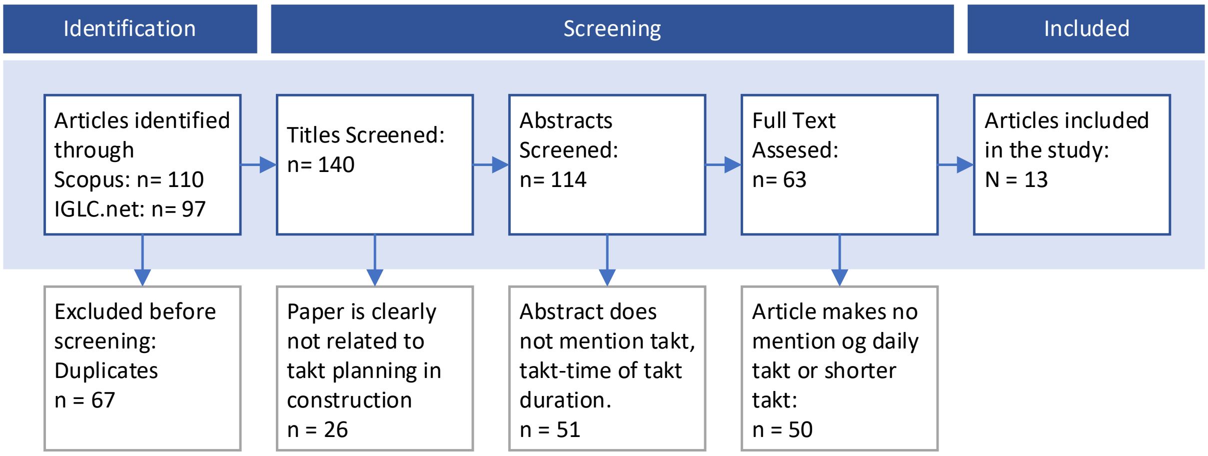

Figure 1: Flow chart for literature search and selection

The included papers were analysed using thematic analysis as described by Robson (2002), aided by an Excel sheet that organised the articles for a concise overview, including details about publication, content, and relevance. This structured approach facilitated easy identification of key points and themes across the literature.

LIMITATIONS

This review has several limitations worth noting. First, it focuses exclusively on peer-reviewed research literature. As a result, potentially valuable insights from non-peer-reviewed sources such as trade magazines, which might discuss practical applications and industry trends, have been omitted.

Secondly, the review did not include PhD dissertations. These works are often rich sources of detailed research but are challenging to integrate into a systematic review due to the lack of a unified database for global PhD theses. This makes a structured and comprehensive search challenging.

Finally, the literature screening process also presents limitations. Relying on skimming full texts to identify mentions of short takt times may result in oversight. This method depends heavily on the authors' ability to detect relevant details, which can be subjective and potentially inconsistent.

RESULTS

This section presents the results from a thematic analysis of the identified literature pertaining to using short takt in construction projects. The study defines *short takt* as any schedule tighter than a weekly cycle, including daily and hourly takt. The main goal was to pinpoint key factors influencing project outcomes when takt times are shorter than the commonly used weekly takt.

Out of the 13 identified and included articles, only one specifically explored the effects of reducing takt time (Binninger et al., 2018). However, 11 of the remaining 21 articles were case studies from projects – with short takt times – that investigated different issues. For instance, examining the general implementation of takt production (Lehtovaara et al., 2019), research on logistics handling during takt production (Heinonen & Seppänen, 2016), and comparing projects with varying takt times to assess effective implementation of takt production (Lehtovaara et al., 2021).

The studies reviewed reported takt times ranging from 25 minutes to 2 days, with many projects opting for a 1-day takt. Short takts were mainly used in the finishing stages of highly repetitive projects, like residential and hotel constructions. Most of the research came from Finland, with additional studies from Norway, Germany, Ireland, and the USA. Table 3 summarises each study’s focus.

Table 1 Overview of included studies

Reference	Country	Case Projects	Takt Time	Project Type
Apgar and Smith (2023) [Conference paper]	USA	1	1-day takt	Data centers
Apgar et al. (2022) [Conference paper]	USA	1	1-day takt	Roofing system
Binninger et al. (2018) [Conference paper]	Germany	1	1-hour takt	Retail space
Frandson and Tommelein (2014) [Conference paper]	USA	1	2-day takt	Health care facility retrofit
Gardarsson et al. (2019) [Conference paper]	Norway	None (Literature review)	Varying, discusses shorter takt	Not applicable
Heinonen & Seppänen (2016) [Conference paper]	Finland	1	25-minute takt	Boat cabins
Keskiniva et al. (2021) [Journal paper]	Finland	1	2-day takt	Residential renovation
Kujansuu et al. (2019) [Conference paper]	Finland and USA	4	From 1-day to weekly takt	Residential
Lehtovaara et al. (2021) [Journal paper]	Finland	6	Varying takt. From 1-day to weekly takt	Hotel and residential
Lehtovaara et al. (2020) [Conference paper]	Finland	24	Varying takt. One project with 1-day takt	Residential
Lehtovaara et al. (2019) [Conference paper]	Finland	1	Varying takt. From 1-day to weekly takt	Residential
Riekki et al. (2023) [Conference paper]	Finland	1	4-hour takt	Hotel
Tetik et al. (2019) [Conference paper]	Finland	2	1-day takt and 40-minute takt	Boat cabins

The thematic analysis of the articles revealed seven themes related to effectively implementing shorter takt times in construction projects: 1) Maturity, 2) Planning and preparation, 3) Production monitoring, 4) Visual management, 5) Use of Mock-up, 6) Logistics, and 7)

Collaboration. The following sections explore each of these areas in detail, shedding light on their significance and the role they play in the success of projects utilising short takt times:

MATURITY (EXPERIENCE)

The literature often emphasises maturity in the context of implementing shorter takt times, referring to organisations with extensive experience and advanced practices in takt production. While several Finnish studies explicitly mentioning 'maturity'(Lehtovaara et al., 2021; Lehtovaara et al., 2020; Tetik et al., 2019; Kujansuu et al., 2019), other studies hint at maturity issues, such as overestimating work capacity (Binninger et al., 2018) or a lack of preparation for takt production's pace (Lehtovaara et al.(2019), without directly mentioning the term. Maturity is often associated with experience in these discussions, though this perspective may overlook other important aspects, such as organisational culture and leadership.

Lehtovaara et al. (2021) emphasise maturity's role in managing short takt times and work zones, noting challenges in projects with low maturity levels due to inexperience with takt production. Despite planned efforts, these projects struggled with workflow efficiency, contrasting with higher maturity ones, which saw benefits from longer, weekly takt times. Lehtovaara et al. (2020) introduced a maturity model for takt production, identifying three maturity levels from basic takt planning to advanced, socially integrated practices.

Tetik et al. (2019) compared takt production maturity in shipbuilding and construction, finding ship cabin production more advanced in integrating takt and logistics solutions. However, it did not explicitly define maturity, viewing it as developing efficient takt and logistics practices in construction.

PLANNING AND PREPARATION

The literature emphasises the necessity of thorough planning for the success of construction projects employing shorter takt times (Apgar & Smith, 2023; Apgar et al., 2022; Binninger et al., 2018; Frandson & Tommelein, 2014; Lehtovaara et al., 2021; Lehtovaara et al., 2020; Lehtovaara et al. 2019; Riekki et al., 2023; Tetik et al. 2019). A study by Riekki et al. (2023) on converting an office building into a hotel with a four-hour takt highlighted how advanced and detailed planning, including a preparatory workshop, dedicated management efforts, and logistics coordination, was critical for project efficiency. Their findings align with the findings of Lehtovaara et al. (2019), which pointed to the importance of detailed planning, takt principle training, and careful production startup.

Additionally, the research notes the common issue of inadequate project definition prior to construction commencement, as seen in Tetik et al. (2019), where plan maturity affected procurement and delivery planning. Lehtovaara et al. (2021) and (2020) further discussed the benefits of early obstacle identification and integrating takt requirements in the design phase for enhanced collaboration and smoother production. They also warned against the pitfalls of minimal buffer areas, highlighting the balance needed to manage delays and unforeseen events in projects with tight schedules and high process variability.

PRODUCTION MONITORING AND CONTROL

The literature underscores the crucial role of rigorous production monitoring, including active management and daily coordination meetings, to adhere to takt times once construction starts. Studies reveal that effective workflow supervision, especially with shorter takt times, is key to maintaining efficiency (Apgar & Smith, 2023; Frandson & Tommelein, 2014; Riekki et al., 2023; Lehtovaara et al., 2021; Gardarsson et al., 2019). In cases like Riekki et al. (2023), where a project adopted a four-hour takt, the intensive monitoring required by management proved essential for project success, offering flexibility and control. Similarly, Binninger et al. (2018) demonstrated that close oversight and proactive management support were vital, particularly after startup challenges in a project with an hourly takt, leading to significant improvements in coordination, efficiency, and project duration reduction from ten to three days.

Several studies highlight the need for additional resources, as well as active production management and daily follow-up in managing projects with short takt times (Keskiniva et al., 2021; Lehtovaara et al., 2019; Apgar & Smith, 2003). With short takt times, limited time is available to address production disruptions. Lehtovaara et al. (2021) point out the need for more resources, particularly in site management and among technical leaders during the planning and startup phases. This increased resource requirement is mainly due to the need for more frequent coordination and management of takt production.

Daily Coordination Meetings

Daily meetings are deemed essential for the day-to-day management of short-take projects. According to Riekki et al. (2023), such meetings help create a shared situational understanding and enable quick responses to work challenges. Other studies support this. Kujansuu et al. (2019) found daily meetings an effective way to start the workday, share information, and evaluate progress from the previous day. Lehtovaara et al. (2019) made a similar observation, highlighting it as a learning point due to the absence of good routines and daily meetings.

Buffers and Plan Adjustments

Buffer management is an approach in production or project management that uses reserves or buffers to handle uncertainty and variations in the workflow (Gonzalez et al., 2008). It involves allocating extra time, resources, or materials to manage unforeseen events without disrupting progress.

Gardarsson et al. (2019) point out that shorter takt times limit the time available to handle delays or unexpected project challenges. Dividing into smaller work zones may reduce total production time and costs but increase the risk of delays. Keskiniva et al. (2021) support this, noting that takt planning with shorter takt times can be rigid, making it challenging to adapt to changes and maintain the pace. Keskiniva et al. (2021), therefore, emphasise the necessity of daily monitoring and adjustments to avoid delays.

Lehtovaara et al. (2021) highlight that short takt times demand a more proactive role from tradespeople in managing capacity and resources, deviating from the buffer of extra time and materials often available in longer takt projects. Effective coordination and resource planning become essential skills for tradespeople to navigate the constraints of shorter tasks successfully.

Riekki et al. (2023) demonstrate that projects with short takts, such as one with a 4-hour takt, can maintain flexibility and manage adjustments effectively with careful planning, including adjustments in work steps, wagon sequence, the addition of new steps, and buffer wagons.

However, Lehtovaara et al. (2019) caution against a “hard start” without a gradual pace increase, as it can lead to subcontractor disengagement and a lack of thorough error inspection. This underscores the importance of a balanced pace and resource allocation from the project’s outset to mitigate potential issues and fully leverage the benefits of shorter takt times.

VISUAL MANAGEMENT

Visual management, utilising digital tools and physical markers, is reported by several studies as beneficial when implementing shorter takt times, enhancing workflow and communication (Lehtovaara et al., 2021; Lehtovaara et al., 2019; Riekki et al., 2023). Digital aids like Building Information Modeling (BIM) are crucial in reporting progress and managing discrepancies. Digital tools help keep schedules aligned with production, support accurate work tracking, and facilitate real-time updates, making them critical for efficient takt management (Riekki et al., 2023; Lehtovaara et al., 2019). However, adjusting takt plans can be challenging and time-consuming, indicating the need for more automated solutions to enhance adjustment efficiency (Lehtovaara et al., 2021).

In addition to digital tools, physical visual aids such as printed takt plans and floor markings significantly improve on-site management and teamwork, as demonstrated in a hotel project employing a 4-hour takt (Riekki et al., 2023). These strategies foster a collective understanding and ease the integration of personnel, underlining the combined value of digital and physical visual management methods in optimizing construction processes.

MOCK-UPS

The hotel project detailed by Riekki et al. (2023) included efforts to create a mock-up of a hotel room outside the actual construction site as part of its planning phase. This initiative aimed to gain early insights into potential work process challenges and opportunities. Unfortunately, the mock-up was not finished before construction commenced, significantly restricting the learning opportunities it could have provided. The study highlights that such attempts can provide valuable insights into potential challenges and opportunities for details in work processes; however, it stresses that such mock-ups need to be completed to benefit from potential advantages during the planning and project phases.

LOGISTICS MANAGEMENT

Logistics management, especially in conjunction with shorter takt times, is crucial for maintaining project momentum, as evidenced by various studies. Riekki et al. (2023) emphasize the necessity of synchronizing material deliveries with the takt plan to ensure smooth progress. The study details a project using a four-hour takt in a city centre, where logistics strategies for different materials—external storage for large items and on-site storage for smaller items—helped maintain low inventory levels and streamlined material flow.

Tetik et al. (2019) and Heinonen & Seppänen (2016) discuss adopting industrialized logistics strategies from the shipyard industry, such as material sequencing and Just-In-Time (JIT) deliveries, to enhance takt production in construction. These approaches – including organizing materials on trolleys for specific cabins and ensuring daily delivery schedules – minimized inventory and optimized logistics management.

COLLABORATION

Two main areas of collaboration recur in several studies as crucial for the successful implementation of projects with short takt times. The first is collaborative planning among design teams, main contractors, subcontractors, and suppliers related to both the takt plan and the logistics management (Apgar et al., 2022; Heinonen & Seppänen, 2016; Riekki et al., 2023). The second concerns the importance of contract models that effectively support takt implementation and facilitate good collaboration. A greater focus on collaboration in contract models is essential to address challenges related to tight deadlines and complex work methods (Heinonen & Seppänen, 2016).

Studies by Kujansuu et al. (2019) and Lehtovaara et al. (2019) highlight the challenges of conflicting contract models and the negative impact of non-collaborative contract terms on project trust and efficiency. These findings suggest a need for contracts that promote openness, manage changes effectively, and support Lean management principles. Moreover, adopting new contract forms that encourage collaboration and innovation could address these challenges, aligning project stakeholders towards common goals and facilitating the successful execution of projects with short takt times.

SUMMARY OF FINDINGS

This literature review has systematically explored the existing knowledge on implementing short takt times in construction projects, identifying seven key themes: maturity, planning, monitoring, visual management, mock-ups, logistics, and collaboration. Table 2 summarises the insights from each of these themes.

Table 2 Summary of findings

Maturity	• Project organizations with higher takt maturity navigate shorter takt times more effectively.
Planning and Preparation	• Thorough planning and preparation are crucial for projects to succeed with shorter takt time – including detailed planning, early integration of takt production requirements, and training in takt principles. • Proactive planning is important to avoid obstacles, reduce the risk of quality errors, and minimize the need for rework.
Production Monitoring and Control	• Short takt requires more active follow-up in the production phase. • Daily coordination meetings are crucial. • The startup phase should facilitate learning and adjustment to shorter takt times. • Continuous plan adjustments and buffer management are essential.
Visual Management	• Digital tools like BIM simplify workflow and communication • Visual tools such as paper takt plans and floor markings enhance on-site management and communication.
Mock-up	• Development and testing in a mock-up can provide valuable insights for planing and executing the takt plan.
Logistics	• Aligning deliveries with takt schedules is crucial for material flow and project progress. • Efficient strategies include systematic planning, material sequencing, Just-In-Time deliveries, and supplier integration. • Advanced inventory management systems minimize time loss.
Collaboration	• Collaborative planning among design teams, main contractors, subcontractors, and suppliers is crucial for short-take-time projects, impacting both takt plans and logistics management. • Conflicting contract models can hinder collaboration, affecting project trust and efficiency. • Contracts should foster openness, effectively manage changes, and adhere to Lean management principles.

DISCUSSION AND CONCLUSION

This paper delivered a systematic literature review focused on using short takt times in construction projects, aiming to synthesize the current body of knowledge and highlight areas for future investigation. A notable discovery is the scarcity of detailed research on short takt times, with just 13 articles addressing the topic. Among these, only one explicitly delves into short takt times, with the rest incorporating short takt cases in their studies, without short takt being the focus of the research. This scarcity raises questions about the specificity of findings to short takt times versus general takt production in construction.

Nevertheless, certain insights emerged distinctly related to short takt times, such as the need for intensified follow-up during production and the observation that organisations with greater experience in takt planning are better equipped to manage short takt times. These points serve as foundational insights for understanding other findings. For instance, while visual management tools are beneficial across takt projects, their value is likely accentuated in projects with short takts. Their use fosters greater transparency and should thereby reduce reliance on managerial oversight.

The study highlighted seven key themes relevant to executing short-take time projects, suggesting these areas as fruitful directions for future research. Although not exclusive to short-take-time projects, they underscore critical considerations in execution, revealing a more complex relationship among them that warrants deeper exploration.

While the themes were presented separately in the results, it is important to recognise the overlap and inherent connections between them. For example, *Maturity*, *Planning and Preparation*, and *Production Monitoring and Control* are closely interrelated. Mature organisations, i.e., those with expertise in takt production,, often have planning processes that anticipate issues and provide early solutions. Mature organisations are better at production monitoring and control, which helps them efficiently manage short takt times, leading to improved workflow and resource utilisation through effective daily coordination and supervision. Thorough planning, including logistics coordination, is essential for managing short takt times. Without it, production monitoring becomes difficult, leading to frequent adjustments that complicate project execution.

The uneven geographical distribution of the studies, with two-thirds originating from Finland, warrants discussion. Why is this the case? There are several reasons. Firstly, the Finnish construction industry has seen a significant rise in the use of takt construction, and Finland has been quicker to adopt shorter takts than other regions. Industry sources indicate that a takt of 2.5 days is now the norm for Finnish projects. Secondly, Finland's research community is very active in takt production research. Over the past five years, Finnish researchers have contributed 30% of all construction-related takt studies, underscoring their significant influence in this area.

Although these factors explain the Finnish dominance in the study, they raise questions about the generalizability of the findings to other regions. While none of the seven themes don't seem directly influenced by cultural factors, future research should consider this aspect.

A notable limitation in the current literature is the lack of in-depth case studies on using short takt times in construction projects. To address this gap, future research should delve into these case studies to better understand how the themes identified in this paper manifest across different regions and project types. This will provide a clearer, more nuanced understanding of the challenges and best practices of implementing short takt times in diverse construction environments.

In conclusion, this paper aimed to consolidate existing knowledge on short takt times in construction through a review of the literature. However, it became evident that the available information is limited. As a result, there isn't enough evidence to offer comprehensive, practical guidance on effectively implementing short takt times in construction projects. Nevertheless, the identified themes serve as a valuable foundation for future empirical research to address this gap, offering insights to guide the development of best practices and strategies in the construction industry.

APPLICATION OF THE WORK DENSITY METHOD TO IN-SITU PILE PRODUCTION IN HEAVY CIVIL ENGINEERING

Anne Fischer[1], Philipp Baumgartner[2], Iris D. Tommelein[3], Konrad Nübel[4] and Johannes Fottner[5]

ABSTRACT

The Work Density Method (WDM) is used in takt planning for defining zones with equal workload. To date, this method has been applied mainly to building construction. This paper investigates the WDM's applicability to equipment-driven processes in heavy civil engineering, specifically to the in-situ production of foundation piles for a highway infrastructure project. Two existing computer-based programs that support the application of the WDM, WoLZo and ViWoLZo, were used to find a suitable grid size based on data from a real-world project. The results show the potential of using the WDM (1) to define zones with equal workloads, given that pile groups are irregularly distributed over the construction site space, (2) to compare different scenarios based on work density as a metric (e.g., scenarios with different uses and sequencing of equipment), and (3) to derive a takt time and process duration when using multiple pieces of equipment that must coordinate their efforts and work in sync. Compared to the building construction application, the heavy civil engineering application reveals new requirements when using the WDM and takt planning in general, regarding the geometrical and logistical needs of equipment-driven operations that constrain how zones can be defined.

KEYWORDS

Production system design, takt planning (TP), Work Density Method (WDM), heavy civil engineering, work structuring, workload leveling, foundation piles, infrastructure project.

INTRODUCTION

As part of heavy civil engineering, in-situ pile production is highly complex due to its variety of variabilities (Fischer et al., 2021). Especially uncertainties related to soil conditions make it hard to plan the piles' production line. The intent of defining a takt plan is to demarcate clear handoffs between predecessor and successor trades, i.e., in-situ pile production followed by the above-ground structure they support, by harnessing variabilities within the production line so that the line's output will reliably meet the customers' target dates (Tommelein, 2020).

The Work Density Method (WDM) was created to methodically support the use of takt when developing construction process plans (Tommelein, 2017, 2022). The method builds on the concept called work density "defined as the time a trade will require to do their work in a certain area, based on (1) product design, (2) scope of the trade's work, (3) specific steps of the operation in their schedule, (4) means and methods the trade will use, and (5) accounting for crew capabilities and size" (after definition in Tommelein et al. (2022)). While this method was first applied to deliver single- and multi-story buildings, it potentially has broader application across the construction industry. Here, we describe how the WDM can be rethought and adapted to suit the specific requirements of heavy civil engineering projects which, in particular in regard to takt planning, differ in several ways from building projects.

Fundamental distinctions between building construction and heavy civil engineering pertain among other things to the number- and specializations of trades involved, the sharing of resources, and the interdependences among them. In heavy civil engineering, major work requires in-situ production, the simultaneous involvement of specialists, and work space requirements that depend on the equipment being used. On projects with earthmoving processes (Kirchbach et al., 2012), considerable variability will likely be encountered. Such variability and other complexity dimensions of heavy civil engineering projects makes characterizing work densities challenging when creating a takt plan.

Our research objective was to determine whether, despite these differences, the WDM can be applied to the specialized field of in-situ production of foundation piles for bridges in a highway infrastructure project, a type of heavy civil engineering projects. The specific research questions were: (1) how to define the grid cells depending on the space the equipment needs to fulfill the work, (2) how to combine these cells into zones while balancing workloads in order to define a takt for the process involving multiple trades, and (3) how beneficial is the WDM when construction work in distributed irregularly over the construction site space?

To answer these questions, we studied the potential application of the WDM using two different computer-based support tools, namely WoLZo by Jabbari et al. (2020) and ViWoLZo by Singh et al. (2020) and Singh & Tommelein (2023a, b). We assessed the suitability of these tools to model the in-situ pile production process while identifying modeling assumptions made for the implementation of these tools that affect the successful use of the WDM in this context. In general, this paper contributes to knowledge by describing the application of the WDM for takt planning of projects of different types and complexity.

LITERATURE REVIEW

Takt planning has been applied to infrastructure projects (e.g., Fiallo & Howell, 2012, Tommelein & Lerche, 2023), on a variety of phases of building projects such as exterior cladding, interior overhead work, and finishes (e.g., Frandson et al., 2013, Linnik et al., 2013), hospitals and hotels (e.g., Riekki et al., 2023), and other types of projects. These projects are characterized by repetitive work and high fragmentation of the work as they require- and due to the involvement of specialized trades. Coordinating these trades to finish the project within the given time, quality, and budget is challenging.

Takt helps to create concurrency in the schedule, thus resulting in shorter delivery times. Takt planning aims to equalize the time each trade needs to complete their scope of work in each zone to achieve a more-or-less continuous flow of work and trades through space. Trades follow each other sequentially, forming a sequence of process steps called a "Parade of Trades" (Tommelein et al., 1999, Tommelein, 2020) or "train of trades" (a term used in the German-speaking areas). Each wagon in the train represents the scope of work fulfilled within one takt time unit by one (or sometimes several) trade(s). In execution, the takt plan may require the use of adjustment mechanisms (Binninger et al., 2017) also known as "throttles" in production system design, e.g., changes in the number of assigned resources.

Figure 1 illustrates the creation of concurrency using takt planning. The top row shows a process with three trades, one following the other, working in a single zone (Z = 1). Each trade needs a specific time to complete their process step, the so-called workload. The workload depends on the scope, means-and-methods selected, capabilities and quantities of resources, and zoning. The maximum amount of time across all trade steps in the process is called the workload peak. In this example, the workload peak, referred to as T(1), is assumed to be six time units/zone. If one can divide the work space into multiple zones, e.g., into two (Z = 2) or three (Z = 3), and correspondingly divide the step of work done by each trade into smaller steps, then the workload peak T(Z) as well as the duration D of the process can likely be reduced. In theory, increasing the number of zones would mean that the duration can get shorter. In practice, however, there is a limit to how small zones can get and still allow for work to take place. The practical size and shape of a zone will depend on the space each trade needs to effectively complete their step of work within the allotted time.

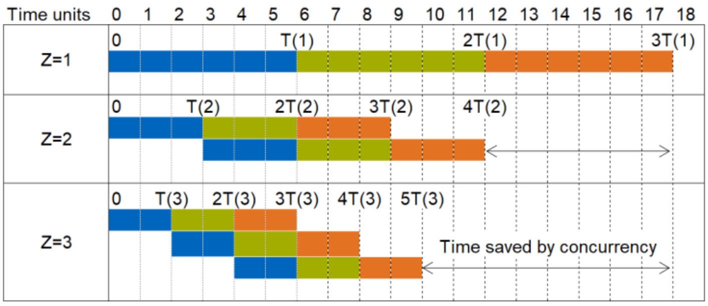

Figure 1: Process with three consecutive process steps, when the work space is divided into one (Z = 1), two (Z = 2), or three (Z = 3) zones to allow for concurrent work (Z: number of zones; T(Z): workload peak) (based on Tommelein (2022))

Formal methods exist to help takt planners with sizing and shaping zones of work. From a workload leveling point of view, data can be used to mathematically determine the work space zoning that minimizes the maximum time any trade in the process needs to complete their work zone by zone. Unlike other space scheduling methods, such as the line-of-balance method, which starts with an *a priori*-defined location breakdown structure, the WDM does not start with *a priori*-defined space units. Instead, it computes each trade's workload in a given zone.

Previous research used the WDM to schedule trades working on interior finishes of building projects. With that type of work in mind, Jabbari et al. (2020) developed a mathematical algorithm, called the Workload Leveling and Zoning (WoLZo) algorithm, to calculate the optimal zoning assuming that the calculated zones would be either rectangular or L-shaped. They defined a zoning to be optimal when it minimizes the workload peak across all steps in all zones. Singh et al. (2020) and Singh & Tommelein (2023a, b) developed a simple visualization of work densities shown in a grid overlaying the work space, programmed in Microsoft Excel. Their Visual Workload Leveling and Zoning (ViWoLZo) program allows users to create zones of any shape. ViWoLZo makes it easy to manually adjust the boundaries of zones, including their size and shape, and compare the workload peak of the process T(Z) to assess whether that process can meet the customers' demand.

METHODOLOGY

APPLIED METHODOLOGY

Since the body of literature relevant to scheduling in-situ pile production processes is limited, we adopted a case-study research methodology. This study was conducted in the context of the master's thesis of Philipp Baumgartner (2023), a co-author of this paper.

To gain fundamental understanding of the study topic, the first and the second authors conducted three semi-structured interviews, 1.5 h each, with four project leaders from three construction companies. These project leaders were considered to be experts in the field, and had been selected on the basis of their local experience and their management position. The interviews centered on understanding the requirements and the details of the Kelly drilling process for pile production in order to document process steps and space needs (Figure 2). The Kelly drilling process is widely used for the production of piles with a large diameter, ranging from 0.6 m to 3 m and up to 125 m deep (Bauer group, 2024). Its flexibility meets various engineering requirements and soil conditions.

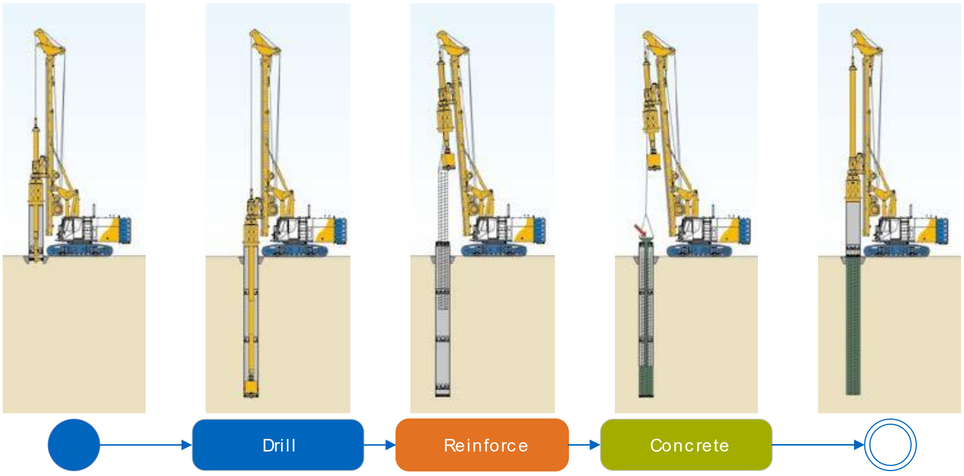

Figure 2: Kelly drilling process: (1) drill, (2) reinforce, (3) concrete
(after image from Bauer group (2024))

To assess the feasibility and effectiveness of using the WDM for process planning of heavy civil engineering work, we obtained input data from a real-world highway infrastructure project. Specifically, we focused on the process pertaining to the in-situ production of bridge foundation piles. This project had unique requirements to accommodate challenging soils conditions: single piles had to be produced in a specific order. Detailed records including extensive datasets were available, detailing production times for each process step in every pile. At the time of our study, all piles had already been produced. We thus mapped the as-built construction process using historical data from this project, informed by the interviews we had conducted previously. We used this data later to calculate the work density corresponding to the grid we chose to superimpose over the construction site (work area). The interviews helped with the evaluation of the results.

IN-SITU PILE PRODUCTION

We next describe the pile production system and compare it with the interior finishing phase of building construction (Table 1). As is the case for materials installed as interior finishes in building construction, the product of heavy civil engineering is installed in well-defined locations. In-situ pile production is characterized by the repetitiveness of the process steps to produce the product, but each product can be unique (e.g., in terms of its geometry and material composition). The process resembles linear assembly line production. The pace-setting resource is the Kelly drilling rig. After the drilling rig is positioned, piles are produced in three main steps: (1) drill, (2) reinforce, and (3) concrete (Figure 2).

In contrast, there are differences in the resources. Building construction is typically done by workers organized in trade crews moving flexibly from one work zone to the other, carrying or carting their tools and materials as needed, and relocating relatively small-sized equipment. Heavy civil engineering is dominated by its equipment with an operator and its support crew.

Movement of the drilling rig and its setup takes times and effort. Besides its sluggishness, the drilling rig needs a specific space to work and allow for a safety clearance, and all its auxiliary devices must be kept within reach. Auxiliary devices include temporarily installed casings to stabilize the drilled hole, oscillators to support the drilling and removal of the casings, and tools to drill in different soil conditions. Small front-end loaders or excavators support this heavy equipment by handling its auxiliary devices and material. Even though the equipment is well-instrumented with sensors to assist the operator, (e.g., automated release of a tool), the quality of pile production depends on the operator's and the supporting crew's know-how and skill.

The differences in the resources lead to differences in the type and degree of digitalization used in the process. Whereas building projects may make use of digital standards and Building Information Modeling (BIM), the process of data collection during execution is still highly manual, in part because people mainly do the work. In contrast, the latest civil engineering equipment is instrumented to support with operator-assistance systems and automatically collect large amounts of sensor data during execution for later process analysis (e.g., Fischer et al., 2023). However, the data describing boundary conditions may be uncertain. For example, digital models may not accurately capture the exact depth of soil layer interfaces, boulders, or groundwater levels. Not knowing the soil characteristics makes it hard to automatically select the optimal tool for the equipment or to determine the tool's optimal soil filling level, so that the operator's and support crew's expert knowledge and intervention is still needed (Fischer et al., 2021). Considering the trend of adoption of construction robotics (Brosque et al., 2020) for equipment-intensive processes, our study can inform how the operations are planned of such systems involving human-machine interaction.

Table 1: Comparison of production systems of interior finishing in building construction with pile production in heavy civil engineering

Characteristics	Interior finishing	Pile production
Product	Rooms	Piles
Process	Process steps are performed by many different trades	Process steps are executed mainly by the same trade crew
Resources	Trade crews with tools and relatively-small equipment	Large equipment and auxiliary devices, operators, foreman, 1-2 construction workers
Flow interruptions	Coordination between the trades	High uncertainty due to the soil conditions
Digital technologies in practice	Collaborative planning using BIM; material tracking with barcodes, RFID, cameras, or notification.	Use of GIS (less use of BIM); material tracking with GPS; digital delivery notes; highly automated equipment with operator-assistance systems.

ADAPTION TO THE WORK DENSITY METHOD

To demonstrate the application of the WDM, we adapted Tommelein et al.'s (2022) example to pile production and rethought how one would partition the work space in zones for takt planning. The objective of this rethinking was to find the number and shape of zones that would balance the workloads of steps in the pile production process, and to possibly create concurrency to reduce the process duration. This potential of rezoning to reduce the duration is stated mathematically:

$$D = (S + Z - 1) \times T(Z) \qquad \text{(Equation 1)}$$

where D is the duration of the process, S the number of process steps, Z the number of zones, and T(Z) is the workload peak, defined as the maximum of all trades' workloads in every process step and every zone. The workload is expressed by trade and in time units (e.g., hours) to complete a certain scope of work in a certain zone, so it could be expressed, e.g., or h/m² or h/pile, with the caveat that zones will likely vary in terms of their physical area (Figure 3).

On the theoretical side, Figure 3 depicts the work density maps referring to the production of two single piles (black circles) installed in three consecutive steps, (1) drill (blue), (2) reinforce (green), and (3) concrete (orange). The number in each cell indicates the work density for that cell, and the darker shade of color in a cell indicates a higher work density.

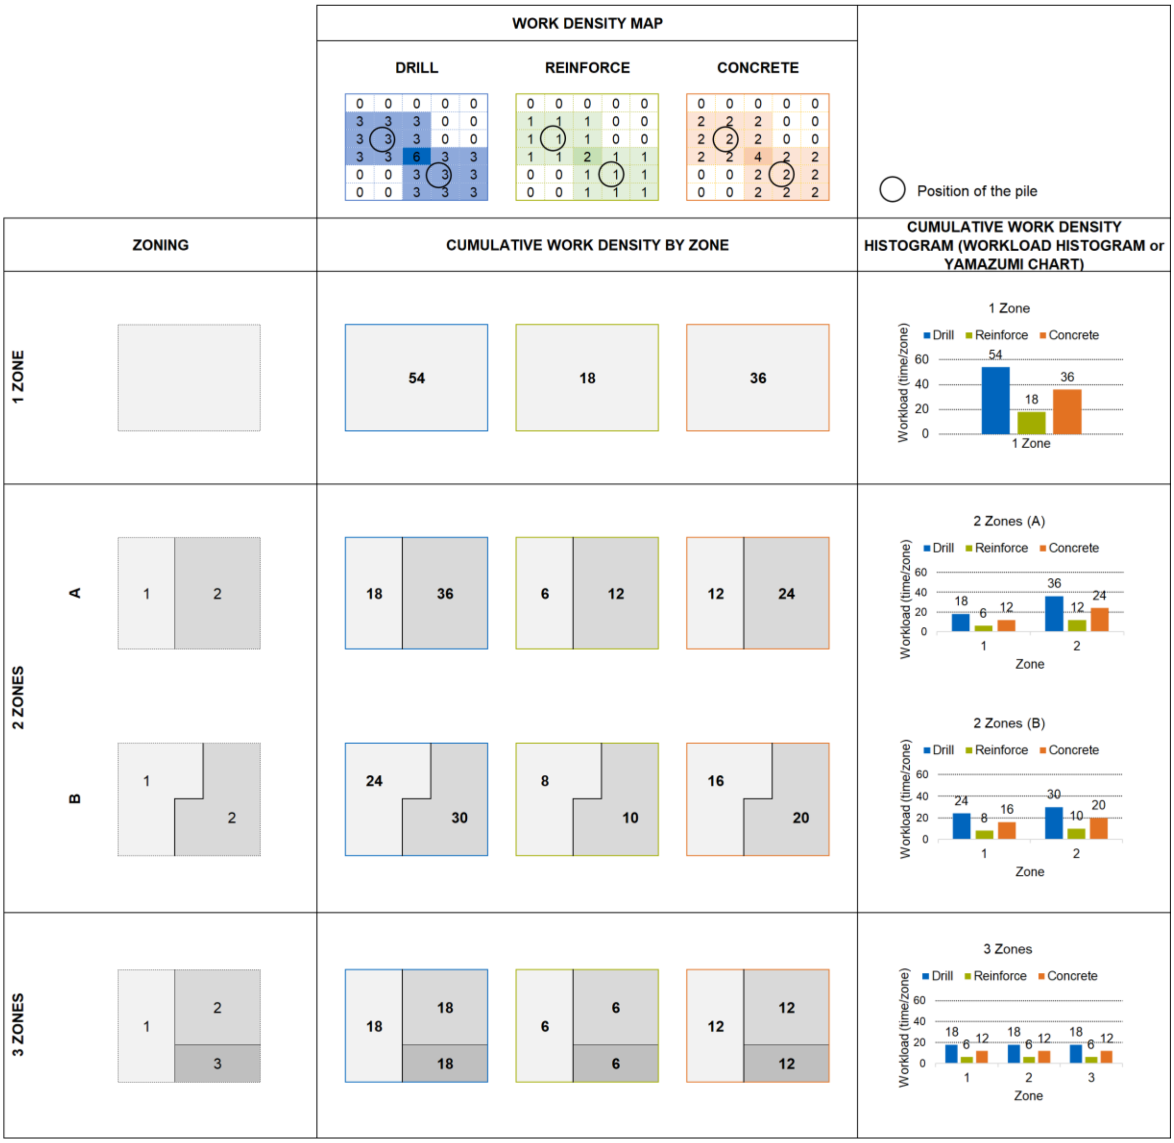

Figure 3: Work density maps and workload histograms for four different zoning alternatives to produce two single piles (after Figure 5 in Tommelein (2022))

For Z = 1, the trade defining the workload peak is the drill trade with T(Z) = 54. In this case, the duration of the process is D = (3 + 1 – 1) × 54 = 162.

For Z = 2, the workload peak may decrease. As the zoning influences the workload, alternative partitions must be considered when trying to even out workloads for any trade, or to reduce the workload peak of the process. The middle of Figure 3 shows partition A with a workload peak of $T(Z_A) = 36$ compared to partition B with $T(Z_B) = 30$.

For Z = 3, the workload peak may decrease further. The bottom of Figure 3 shows one such zoning. In this exceptional circumstance (where the work density maps of drill, reinforce, and concrete are multiples of each other), it is possible to achieve workload evenness within each trade, although there is still unevenness across trades. Evenness across trades can be achieved by combining the reinforce- and concrete trades into a single step.

On the practical side, a certain zoning may be rendered infeasible due to overlapping: if the distance between the piles is too narrow, the space the equipment needs to produce the piles overlap (darkest cells). The space needed depends on the swing radius of the drilling rig (production line) and the auxiliary devices or vehicles (logistics), e.g., casings, tools, a wheel loader for material supply and disposal, or a concrete mixer. Relatively speaking, partition B follows these restrictions best; nevertheless, it is still infeasible due to the overlapping of the zones.

In the case of building construction processes when workload unevenness occurs across trades, it is common to assign more (or fewer) people to trade crews to decrease (or increase) their workload. In the case of the pile production, where the dominance of the drill process step is obvious in all zoning alternatives, the workload per zone cannot be decreased by increasing the number of human resources (but it may be decreased by increasing the skill level of workers, in particular the skill of the equipment operator). One alternative for speeding up the process is to decouple the process steps, so that they are executed by different equipment trades, e.g., (1) drill: for the upper layers of a hole use a drilling rig smaller than the rig needed to drill the deeper layers; (2) reinforce: free up the drilling rig by installing the rebar cage by crane; (3) concrete: pull out casings during concreting by using an oscillator installed in front of a drilling rig.

To sum it up, first, an increase in the number of zones Z can lead to a decrease in the workload peak T(Z) for a certain zoning and, therefore, in the duration D. Second, the workload peak depends on how zones are defined. As mentioned, there is a limitation on any zone's size and shape depending on the space the work practically needs (Jabbari et al., 2020). In the case of pile production, the process is dominated by a highly specialized piece of equipment with a fixed crew. The pile production process duration can be shortened by using multiple pieces of equipment working concurrently in multiple zones.

CASE STUDY

OVERVIEW

The input data are from a completed highway infrastructure project in Rosenheim, Germany. This project involved the construction of a bypass road including two bridges near the German-Austrian border. The project consists of 32 bridge piers, each including any number from 5 to 17 large-diameter bored piles of the same type and ranging from 26 m to 50 m in length. Data from 232 piles in total was used for the case study, including their location on the construction site as well as their production rate. This data was used to test out both computer-based programs, (1) WoLZo and (2) ViWoLZo, made available by the third co-author.

WOLZO

First, we used WoLZo to apply the WDM to the case study. Figure 4 shows the construction site layout overlayed with a grid mesh. We experimented with different grid mesh sized but chose this grid mesh to include multiple piles (independent of their pile groups), allowing the experts enough work space within a grid cell for adjustment during planning and operation.

The production times for all piles within each cell were summed up to create three work density maps, one for each process step. These maps were input to the WoLZo algorithm. The algorithm groups work density grid cells into zones, balancing the cumulative work densities (aka. workload) by zone and by trade to minimize the workload peak of the process and, consequently, determine the achievable takt. The algorithm, constrained to rectangular shapes, achieved optimal results when dividing the area into 14 zones (Figure 5). Figure 6 shows the corresponding workload histogram of the three-step process (S = 3). The workload peak is T(Z) = 41 h and the duration of the process is D = (3 + 14 – 1) × 41 h = 656 h (rounded up to 66 work days of 10 hours/work day).

This first result indicated that: (1) A limit was reached regarding the division of the work space into more zones, as the workload peak was found to correspond to a single grid cell, namely Zone 7 (Figure 5). This high workload is due to the presence of many work-intensive piles in this central location on site. (2) Despite WoLZo's calculation of the optimal zoning, the workloads in the different zones are still uneven. (3) The analysis revealed uneven workloads between process steps across zones.

This unevenness prompted us to combine the reinforce- and concrete step. In theory, the workload is distributed more evenly (Figure 7). In practice this combination is possible, indeed, since the equipment trade of the concrete step uses a drilling rig, and that drilling rig can install the rebar cage. The results show a more even workload histogram across trades (S = 2). The workload peak remains the same, however, the reduced number of process steps results in a reduction of the duration of the process: D = (2 + 14 – 1) × 41 h = 615 h (62 work days).

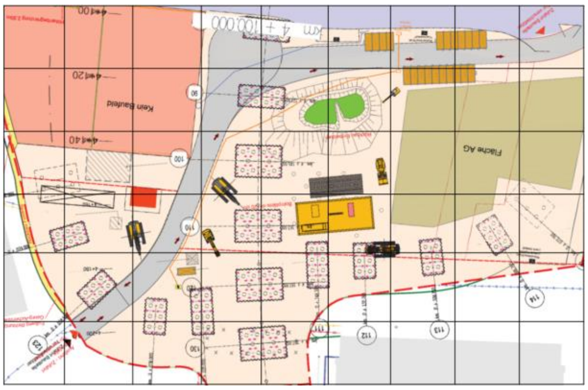

Figure 4: Construction site layout of the case study project overlayed with grid mesh

Figure 5: WoLZo optimal zoning with rectangular shapes for Z = 14

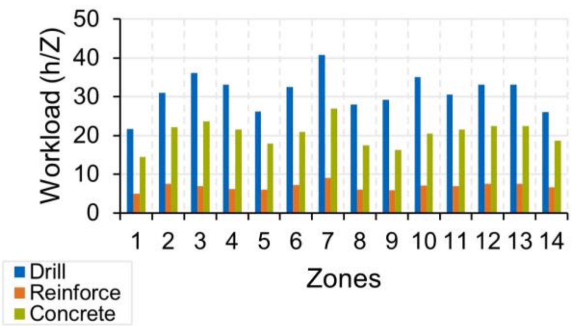

Figure 6: Workload histogram of process steps by zone for three trade steps (S = 3)

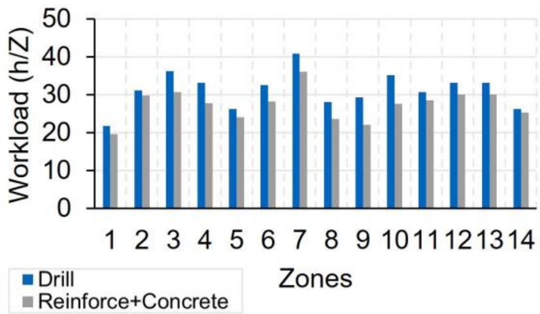

Figure 7: Workload histogram of process steps by zone for two trade steps (reinforce and concrete combined) (S = 2)

VIWOLZO

To further level the workload histogram, the same grid mesh and two work density maps (S = 2) were input to ViWoLZo. Using trial and error, the ViWoLZo user found a better result by going from 14 rectangular zones in the WoLZo calculation to 11 zones (Figure 8). "Better" here means that the distribution of the work densities is more balanced (Figure 10). The new workload peak is T(Z) = 47 h and the duration of the process is D = (2 + 11 – 1) × 47 h = 564 h (57 work days). Compared to the WoLZo results, the process duration is reduced by 51 h which is more than a work week. Despite this improvement, one single grid cell still hasa very high work density (Zone 7). Furthermore, the manually calculated zones are irregular and Zone 5 is split, which may be impractical. Whether to allow zones to be spit, and what shapes zones might take on, are modeling questions (e.g., see Figure 5 in Jabbari et al., 2020).

In pursuit of further improvement, knowing that a finer mesh might enable a zoning with a lower workload peak, the final model focused on the grid mesh size of a cutout of the construction site area, including only four pile groups (frame with dashed lines in Figure 8). Figure 9 shows this cutout with a grid where each cell contains one single pile. It also shows the result of the manual zoning process of this cutout using ViWoLZo, considering the work space needed. The nine zones achieved the most even workload distribution (Figure 11). The workload peak of this cutout is T(Z = 9) = 20 h and the duration D = (2 + 9 – 1) × 20 h = 200 h (20 work days). This final model illustrates the importance of defining a suitable grid mesh and giving careful consideration to process step sizes in order to ensure that zones can accommodate all equipment.

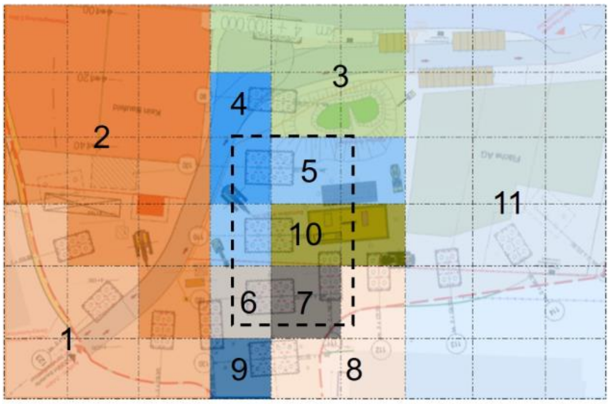

Figure 8: ViWoLZo optimal zoning with manually chosen shapes for Z = 11

RESULTS AND DISCUSSION

The case study showed that the WDM can be applied to in-situ production of foundation piles for a highway infrastructure project, which requires consideration of equipment dependencies. Using a process defined by its steps and the corresponding work density maps as input, two computer-based programs, WoLZo and ViWolZo, were used to zone the work space while achieving a more-or-less even workload distribution for all process steps. Constraints put on the grid mesh regarding work space, the number of process steps, the shape of each zone, and the number of zones all affect the total duration of the process.

The WoLZo algorithm calculated the optimal size and shape of the zones, restricted to rectangular and L-shapes. The resulting zones' workload distributions revealed unevenness, especially per process steps across the zones: the workload for installing the rebar cage (reinforce), and for concreting (concrete) is lower relatively speaking than the workload for drilling the hole (drill). The process steps, reinforce and concrete, were therefore combined in the follow-on study. ViWoLZo gives the flexibility to manually size and shape zones in order to find a more even workload distribution. The zoning obtained show a reduction of the process duration by about 5 work days out of 60, or about 8%.

The study confirmed two notable observations regarding the definition of the mesh size of the grid used in any model. The smaller the grid cells (here one pile in one grid cell), (1) the more flexible the zoning is, and thus the ability to find a lower workload peak (or other process optimum), but (2) the less constrained the zoning is in regard to ensuring that all space requirements are satisfied (e.g., the zone must be accommodate the area of the equipment footprint and requisite surrounding work space).

The case study results reflect the use of a single equipment trade for drilling, reinforcing, and concreting. Further study might consider multiples of that single equipment trade, e.g., using a single equipment trade for a single process step (one for drill, and one for reinforce and concrete), working sequentially from one zone to the next. Decoupling of process steps should allow for a smooth and stable handover from one- to the following step. This further study could be conducted, e.g., through experimental modeling using simulation (Abdelmegid et al., 2022). Practical challenges, such as soil disposal and excavation management, underscore the importance of considering logistics in takt planning. One must balance multiple flows (trades, material supply and removal, equipment, etc.) instead of one flow with a single criterion (here trades) (Tommelein et al., 2022). Besides process requirements, organizational requirements must also be addressed to enable a continuous assembly flow between different trades (Kujansuu et al., 2019). In the presented case study, the zoning was based only on spatial and process constraints. Cost and other resource requirements were not considered.

The case study results significantly underestimated the actual duration of the pile production process, which took 119 work days. Reasons are that the models based on work density did not account for work breaks (e.g., overnight breaks between process steps, with a step ending before the end of a 10 hour work day), nor for the movement and installation of the drilling rig from one pile location to the next. Furthermore, no disturbances or irregularities were considered. However, regularity was embedded in the actual schedule (though it was not takt plan) to facilitate the coordination between specialists, e.g., concrete delivery was scheduled for a specific time each day, even though that resulted in waiting time for the drilling rig.

CONCLUSION AND OUTLOOK

This study's aim was to assess the applicability of the Work Density Method (WDM) in heavy civil engineering projects, demonstrating its requirements within a specific case-study project. Applying a takt planning approach seemed promising for synchronizing the use of resources and process duration planning. The case study showed that takt planning applies to equipment-driven processes. It did so by illustrating the use of the WDM, one method to zone the work space by equalizing workload. Two different computer-based programs, WoLZo and ViWoLZo, were used.

Compared to building construction projects, heavy civil engineering projects have different dimensions of complexity; they can be equipment-driven with a single piece of equipment setting the pace for the overall process. The highly specified equipment trade seems to act like a one-piece workflow, which makes it hard to throttle up and down the pace. This notwithstanding, the case study showed that zoning according to WDM helps even out workloads to reduce the process duration.

Regarding the research questions 1 and 2 on how to define and combine grids and zones, the answer is that equipment space needs as well as logistics must be added as considerations in new models that could build on algorithms such as WoLZo's. In its current implementation, WoLZo constrains zones to be rectangular or L-shaped, and the cells in zones must be contiguous. In contrast, in its current implementation, ViWoLZo allows for flexibility by allowing zones to be split and irregularly shaped (research question 3), but it too needs augmentation to address the aforementioned considerations. Further model extensions could provide support to better represent space needs for equipment, pile groups, etc., and to investigate concurrency by multiple pieces of equipment.

The case study highlighted the need to adapt the WDM to the unique characteristics project types. Further research can look into optimizing crew- and equipment coordination, developing logistics strategies, considering sustainability factors, and integrating the WDM with project management software to enhance project delivery. Validation through benchmarking, education, and training is in order to facilitate the WDM's adoption and success in the heavy civil engineering sector.

IMPROVING REASONS FOR NON-COMPLIANCE DOCUMENTATION USING UAV ON CONSTRUCTION PROJECTS

Mauricio J. Toledo[1] and Brian E. Sánchez[2]

ABSTRACT

Most Last Planner System® (LPS) research focused on finding the Reasons for Non-Compliance (RNC) and their origins come from indirect means such as perception surveys, therefore, registered RNC are based on opinions and not facts. This situation causes an incorrect categorization of RNC, and consequently, these RNC remain unsolved and they would probably happen again.

The aim of this research is to create a formal registry of RNC on construction building projects during rough works for improving RNC documentation, using photos taken by an unmanned aerial vehicle (UAV). We performed 3 case studies: one using a traditional planning method, and two other projects using partial LPS implementation. We took aerial photos with the UAV to register unfulfilled Work Commitments (WC), their RNC and to propose a Corrective Action (CA) that would solve the RNC. This registry is supported by analyzing the RNC with an Ishikawa Diagram and using the 5 Why 2 How method (5W2H) to systematically propose a CA. We documented all this information in a "RNC Form" for each RNC detected. We took photos once a week for the project with a traditional planning method and twice a week for the projects with partial LPS implementation. We created 22 RNC Forms, which we shared with the project team professionals to receive feedback.

The results are a methodology that accounts for a standardized process on how to carry out the UAV flights, photo taking and subsequently, how to document the RNC creating a RNC Form. This shows a more objective and visual record of the RNC, from which a process of continuous improvement is encouraged, by proposing a CA that solves the identified problem. The methodology and the RNC Form were validated with surveys on a Likert scale, from 1 (strongly disagree) to 4 (strongly agree). We interviewed 7 construction field professionals from the three projects. The composition of the RNC Form and the future use of the proposed methodology reached a score of 4.0 and 3.9 respectively; therefore, they were highly valued by the field professionals.

KEYWORDS

Reasons for non-compliance, RNC, UAV, LPS, corrective action.

INTRODUCTION

Since its introduction by Glenn Ballard and Greg Howell at the end of the 20th century, the Last Planner System® (LPS) has proven to be an efficient tool in project management, evolving from short-term planning and problem solving to a unified, continuous process improvement system for planning and control of projects throughout their entire life cycle (Ballard & Tommelein, 2020).

1 Assistant Professor, Head of Civil Engineering Department, Universidad Andres Bello, Chile, mauricio.toledo@unab.cl, orcid.org/ 0000-0002-3903-7260

2 Student, Civil Engineering Department, Universidad Andres Bello, Chile, b.snchezramos@uandresbello.edu

Despite the adoption of LPS, a large majority of construction projects implements only partial LPS, and they usually focus on short-term planning. The Percentage of Plan Completed (PPC) and Reasons for Non-Compliance (RNC) are the most used metrics on LPS projects (Daniel et al., 2015). However, RNC, which are recorded to generate a Corrective Action (CA) and thus prevent future recurrence, usually come from single case studies or indirect means such as perception surveys (Lagos & Alarcón, 2021). This indirect process may result in failure to identify the real source of the RNC, causing the proposed CA to be incorrect and not providing an adequate solution to the problem. Thus, our research question is: What should be the procedure to improve RNC documentation?

Therefore, this research proposes a methodology for documenting the RNC. We propose to use a type A3 document (Gupta et al., 2019; Koskela et al., 2020) called "RNC Form" to visually document site conditions related to detected RNC. The RNC Form provides background information about the Work Commitments (WC), it describes the RNC type and its impacts and once the problem is identified, it recommends a CA, which provides a solution to the problem. Site photos taken using an unmanned aerial vehicle (UAV) support this process. We also use the project schedule, and the construction methodologies to visually show the unfulfilled WC for short term planning. Our aim is to standardize the proposed methodology, indicating the relevant parameters for an adequate documentation and the required time to carry this out. We expect to replicate this procedure in future projects.

LITERATURE REVIEW

Reason for Non-Compliance (RNC) is defined in the Last Planner System® (LPS) literature as the reason why short term Work Commitments (WC) are not fulfilled (Ballard, 2000).

Most of the RNC are caused by the general contractors (construction companies) and subcontractors in high-rise building projects (Lagos & Alarcon, 2021). The lack of workspace is a frequent problem that construction companies must constantly coordinate and review to avoid site congestion and interference among trades that affect the work performance for the rest of the team (Sabbatino et al., 2011). Subcontracts fail in what is generally the most frequent RNC in the construction industry: lack of labor (Sabbatino et al., 2011).

Registry of RNC usually comes through third parties (Lagos & Alarcón, 2021) or indirect means (Daniel et al., 2015), which can lead to erroneous registry and consequently to persistent unsolved construction problems. This deficiency of current LPS practice should be addressed. According to López (2013) the average PPC in construction projects does not exceed 70%, therefore this represent a big problem. The lack of an accurate RNC registry can be addressed using the Ishikawa Diagram analysis to visually identify the root causes of RNC in 6 generic categories of idea generation (Tague, 2005).

We identify the RNC to understand the causes of the problem and to generate a corrective action (CA). Thus, we create a continuous improvement process and we avoid the repetition of RNC for subsequent WC (Ballard, 2000). We used the 5W2H method for this purpose (Tague, 2005) and we asked 7 structured questions to briefly explain the proposed CA, to describe the procedure to follow and justify its cost. As input, we use all relevant information about the detected RNC (problem).

The use of a camera-equipped UAV provides an unprecedented opportunity for inexpensive, easy and fast documentation of the execution of on-site planning (Ham et al., 2016) and this information allow us to find of a large number of spatial interferences (Zapata & Sánchez, 2020). UAVs have been used in the construction industry for different purposes, such as: safety inspections (Irizarry et al., 2012), applications in construction management like land surveying, logistics, on-site construction, maintenance and demolition (Li & Liu, 2019). They have even been used for progress tracking (Álvares & Costa, 2018). However, commercial use of UAVs has experienced an exponential growth in recent years, which has consequently led to an increase of aerial incidents recorded in the last decade (Pérez & Ortiz, 2020). Therefore, we need an UAV flight strategy adequate to each project´s site conditions.

Bordin et al. (2018) noted the use of A3 reports as a Kaizen tool to provide context of a problem, describe the current situation, the improvement objective, provide an analysis, and an action plan that addressed the situation to be improved. According to Gupta et al. (2019), A3 documents have a great potential to improve the effectiveness and communication of information in the construction industry. Therefore, we standardized the format to describe the information gathered in the field and to present the analyses performed using an A3 document as a single page report.

METHODOLOGY

We followed the CIFE Horseshoe (Fischer, 2006) to guide our observation of a practical problem, to develop a plan to address it. In our literature review, we identified the lack of objectivity in the registration of RNC as a problem and we found that UAV use might facilitate visual information to perform such registration (Chica et al., 2019; Zapata & Sánchez, 2020). The most common RNC in Chilean construction projects during rough construction are: lack of labor, lack of workspace and missing prerequisites (Sabbatino et al., 2011), therefore that will be our initial research focus. Then, we will document non-compliance of work commitments (construction activities) using UAV pictures.

We carried out three case studies on Chilean building projects during the rough works stage. One of the projects used traditional planning, while the other two had a partial LPS implementation. We conducted on-site monitoring for a maximum of 6 weeks per project. We planned UAV flight strategies for each project to take high-resolution photos of workspaces and to avoid possible accidents both on the field and on its surroundings. Figure 1 shows the three case studies. Figure 1a shows a 2-story building in a low-density neighborhood. Figure 1b and 1c show cases 2 and 3, both midsize residential buildings on high density neighborhoods.

We analyzed the RNC using the visual information of unfulfilled work commitments (WC). We briefly explained the factors causing non-compliance using an Ishikawa Diagram. After analyzing the RNC, we proposed a Corrective Action (CA) using the 5W2H methodology, providing a brief explanation of the procedure. We created a RNC Form that documents the analysis and visualization of the detected RNC and we shared it with the field office to receive feedback.

Figure 1: Case Studies: (a) 2-story reinforced concrete and confined masonry building (384 m2); (b) 7-story reinforced concrete building (approx. 2,000 m2); (c) 7-story reinforced concrete building (approx. 900 m2).

Finally, we applied validation surveys to the project team members for each case study to quantify the impact of this research. 7 construction professionals (civil engineers and construction managers with 5-10 years of construction experience), answered our survey after a 30-min presentation of our methodology. Their familiarity with the project, with our work and the weekly feedback received during the on-site monitoring brought valuable feedback to our proposal. The validation survey had 11 question and we used a Likert scale, from 1 (strongly disagree) to 4 (strongly agree) to receive feedback about the proposed methodology, the structure of the RNC Form and the future use of the proposed methodology.

RESULTS

We created 22 RNC Forms that we shared with project team members for each case study to validate our hypothesis about the need of an objective RNC registry. At the end of the 6-week construction project monitoring, we showed our RNC Forms and methodology to each field office team and asked them for feedback with a validation survey. The purpose of this survey was to demonstrate the usefulness of the proposed methodology, the adequate visualization and understanding of the RNC Form structure and to test the potential adoption of this process in future projects.

PROPOSED METHODOLOGY

Figure 2 summarizes the main three components of the methodology: (i) Creation of a flight strategy in a simulated environment (steps in light blue); (ii) Weekly site visits (steps in gray); and (iii) Creation of the RNC Form (steps in orange). The time required for the execution of the proposed methodology is divided into two categories:

1. One time processes: They establish the flight strategy for each case study. They have a total duration of 4:30 hours and we show them in light blue in Figure 2.

2. Periodically executed processes: Steps that are executed every week. Total execution time depends on the number of weekly site visits and the number of RNC Forms made. The site visit includes the request of the weekly planning, thus, we know the weekly work commitments and workspaces beforehand and we plan the UAV flight strategy and capture pictures accordingly. The RNC Forms register the unfulfilled WC and their RNC, according to the weekly planning. Figure 2 shows that each site visit takes 45 minutes (grey steps), and that the estimated time to create a RNC Form is 1 hour (orange steps).

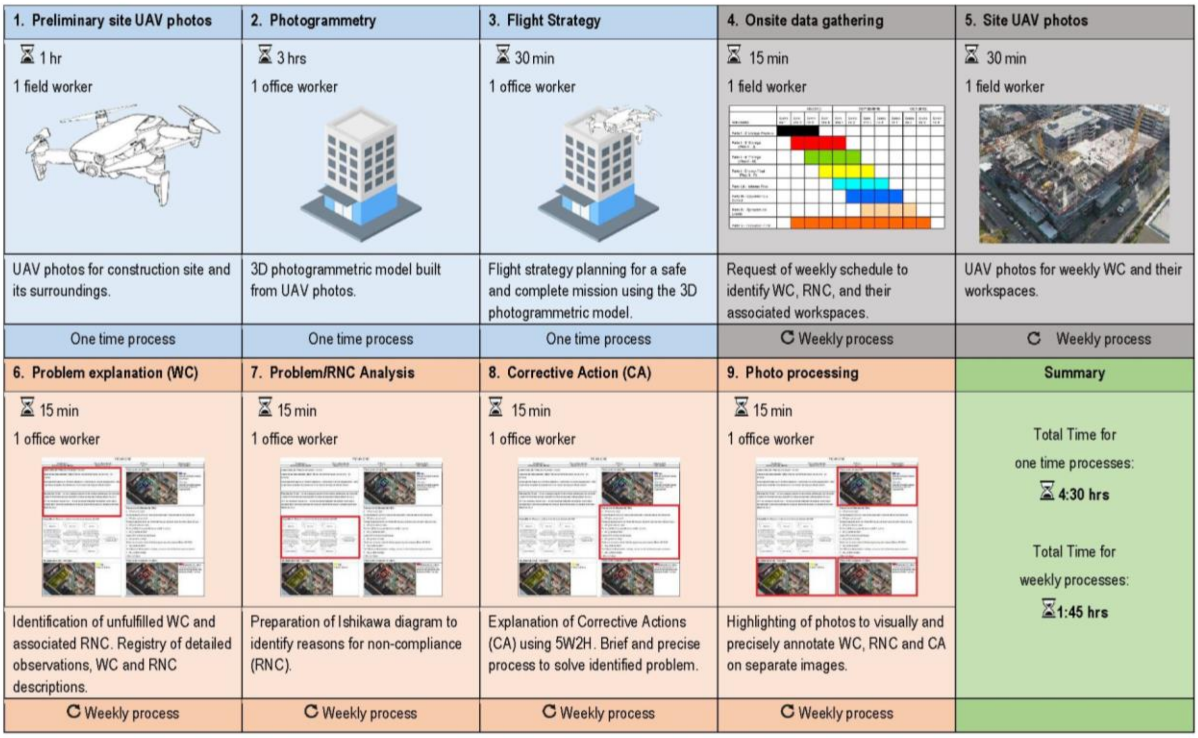

Figure 2: Proposed methodology and execution time summary.

Flight Strategy

We created photogrammetric 3D models to develop a flight strategy for each project. These models, shown in Figure 3, allowed us to explore the construction site and its surroundings for each case study, in order to plan the weekly UAV photo shooting and avoid obstacles. We built the photogrammetric model from a single grid flight mission around each project site. Each model is approx. 100 m by 100 m. These parameters allowed us to generate photogrammetric models with a GSD of less than 2 cm/pixel. On these 3D photogrammetric models, we planned/tested the flight strategies. In most cases, we chose circular flights around fixed points on site, with a target flight height of 40 m and a radius of 30 m (as shown in Figure 3).

Case study 1: The project size is approximately 12 m by 32 m, so our flight strategy captured the entire project with a single circular UAV flight, as shown in Figure 3a.

Case study 2: The largest project required 3 circular UAV flights to cover the entire project site, as shown in Figure 3b. Unlike the other case studies, this project was near completion of the rough works during our research, thus we only spent 4 weeks on-site and consequently we built fewer RNC Forms.

Case study 3: The buildings surroundings and the presence of a tower crane in this project, forced us to reduce the flight strategy to a semicircle (as shown in Figure 3c) and to elevate the flight height from 40 m to 60 m to avoid collision with the crane.

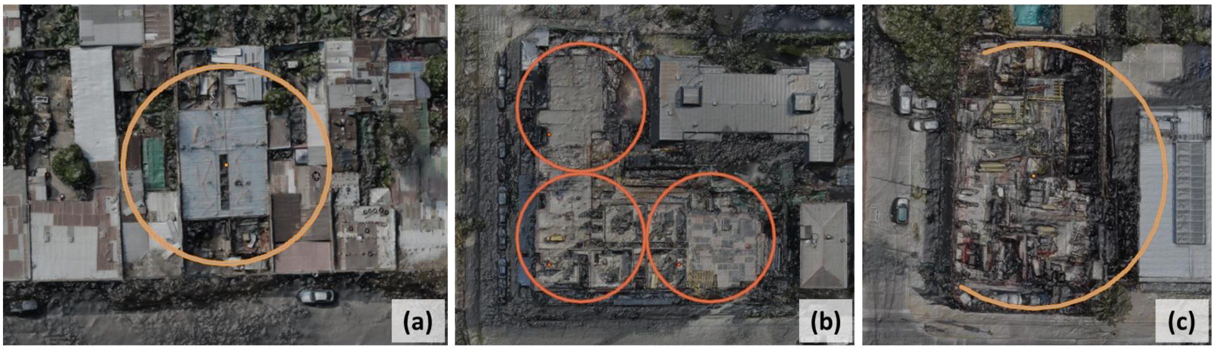

Figure 3: Flight Strategies: (a) Case study 1: single circular flight; (b) Case study 2: large project footprint demands 3 circular flights; (c) Case study 3: obstacles and tower crane presence force a semicircle flight.

Weekly Project Visit

We visited each project twice a week during the construction project monitoring. We executed our UAV flight strategies to take site photos. We asked about the construction processes and WC for each case study, and we gathered information about the weekly planning. We also showed the RNC Forms from past weeks to the field professionals. The visits were at least 1 day apart, to be able to notice significant changes between one visit and another. Case study 1 was the smallest project and it used a traditional planning method. It did not show much weekly progress, thus we reduced the site visits to once per week.

RNC FORM

The RNC Form is divided into 2 main parts: left and right. The left part seeks to describe and provide context to the unfulfilled WC, the identification of the associated RNC and its analysis using the Ishikawa Diagram, and an illustration of the WC and its location in the field. The right part seeks to illustrate the RNC, how to achieve the CA using the 5W2H method and a picture showing the CA location. Figure 4 shows a RNC Form that has 7 major sections: (1) General Information about the construction company, date and time of photos for the CNC Form, and the UAV operator's name; (2) Background about the name, description, and explanation of the WC and RNC; (3) Ishikawa Diagram that explains the factors causing unfulfilled WC; (4) WC

Visualization that shows an annotated (yellow) photo of the WC location, and a brief text description; (5) RNC Visualization that shows an annotated photo (blue) of the RNC location and type; (6) Corrective Action (CA) that describes the solution to the RNC according to the 5W2H method; and (7) Visualization of the CA that shows an annotated photo (red) of the CA location, accompanied by a brief explanation.

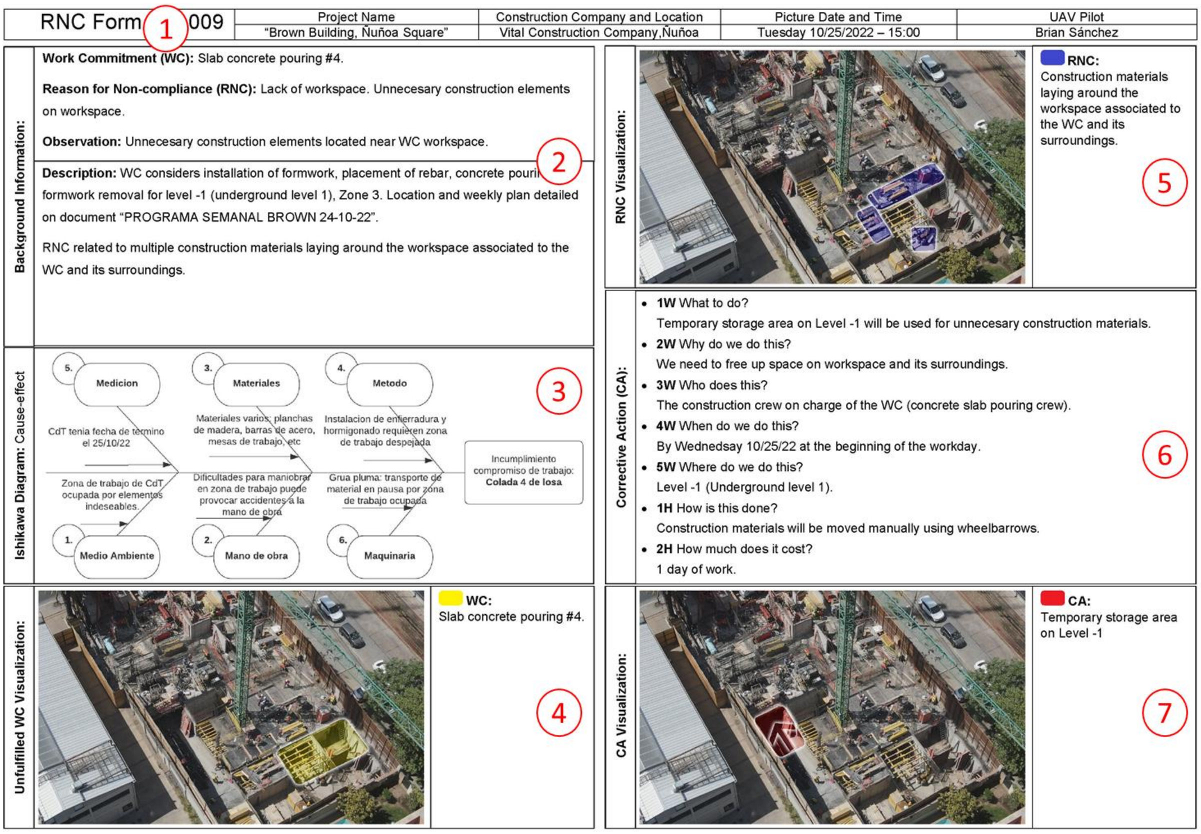

Figure 4: RNC Form 009, Case Study 3 – Brown Building, Ñuñoa Square.

We analyzed the photos taken during the week to identify and describe the unfulfilled WC and to identify and classify the observed RNC.

RNC are different in nature, thus for each type of RNC studied, we built a detailed definition of the 6 categories of the Ishikawa Diagram: Measurement, Materials, Method, Environment, Labor and Equipment. For instance, *RNC lack of workspace* refers to any undesirable element that prevents the realization of the WC. This can be dirt, debris and/or disorganized storage of materials. In this case, *Environment* is the most relevant aspect for the RNC (what can I find in the workspace? and why it hinders WC?). We list each category according to its importance for each case: 1 is the most important factor in the diagram and 6 the least important. This ranking varies for each RNC type. However, for the same RNC type, the main category is always the same. *Labor* is the most important factor for *RNC lack of labor* and *Measurement* is the most important factor for *RNC missing prerequisites.*

For each recorded RNC, we proposed a corrective action (CA) to solve the problem using the 5W2H method (Tague, 2005). After defining the CA, we searched among the UAV photos to find the one that best visually depicts the site conditions. We use yellow, blue and red annotations in the picture to highlight the location of the WC, RNC and CA respectively. We highlight them in separated pictures to avoid annotation overlapping, as shown in Figure 4.

We prepared at least 1 RNC Forms for each site visit and we showed them to the field professionals for each project the following week. We shared the RNC Forms in A3 format as shown in Figure 4 in both electronic (PDF) and printed form.

We prepared and shared 22 RNC Forms for the 3 case studies with the field professionals and we periodically received their feedback and validation regarding the RNC, its depiction, and the associated CA. Several of our suggested CA were actually implemented. We did not find *RNC lack of labor*. We found 9 instances of *RNC missing prerequisites*, 8 instances of *RNC lack of workspace* and we had to define a new type we called *RNC lack of materials* (5 instances). We created 6 RNC Forms for Case Study 1 (our guinea-pig project), 6 RNC Forms for Case Study 2 and 10 RNC Forms for Case Study 3.

VALIDATION

We applied a validation survey to 7 field professionals from the 3 case studies. The survey has three major groups of questions. First, we asked whether the proposed methodology is adequate as a tool for creating an objective RNC registry for short term planning. We asked about the suggested procedure and the time required for its execution. Second, we asked whether the RNC Form structure is clear. We asked if the RNC Form adequately explains, analyzes and visualizes the WC; and if it adequately describes and visualizes the RNC; and if it adequately explains the proposed CA and its visualization. Third, we asked about the future use of the proposed methodology for construction projects during rough works. We used a Likert scale for the validation survey with multiple-choice answers ranging from 1 to 4, where: strongly disagree (1), disagree (2), agree (3) and strongly agree (4). The validation results are shown in Figure 5.

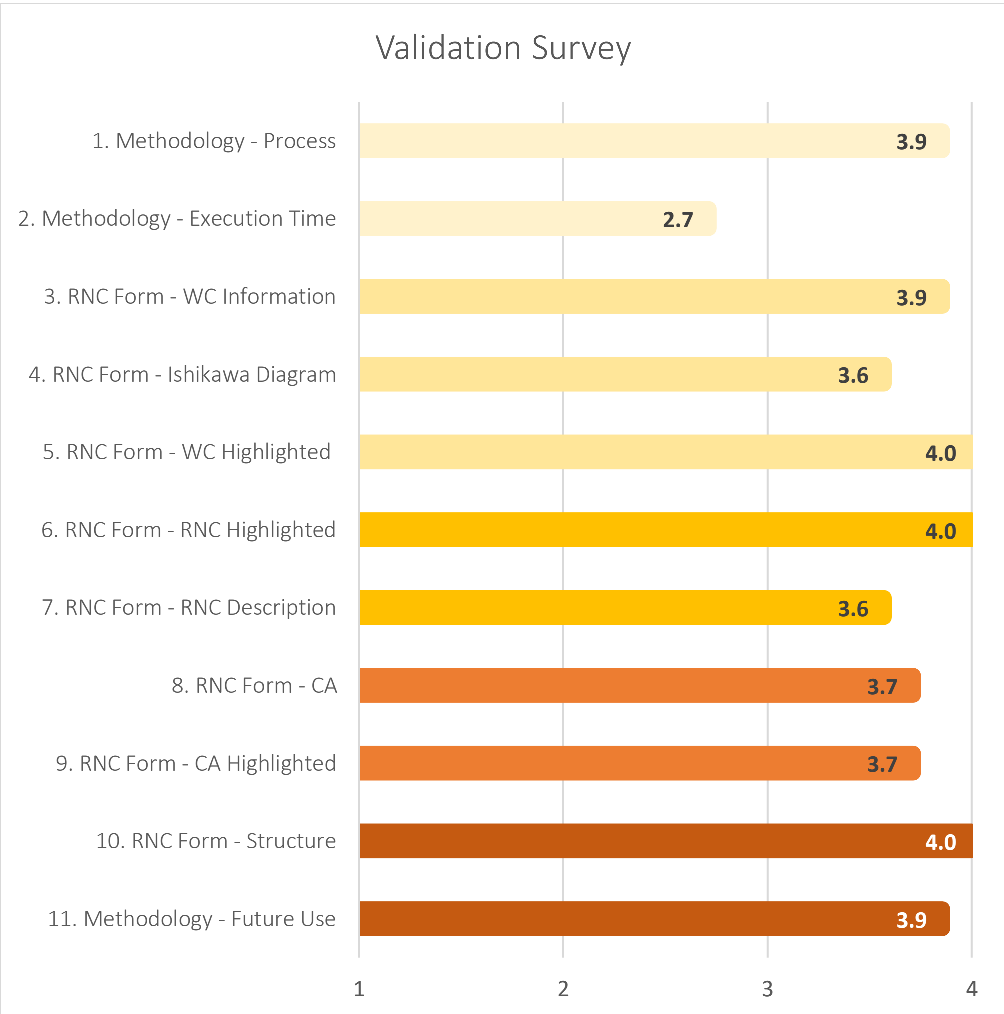

Figure 5: Validation Survey Summary Results.

In the first group of questions, we asked about the proposed methodology and it was well received with an average score of 3.3 (Q1 & Q2). For the second group of questions we asked about the RNC Form and its structure as a registry for RNC. We received a high level of approval with an average score of 3.8 (Q3 to Q10). In the third group of questions, we asked about future use of our methodology and we obtained the best results with an average score of 3.9 (Q11). Thus, as a whole we obtained an overall score of 3.7 in the survey, which means that our methodology was highly valued by the field professionals.

Respondents liked the proposed research with an average score of 3.9, but they pointed out that was a lengthy process with a score of 2.7, as shown in Figure 5. Regarding the RNC Form, respondents valued the WC section, and they rated the WC background context, the explanatory Ishikawa diagram and the WC visual annotation with scores of 3.9, 3.6 and 4.0 respectively. They also valued the RNC visualization and the explanation for each annotated picture, with scores of 4.0 and 3.6 respectively. Respondents also valued the CA proposed using the 5W2H method and its annotated picture, where both received a score of 3.7. Finally, the respondents had a positive feedback about the structure/organization of the RNC Form and they were willing to use the methodology in future projects, with scores of 4.0 and 3.9 respectively.

DISCUSSION

In our literature review, we identified the "lack of labor" as a relevant RNC during rough works projects; however, we could not capture this type of RNC in our UAV flights for the three case studies. We took photos during our site visits centered on the workspace for each WC, but the crews of construction trades were constantly moving throughout the construction site and we could not document missing workers. Therefore, we were not certain that unfulfilled WC were due to lack of labor.

Depending on the project scheduling sophistication, the project team valued differently our proposed methodology. Team members from Case Study 1 (traditional planning) valued the suggested CA for unfulfilled WC. For instance, in our 1st RNC Form we suggested the implementation of a temporary staircase that would provide safe access to the 2nd floor. Our RNC Form documented the problem and CA proposed and the project team built such staircase (on a different location though). For Case Studies 2 and 3 (partial LPS planning), the project team particularly valued the usefulness of the RNC analysis shown in the Ishikawa Diagram of the RNC Form. As no formal RNC registry existed, they valued the RNC analysis, which complemented the weekly planning and project PPC metric (Percentage of Plan Completed).

Our RNC Form arose from the need to summarize the analyses of the proposed methodology in a compact format and using weekly visual information from the UAV pictures. The RNC Form final version corresponds to the 7th iteration of this process. We modified preliminary versions of the RNC Forms, both by incorporating the feedback obtained in each project from the field professionals and by continuous improvement.

CONCLUSIONS

The purpose of this research was to create an objective RNC registry, based on actual weekly site conditions. We proposed a methodology that standardized the analyses for the WC, the RNC and its associated CA, and that is visually supported by photos taken using an UAV. We called it the RNC Form. We built 22 RNC Forms for the 3 case studies. We received feedback and validated the RNC Form and our methodology with field professionals.

Our methodology has an estimated execution time of 1 hour per week per RNC Form and can be summarized in three parts:

(1) Flight strategy in a simulated environment: We use a 3D photogrammetric model to create a safe and efficient UAV flight strategy for each project. This process is done only once per project and has an estimated duration of 4:30 hours.
(2) Weekly site visits: We gather site information to build a RNC Form. We asked for the project weekly planning and used the flight strategy for taking UAV photos of the workspace associated to weekly work commitments (WC). This weekly process lasts approximately 45 minutes.
(3) RNC Form: Given the weekly schedule, the unfulfilled WC and the RNC, we built visual RNC Forms that proposed a CA. This weekly process lasts approximately 1 hour per RNC Form.

Our validation survey shows that field professional valued our visual RNC Form (The overall score of 3.7). They considered adequate the explanation and description of the WC, the RNC analyses, and the suggested CA (with an average score of 3.8). They are willing to use the RNC Form in future projects (average score of 3.9).

FURTHER RESEARCH

Our methodology aims to work in support of field professionals, i.e., we do not want to interfere in the construction processes or planning used in building projects. We want to enhance the scheduling process, using an LPS-based tool to document RNC that interrupt the workflow and propose a solution (CA) that eliminates waste.

We see opportunities for future research implementing RNC Forms on different types of construction projects as well as exploring other types of RNC. We applied the methodology on 3 case studies during the rough works, but we see potential for use during other construction phases such as excavation. We worked on an urban environment, but we could also explore the application of our RNC Forms on other building types on rural or/and remote environments.

Finally, if we are able to systematically create RNC Forms for ongoing projects, which seems plausible given the acceptance and willingness to use them by field professionals, we could perform a better categorization of RNC Forms, beyond the three types we found with our UAV-pictures (*RNC missing prerequisites, RNC lack of workspace* and *RNC lack of materials*). Once we have a large number of RNC Forms, we could perform statistical analyses of RNC or explore the effectiveness of CA to avoid recurrence of RNC.

ACKNOWLEDGMENTS

We would like to thank the project teams from each case study, for the access to the building projects and their invaluable feedback both during the development process and at the end answering our validation survey.

QUANTITATIVE INDICATORS IN TAKT PRODUCTION CONTROL: AN EMPIRICAL ANALYSIS

Jaakko Riekki[1], Olli Seppänen[2], Joonas Lehtovaara[3] and Antti Peltokorpi[4]

ABSTRACT

Takt production has improved lead times and stability of lean construction projects. There are several studies about takt planning but research on takt control is scant. Although some quantitative indicators have been proposed for assessing how well sites are able to follow the plan, there are no studies which have used these indicators on real projects on a work package and daily level of detail.

This paper investigates through a case example how previously proposed quantitative indicators of takt control work on a detailed level. We also discuss how the indicators can be interpreted for understanding plan adherence, control actions, and improvement opportunities.

Studying takt control aims to learn why and how production deviates from the plan and how management should act to get the intended production realized. Quantitative analysis with progress data and indicators calculated from them can be used to measure deviation from the plan and the performance of the production system. This paper shows how takt control can be analyzed with flow efficiency and punctuality indicators. Indicators reveal improvement opportunities in outlier trades and takt areas in flow efficiency, the relationship of product and operations flow and go-back work areas.

KEYWORDS

Takt production, production control, quantitative indicators, progress tracking, improvement

INTRODUCTION

Takt production in construction has seen increasing attention from lean construction scholars. So far, the focus of takt production development has been on takt planning, but studies such as Lehtovaara et al. (2021) have qualitatively assessed the effects of takt production in execution. Their results indicated that takt projects tend not to follow the plan exactly but did not elaborate on the nature of issues encountered. Takt control has also been qualitatively touched by Binninger et al. (2017) in the form of proposing a set of possible adjustment mechanisms.

However, studying takt control with quantitative methods could increase understanding on detailed level. The challenge is that quantitative analysis requires gathering data by tracking and recording progress of the schedule on a detailed level. Detailed progress tracking and

recording can be tedious for the site management team although it can be aided by technology (Keskiniva et al., 2021). Zhao et al. (2021) showed how tracking workers and materials and linking them to schedules can be done with indoor positioning, but this technology is not yet very prevalent.

Despite the challenge, quantitative methods have been used previously for production control in construction in several settings. Hamzeh et al. (2019) proposed a set of metrics and a dashboard aimed at evaluating the performance of the Last Planner® System (LPS) of production planning and control on the team and project levels. These metrics measure the reliability of planning of future work and whether the system is on track towards milestones, but not adherence to a set schedule per se. In location-based management system (LBMS) studies, quantitative methods have been used for assessing production flow. Seppänen (2009) analyzed three LBMS cases quantitatively in detail. Sacks et al. (2017) proposed a quantitative construction flow index (CFI) and tested it in a number of LBMS case projects. For takt production, methods for calculating quantitative flow efficiency measures have been published by Binninger et al. (2019). Binninger (2021) also quantitatively showed the flow properties of an aggregated set of takt cases on a project portfolio level. Further, Alhava et al. (2019) showed with data, how takt production does not always follow the plan but did not analyze the data in detail. Conceptually, Keskiniva et al. (2023) suggested several indicators for takt production performance assessment. However, none of the above-mentioned studies have analyzed takt production quantitatively on a daily and work crew level of detail. This motivates further quantitative analysis in the takt production control context with finer granularity to better understand the actual performance of takt production in execution.

The aim of this paper is to investigate through a case example: (1) How do previously proposed quantitative indicators of takt control work on a daily and work crew level of detail? and (2) How can these indicators be interpreted for understanding plan adherence, control actions and improvement opportunities?

To achieve the aim, a detailed set of progress records of a takt phase of a case project was analyzed. A set of pre-published indicators were used to investigate how they behave with real project data.

METHOD

We first briefly describe the case project and the method of data gathering and extraction, because it has implications on choices that were made for the calculation of the indicators. After that, we introduce the indicators and explain how they were calculated from the data.

CASE PROJECT DESCRIPTION

The case project was a 3-year new construction site that included several phases. One of the phases, the focus of this study, consisted of 178 hotel rooms that were built using takt production. The hotel rooms were small (about 24 m^2) and very repetitive which motivated planning the phase with a two-hour takt time. Each work package, i.e. work done by one trade in a takt area at a takt time, formed their own takt wagon so that the terms work package and wagon are interchangeable, and the term work package is used in this paper. Hotel rooms were done with the takt time of two hours. Production speed was therefore 4 rooms per day since a working day was 8 hours.

The first author participated in the case project in the planning phase and at the beginning of the control phase but was not part of the management team. The first author visited the site and discussed with the management team frequently during the project and occasionally after it had been finished.

SCHEDULE AND PROGRESS DATA

The takt schedule was created in a spreadsheet. The schedule was updated with modifications and progress records by working in one master file. A site manager made the progress record updates daily by marking each work package either started or done. Partial progress rates were not used due to the short takt time. In addition, the site manager modified the plan as required. Copies of the master file were taken daily, and the date was added to the filename. This resulted in a set of 90 schedule version files that represented the current state of plan and progress for each date. Since the progress was recorded daily instead of per takt time, the per takt progress during a day is not distinguishable in the data. This leads to the progress records showing up in batches of four takt times. This has implications for calculating the indicators, which are explained in the following subsection.

The schedule version files were read with a custom program into a custom data structure that contained the progress record for each work package in each takt area at each takt time as well as the planned time of each work package in each takt area at each date. The indicators presented in the following subsection were calculated using custom algorithms that used this data structure. The custom program and algorithms were created by the first author.

INDICATORS

The following indicators were chosen for the analysis: (1) Flow efficiency from product perspective, (2) Flow efficiency from operations perspective and (3) Punctuality. How they are calculated is explained in the subsections below. The flow efficiency (FE) indicators were chosen because they are important measures of value creation and waste and have already been established in previous research by Binninger et al. (2019). Punctuality, as conceptualized by Keskiniva et al. (2023) was chosen because it measures plan adherence, which is also important, but which the FE cannot describe. Other indicators such as continuity, sequence adherence and work in progress are also of interest and require investigation in future studies.

Indicators 1 and 2: Flow efficiency from product and operations perspectives

The general formula for calculating flow efficiency is presented in equation 1. It is the ratio of value-added time to total time such that any non-value-added time between segments of value-added times is added to the divisor (Binninger et al., 2019).

$$FE_i = \frac{t_{i,\text{value added}}}{t_{i,\text{ value added}} + t_{i,\text{ non-value added}}} \tag{1}$$

This can be calculated from two perspectives and separately for planned and actual as presented by Binninger et al. (2019).

The product perspective looks at a single takt area or row in the takt schedule. The times any work package is planned in the takt area are planned value-added times. The times between the value-added times, where there is nothing planned are planned non-value-added times. Takt times before the first or after the last value-added time in the takt area are not considered.

The operations perspective looks at a single work package through takt areas. The times the work package is planned in any takt area are planned value-added times. The times between the value-added times where the work package is not planned in any takt area are planned non-value-added times. Times before the first value added time or after the last value-added time, when all planned takt areas for the work package are finished, are not considered.

The actuals are calculated similarly but instead of looking at the planned times the times recorded with progress are considered.

The flow efficiencies are first calculated for all takt areas and work packages. They can then be averaged over the takt areas for the average product flow efficiency and over the work packages for the average operations flow efficiency. The flow efficiencies can also be calculated in a time series that shows how they change over time. At any given time, the flow efficiency can be calculated as a cumulative value up to a selected time or as a moving average of a chosen time period before the selected time. With a moving average the local behavior of flow efficiency can be understood better compared to the cumulative value.

Also, the total planned flow efficiencies of the schedule can be calculated in a timeseries by considering the active schedule version at each time point. Any changes in the planned flow efficiencies in the timeseries indicate plan changes.

The batch size i.e. how big or small the combination of takt time and takt area is may have a drastic effect on the value of the flow efficiencies, as explained by Binninger (2021). A schedule of the same scope of production planned with a one-day takt time tends to reveal buffers that are implicit in a schedule planned with a one-week takt time. These implicit buffers are calculated as non-value-added time in the flow efficiency equation only for the smaller batch size. For this reason, only schedules with a similar batch size can reasonably be compared directly. In the case of this paper progress was recorded daily instead of per the planned two-hour takt. For the planned flow efficiencies to be comparable with the actual flow efficiencies, the planned flow efficiencies were aggregated to batches of four takt times.

Indicator 3: Punctuality

Based on LBMS delay indicators (Seppänen & Kankainen, 2004) Keskiniva et al. (2023) defined punctuality (P) as the difference between planned and actual work package start (and finish) takt times. The start and end punctualities are calculated by subtracting the ordinal number t_{ordinal} of the planned start or end takt time from the actual start or end takt time for each work package i and takt area j. The general formula is in equation (2).

$$P_{i,j} = t_{\text{ordinal},i,j,\text{actual}} - t_{\text{ordinal},i,j,\text{planned}} \tag{2}$$

This results in two values (the start and the end punctuality) for each work package in each takt area. These can be charted in several ways, for example by showing the punctuality of a work package in each takt area. A negative value indicates delay.

The batch size affects the unit of time that the punctuality is calculated in. For a two-hour takt, the punctuality could be calculated as two-hour units. In the case of this paper the batch sizes of planned and actual do not match and comparing plan with actual with different batch sizes would be misleading. Because of this the planned time of a work package was mapped from the takts to the days that they are in. This leads to a time unit of one day for the indicator.

FINDINGS

A visualization of the schedule and progress record data presented in Figure 1 (interpretation inside the figure) was generated to get a general understanding of how the work progressed. The plan is shown as it was at the end of the phase. There were plan changes during the phase, so the plan would look different depending on the chosen date. The schedule analyzed is also of a limited scope of the phase. Concrete floor drying times caused a delay of several weeks and considerable disturbance for the latter portion of the phase. This was ruled out to not cause unnecessary difficulties for interpretation of the analysis.

Some work packages in front of the train were planned faster than the takt, and some of them were completed faster than planned. This was possible because the limiting factor for starting work was getting water tightness at the top of the building, after which there was plenty of space for the first faster work packages.

It is clear from Figure 1 that the progress tracking breaks down during and after the break planned for two weeks to account for holidays. After the break, there were two large and several smaller batches of tracking data. After those batches, regular updates were resumed. The large batches do not represent reality because they represent several days' worth of progress but are recorded in one day. Due to this, the analysis was done in two parts: (1) a general analysis on the whole schedule with averaged indicators and (2) a more detailed analysis on a segment of the schedule in the beginning of the phase (shown with a dashed line in the bottom left of Figure 1) where production was relatively stable. In the latter we investigate indicators representing individual takt areas and work packages.

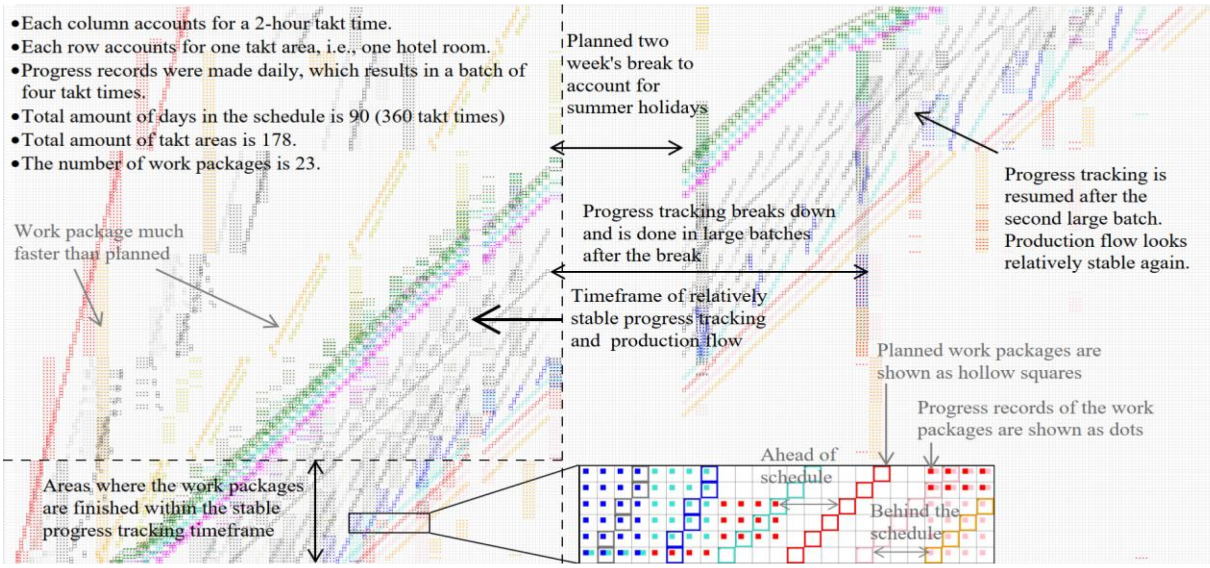

Figure 1: Visualized overview of the schedule and progress record data.

ANALYSIS OF THE WHOLE SCHEDULE WITH AVERAGES

From the schedule visualized in Figure 1, overall flow efficiencies were calculated by averaging over the 178 takt areas for the product perspective and over the 23 work packages for the operations perspective (Figure 2). The planned flow efficiencies represent the average planned flow efficiency of the schedule at the point in time.

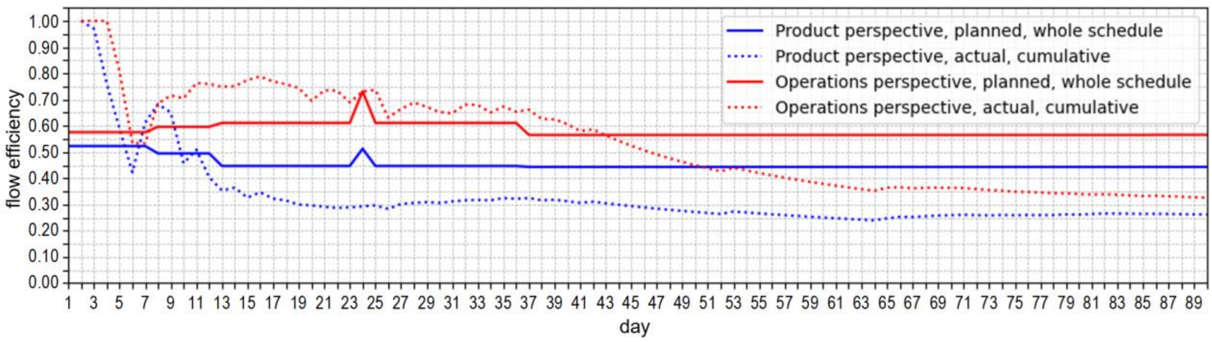

Figure 2: General flow efficiencies averaged over all work packages or takt areas.

The indicators show that plan changes were made at 8, 13, 24, 25 and 37 days. The change at the 24th day seems to have been retracted at the 25th day. In the first plan changes, the operations flow has increased whereas the product flow has decreased. Here some of the faster work packages in front were moved closer together. This decreased the non-value adding times in the operations flow but increased the non-value-adding times in the product flow.

The actuals in the Figure 2 were calculated cumulatively from the start of the work package for the operations flow and from the start of the takt area for the product flow. In the beginning they fluctuate heavily because even one non-value adding time unit will decrease the ratio when the total accumulated time is still short. The further in time the cumulative average is calculated, the more stable it becomes as it approaches the final value at the end of the phase. Both actuals start to decline at about the 42nd day. Here the progress tracking broke down, which caused big gaps in recorded value adding times. The actual indicators lose meaning at that point, but they can show a problem like this. Before breaking down and after the initial fluctuations, the flow efficiencies fluctuate somewhat but stay at a relatively steady level. For product flow the actual is mostly lower than planned, whereas for operations flow the actual stays above the planned before the 42nd day. On average, the work packages have less gaps in their flow relative to what was planned whereas the takt areas were not being worked on as often as was planned.

In the timeframe before day 42, the visualization shows, and site observations confirm, that despite the actual product flow efficiency being below the planned, the phase was mostly able to meet the schedule. Even if there were more gaps than planned in the product flow, the overall flow was good enough. Through the visualization and discussions with the management it was discovered that in some cases one worker had two adjacent work packages and worked on them at double speed but alternating between the two every day. This way they made the same takt but the planned operations flow for both of the work packages was only 50 %, although for the worker the planned flow efficiency was 100 %. This is an effect that was not but should be accounted for when calculating the flow efficiency, and it may be a cause for the higher than planned operations flow efficiency.

The punctuality indicator was calculated by averaging the punctualities of work packages in each takt area. The averaged start and end punctualities of the work packages in the takt areas are presented in Figure 3. The takt areas were worked on in order from left to right. The planned time was aggregated from the two-hour takt to a day.

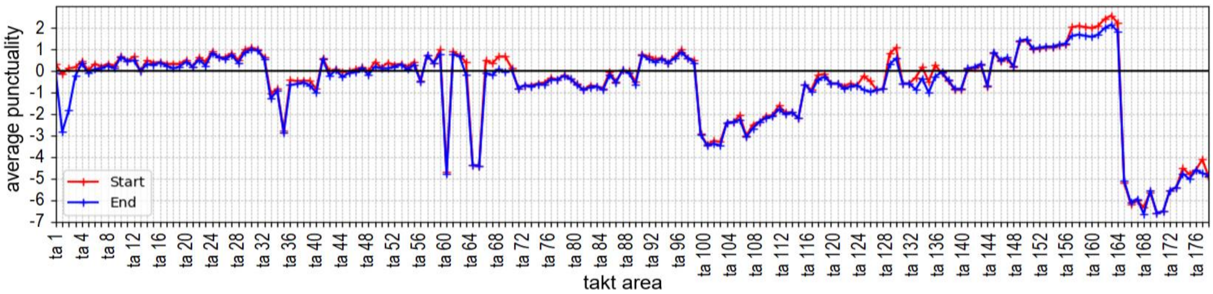

Figure 3: Punctuality at takt areas averaged over all work packages. On the horizontal axis are the takt areas in order from 1 to 178. On the vertical axis is the punctuality in days.

In the second and third takt area from the left, there is a large gap between start and end punctuality. This was due to one work package that was started on time but finished very late because of go-back work in those takt areas. From the third takt area onwards, the punctualities show that the work packages were started and finished ahead of schedule and very close in time to each other. Being ahead of schedule builds up to takt area 33, after which there is a dip to below zero. This is because the last work packages in those takt areas were planned to be finished before the break but were recorded finished in one of the big batches after the break. In takt area 36 that goes deepest below zero, there was a similar kind of go-back work problem as in the second and third takt areas, only this time, the work package was not even started in time. Takt areas 61, 65 and 66 are also outliers of this kind. If outliers are not considered, there is an upward trend in the punctuality after takt area 36, which is expected because the big batch of records is getting nearer in time in each subsequent takt area. In the middle segment of the graph there is more erratic behavior that can be traced to the progress record batches but are not studied here in detail. After the clearest example of batch recording at takt area 100, there is again an expected upward trend. The big dip at takt area 165 on the other hand corresponds to the start of the last floor of the building where the layout was different from the previous ones. Site observations confirm that the production flow was affected by this. The punctualities show that production falls quickly several days behind schedule, but that progress continued after that. Disregarding the progress record gaps, the punctuality clearly indicates whether production is ahead or behind the schedule.

ANALYSIS IN MORE DETAIL DURING THE STABLE TIMEFRAME

More detailed analysis is limited to the takt areas that are finished within the stable timeframe. For the operations flow, the focus limits only to the timeframe. The number of days in the analysis is 41, the number of takt areas is 33 and the number of work packages is 23.

Product flow of takt areas is presented in Figure 4. The cumulative values fluctuate in the beginning and gain stability as they approach the final value at the end. Fewer disturbances are shown by the cumulative indicator at the end of the time series. In contrast, the moving average shows how the flow efficiency behaves locally.

The graphs in Figure 4 show that in general the actual flow efficiencies of the takt areas are at a lower level than planned. The actuals also continue further in time than planned because they were finished later than planned. By visual inspection, there also seems to be more variation in the flow efficiencies both in the cumulative and the moving average. The indicator also shows that the actual flow efficiencies seem to get lower towards the end of the phase. Based on discussions with the site management team, this may be due to the last work packages in the work queue having a lower work content compared to their predecessors. To optimize operations flow, the crews wait for several takt areas to be available so that they can finish them in a bigger batch. This also explains why some of the takt areas are finished later than planned.

The large spread in the first half of the planned moving average is explained by the early faster work packages that create a gap of non-value adding time before the next work packages. This gap is small for the first takt areas but gets larger for the subsequent takt areas. Moving average eliminates this effect after day 20.

Holidays, especially when close to the beginning of a work package, cause a disturbance in the cumulative flow efficiency. Holidays were planned breaks, but work was allowed as extra buffer and therefore they were not removed from the schedule and analysis. Plan changes also cause difficulty for interpretation, especially if they happen retroactively.

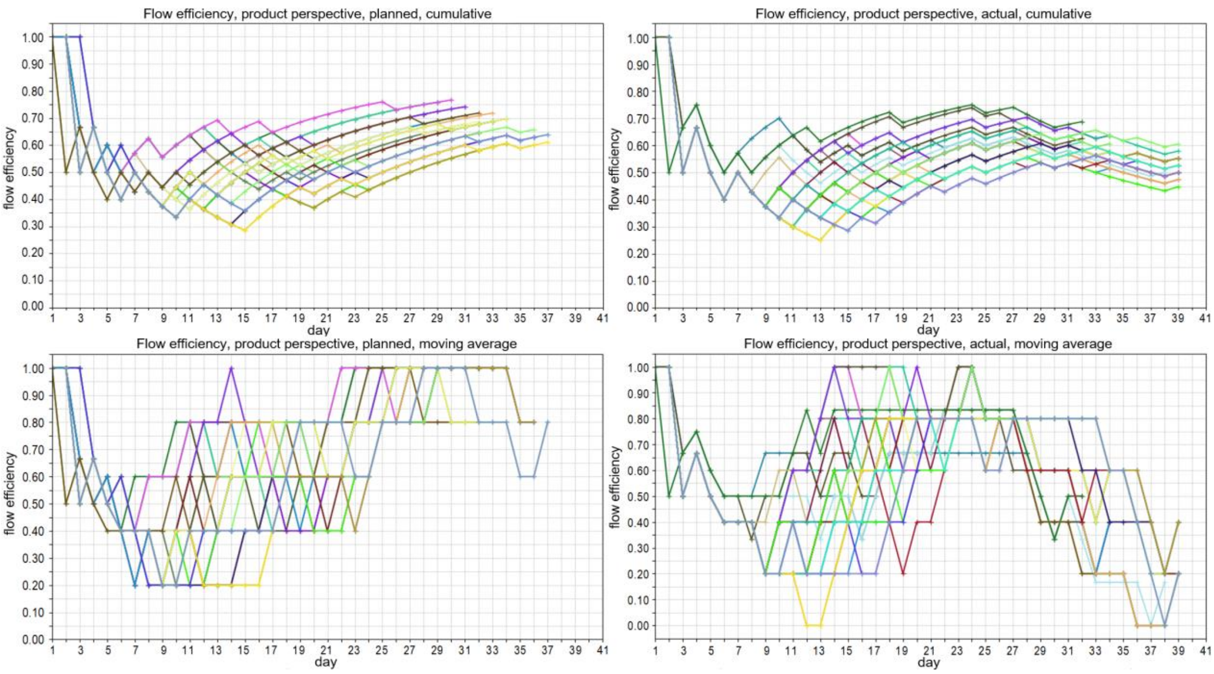

Figure 4: Flow efficiency from product perspective of 33 takt areas. Each line represents one takt area. Top left planned is cumulative, top right is actual cumulative, bottom left planned moving average, bottom right actual moving average.

An example of operations flow of work packages is presented in Figure 5. By visual inspection, the variation in the actual flow efficiencies of different work packages is bigger than planned. Some of the work packages have lower than planned actual flow efficiency, but others have a higher than planned actual flow efficiency. As the averaged analysis suggested, the actual operations flow seems to be on a higher level than planned for most of the work packages, which could be caused by two work packages assigned to one worker. Others however had more gaps than planned, which could be due to them having waited for a batch of takt areas before coming to finish them in one go. The root causes for this kind of variation should be investigated to better understand how to balance the schedule.

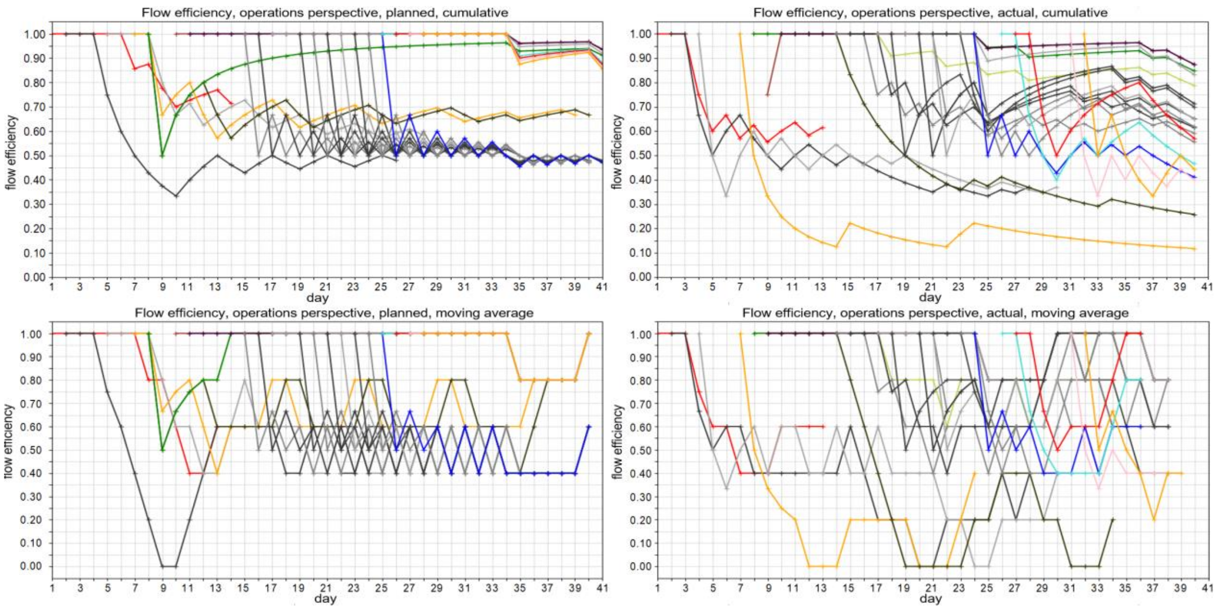

Figure 5: Flow efficiency from operations perspective of 23 work packages. Each line represents one work package. Top left is planned cumulative, top right is actual cumulative, bottom left is planned moving average, bottom right is actual moving average.

The start and end punctualities of the work packages in the 33 takt areas are presented in Figure 6. For the most part, the start and end are close to each other, which means that work was finished quickly after starting. The punctualities fluctuate around zero but seem to be more ahead than behind. This suggests that production was mostly able to keep to the schedule even though it was not followed rigorously. In the end punctuality, the outlier that falls out of the figure caused the drop in the averaged case. The yellow line with chronically low punctuality is the last work package (closing the lowered ceiling drop) in the phase considered. By investigating the individual work packages the causes for effects in the averaged analysis can be narrowed down. The single outlier point in takt area 14 is due to a work package that was not planned in its adjacent takt areas.

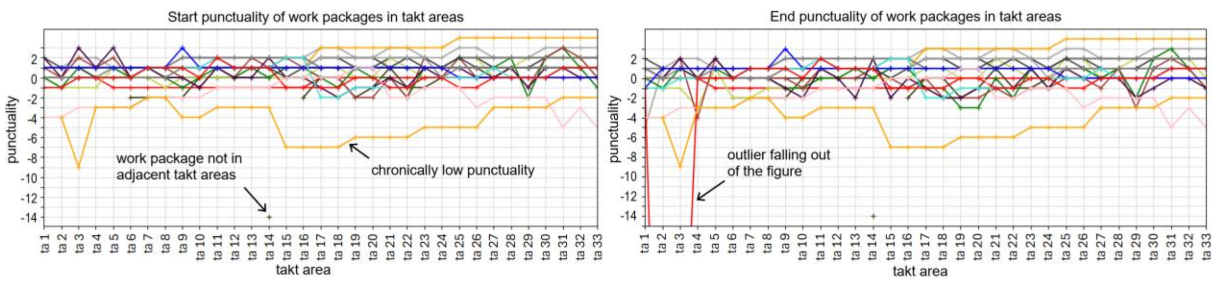

Figure 6: Start and end punctualities of each of the 23 work packages. Each line represents one work package. On the left is the start punctuality, on the right is the end punctuality.

Figure 7 shows how the flow efficiencies behave when looking at individual takt areas. Takt areas to look into were chosen from the punctuality graphs in Figure 6. Takt area 2 was outlier related to end punctuality, but its effect is not visible in the flow efficiency of the same takt area. On the other hand, takt area 8 seemed like one of the least problematic from the point of view of punctuality, but it shows more fluctuation in flow efficiency compared to the takt area 2. This tells us that the indicators do not predict the behavior of the other and indicate different qualities of the production system. In both takt areas, the actual product flow is again mostly lower in efficiency than planned. But it can be noted that there are also periods where the actual flow efficiency is higher than planned. This indicates that the time periods where production is not planned are still used to do work in the takt area. The effect of having a lower flow efficiency at the end is visible here also.

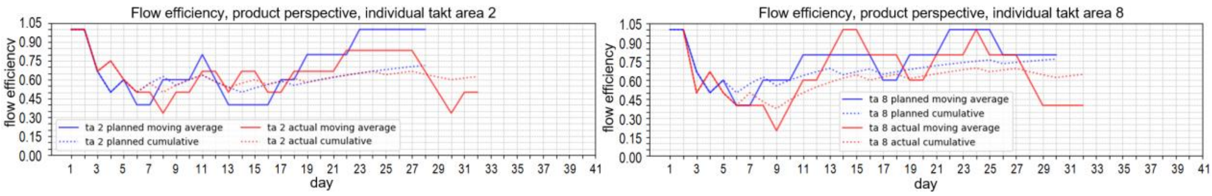

Figure 7: Flow efficiency from product perspective of two individual takt areas. Takt area 2 on the left and takt area 8 on the right.

Figure 8 shows in more detail the flow efficiency of individual work packages. These were chosen to investigate what the difference between two adjacent work packages may look like. The work package 8 was before the work package 9.A in the work queue. Work package 8 has very stable and high flow efficiency with only one interruption on day 25. This does not, however, indicate that the work package necessarily worked the takt areas in the order that was planned, only that the work crew worked somewhere at almost every takt time. Since the product flows were, in general, lower than planned, it is highly probable that this work package took advantage of any free takt areas to prevent interruptions. This could be taken as evidence of adjustment mechanisms being used. Although 9.A has lower flow efficiency, here it is seen for a single work package, how the actual operations flow is higher than planned. This seems like an example of a work package that was planned every other day. The visualization confirms this and that it was planned at double speed to keep following the takt. Through discussions with the management team, it was found out that the worker assigned to this work package was indeed assigned to the adjacent similar work package to work on in the in-between days. The operations flow efficiency indicator as it was calculated here for a work package of this kind is therefore misleading and should be modified to account for the workers used.

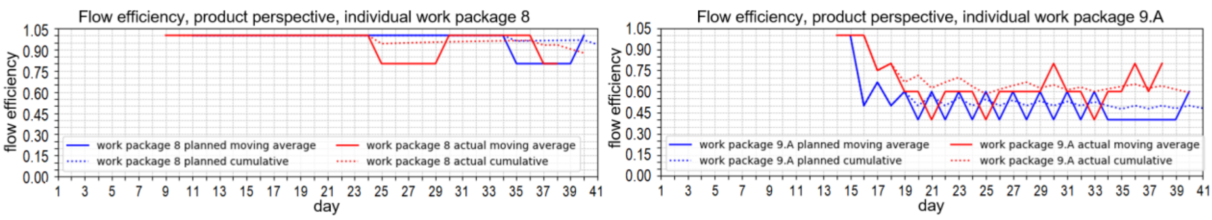

Figure 8: Flow efficiency from operations perspective of two individual work packages. Work package 8 on the left and work package 9.A on the right.

DISCUSSION

The punctuality shows that the schedule was mostly met even with lower than planned product flow. That takt production can provide sound production control even if the plan is not followed exactly has been found in previous qualitative studies such as in (Lehtovaara et al., 2021). The higher than planned operations flow efficiency could be caused by workers alternating between two double speed work packages but also by its prioritization over the product flow as suggested by Binninger et al. (2019). The calculation method could be modified so that it considers the flow efficiency of workers instead of work packages.

Seppänen and Kankainen (2004) found in LBMS studies that discontinuities were the main disturbance that caused late finishes although tasks were started early. They also found that time buffers decrease interruptions. Here in contrast time buffers were minimal but tasks were mostly finished close to starting, which suggests few disturbances. Also, strong signals of cascading delays as described by Seppänen (2009) in LBMS case studies were not found. This supports the interpretation that time buffers recommended by LBMS are not essential to avoid trade collisions and production slowdowns in takt production.

It must be noted that the study focused on a limited single phase in a single 2-hour takt time case. The limitation was intentional to be able to focus on investigating the indicators. Had the whole scope of the phase or the project been considered, the results would have been more difficult to interpret. Therefore, although the discussion above does indicate the applicability of the indicators for studying takt control, it does not, however, allow for generalization.

Other indicators such as continuity used by Seppänen and Kankainen (2004) in LBMS studies or the proportion of work performed out of sequence parameter of the CFI (Sacks et al., 2017) could also be adapted to takt production. In addition to the punctuality, Keskiniva et al. (2023) conceptualized six more indicators to evaluate takt production performance. These could be further investigated to find out their value and applicability.

Also, as Binninger (2021) pointed out, the connection between different levels of planning and control (so called macro, norm and micro levels) have different perspectives. A 2-hour takt time is very close to the micro level and the way the indicators translate to the norm and macro levels should be investigated. One issue of this sort was run into in the discussion above about whether to track a worker or a work package. Further, affirming the findings of Binninger (2021), this study also indicates that there is much room for improvement through improved control practices and methods.

CONCLUSIONS

Returning to the research questions, it was shown in this paper that with progress record data, quantitative indicators such as flow efficiency and punctuality can be used to understand the nature of production on a daily and work crew level of detail. The indicators can show how the production system works overall and trace deviances to individual work packages or takt areas. For example, outliers and peculiarities can lead to relevant conclusions about takt control. They can also reveal plan changes and variabilities involved in production flow. There is plenty of opportunity for more research with more case projects in different settings and with a wider range of indicators. For example, understanding better the question of flow perspective prioritization and how and why takt production reduces the disturbances expected by LBMS could be some of the goals. Also, with such a short takt time as two hours the indicators relate to individual workers but with longer takt times such as one week the interpretation will probably be different. Expanding to other settings such as these warrants for future research.

In future research, setting up a link between the production control indicators and project delivery outcomes could be valuable. Companies should be able to set quantitative project level objectives and use the indicators to assess and direct improvement towards them across projects. This could also reveal common pain points to focus management attention.

Also, forecasts of the indicators could be developed to highlight the impact of problems, to set policies and to help commit to control actions. Dashboards of real-time indicators could allow site management to get focused information of deviations.

REVISITING THE TAKT MATURITY MODEL AFTER THREE INTERNATIONAL TAKT FORUMS

Jaakko Riekki[1], Joonas Lehtovaara[2], Iris D. Tommelein[3], Olli Seppänen[4] and Aleksi Heinonen[5]

ABSTRACT

Takt production has gained wide interest as a change agent for systemic change in recent years. A maturity model for the adoption of takt production based on and validated with Finnish case projects was published in 2020. However, that maturity model has not been validated internationally and companies have continued their development of takt-based operations. In this paper, we suggest updates of the maturity model by reviewing the best practices presented in three international takt forums. We also validate the model using international case projects presented in the takt forums. Industry participants have taken routes to takt production implementation other than those assumed in the initial model. Some have advanced to levels that were not included in the original model. Our suggestions consist of adding four new requirements and modifying the descriptions of eight existing requirements. A modification to the description of one of the levels in the model and the model itself are also suggested. The contribution to knowledge is a new maturity model to use for benchmarking and as a roadmap for improvement of takt production.

KEYWORDS

Takt production, maturity model, takt forum, driving change

INTRODUCTION

The use of takt production as a production planning and control method is becoming more common in the architecture-engineering-construction (AEC) industry. A range of practices and variations thereof can be observed on projects around the world. At the same time, certain companies are advancing the state-of-the-art practices of takt production, (1) to refine its use on the types of projects where proof-of-concept has already been delivered, (2) to extend its range of application from specific phases of construction, to applications upstream in design and downstream in commissioning, and (3) to change the whole company based on takt production principles, rather than consider individual projects only. A lot can be learned from

5 Consultant, Vison, aleksi.heinonen@vison.fi, orcid.org/0000-0003-2027-9646

these practices and their characteristics, and lessons learned can be compiled into levels of maturity.

In this paper we build on the maturity-level model for takt production introduced by Lehtovaara et al. (2020). The original maturity model can be found in Table 2 at the end of this paper for reference (black text is original, modifications are in green). This model was developed based on 24 Finnish takt production cases. It includes 15 requirements structured at three levels into (1) technical takt planning, (2) social integration & takt control, and (3) continuous improvement levels. According to the model, companies can start takt production implementation using existing contractual structures, but higher levels of maturity require wider engagement of stakeholders in the supply chain (SC) and learning between projects. As the model was created after just a few years of experience in the Finnish market, further validation and development is needed.

To hear how leading AEC practitioners are deploying takt production, P2SL, Vison, Aalto University, and RIL (Finnish Association of Civil Engineers) have been organizing online forums for practitioners around the world to share their knowledge about takt production. Three such forums have taken place to date, a 1.5-day forum on 18-19 August 2022, and two 0.5-day forums respectively on 9 November 2022 and 23 May 2023. The presentations and discussions at the forums give reason to revisit the takt maturity model.

This paper presents insights the forum organizers gained as they relate to the maturity model. Suggestions for updates to the maturity model are extracted through revisiting the recorded presentations and discussions. Validation of the maturity model with the international case examples is also discussed.

METHOD DESCRIPTION

Three takt forums were held with sessions addressing 8 themes, including 23 15–20-minute presentations and an additional 5-minute Q&A. For each theme, the organizers gave a 5–10-minute introduction and led a 10–25-minute discussion and Q&A. Small group discussions for each theme took place in breakout rooms, but these were not recorded and are therefore not part of the analyzed data. The breakout room discussions informed the theme discussions that were recorded. During the presentations and break-out rooms, Menti.com (an online interaction platform) was used for gathering questions and comments from participants, which facilitated the discussion. Menti was also used to survey participants about their familiarity with takt production and the Last Planner® System (Ballard & Tommelein, 2021). Table 1 presents the forums, sessions and presentations. The second, third and fifth author were organizers of all of the forums, and the fourth author was an organizer in the first one only. The selection of session topics and presenters was a result of discussions amongst the organizers while they were planning the forums. The aim was to invite the most mature state-of-practice companies to present their experiences.

A qualitative thematic analysis was carried out to synthesize the data. All authors were familiar with the data from the three live forums they participated in. As a first pass, the first author skimmed through the recordings to extract tentative topics (e.g., supply chain management (SCM)) for analysis. After identifying these tentative topics, the first author rewatched all the recordings and noted in a table the points of discussion that relate to the topics. The tentative topics and the most prevalent notes related to them were then discussed among all the authors, which resulted in three categories, presented in the following section. All authors then discussed the key findings and topic-related suggestions. The resulting topics were discussed and connected to the maturity model requirements in Table 2 of (Lehtovaara et al., 2020). Some discussion points noted in relation to the topics do not, however, correspond directly to maturity-level requirements. These connections and differences are discussed in the findings.

Table 1: Takt forum sessions and presentations

Session	Presentation
Forum 1, day 1: 2022-08-18	
1. Strategic takt planning and using takt in design	1. Aleksi Heinonen (Vison Oy, [F])
	2. Adam Frandson (DPR [US])
	3. Cory Hackler (DPR [US])
2. Takt plan development and supply chain management	1. Van Kristensen (Turner [US])
	2. Marco Binninger (Weisenburger bau [G])
Forum 1, day 2: 2022-08-19	
3. Takt control including daily takt plan management and change management	1. Jukka Rannisto (Haahtela [F])
	2. Samir Emdanat (vPlanner [US])
4. Future of takt production in construction	1. Olli Seppänen (Aalto University [F])
	2. Iris Tommelein (UC Berkeley [US])
	3. Kim Lindholm (HOAS [F])
	4. Digby Christian (Sutter Health [US])
Forum 2: 2022-11-09	
1. Cultural change with takt production	1. Takt production in Skanska Nordics – We are better together (Pekka Kujansuu and Magnus Vissebråten, Skanska Norway/Finland [F], [N])
	2. Takt as a production system: Business portfolio flow and situational awareness (Kasperi Koivu, Fira [F])
	3. Takt method in everyday life of the SME company – journey to get there (Mikko Hirvonen, Respect Project [F])
2. Client involvement in project delivery with takt	1. Delivery of a megaproject with 1-day takt: Helsinki airport terminal 2 (Jasmiina Hietala, SRV [F])
	2. Why a superintendent uses takt even when the owner does not ask for it (Dan Murphy, Turner [US])
	3. Industrial owner's strategy with takt (Janosch Dlouhy, BMW [G])
Forum 3: 2023-05-23	
1. Learning takt production from other industries: manufacturing, marine refurbishment and construction	1. Lean cruise ship cabin refurbishment (Jaakko Mäkikalli, Makinen [F])
	2. Plan for every part (Ari Viitanen, Carinafour [F])
	3. Concept of takt time in construction and other industries (Peter Meijnen, Denkyu Consulting [G])
2. Takt beyond phase planning in building construction	1. Application of takt production in underground linear infrastructure construction projects (Veronica Ksiazenicki, Stiler [U] and Carlos Formoso, UFRGS [B])
	2. Takt in design at the Life Science project / The journey of applying takt (Hans Thomas Holm Statsbygg [N])
	3. Takt – LPS connection (Spencer Easton, Mortenson [US])

Notation: Presenters reported on projects in the following countries: B: Brazil, F: Finland, G: Germany, N: Norway, U: Uruguay, US: United States.

FINDINGS

The authors grouped the findings in three categories to emphasize what was deemed novel and controversial, and to de-emphasize repetition of points that have previously been discussed in takt production research. The goal was to suggest how the maturity model could be improved.

The three categories are (1) Strategic takt planning, which refers to an early holistic conceptual approach of applying takt production; (2) Supply chain management, which covers preconditions to be met before production (tasks) can happen on site, such as the design process, trade partners, procurement, prefabrication, and material flow, and (3) Driving change, which refers to using takt production to identify potential production system improvements (e.g., Tommelein & Emdanat 2022). These categories connect many detailed requirements together and can be seen as "change agents" towards successful takt production implementation.

In the following, the contents of the forums are discussed in light of the maturity model divided into these three categories. The data is referred to with the following notation: F: Forum, i: introduction to session, p: presentation, d: discussion and Q&A of the session, with the numbering of the forums, sessions and presentations as presented in Table 1.

CATEGORY 1: STRATEGIC TAKT PLANNING

Strategic takt planning is defined here as engaging in takt planning early in the project while taking a holistic view of the whole scope of production. Approaching takt production as a project's operations strategy has previously been introduced in Lehtovaara et al. (2021). A similar view of planning in levels of detail is also found in the three-level method of takt production (Dlouhy et al., 2016) and was introduced much earlier in the planning levels of the Last Planner® System (Ballard & Tommelein, 2021). The key idea about strategic takt planning is to enable early responsible commitments and create a concept that sets targets for future development of the plan. The early concept should be based on data such as historical knowledge of production rates. (F1.1.i), (F1.1.p1), (F1.1.p2)

An early concept, i.e., a generic idea of a takt plan where takt production principles are applied, enables choosing and integrating supply partners who are willing and able to deliver to the takt. This may affect the cost structure and business plan of the partners and is therefore important to know before signing a contract. The early takt concept can set requirements for the supply of design, labor, and materials before they are procured. It enables the potential partners to evaluate whether they can conform to the plan and speak up about their concerns. This is also a tool for gaining client involvement since the plan is built to their targets and crucial decision-making points can be identified early. Strategic takt planning can drive takt production on an organizational level. Integration of trade partners with an early concept is at the same time an opportunity for training. It is a way to build organizational competence for aligning everything that has to come together for a stream of projects to work, to get better across projects, and to enable sustainable profits for all companies involved. (F1.1.p2), (F1.1.d), (F1.2.p1), (F1.2.p2), (F1.4.p4), (F1.4.d), (F2.2.p3), (F2.2.d), (F3.1.p3)

Strategic takt planning is not mentioned in the maturity model although the requirements R1 (The production plan fits the client's requirements) and R2 (Takt areas, takt time and wagons with resourcing are unambiguously determined) on level i) (Technical takt planning, project-level) of the model can be interpreted to have a similar intent. The SC integration view is on level ii) (Social integration & takt control, project and organization level) with R5 (The logistics are integrated and takted with the production plan) and R6 (The design process is integrated and takted with the production plan) but there is no clear connection to the strategic planning level. The organizational level of continuous improvement is the intent of level iii) (Continuous improvement, organizational and regional level) but, again, the maturity model lacks explicit reference to the strategic planning level.

The early takt concept should show how the flows of work in different phases of construction are connected to create an overall flow. The aim is to meet the client's demand even at the expense of loss of capacity in the short term in some parts of the system. Different phases may have different kinds of variabilities and challenges. For example, they may have different location breakdowns, different buffering strategies and different batch sizes, i.e., takt time and takt area combinations. Unique areas of the project that do not fit well into the production system of other phases should be identified and pulled to the overall flow of the project. Possible workable backlog areas should be identified as they can be leveraged to make up for low density work in other areas. The phase breakdown can also be used to divide management responsibilities. The early overall takt plan should give an anchoring point to the project. As the project advances towards the execution phase, the strategic takt concept is developed into a takt plan where the details are filled in to meet the targets. (F1.1.p1), (F1.1.p2), (F1.1.p3), (F1.1.d), (F1.2.p1), (F1.3.d), (F2.1.p2), (F2.2.p2), (F2.2.d), (F3.1.p3)

Breaking up the project into phases and connecting them to an overall project flow is not explicit in the maturity model. Requirements R1, R2 and R3 (Effective visual management is ensured) on level i) include this intent but it is not clearly visible.

Historical knowledge of past projects should be gathered and used when shaping the early strategic takt plan. Reusable production steps and work packages (i.e., standardized operating procedures for construction) are created and developed on the execution level, but knowledge of indicators that describe them can be used for setting goals on the strategic level. These may also vary depending on the geographical area and on the trade partners to be considered, so understanding the variabilities involved would be useful. The historical data could be used to set up a production strategy in new projects early and to guide improvement activities. The mathematics of takt production on a strategic level can be simple but the ability to handle the complexity that comes with integrating the SC and the large amount of data requires digital tools. (F.1.1.d), (F1.1.p1), (F1.1.p2), (F.1.1.d), (F1.2.p2), (F1.3.d), (F1.4.p1), (F1.4.p2), (F1.4.d), (F2.1.p3), (F2.2.p1), (F2.2.p3)

Leveraging data is mentioned in R14 (Standardized, takt-based work quantity libraries) and R15 (Improving through KPI's and data-driven decision making) but the use of data to create an early strategic takt concept and to manage the complexity is not clearly visible.

Suggestions for augmenting the maturity model:

- S1: Level i) should be modified to consider only one phase and to the second level a requirement should be added that most or all project phases are considered.
- S2: To level ii) of the maturity model, a requirement should be added for the ability to form a takted production strategy before supply-partner contracts are signed.
- S3: On level iii), requirements R14 and R15 should be modified to include the ability to leverage historical knowledge of production rates and other indicators.

CATEGORY 2: SUPPLY CHAIN MANAGEMENT

A takt production environment creates a clear and stable demand for products and services to be supplied as needed for production. It enables delivery of smaller batches following the just-in-time principle. Proper SCM requires attention at the early strategic planning level and is crucial at the project execution level. (F1.2.p1), (F3.1.p1), (F3.2.p3)

Delivery strategies for different types of material flows must be planned strategically. Strategic takt planning changes the conversation in the SC from describing general needs to defining more understandable chunks. It also enables standardizing the SC processes to a takt plan and helps in mapping out the whole SC. Creating an overall vision of the flow of the project depicted in a strategic takt plan is important because the complexity of SCM can grow very quickly. (F1.2.p1), (F1.2.d), (F2.1.p2), (F1.3.p2), (F2.2.p1), (F3.2.d)

SC integration is mentioned in the maturity model in R5 and R6 on level ii) and in R13 (Industrialized logistics and material flow) on level iii). They do not clearly show how SCM should be considered early in a project on the strategic level.

Design development is better done by setting milestones and defining points of design deliverables based on the takt plan instead of managing design activities directly. Defining the milestones and deliverables should start with defining the functionality of the building; the design deliverables can then be packaged to supply the project by pulling to the takt plan. This also enables the decentralization of the design process to create flexibility for the design teams. The milestones and deliverables should match defined design-value steps that follow a model of design maturity for defined purposes in a takt plan. At each point of design development, the designers need to understand what is fit for purpose (aka. 'good enough') for the next customer in the SC to use their deliverables. Standardizing design and taking full advantage of Design for Manufacturing and Assembly (DFMA), prefabrication, and industrial construction must also be done at the early strategic level, with continuous improvement across projects.

Planning design to a takt in smaller batches is a problem, because designers are not used to thinking about the design process in such a way. The execution-phase design work (aka. construction documents) should be attuned to the takt plan and be made responsive to any issues encountered on site, especially in a project where information required for the final design is discovered only during construction. This is why designers should also understand the principles of takt production. (F3.2.p2) (F2.2.d), (F3.2.p2) (F2.1.p2) (F3.2.p2), (F3.2.d)

Design process integration and its connection to the takt plan is included in the maturity model in R6 on level ii). The connection to strategic takt planning is however not clear. The execution level of design process management covers many smaller steps that are not detailed in the maturity model.

At the execution level material delivery strategies such as designated logistical routes, the use of off-site buffers for just-in-time deliveries of large materials and on-site buffers (supermarkets) for smaller materials must be planned in connection with the takt plan. To make the just-in-time deliveries in small batches to suit the takt plan, logistics operations and material flow should be separated from trade work. Although the takt plan defines the logistical process, logistics can be used to control production by delivering the materials to be installed to work areas according to the takt plan. Smaller material and WIP buffers require better management of prerequisites, but they also enable better management by bringing clarity to the delivery needs. Any data that accumulates in a digital material handling system offers a way to learn about production flow. (F1.3.p1), (F2.2.d), (F3.1.p1) (F3.1.p3) (F1.3.d), (F2.2.p1), (F2.2.d) (F3.1.p2)

The requirements R5, R6 and R13 cover the intent of these viewpoints. However, the use of logistics for controlling production and leveraging data in material management systems are not described in the maturity model.

Execution-level design and material planning are a crucial part of a takted production system although they are not directly a part of the production system on site. The design must be developed to serve detailed material planning to meet the planned needs. Just-in-time material deliveries to the takt plan in small batches require detailed bills of materials, especially when striving for greater production speed. The bills of quantities used for cost estimation and workload calculations are not detailed enough for industrialized material flow management. In addition to providing the design documents for the trades following the takt plan, the design process could be connected to the takt plan to deliver the bills of materials as required by the material procurement lead times. (F.1.1.d), (F1.3.p1), (F1.3.d), (F2.1.p1), (F2.2.p1), (F3.1.p1), (F3.1.p2), (F3.1.d), (F3.2.p1), (F3.2.p2), (F3.2.p3) The maturity model does not consider the dependence of material flow management on design maturity.

Client decision making is also considered here as a part of the SC. Takt production speeds up construction, which sets new requirements for the client's ability to make timely decisions. Client decision-making delays have been brought up as a cause for delays and they may also amplify the risks of trade partners who have resources committed on site. However, a takt plan is also a tool for guiding the decision-making process by bringing clarity to the required decision-making points at the last responsible moments. Decisions to be made need not follow the takt plan directly but understanding the decision-making time is important for alignment to site requirements. (F1.2.p2), (F1.2.d), (F1.4.p4), (F2.1.p3), (F2.2.p3), (F3.1.d), (F3.2.p1), (F3.2.d) The client decision-making process is not considered in the maturity model.

SCM is referred to in the maturity model in the requirements R5, R6 and R13 but the emphasis on the subject in the takt forums gives reason to highlight its importance even more. The points of view of design and material flow warrant maturity models of their own or could be detailed with sub-requirements to the existing requirements.

Suggestions for augmenting the maturity model:

- S4: The project production strategy view to SCM should be considered in the maturity model with a new requirement on level ii). This can be combined with the earlier suggestion S2.
- S5: Description of R6 should be updated to consider maturity of design to milestones set by the takt plan and to require understanding of takt principles from designers.
- S6: To level iii), a requirement should be added for the ability to standardize and continuously improve the design process and design handoffs to improve efficiency through Design for Manufacturing and Assembly (DFMA) and prefabrication.
- S7: Description of R5 should be augmented with detail of different types of material flows. Description of R13 should be updated with the use of logistics and material deliveries to control production, and the use of material handling system data for improvement.
- S8: To level ii), a requirement should be added for the ability to manage client decision making. Description of R11 should be augmented with requirements for the client.

CATEGORY 3: DRIVING CHANGE

Takt production can be a gateway to lean. Its implementation requires structuring everything in the production system, standardizing processes, and developing tools and methods to overcome problems. Takt production requires many other lean principles to be in place to work well. The journey advances in stages, first the project level, second the production system across projects, and third the corporate view, culture, and leadership. (F1.2.p2) (F2.1.p1), (F2.1.d)

While takt planning can be a gateway to lean, for many project teams especially in the US, the segue into lean came with implementation of the LPS (Ballard & Tommelein, 2021). In the LPS, takt production (called operational takt planning) was first seen as a work structuring and production method applied on the phase planning level. Work structuring is the process of breaking work into pieces to promote flow and throughput, and production strategy includes an optimization process of planning the project in interconnected but separate phases. The case study by Tommelein and Pak (2019, Figure 6) then pointed to the strategic importance of trade partner- and SC alignment to takt planning on the master schedule level (called strategic takt planning). The route to takt production via LPS is however not mentioned in the maturity model.

Previous publications also suggest that takt production can drive change (Peltokorpi et al., 2021), (Tommelein & Emdanat, 2022). The maturity model itself is built to drive change by showing takt implementation as a journey. Adding a fourth layer to the maturity model aimed at driving cultural change was conceptually suggested in (Peltokorpi et al., 2022), although it was not discussed in detail.

The maturity model implies that takt production starts with technical takt planning on site on the project level. After getting good initial results, developing social integration of the SC and takt control begin on the organizational level. Going forward with the requirements should increase benefits until the third organizational and regional level of continuous improvement is achieved.

The maturity model was based on and validated with only with Finnish cases. Of the forum presentations, the cases (F1.3.p3) (Finnish), (F1.2.p2) (German), (F2.1.p1) (Norwegian), (F2.1.p3) (Finnish) and (F2.2.p1) (Finnish) seemed to have followed a journey similar to what the maturity model suggests. But cases (F1.1.p3) (US), (F1.2.p1) (US), (F2.1.p1) (Norwegian), (F2.2.p2) (US), (F3.2.p1) (Uruguay) and (F3.2.p3) (US) referred to LPS as a starting point to their takt journey. The Norwegian case (F2.1.p1) cited both LPS and the maturity model in their presentation. However, in all these cases, the general structure of the maturity model still seems to have been followed. This suggests that the maturity model has some international validity.

Presentations (F1.2.p4) (US), (F2.2.p3) (German), (F3.1.p1) (Finnish, cabin refurbishment instead of construction) and (F3.2.p2) (Norwegian, design process management in construction by the owner) suggest that owner demand can also function as the driver for starting a takt implementation journey. The reasons for owner demand are manifold. (F1.4.p4) and (F3.2.p2) addressed the owner's desire for clarity of milestones in a takt plan, (F1.4.p3) and (F3.1.p1) aimed for speed of production, and (F2.2.p3) pursued increased stability and flexibility in addition to speed. Owner demand as a driver was also discussed in (F2.2.i), (F2.2.p1) and (F3.2.d). One case (F1.1.p3) (US) mentioned, in addition to referring to takt production as a part of their LPS journey, an organizational lean leadership training program as a starting point. One case (F3.1.p2) (Finnish, ship building) focused on a "plan for every part" philosophy, where managing the material flow is regarded as the first step. These examples suggest that the maturity model outlines but one progression for companies to implement takt production.

Shifting people's mindsets is an important and difficult step in implementing takt production. Thinking in smaller batches, especially in the design process, is not something that people are used to and the takt principles may seem counterintuitive and constraining for people who are used to traditional production management methods. Gaining alignment with the people involved in a project can be a bigger problem to solve than creating technically sound plans. To overcome this barrier people should be prepared before they embark on takt planning. Preparation would include lean leadership training, teaching the terminology and definitions of takt production, simulation games, and showing the mathematics of takt production. On a hopeful note, it was mentioned that by bringing clarity, takt production can help with making the construction industry a less toxic environment for people to work in, which should make it more attractive to new talent. (F.1.1.d) (F1.1.p2) (F1.1.p3) (F1.2.p1) (F1.2.d), (F1.4.p4) (F1.4.d) (F2.2.p1), (F2.2.p3) (F2.2.d) (F3.2.p2) (F3.2.d)

The required mindset shift is implicit in the model in R4 (Training and involvement of the project participants is ensured) on level ii) and in R10 (Formulation and development of teams) on level iii). The need for learning new and unlearning old habits is not, however, emphasized.

Integrating the SC implies developing partnerships. Supply partners all the way to the worker level should see the benefit of takt production so that they want to come back to takt projects. The value on sites is created by companies, many of which may be small and medium-sized, so to change the industry, they must be involved in developing the production system. Organizations on higher levels of maturity should provide support for the newcomers through training and building partnerships. Lean enabled by takt production can provide structure for managing different levels of hierarchy in the organization, including sharing knowledge and sustainable problem-solving at the right levels. Building a more holistic production system with takt principles should not lead to more centralized management but better onboarding, more involvement, and more transparent risk management. Building partnerships around takt production may lead the market to segregate groups of companies willing to adopt takt principles from those who are phased out because of lack of interest. Takt production will start to dissolve trade boundaries so that the overall system can be balanced better. (F1.1.p2), (F.1.1.d), (F1.2.p1), (F1.2.p2), (F1.2.d), (F1.3.p1), (F1.4.p3), (F1.4.p4), (F2.1.p1), (F2.1.p3) (F2.2.p1), (F2.2.p3), (F2.2.d), (F3.1.p1)

Partnership building is not explicit in the maturity model, although R4, R5, R6 and R8 (Barriers are tackled through continuous and collaborative improvement) on level ii) and R10 and R11 (Contractual integration) on level iii) can be interpreted to have the same intent.

Technology is seen as a part of the takt journey. Software tools are required to handle the information flows and data that comes along with detailed planning, smaller batches, and the upstream SC processes. Digital data handling leaves a footprint that can be structured around the takt production system and leveraged for improvement. Sensors, automated monitoring, and visualization tools built around the takt production system can improve situational awareness, inform workers of site conditions such as humidity and temperature, and support data gathering for improvement metrics and control (including replanning). Prefabrication and robotics may change the way work is done, and sites planned with takt can help to reveal the best opportunities to serve the overall system. (F1.1.p2), (F1.2.p2), (F1.3.p2), (F1.3.d), (F1.4.p1), (F1.4.p2), (F1.4.d), (F2.1.p2), (F2.1.p3), (F2.2.p1), (F2.2.p3)

Technological competence is not considered in the maturity model. Including a requirement for adoption of technology in the maturity model was discussed among the authors. It is however left for future research because the practical case presentations in the takt forums did not show sufficiently detailed examples to make relevant suggestions.

Suggestions for augmenting the maturity model:

S9: To the description of the maturity model should be added that there can be starting points for takt production other than an urge from the site, projects where the Last Planner® System is used, and client demand.

S10: A more explicit requirement for development of people should be included by modifying the description of R4 to include general lean leadership training, changing of habits, the use of simulation games, and the mathematics of takt planning to shift mindsets.

S11: A requirement for building partnerships between companies should be added by modifying R10 to include the formulation of partnerships in addition to teams, and by emphasizing in its description that this should happen across companies. R10 should also say that more mature organizations should help build the capabilities of the runners-up.

DISCUSSION

The maturity model updated with the suggestions is presented in Table 2. In the model's description, it should be added that takt production implementation can have several starting points such as (1) urge from construction sites (2) as a part of LPS, and (3) client demand. The description modifications of requirements denoted with an asterisk (*) are not included but the authors intend to publish an updated model with this detail in the future.

In the process of writing this paper, a discussion came up regarding the importance of legal and commercial terms between the owner, trade partners, and labor, to drive change in the behavior of companies and people implementing their takt production journey. This was touched upon in (F1.4.p3), (F1.4.p4) and (F2.1.p3) but warrants further study with more data.

All requirements of the model except R7 (The common situational awareness during production is ensured), R8, R9 (Quality control is systematic and takted) and R12 (Systematic waste elimination over projects) are impacted by the suggestions. However, the intent of R7 might be impacted by new requirements addressing technology adoption. R8 and R12 relate to building partnerships and R9, that quality tends to improve in takt production, was touched upon in (F1.4.p3) and (F2.1.p3). Updates of these requirements also deserve further study.

Based on the takt forums, the maturity model seems valid for the most part, but note that companies that presented in these forums would not necessarily gain from meeting the requirements of the model exactly in the order presented, level-by-level. Every company is on its own journey; nevertheless, this raises the question whether some requirements should be characterized differently or reassigned to different levels. This also warrants further study.

Finally, we propose two additional avenues for future research. First is to expand the model to include relevant metrics to assess the organizations' advancement through levels and requirements; and second is to explore longitudinally how implementing the model impacts an organizations' effectiveness in advancing takt production and its related benefits.

Table 2: The updated maturity model (changes in green, (*) denotes description update)

Level i)	**TECHNICAL TAKT PLANNING IN ONE PROJECT PHASE (project-level)**
R1	The production plan fits the client's requirements
R2	Takt areas, takt time and wagons with resourcing are unambiguously determined
R3	Effective visual management is ensured
Level ii)	**SOCIAL INTEGRATION & TAKT CONTROL (project and organizational level)**
NR1	All or most of the phases of the project are takted and connected
NR2	The strategic takt concept is formed before the selection of supply chain partners
R4*	Training and involvement of the project participants is ensured
R5*	The logistics are integrated and takted with the production plan
R6*	The design process is integrated and takted with the production plan
R7	The common situational awareness during production is ensured
R8	Barriers are tackled through continuous and collaborative improvement
R9	Quality control is systematic and takted
NR3	The client decision-making process is systematic and takted
Level iii)	**CONTINUOUS IMPROVEMENT (organizational and regional level)**
R10*	Formulation and development of teams and partnerships
R11*	Contractual integration
R12	Systematic waste elimination over projects
NR4	The design process and design handoffs are standardized to meet Design for Manufacturing and Assembly (DFMA) and prefabrication requirements
R13*	Industrialized logistics and material flow
R14*	Standardized, takt-based work quantity libraries
R15*	Improving through KPI's and data-driven decision making

CONCLUSIONS

In this study, we revisited the takt production maturity model formulated in 2020. This was done by analyzing recordings of three online takt forums held in 2022 and 2023. These forums provided insights into the most recent industry advancements of takt production implementation, thus providing grounds for validating and updating the model.

When revisiting the model against the forums' insights, even though the models' initial levels and requirements reflected the industry's experiences quite well, we found several interesting areas where the model could be updated to reflect the current state of practice. Through three formulated categories (strategic takt planning, supply chain management, and driving change) 11 suggestions (numbered in the findings section) were presented to update the maturity model. Following these suggestions an updated version of the maturity model table was presented.

IMPLEMENTING DIGITAL VISUAL MANAGEMENT: A CASE STUDY ON CHALLENGES AND BARRIERS

Ana Reinbold[1], Eelon Lappalainen[2], Petri Uusitalo[3], Olli Seppänen[4] and Antti Peltokorpi[5]

ABSTRACT

The construction industry (CI) has an increasing interest in achieving better situational awareness (SA) in complex projects, by focusing on sharing real-time information among project participants, allowing decision-making based on the project development's up-to-date situation and status. The implementation of digital visual management (DVM) tools as means of communication to increase SA in CI projects has the potential to simplify information dissemination. This paper identifies the challenges and barriers faced during the implementation of a DVM tool. The authors interviewed nine project management professionals who were part of the client organization in a complex infrastructure project of the western part of the Metro in Helsinki and Espoo, Finland. The findings show that the lack of digital tools for collecting and analyzing project data, the focus of the DVM on the top management, and the lack of trust among the actors involved in the project undermine the success of DVM implementation. Thus, digitalizing data collection, increasing trust among project participants, and disseminating information are crucial for successful DVM implementation.

KEYWORDS

Visual management, digital visual management, situational awareness, construction reporting

INTRODUCTION

The complexity of construction projects requires information sharing to increase and spread situational awareness (SA) among project participants. An important component of lean philosophy is the visualization of the flow of production activities, which also allows waste identification and elimination (Koskela, 1992). Shared SA in complex projects in the construction industry (CI) results in a better understanding of the task flow and an easier identification of problems, combined with a more efficient decision-making process. In recent years, the academic community and practitioners have increased their interest in studies and applications of SA models and systems in the CI (Lappalainen et al., 2021). Such interest stems

from the fact that the information bottlenecks, as well as the costs and time involved in collecting, updating, and sharing data, are also symptoms of the lack of SA in construction projects (Akinci, 2014).

During military operations, SA began to be defined as the perception of environmental elements in time and space, comprehension of their meanings, and projection of outcomes in the near future (Endsley, 1995). In the CI, SA was initially related to safety management (Gheisari et al., 2010), but the term has also been applied to the construction phase of projects, with different areas of focus, such as the role of building information modeling (BIM) in SA (Li et al., 2018), location-based construction planning and controlling (Dror et al., 2019; Reinbold et al., 2019; Görsch et al., 2020), and construction logistics management (Seppänen & Peltokorpi, 2016; Tetik et al., 2020).

To increase SA, visual communication, and visual management (VM) have been successfully implemented and documented in distinct phases of construction projects (Tezel, 2011; Pedó et al., 2022). As part of the Toyota Production System, VM focuses on the visual representation of information that can be retrieved at a glance during the execution of tasks and is often connected to Lean Management (Koskela, 1992; Galsworth, 1997; Liker, 1997; Formoso et al., 2002).

Controlling the status of complex projects is an essential element to create and distribute SA. Usually, projects rely on the use of key performance indicators (KPI's) to share the current situation among project participants. Performance indicators are compilations of information applied to measure and assess performance (Edwards and Thomas, 2005). The indicators used can be leading or lagging. Lagging indicators represent realised outcomes of a process. Leading indicators represent likelihood of a particular outcome (Moore, 1983).

The use of performance dashboards to display and share KPI's had been continuously applied during complex projects, creating an important link between the project controlling activities and the use of VM in the distribution of shared SA. Through a dashboard, staff members can stay in touch with the strategic direction of the company and present their contribution to it (Shermach, 2005). Effective dashboards provide important data that can be rapidly read and understood (Few, 2006; Middleton 2005).

Other promising tools capable of increasing SA in construction projects are related to digitalization and information technology (Olivieri et al., 2017; Dror et al., 2019; Pica & Abanda, 2019). These tools allow system-to-system, human-to-system, and system-to-human communication, enabling more effective data collection and sharing with the right person at the right time (Dave et al., 2015). These tools have different areas of focus and applications, including 3D laser scanning, location-based information from construction crews, and display and management information systems.

Naturally, with the progress of research and application of VM and digital tools in the CI, the possible connection between both approaches has also raised interest among scholars and practitioners, opening the field to digital visual management (DVM) concepts and tools. Previous research has found that to select the right mobile computing strategy for managing information in construction sites, it is necessary to clarify the information management process, create an overview for mobile computing, and choose the appropriate technology (Chen & Kamara, 2008). A set of VM requirements applicable to digital support and control during the design phase has also been examined (Pedó et al., 2022). Nevertheless, the investigation into the challenges of and barriers to DVM adoption in CI projects continues to be limited (Reinbold et al., 2022).

Current developments show DVM's potential to both provide information in a visual manner and allow more effective data collection and display in the CI's complex projects. However, so far, mostly the benefits of DVM have been discussed. Because these systems are not yet widely used, there is a need for more knowledge about the challenges and barriers related to implementing such systems.

This paper aims to identify the challenges of and barriers to the adoption of such tools and to understand the current stage of DVM adoption in the CI. This investigation is conducted in the context of a case study that explores the adoption of DVM during the reporting of a complex infrastructure project in Helsinki and Espoo, Finland. To identify the challenges of and barriers to DVM implementation, the researchers analyzed the visual reports produced by seven different contractors and interviewed nine project management professionals involved in the project.

METHODS

The chosen research method was a case study of a Finnish subway construction project encompassing seven separate sites. Case study involved a public project company building a subway project. The case was selected because the project had experienced considerable difficulties in managing the project status information in the previous stages of the construction. Disruption and recovery are often research opportunities worth documenting and analyzing since the findings often reveal insights into general processes (Yin, 2018). The project management team, which had progressed to its second phase, had been involved in developing a system to combine the collected data into a central dashboard and use it to manage the whole project.

In the prevailing literature, increasing the availability of visual information is a significant contributory factor for operations in complex and dynamic systems (Beynon-Davies & Lederman, 2017; Koskela et al., 2018). According to Beynon-Davies and Lederman (2017), VM systems are associated with concrete artifacts designed for informational purposes, the possibility to manipulate them for information and choice, and the location of the function in a physical space. The selected case addresses all these essential elements of VM, with the addition of digitalization.

A physical control room had touchscreens displaying the main Key Performance Indicators (KPIs) of the project, updated at 1–2-week intervals, depending on the data source. The data were collected mainly by the project management contractors working on site and a separate five-member status team, mostly using spreadsheets and web-based data, with no software integration or automation of data collection or use of sensors. A team ensured the quality, availability, and analysis of the data for the biweekly management sessions. During the sessions, the project management team assessed the situation and made decisions accordingly. The DVM system focused on the schedule, cost forecasting, and health and safety level of the project. At the time of this study, the system was used to manage the status of the final documentation and testing. The project had an 8-year duration and a budget of M€ 1,200.

The case study's location in Finland allowed the researchers access to the research data and enabled them to conduct face-to-face semi-structured interviews with DVM users. The preferred method of interviewing in this study was face-to-face, which the researchers considered a more effective way of observing body language and facial expressions than digital interviewing (Irvine et al., 2013). These observations were made during the interviews to the extent practicable. One of the factors that influenced this was whether or not the interview occurred in a room with VM tool/system access. Observations were documented during the interview. The informants were also interviewed in their familiar work environments. All interviews were conducted in Finnish by two researchers, one interviewing and the other observing and taking notes. Interviewees were asked to describe the DVM they use, including its functions, applicability, and the information it provides. They were also asked to describe the connections between the DVM and different aspects of the project, such as design, procurement, and logistics, and to identify any functionality that was automated. Interviewees were also asked to describe recent cases where they or someone else had used DVM in a user role. Table 1 provides background information of the interviewees.

Table 1. Informant description.

NO.	ROLE	EMPLOYER	INTERVIEW DURATION (MINUTES)
1	Project director	Consulting company	107
2	Construction director	Owner	107
3	Site manager	Owner	76
4	Project engineer	Consulting company	77
5	Project engineer	Consulting company	82
6	Project engineer	Consulting company	74
7	Scheduling manager	Consulting company	78
8	Financial director	Owner	62
9	Project manager	Consulting company	50

The durations of the responses reflect the fact that the research project included also other questions and themes than DVM. The durations of the interviews include all themes, not just the time spent by the respondent on the DVM theme.

The research data thus consisted of visual reports generated by the digital system and the interviews. The approach used in this study aims to gain an in-depth understanding of the use of DVM in project management (Fellows & Liu, 2021). Data triangulation was employed, utilizing both interviews and observations during the interview as sources of data. The crucial aspect in this case was to have two interviewers, allowing one to concentrate on doing the interview while the other focused on observing. Before the interviews, a methodology for observation was created, consisting of two sections: descriptive observation and reflective observation. The observations were documented in interview notes, which consisted of handwritten records that contained both the notes taken during the interview and the observations made. To effectively triangulate, careful analyze of any inconsistencies or similarities between the statements by the interviewees and the observations were made by the researchers.

DVM REPORT

Considering the complexity of the project and the communication channels among the seven contractors and the project owner the involved understood the need for standardizing the reporting of construction site key performance indicators (KPI's) as a tool to improve and increase the stakeholders SA sharing.

The chosen type of report was a dashboard and the efforts resulted in a standard reporting system that followed up seven lagging KPI's:1) the percentage of work planned, 2) the percentage of the work completed, 3) the deviation between planned and executed work in percentage, 4) planned costs in million euros (M€), 5) executed costs (M€), 6) health and safety in percentage, and 7) collaboration work in percentage. Concerns were raised about ensuring the report's comprehensibility and accessibility to all stakeholders. Consequently, elements that enhance visualization and colour codes were implemented.

The report adopted is represented in Figure 1. If there were no delays, the schedule report had a green circle. If the work was delayed, the circle was red. A Finnish method was used to measure occupational health and safety. The measure is based on the share of successful health and safety observations of total observations. For this health and safety KPI (Key performance indicators) green colour was used for indicator values above 95%, otherwise the KPI was red. Collaboration was measured via a questionnaire responded by those involved in the project, and the KPI measured the share of positive answers. For the collaboration KPI, the circle would be represented in green colour for indicator values above 80%, otherwise the circle would be represented in red colour. Other KPI's related to quantity of work executed and quantities were also followed. The report adopted is represented in Figure 1.

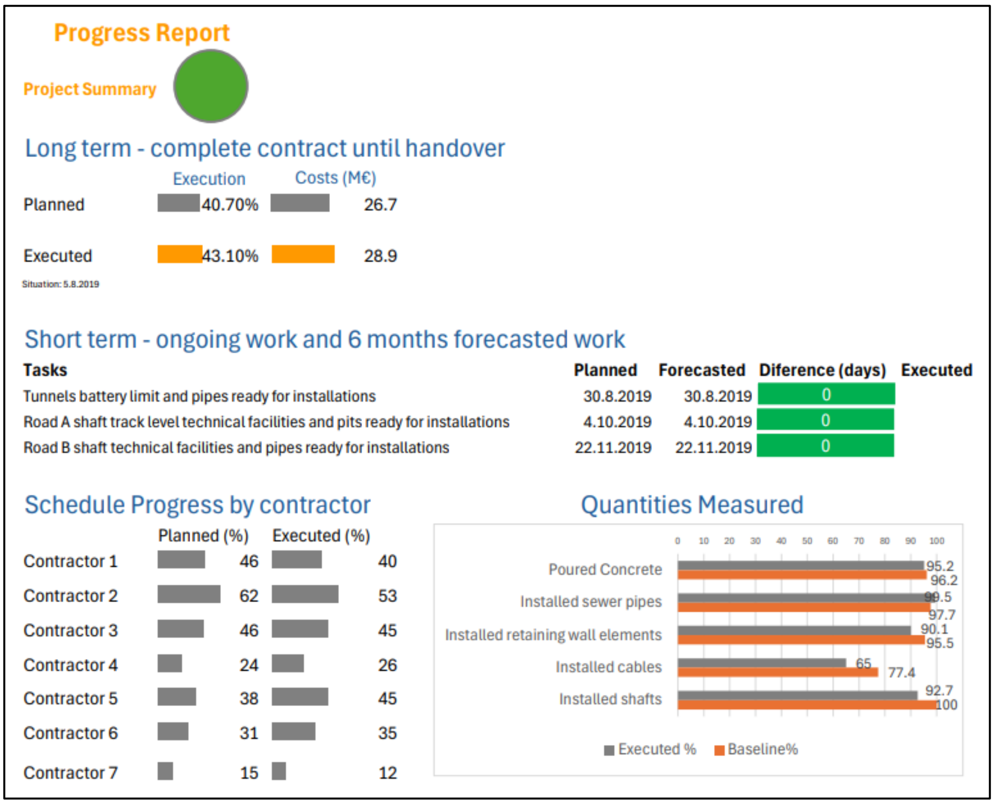

Figure 1: Visual Report of KPI's adopted during the project (source: adapted and translated from Finnish to English by the authors)

Having in mind the shared SA, the reports were displayed digitally in a "War Room", a management room for the project, that was accessible to the stakeholders. A picture of the digital displaying of the reports is seen in Figure 2.

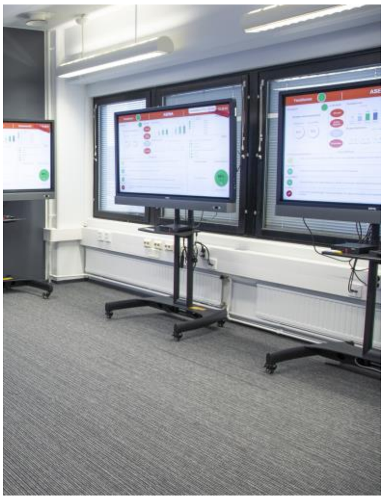

Figure 2: Digital display of visual report (Original photo: Timo Kauppila, NDAV)

BARRIERS AND CHALLENGES OF DVM IMPLEMENTATION

The interviews were transcribed, and the quotes were open-coded and categorized using Atlas.ti software. The authors then selected the quotations that mentioned reporting, automation of data collection, and collaboration. From this first handling of the quotations, 73 were subcategorized.

The authors created the following subcategories: 1) information and communication technology (ICT) and tools, 2) process and 3) people and culture. The following sections provide descriptions and examples of the categories with quotations from the interview transcripts and categorization. Some of the quotations were assigned to more than one subcategory. For example, the quotations that mentioned data collection and lack of trust in the reported data were categorized as *both* ICT and tools *and* people and culture because they pointed to the lack of digitalization in the data collection and analysis and emphasized that the data reported and collected were not always trustworthy.

Lack of ICT tools leading to manual workload

All quotations that mentioned tools for data collection and analysis, adoption of new tools and systems, information systems, information silos, and interoperability issues were classified under the ICT and tools subcategory. In total, 50 quotations were linked to this subcategory.

Several interviewees expressed their concern that the lack of a standard and unified tool for reporting increased the workload for this function, as illustrated in this quote:

“Well, yeah, there are, there are clearly flaws in the thinking, that no one had thought through to the end, all those reporting templates…”.

The adoption of a standardized DVM report required training of the project members involved in the reporting phase, their work tools and processes adaptation and adjustments in the reporting process. These points created resistance to the adoption of DVM reporting. The change process was not considered a smooth transition but a contractual obligation.

Two other significant barriers to the adoption of the DVM report were manual data collection and analysis. Different systems are used to follow up on the various aspects of the construction progress. An interviewee mentioned the use of five different data collection and reporting systems, one each for financial reports, schedule monitoring, health and safety data and reporting, and tracking the quantities completed on the construction site. To consolidate all the information into the DVM report, the data were extracted manually from different systems, which required time and was considered inaccurate by the interviewees.

It was clear that the systems used were not interoperable and the extraction and exchange of information had to be processed manually, which is an important challenge to be addressed when digitalizing reporting and implementing DVM approaches in construction projects.

“From what you’ve heard, the situation picture is quite manual, and its updating has evolved a lot during the time I was involved. Initially, I was involved in maintenance, and then quite quickly, also in development, both technical solutions and things like, well, I don’t know, maybe not so much in processes, but if you think about quantity tracking and KPI tracking, in their deployment, the contractors didn’t have information about what it practically means and how it works”.

Inconsistent process of collecting and publishing data

This subcategory includes mentions of necessary changes in both the data collection and reporting processes. Reporting process issues such as the contractors’ neglect and delay in publishing information and the increased workload in processing the reports are covered as well. With the implementation of the DVM reporting system that was new to the project participants, the processes for creating reports and collecting data were not well defined, and their development occurred simultaneously with the implementation phase.

The processes for creating the DVM reports were only developed due to the contractual obligations to produce and update such reports, which generated negative feedback related to project reporting. Many of the interviewees stated that the DVM reports contained unnecessary information, the updating of the information was often inaccurate, the same status was repeated over the weeks, and the reporting was not prioritized.

"When facing a tight schedule, reporting is often the first thing to be neglected. People just try to get through each day, and reporting is seen as an extra task."

"They often feel like, 'Why do we have to create this report?' And if your response is, 'Because it's in our contract that you provide it,' it immediately becomes additional work for them."

This resistance to the implementation of DVM reporting was also often perceived by an underrating about the utility and importance of the report. Some of the interviewees involved in the DVM reporting perceived it as an extra task to repeat the same information that had been reported previously, but in a different way. This reflects the lack of standards in the CI, as well as how management and tools differ from one project to another.

As project organizations change from one project to another, the implementation of DVM tools and reporting is not a standard process, which poses a barrier to the consolidation of the adoption of such approaches.

Culture of mistrust and resistance

All mentions of resistance to the implementation of a new process, mistrust in the reporting partners, the belief that someone was hiding information, the lack of information sharing with others, and the change of behaviors toward the DVM after its implementation were classified under the *culture of mistrust and resistance* subcategory.

In the interviews, the mention of the resistance to the implementation of the DVM reports was identified for different reasons. The resistance to the adoption of a new process and a novel manner of reporting, which belongs to the *people and culture* subcategory, concerns matters that need to be addressed. The changes should be dealt with before the implementation phase, and the discussions must clearly state the importance of the DVM and its benefits to the project. The contractual obligation is not enough to ensure the success of the implementation and can even contribute to the resistance to it, resulting in an attitude of adoption only due to contractual enforcement.

The most common mention regarding people and culture is related to the lack of trust. The existing culture of mistrust in the CI was also identified in this project by the authors. Several interviewees brought up the issue that contractors concealed information or tried to do so while manipulating the shared data and information. This mistrust encompassed how data were collected and by whom; the interviewees stated that when the data were collected and analyzed manually, the reports often contained outdated information, or the published information did not reflect reality. It came to light that mistrust also originated from people's behavior, with the interviewees admitting that they had also hidden information in some situations.

The mistrust culture is a major barrier to be overcome during DVM implementation, as it undermines trust in both the information and the SA shared. It also raises doubts about the decision-making process since the parties involved might make decisions based on outdated and mistrusted information.

Counterbalancing the mentions of the barriers and challenges during the DVM implementation, several interviewees identified two positive aspects that can be classified (under the people and culture subcategory) as enablers of the implementation. The first one was that when the project stakeholders were committed to the DVM implementation, the positive feeling about such adoption increased, and it was more often recognized as successful.

"In my opinion, it's important that if you go through it together, you can get the contractor more easily committed to it. So, we agreed that we would go through it together and streamline it in a way. In my opinion, it's a good commitment model in that sense then."

The second positive aspect was that after implementation, the interviewees felt that the DVM report facilitated their work, information sharing, and understanding of the project, thus increasing the SA of the project participants.

"In that, I feel that there was a very good, very strong; if we didn't have such a system, we would have been completely lost there, where those specific sites [were] going. Perhaps, with the traditional model, we wouldn't have obtained so much [information]."

These two points emphasize that involving the stakeholders and assuring their commitment to the DVM implementation create an environment conducive to making the transition and overcoming the initial struggles. The DVM implementation also increases the trust and understanding of the project SA.

Table 2 summarizes this study's findings.

Table 2. Identified barriers and enablers to DVM adoption.

Category	Barriers	Enablers
ICT and Tools	- Lack of standards for information sharing; - Use of different systems for different data; - Lack of interoperability among systems.	-
Data Collection and publishing	- Increased work for manual data collection and analysis; - Publication of outdated data; - Lack of clear understanding of the report utility.	-
Culture and People	- Lack of trust among project members; - Mistrust on data collection methods; - Lack of commitment from the project actors towards the reporting; - A shared culture of hiding information; - Resistance to the adoption of new methods and tools at work.	- The commitment of project stakeholders to the DVM adoption increased the positive feeling about the process and it was more often considered successful; - After the initial struggle with the report implementation, participants felt that the DVM report facilitated information sharing, project understanding and increased their SA.

DISCUSSION

This study aims to bring clarity to the barriers and challenges encountered while implementing DVM in a complex infrastructure project. During their research, the authors realized that the data were collected and analyzed manually for the purpose of generating the DVM report. Although the creation and sharing of a standard report facilitated the understanding and dissemination of information using DVM, there was noticeable mistrust in the data quality and the data reported. This is not a new discovery; despite the modest progress made in the digital evolution of construction projects, there remains a lack of trust in digital workflows (Soman & Whyte, 2020).

The lack of interoperability among the systems, which emerged from the interviews in this case study, requires much more advanced digital infrastructure and interoperability (Shibeika & Harty, 2015). For example, the traditional monthly reporting schedule and compilation of the data in the DVM reporting system used in this study appear to constitute a process that lags behind the digital era. The lack of interoperability among the different systems used could be addressed through digital systems that have the ability to connect and exchange information with one another. However, specialization in the construction sector continues to be a trend in terms of both professional roles and systems, and the integration of different systems and skills cannot be avoided (Turk, 2020). Therefore, the critical comments of the interviewees in this study can also be assessed as opportunities rather than just threats.

In this study, the process of creating and standardizing reports with a DVM approach, involving seven different contractors, provides evidence that systems lacking interoperability considerably increase the time required for reporting. This issue creates barriers to the adoption of such an approach, resulting in the neglect of the reporting when the project activities are urgent. Another interesting finding is that with information scattered in different systems, the increased time for reporting also hinders the implementation of DVM approaches. The underlying reason is that the involved parties might analyze the situation as entailing additional work without financial compensation. This perception reflects DVM practices' limitations regarding their simplicity and presentation of excessive information, as well as the lack of prioritization of information (Pedó et al., 2022).

This study's findings corroborate previously noted challenges in the adoption of DVM during construction projects. The DVM report followed an analog logic, where the data were collected and handled manually, with the digital format used only to display information (Reinbold et al., 2022).

The cycle of mistrust in the CI was a barrier to the implementation of DVM applications. This mistrust was also expressed as a lack of confidence in the reported data. Once a new process and a novel approach to reporting are implemented, engaging in constant work, with the commitment of the parties involved, as well as taking actions to increase trust among the participants in the process of data collection and reporting, become essential for the successful implementation of DVM.

CONCLUSIONS

In this paper, the authors have investigated and analyzed the impacts of creating a DVM process when reporting different KPIs for a complex infrastructure project, involving seven different contractors and client representatives.

The commitment of the stakeholders involved in the project is paramount for the success of DVM implementation. The present culture of mistrust in the CI is fueled by the lack of digitalization of processes. If data are analyzed and reported manually, even when generating a digital report, there is constant mistrust that the data are incorrectly collected or gathered at the wrong time. Due to such manipulation of data and reporting, there is also a persistent suspicion that contractors hide information.

In the studied case, the project stakeholders' resistance to the implementation of the DVM tool diminished after they overcame the initial challenges, identified the increase of shared SA, and acknowledged that the report supported their work.

This paper was limited to one complex infrastructure project in Finland and focused on the implementation of a specific DVM report, the generalization of results should be carefully considered. Further investigation of the information needs from users and the disparities between those and the information displayed is necessary.

UNVEILING THE HIDDEN HIGH VARIABILITY IN PROCESSES WITH STABLE AND GOOD PPC RESULTS

Omar A. Samaniego[1]

ABSTRACT

Despite high and stable Percentage of Plan Completed (PPC) values obtained in projects where Last Planner® System (LPS) was implemented, construction processes often conceal variability, undermining true completion. Likewise, LPS metrics rely on a deterministic approach for measuring the performance of processes without contrasting them with non-deterministic variables, which can provide a new perspective and new room for improvement. This is why, this paper introduces four new metrics – Percentage of Plan Completed+ (PPC+), Percentage of Plan Completed++ (PPC++), Percentage of Plan Completed+ based on random scheme (PPC+r), Rate of Waste (Rw), and Rate of Planning Assessment (Rpa) – to unveil hidden variability around activity daily schedule, rework, excess capacity, and planning. Further, utilizing statistical modeling to define the pioneering stochastic indicator Rpa, the study presents an important leap from traditional LPS deterministic metrics. Thus, by also conducting one survey among LPS practitioners on PPC conception and usage, it illuminates how seemingly stable estimated PPC values can misrepresent process performance.

These metrics offer a transparent brand-new assessment way, revealing new opportunities for improvement aligned with lean principles. The study also provides foundation and directions for further research on hidden variability which can propel the current LPS approach.

KEYWORDS

Lean construction, Last Planner® System, PPC, metrics, stochastic indicator.

INTRODUCTION

This approach introduces a novel method for evaluating hidden variability within the context of the variability research field on PPC results, addressing existing gaps in this field. This becomes apparent when the study quantitatively shows that even when a process maintains a consistent PPC of 100%, variability may persist unnoticed.

The newly introduced PPC+ and PPC++ metrics scrutinize daily fluctuations within weekly PPC assessments, revealing variability in activity leaps and its impact on deliverable completion, respectively. Completion, within this framework, pertains to fulfilling technical requirements, distinguishing it from mere quantity or activity execution. Similarly, Rw highlights the waste of hidden resources employed to address unnoticed variability.

Moreover, taking note that randomness can be explained as out of control variability (Hamzeh, 2009), and adhering to the principle that planned results are diametrically opposed to random outcomes, and the closer planned results align with random outcomes, the poorer the planning execution, Rpa serves as a stochastic indicator utilizing a random variable (PPC+r)

[1] Engr., Master, NEC-ECC PMA, VDC, PMP®, PMI-RMP®, Risk Management Program Director, Universidad Peruana de Ciencias Aplicadas, Quality Consulting Solutions Director, author and independent researcher, comercial@quality-consulting.org, osamaniego@pucp.pe, https://orcid.org/0000-0003-4352-2610

obtained by estimating the most probable PPC+ value within a random scheme for a particular process model. For defining this, the author conducted a simulation with a constant 100% PPC while varying PPC+ values.

The author doesn't assume that the basis of LPS approach takes completion as independent of meeting technical requirements. However, he asserts that there are signs that in Peru LPS practitioners understand PPC as an outcome of finalized activities, assuming that these activities result in deliverables meeting the technical requirements. As a result of this assumption, there could be a distortion in the PPC, as certain packages assumed to be finished may still require additional work subsequently. As LPS does not explicitly include formal procedures for quality control, relying on existing quality management systems to ensure the quality of completed work packages (Ibarra et al., 2022), there is a need to define indicators aligned with the LPS approach regarding completion.

TERMINOLOGY

Completion

The project scope's completion is assessed in accordance with the project management plan, whereas the product scope's fulfillment is evaluated based on the product requirements (PMI, 2017). In this paper, completion is accomplished only when deliverables meet technical specification, and since defects are not part of the specifications, completion also means free of defects.

Deliverable

Any unique and verifiable product, capability or result to perform a service that is required to be produced to complete a process, phase, or project (PMI, 2017).

Requirement

The term *requirement* is defined as a capability or condition that is required to be present in a product, service, or result to satisfy an agreement or other formally imposed specification (PMI, 2017).

PURPOSE

The aim of this study is to propose new metrics PPC+, PPC++, PPC+r, Rpa, and Rw, which collectively unveil hidden variability in regular high-performance and low-variability PPC results. Likewise, this paper presents Rpa as a pioneering stochastic indicator for LPS approach, opening the door for further indicators of this kind.

METHODOLOGY

Observation and Hypothesis

Describe regular construction process characteristics, how they are understood and measured by LPS practitioners, and provide possible explanations.

Literature Review and Foundations

Conduct a comprehensive literature review on the LPS key metrics, establishing the theoretical foundations for new metrics, including the understanding of completion, deliverables, and requirements.

Assessment of PPC Understanding

Conduct a poll among LPS practitioners to explore their understanding on completion. Evaluate emerging insights to identify potential misconceptions to later assess the necessity of introducing supplementary metrics to address these misconceptions

New Metrics Definition

Define the PPC+, PPC++, PPC+r, Rpa, and Rw metrics in detail, explaining the rationale and formulas for each. Describe the underlying assumptions and constraints applied.

Simulation and Theoretical Results

Assess selected metrics through simulation modeling and analyze results to uncover hidden variability despite a consistent 100% PPC. Obtain statistical values for PPC+ in a random scheme, describe its theoretical relation with Rpa.

Site Research Project

Propose starting points, procedural steps, and recommendations for conducting on-site research to validate the theoretical findings.

Conclusions

Synthesize theoretical and practical findings on PPC understanding and completion. Assess new metrics' utility in uncovering hidden variability and improving PPC estimation.

OBSERVATION AND HYPOTHESIS

In Peru, LPS practitioners commonly evaluate variability by monitoring PPC and other LPS metrics' behaviour, relying on measured resultant data, which unveils a prevalent deterministic approach. While this practice illuminates processes and guides actions, inherent biases may prevent thorough examination of resultant data upstream, alongside to misconceptions about key definition of completion in terms of deliverables rather than solely activities.

LITERATURE REVIEW AND FOUNDATIONS

PPC stands as the predominant metric in LPS, typically associated with effective weekly work planning and successful LPS implementation. It serves as a *post-production* gauge of the reliability of weekly work planning (El Samad et al., 2017). Likewise, other well-known metrics are the now called Tasks Anticipated (TA) and Tasks Made Ready (TMR) (Ballard, 1997) which can be used to align the weekly work plan assignments with the lookahead plan. On the other hand, Planned Work Ready (PWR) is a metric used for assessing the quality of the lookahead process; this metric serves as a forecast and can provide a better evaluation of schedule performance when complemented with PPC (Mitropoulos, 2005). In terms of quality of the deliverable resulting from activities, Sukster (2005) proposed the Percentage of Packages Concluded with Quality (PPCQ) determined by the ratio of packages concluded with quality to the total number of packages concluded, and the Percentage of Packages Really Concluded (PPCR) determined by the ratio of packages concluded with quality to the total number of planned packages. Jang and Kim (2007) proposed Percent of Constraint Removal (PCR), to measure the performance of the make ready process. Alarcón et al. (2014) observed that for successful projects, it is not sufficient to possess high values of PPC and PCR; it is also essential to control their variability.

The above is a sample of the most relevant LPS metrics which, in all cases, are deterministic and do not arise from statistical modeling. In terms of variability assessment, Emdanat et. al. (2016) proposed the Percent Required Completed or Ongoing (PRCO), which evaluates the percentage of required activities completed by their promised dates, encompassing ongoing activities projected for completion by their original promised dates after team members update remaining durations to align with remaining work. Additionally, they introduced the Milestone Variance (MV), denoting the gap in days between the anticipated completion date for all pending tasks and the milestone's prescribed deadline. Although these last-mentioned indicators are an attempt to analyze activity variation, all of this still remains within a deterministic estimation realm.

When it comes to simulation experiments, studies are founded on simulating process behavior to offer valuable insights, though new specific stochastic indicators are not provided. In this regard, Tommelein (1997) conducted a simulation that enabled experimentation through modeling push- and pull-driven sequencing of resources. Likewise, Hamzeh and Langerud (2011) conducted a simulation to study the relationship between increasing Task Anticipated (TA) and PPC increase, and the concerning impact on project performance. The study results showed that even a small change in TA may significantly affect PPC. More recently, there have been approaches to simulation games such as that proposed by Alves et al. (2022), who presented an analogue simulation game concerning Takt Time Planning (TTP) and Takt Control (TC) and showed, employing a case study, one way in which Lean Construction and Building Information Modeling (BIM) can be linked through QR codes. In author's opinion, concerning BIM models can serve as a graphical base for running future stochastic analysis.

ASSESSMENT OF PPC UNDERSTANDING

POLL RESULTS ON PPC UNDERSTANDING

The term *completion* is commonly used in LPS literature, typically in relation to activities. Therefore, *activities completion* implies that there is nothing more to add to those activities. However, there is a trend among Peruvian LPS practitioners to measure this in terms of quantities related to finished activities instead of completed deliverables. In this paper, a deliverable is considered complete only when technical requirements are met, signifying that the presence of defects indicates a lack of requirement compliance.

In this context, a survey was conducted with the aim of assessing the knowledge of PPC estimation among Peruvian LPS practitioners (see Table 1). To achieve this, a survey database built in Peru was selected, indicating that a majority of the emails correspond to this country. In this regard, preliminary observations derived from the results might be mostly applicable to Peru. The survey question was intended to replicate the common questions raised when estimating the PPC, and it includes a section regarding defects, stating that it has a delimited impact. The question was as follows:

"Considering that PPC is the percentage of plan completed, answer the following: There are 10 concrete slabs, each with a volume of 5m3. If you plan for 10 concrete-cast activities in a week and 9 of these activities are done within that time period, what is the value of PPC? Taking into account that the strength of the slabs is satisfactory; there are pending corrections, but they impact a maximum of 10% of the time or resources."

Table 1. Survey specs on PPC estimate

Location	Peru	**% Peru responders**	52.2%
Size	45	**% other countries**	47.8%
Mean	Emailing, WhatsApp	**Dates**	15 to 26 Jan, 2024
Tool	Google Forms	**LPS Years Exp. (LPSYE) Avg.**	4.13
Source	Database built in Peru	**LPSYE Standard Deviation**	3.31

To answer this question, it should be note that an activity finalized with a slab with pending corrections is actually *not completed*, then it remains as *work in progress*. The correct answer to the question above is *Need More Data*, as the number of not completed slabs (resulting from unproperly finalized activities) can vary and is not mentioned.

Figure 1 helps to explain why we need more data to answer the question. Here, NS means *not started*, WIP means *work in progress*, indicating either started activities not yet finished or the presence of defects, signifying incompleteness. Finally, OK means *complete*, denoting full technical requirement compliance. The first alternative indicates a real PPC equal to 90% as there are no defects, and activity finalization did not result in incomplete slabs (there is no pending corrections); here, the nine resulting slabs are OK. On the other hand, the rest of the possible alternatives show concrete-casted slabs, but there are defects affecting a different number of slabs tagged as WIP; those defects have the same impact in any alternative, as the impact is measured in terms of time or resources (10% impact as per the question), not in terms of deliverables. PPC estimates are based on activities and will differ from deliverable-based estimates if those activities are *wrongly assumed to be finalized with defects-free slabs*.

Figure 1. Number of slabs at different completion states related to the answer for the Poll on PPC estimate

Thus, to respond to the poll question, we require data regarding the number of deliverables associated with activities. Furthermore, considering the Lean Philosophy's emphasis on delivering value to the client, the inclusion of deliverables in PPC assessment is crucial, as they encapsulate the value created by the project. The results in Figure 2 shows the value of 90% as the most selected answer to the poll. Yet, the sample size is statistically not representative and need to be increased, these results are very consistent with the hypothesis that, in Peru, PPC is solely assessed based on activities without delving into the results, wrongly assuming that the results (deliverables) are in accordance with requirements. As quality is defined as the degree to which a set of inherent characteristics of an object fulfils requirements (ISO, 2015) then quality, in essence, is assumed, not assessed when estimating PPC for this population.

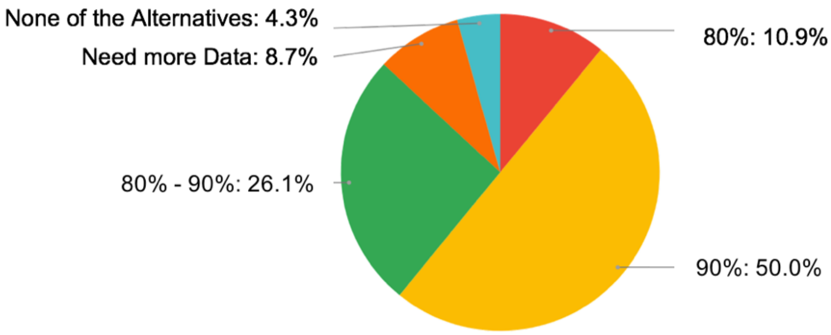

Figure 2. Proportions in answers for the poll on PPC estimate knowledge

A more extensive poll, displaying the same pattern, would suggest that common LPS practitioners make no further analysis of activities' results and consequently fall into wrong assumptions about completion and planning. The author doesn't claim that LPS practitioners usually wrongly estimate PPC but states that there might be a bias in the first glance assessment of PPC that may lead to wrong PPC estimates in Peru.

NEW METRICS DEFINITION

PPC+ AND PPC++

Percent Plan Complete (PPC) is the percentage obtained by dividing the number of completed planned activities by the total number of planned activities (Ballard, 2000). PPC is a well proven way for measuring schedule reliability and is used as a basis for an additional set of metrics introduced in this paper called PPC+ and PPC++. PPC variability may reduce and average PPC value may also increase in a given set of periods of time converging to 100%. Then, assuming that it consistently reaches the 100% for a set of periods, intuition may lead us to believe that there is no more variability to address; however, another kind of hidden variability remains, and can be out of control yet. The hidden variability is related to daily changes (back and forth leaps) in scheduled activities execution and reworks required at deliverables level, compromising completion; all of this is not measured by PPC. In some situations, changes in the sequence can result in poor quality, which might affect subsequent work, potentially necessitating the need for rework at later stages of the project (Fireman et al., 2013).

In the figures of this section the author explains these situations. Here, every activity is independent of one another, and there is no constraint to reschedule any of them ahead of or after the schedule. Furthermore, all activities are carried out in the same shown week.

Figure 3 illustrates five scheduled activities, each of them pertaining to a specific deliverable (e.g., concrete casting for one column). The assignment of two laborers for one activity every day is taken into account. In this scenario, the expected performance of two laborers is estimated to be *well*, achieving the completion of one column per day. It is noteworthy that in this example, no additional deliverable-related activities are introduced. In Figure 3, it can be also observed that when each column is completed on the respective day, the PPC equals 100%. This value remains consistent even if activities are rescheduled during the same week.

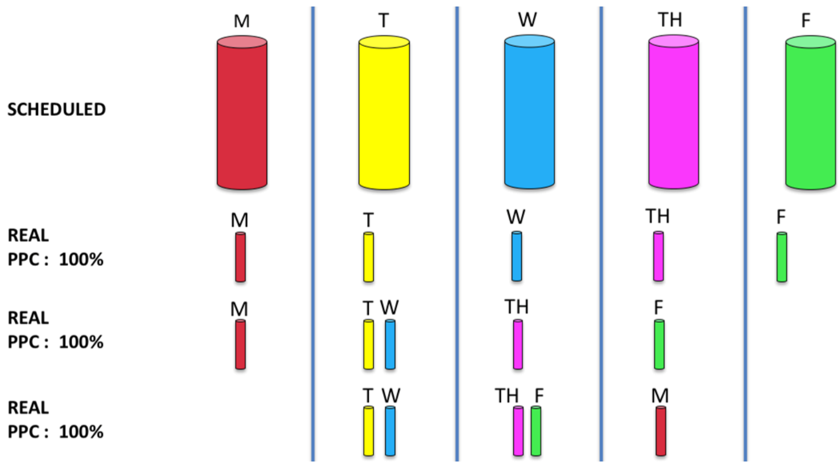

Figure 3: Common PPC estimate in Peru as per author's observation (Samaniego, 2021)

In Figure 4 PPC+ is estimated by taking into account only concrete casting activities done when scheduled. Thus said, there are only three activities completed when required, then PPC+ equals to 60%. In Figure 5, for obtaining PPC++ only concrete casting activities are taken into account if the resulting deliverable (column) is completed as daily scheduled – that means according to requirements and then free of defects; in this sense, as there are only two successful activities, then PPC++ equals to 40%.

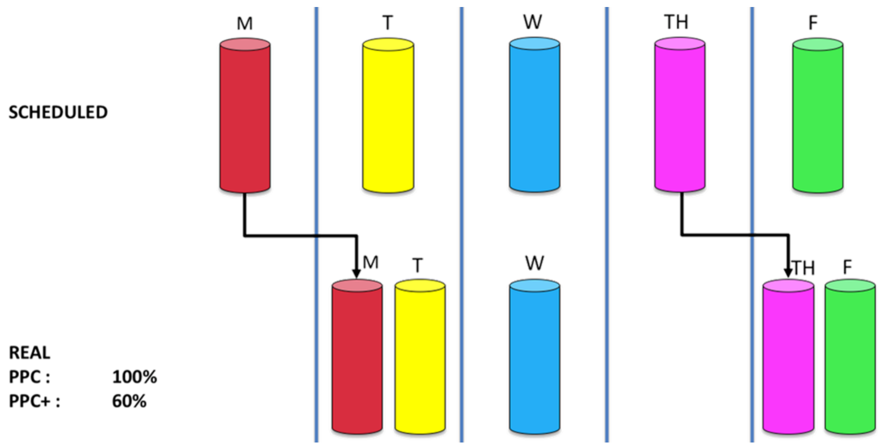

Figure 4: Application of PPC+ (Samaniego, 2019)

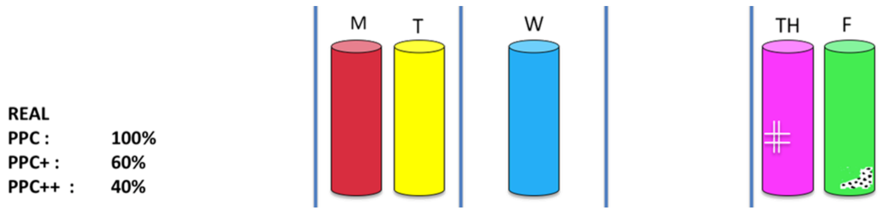

Figure 5: Application of PPC++ (Samaniego, 2019)

The author anticipates that both PPC+ and PPC++ will be subject to constant variability, even though PPC consistently reaches 100%, as shown in Figure 3. Additionally, defects will later lead to informal rework packages (Fireman et al., 2013), and the impact of defects is unveiled by PPC++.

RPA AND RW

Taken into account Figure 3, it can be seen that the number of possible combinations of PPC+ for a given PPC at 100% is equal to 5^5, meaning 3,125 outcomes. Then, it is possible to obtain the different values for PPC+ and define the most frequent as PPC+r. The relation between the PPC+ site obtained and the PPC+ randomly obtained (PPC+r) defines the Rpa (Ratio of Planning Assessment) as follows:

$$R_{pa} = \frac{PPC +}{PPC +_r}$$

In regards to resource usage, in the model, it can be seen that since there are days where *two* columns are concrete casted by *one labor* (e.g., Tuesday), then the previous well estimated one column per *two labor* day proves to be wrong, meaning that there is one labor in excess; so, there is room for improving labor efficiency. These unnoticed added resources (two labor instead of one labor) are the way schedulers face uncertainty and variability. This is a kind of capacity buffer to reduce the impact of variability on a system's operation at different locations along the chain (Hamzeh, 2009). As the PPC+ only considers the activities done when actually scheduled, it will be equal to PPC only when full labor resources are used when scheduled. Thus, the following relation defines the ratio of wasted resources (Rw):

$$R_w = \frac{PPC+}{PPC}$$

Thus said, in given e.g. ten weeks where ordinarily applied PPC could consistently reach 100%, there is, apparently, an optimal case not only due to PPC value but also due to zero variation. However, any of these weeks could have a huge range of PPC+ and/or PPC++ values, as per the example above.

SIMULATION AND THEORETICAL RESULTS

In this section, the study utilizes the theoretical case described in Figure 3, where three possible outcomes demonstrate variability in PPC+ and PPC++ for a constant 100% PPC value. The simulation will consider all possible outcomes from randomness and define the most probable value for PPC+. Thus, by defining the Rpa, this paper links PPC+ with PPC+r, which represents PPC+ estimated from a random scheme.

SIMULATION FOR PPC+

The author organized the data in a spreadsheet for the case under study (see Table 2). In this arrangement, ‘0’ indicates that the activity was completed as scheduled, ‘-1’ signifies that the activity was finalized one day earlier, and ‘+1’ indicates a one-day delay. This is what is called back and forth leaps. There are 3,125 combinations, as aforementioned. One section of the combination record is shown in Table 2. In Table 3 and Figure 6, It can be observed that the most common random PPC+ for this case is equal to 20%. Therefore, any PPC+ result site-obtained close to 20% indicates poor plan execution, as it aligns with the most probable random outcomes. Conversely, a PPC+ close to 80% is highly uncommon, signifying a deviation from randomness and alignment with planned results, indicating good planning and execution.

Table 2. Sample showing rescheduled activities combination with related PPC+ values

ID	M	T	W	T	F	PPC+
1	0	-1	-2	-3	-4	20.0%
2	0	-1	-2	-3	-3	20.0%
…	…	…	…	…	…	…
3124	4	3	2	1	-1	0%
3125	4	3	2	1	0	20.00%

Table 3. Frequency of PPC+r

$PPC+_r$	Occurrences	Frequency (F)
0.0%	1024	32.8%
20.0%	1280	41.0%
40.0%	640	20.5%
60.0%	160	5.1%
80.0%	20	0.6%
100.0%	1	0.0%
Grand Total	**3125**	

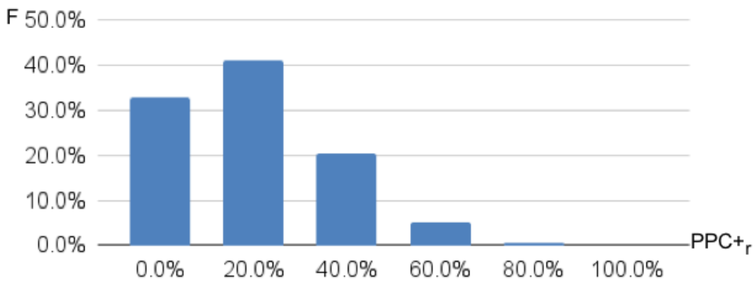

Figure 6. Frequency distribution for PPC+$_r$

Also, Table 4 presents the rescheduling frequency in a random scheme; here, the most frequent value pertains to the not rescheduled activity represented by the '0' value. This symmetrical distribution is expected given the conditions for this scheme explained before.

Table 4. Number of activities rescheduled (back and forth leaps)

Leaps (L)	-4	-3	-2	-1	0	1	2	3	4
Leaps Number (LN)	625	1250	1875	2500	3125	2500	1875	1250	625
Leaps Freq. (LQ)	4.0%	8.0%	12.0 %	16.0 %	20.0 %	16.0 %	12.0 %	8.0%	4.0%

It is worth noting that in a regular project, a trend of delays is the norm. This is addressed to ensure compliance with the weekly schedule, as illustrated by one hypothetical weekly progress recovery curve (dotted curve) in Figure 7. The preventive weekly acceleration curve (continuous curve) depicts the opposite hypothetical pattern in order to keep progress on track, reflecting an intentional early acceleration trend to achieve the weekly schedule. In both cases, this is only possible if labor resources are in excess, and their usage efficiency can be unveiled by Rw. Both hypothetical curves show a schedule compression, this can also biases workers towards getting their tasks done, even when that means spending less time on validation and quality assurance (Ford et al., 2003). Analyzing this, along with trends in site-obtained Rw, can illuminate how excess capacity can be optimally utilized, resulting in cost savings for the project. On the other hand, Table 5 and Figure 8 present the Rpa behavior for different values of a given PPC+r. As the most probable PPC+r value is 0.2, a higher Rpa approaching 5 indicates that the results deviate significantly from randomness, attributed to PPC+ equaling 1.

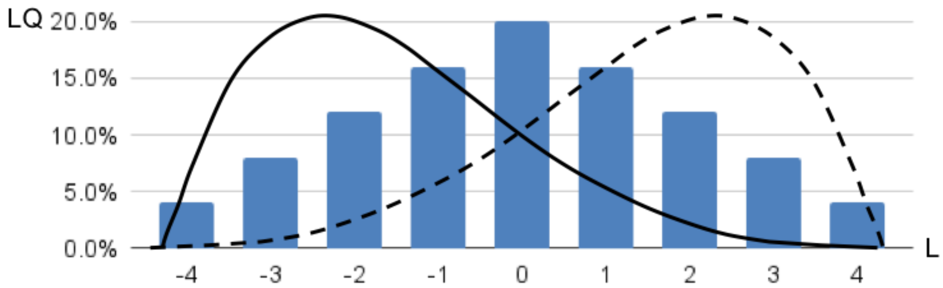

Figure 7. Symmetrical rescheduled activities (back and forth leaps)

Table 5. Rpa value per different PPC+r values

PPC+	PPC+r	Rpa
1	0.0%	---
1	20.0%	5
1	40.0%	2.5
1	60.0%	1.67
1	80.0%	1.25
1	100.0%	1

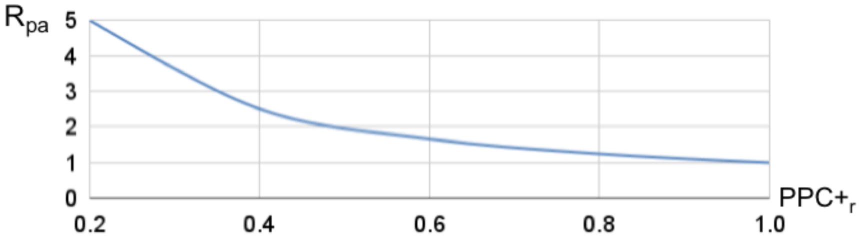

Figure 8. R_{pa} curve per $PPC+_r$ value

SITE RESEARCH PROJECT

The points of departure of this study are based on observations described in this paper, which pertains to misconceptions among LPS practitioners in Peru on completion and PPC. An extended research can be done to strength these observations by: (1) Conducting extended polls about concepts exhibited in this paper among LPS practitioners; (2) Running focus groups among both senior and junior LPS practitioners; (3) Reviewing PPC estimates in active projects. In respect to the new metrics, site validation experiments should consider the following: (1) Conducting experiments in five building projects (towers); (2) Senior LPS practitioners works in the aforementioned projects; (3) The selected project portion shall contain activities independent of one another, without any constraint to move them back of forth (to replicate the conditions of the presented simulation); 4) Daily recording of new indicators and researcher's immersion in the project for a period of one month and applied to selected trade(s).

CONCLUSIONS

This study provided an overview of key LPS metrics developed thus far, with PPC being the most frequently used metric in the industry. While LPS has been proven to enhance planning reliability and reduce workflow variability, there is still room for improvement by identifying hidden variability not yet addressed by LPS deterministic metrics. Additional metrics, PPC+, PPC++, PPC+r, Rw, and Rpa, are presented to address hidden variability and reveal hidden resource waste. Among all of them, Rpa stands out as a pioneering stochastic indicator for the LPS framework.

The study presents a new focus on deliverable completion, which differs from the common focus on activity completion. The consistent results of the polls, though small, provide insights for future studies on PPC estimates and decision-making processes related to completion achievement. In light of this, a research project is proposed to strengthen the findings on LPS Peruvian practitioners' completion understanding. To address related misconceptions, the study provides PPC++, which, in addition to measuring what PPC+ does, adds the criterion of physical deliverable completion. Thus, PPC++ assess if there are zero non-compliances with technical requirements related to properties and characteristics of the deliverable; in other words, PPC++ also serves as a brand new LPS quality metric for deliverables. As planned results are the opposite of random results, and the closer the results are to randomness, the poorer the planning was, a stochastic indicator (Rpa) was developed to provide a random value against which performance results can be compared. In this development, a simulation was conducted on a delimited process model, based on the number of possible combinations of activity leaps, resulting in the most probable value for PPC+ in a random situation (PPC+r). Thus said, should site obtained PPC+ closes to PPC+r, the poorer plan execution was, as this relation is shown by Rpa. Additionally, as the study shows that in order for the activities leaps to exist, there is a need for sunk additional resources, this study proposes Rw (which relates PPC to PPC+), shedding light on hidden resource excess to address variability expressed in activities' back and forth leaps. Finally, the study provides a foundation and directions for further research and on-site validation to refine and expand the application of these novel metrics.

THE RELATIONSHIP BETWEEN MAKING-DO WASTE AND GOOD MANAGEMENT PRACTICES IN THE CONSTRUCTION INDUSTRY: A SYSTEMATIC LITERATURE REVIEW

Tatiana Gondim do Amaral[1], Renato Rafael Del Grosso Filho [2], Rúbia Cristina de Souza Pessoni[3] and Beda Barkokebas[4]

ABSTRACT

The need within the construction market to increase control, performance, reduce waste and impacts on the environment is of utmost importance. In order to fully understand and contextualize the construction management process and help managers make decisions, this study aims to investigate studies through a systematic literature review which address the relationship between good management practices and losses from making-do within good construction practices. The search for articles was conducted in the Scopus, Science Direct and Web of Science databases. This diagnosis revealed the good management practices presented in the literature, which can be facilitating activities or good practices that reduce losses from making-do, guarantee compliance with the minimum requirements of the complete kit or the resilience of the process. The categories of knowledge gaps were structured into: Industry 4.0 and 5.0, Big Data, Multi-criteria decision making, Discrete event simulation, Resilience and Literature review.

KEYWORDS

Making-do. Wastes. Lean construction. Reworking. Planning.

INTRODUCTION

The construction sector becomes competitive when the market and segmentation impose such a perspective, demanding quality and performance from construction companies. As a result, it is necessary to increase control and performance, reduce waste and impacts on the environment (Adewuyi et al. 2014; Ansah et al., 2016). This environment is conducive to applying methodologies, principles and concepts such as lean construction with the aim of reducing costs, waste, improving predictability, and increasing transparency, among other aspects related to production performance.

The use of lean construction concepts within the planning, execution and control of operational flows and their processes in civil construction ensures that the cost of productivity is achieved with the minimum of available resources. Thus, the high production cost within the civil construction process is related to the waste that exists throughout the construction processes and should be understood as any inefficiency in the use of equipment, materials, labor and capital (Formoso et al., 1997; Viana et al., 2012).

Proponents of lean thinking argue that reducing and eliminating waste leads to improved conversions (Womack and Jones, 1996). Waste measurement has been widely used in the manufacturing industry to evaluate the performance of production systems, as it generally allows areas for potential improvement and the main causes of inefficiencies to be identified (Ohno, 1988; Dinis-Carvalho et al., 2015).

An analysis of areas for potential improvements and identifying the main causes of inefficiency guarantee the existence of a complete kit of activities. The complete kit concept was presented by Ronen (1992), which is the set of components, drawings, documents and information necessary to complete a specific assembly, subassembly or process, highlighting the importance of starting activities only when all the resources necessary for its execution are met.

An important increase in lean construction was the designation by Koskela (2004) of a new category of losses, losses from making-do, supported by the concept of a complete kit proposed by Ronen and added to the widely known and applied list of Ohno (1997) and Shingo (1989).

Since then, research related to ways of using the concept of loss from making-do to minimize or eliminate activities which do not add value to the process has been developed at various stages of the life cycle (from project conception to maintenance), such as in project preparation, in construction site logistics (Ghanem et al., 2018); in the supply chain and its relationships (Taggart, Koskela and Rooke, 2014); in production slack (Fireman, Saurin and Formoso, 2018); in the development or increase of methods or tools, virtual or not, to facilitate the identification of these losses (Sommer, 2010; Fireman, 2012; Leão; Formoso; Isatto, 2016); or identifying other losses in a discussion of cause and consequence in relation to the loss from making-do (Formoso et al., 2011; Fireman, Formoso and Isatto, 2013; Santos and Santos, 2017; Pérez, Costa and Gonçalves, 2016; Pérez; Costa, 2018; Amaral, 2023).

The management process is the logical sequencing of four steps: planning, organizing, directing and controlling to achieve a certain objective. In this sense, Almeida (2002) emphasizes that process management involves evaluating each phase of the process and seeking the best way to execute it with excellence. Thus, the importance of the manager and the concept of resilience is highlighted, which for Hollnagel and Woods (2005) is the ability to recognize, adapt and absorb variations, changes, disturbances, ruptures and surprises, especially those which the system was not designed for, as it is from them that the management process takes place.

In view of the above, this study proposes to investigate the development of work on the relationships between good management practices and losses from making-do within civil construction through a systematic literature review (SLR) in order to understand and contextualize the management process of civil construction and aid managers in decision-making.

Work found in the bibliometric research phase indicates that incorporating good practices can reduce losses (Grosskopf, 2013). They also confirm that activities which do not add value account for more than half of all activities in a project (Daniel et al., 2019; Nassri et al., 2023).

Good practices in the construction field can be understood as solutions used to suppress interruptions in some activity on the construction site (Mesquita, 2014), but it can also be seen as the best way identified by a professional to satisfactorily complete a task (Cleto et al., 2011); in addition, according to the perspective of Sáez et al. (2014), practices which enable better management of processes in order to favor reduced material waste. This means that good practices do not have a unanimous definition in the literature and can be applied to different knowledge areas. Herein, we highlight those good practices used on construction sites and which are based on the philosophy of lean construction, which can be called good lean practices or just lean practices (Liker; Meier, 2008).

Adopting good practices on construction sites leads to improvement in aspects which encompass this environment (Grosskopf, 2013). According to the author, there is a reduction in the executive schedule of projects, reducing delays, as well as an improvement in quality, lower costs, in addition to cooperating with the reduction of environmental impacts all being considered among the benefits caused by adopting these practices.

A SLR aims to identify a set of completed studies which address a given research question and evaluate their results to highlight conclusions on a given subject through a protocol. The SLR protocol used in this work is detailed in the materials and methods section.

Thus, the good management practices raised can be techniques, concepts, facilitating activities or good practices as long as they reduce losses from making-do, guarantee compliance with the minimum requirements of the complete kit or the resilience of the process. These good practices were arranged at each stage of the construction life cycle according to their history or potential application. The phases of the construction life cycle will be defined based on the concepts proposed by Gobin (1993).

METHOD

MATERIALS AND METHODS

A Systematic Literature Review (RSL) is a review planned to answer a specific problem using explicit and systematic methods to identify, select and evaluate studies, and then critically analyze the data present in them that relate to the research questions (Rother, 2007). The guidelines proposed by Kitchenham (2004) were used in order to define the method for preparing the systematic mapping of literature, dividing the study into three stages as described in Figure 1.

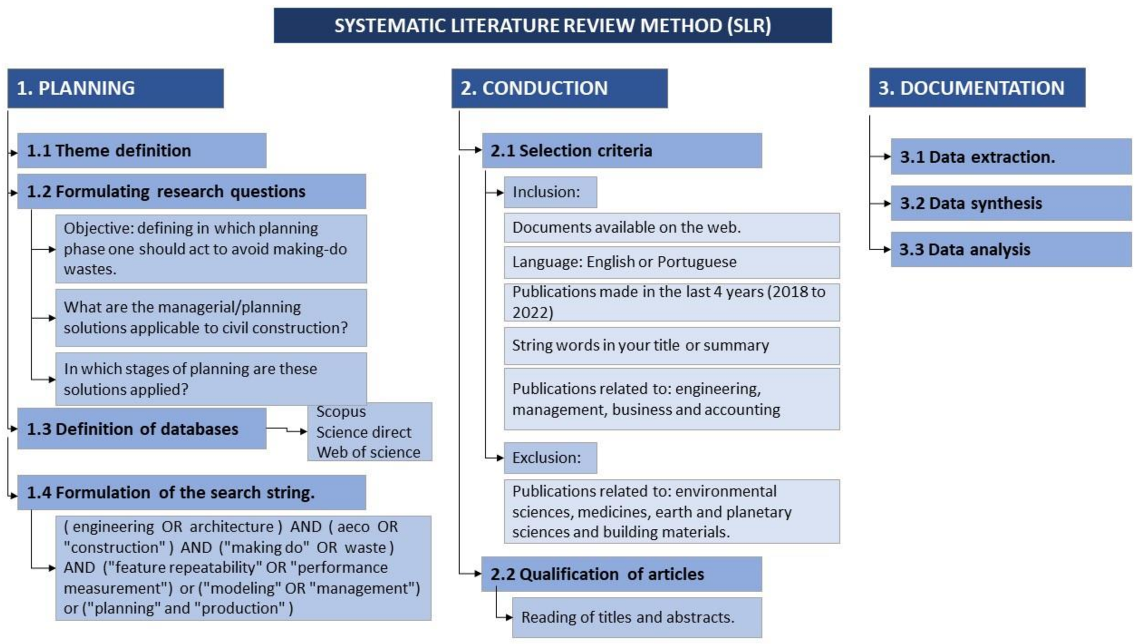

Figure 1: Systematic literature review (SLR) method (source: the authors)

RESEARCH STAGES

Planning

The possible good management practices which are used in different types of industries and can be used within the life cycle phases of the construction industry can be outlined during the planning stage. Thus, the following research questions were formulated: "What are the good management/planning practices applicable to civil construction?" and "In which planning phases are these good practices applied?"

Next, data from articles published in the following databases were collected to conduct the SLR: Scopus (access at: https://www.scopus.com/), Science Direct (access at https://www.sciencedirect.com/) and Web of Science - SciELO Citation Index (access at: https://www.webofscience.com/). The choice of these databases is justified by the greater number of articles related to the research areas of engineering and management. These databases have summaries and citations of articles covering national and international titles in the scientific and technical fields. These databases have tools which enable analyzing the impact of an article, as well as ranking of journals, author profiles, number of articles published by a journal and frequency of use of scientific terms, enabling an analysis of publication trends.

An advanced search was used on all platforms using the following string: (engineering OR architecture) AND (AECO OR "construction") AND ("making do" OR waste) AND ("feature repeatability" OR "performance measurement") or ("modeling" OR "management") or ("planning" and "production").

SLR Conduct

Figure 2 describes the methodology for selecting and extracting articles from the researched databases.

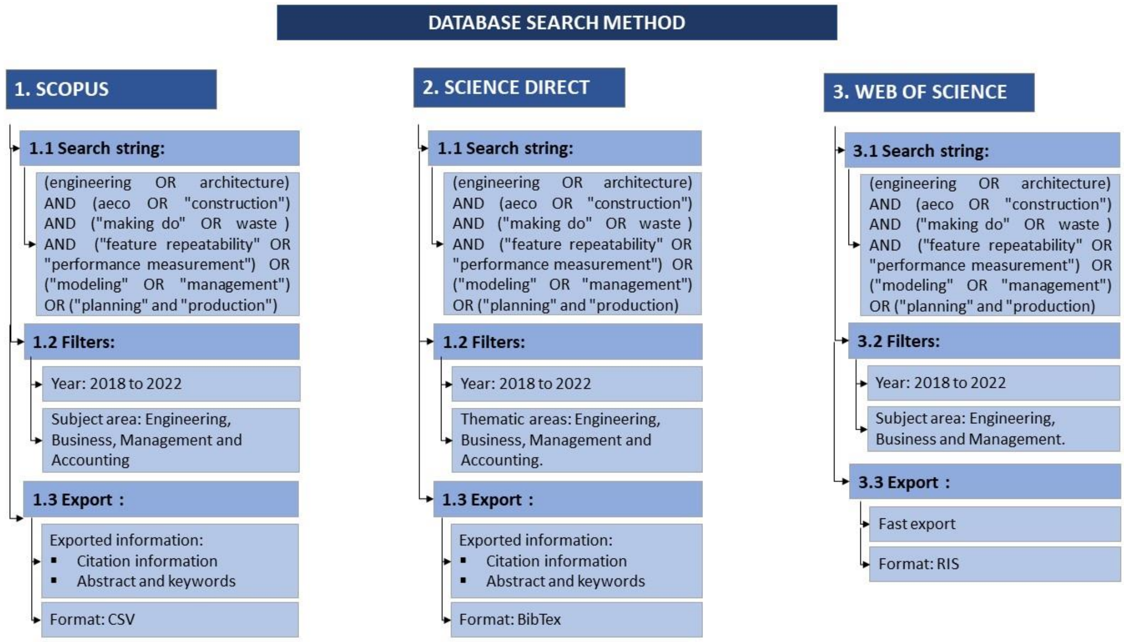

Figure 2: Database search method (source: the authors)

After data collection, all documents obtained at this stage were imported to the Rayann website (accessed at https://rayyan.ai/) and the studies were managed there. The choice of documents began following the protocol:

- Removal of duplicate files;
- Selection and exclusion based on reading the title and then the abstracts, following the following criteria.

Definition of inclusion criteria:

- Work related to: engineering, management, business and accounting.
- Documents available on the web;
- Language: English or Portuguese;
- Publications in the last 4 years (2018 to 2022);
- String words in the title or summary.

Definition of exclusion criteria:

- Work related to: environmental sciences, medicines, earth and planetary sciences and construction materials.
- Works that do not meet the inclusion criteria.

Documentation

We attempted to perform a bibliographic analysis during the documentation stage. This analysis considered the following parameters: selected articles, authors, number of annual publications, place and institution of publication and main keywords. Complementing the documentation stage, the selected articles were divided according to the application of the concepts presented and how they can be used within the phases of the construction industry's life cycle. The construction life cycle phases were divided following the three categories proposed by Gobin (1993) as detailed in image 4.

Microsoft Excel® was used to analyze the data from the selected articles, which had the function of standardizing relevant data such as title, authors, year, publication annals and references for use in the Microsoft Power BI® program.

RESULTS AND DISCUSSION

Searches in the databases according to the method represented in Figure 2 returned a total of 1,411 works, of which 36 were discarded because they were repeated in different databases. Thus, 1,375 publications were analyzed, distributed according to graph 1. The database that presented the highest number of results was Web of Science with 40.87%, followed by Scopus with 29.74% and Science Direct with 29.38% of the works.

After selection and exclusion of repeated publications, the article selection stage began. The results of this stage are presented in Table 1. After reading the title, 173 articles (12% of the total) were selected, and then the number was reduced to 114 (8% of the total) after reading the abstracts. No articles were obtained through snowball sampling. Thus, the number of articles analyzed remained at 114.

Table 1: Quantity of articles in the SLR stages (soruce: the authors)

STAGE	RESULT
Found in all databases	1411
Found in all databases (excluding repeats)	1375
Selected after reading the title	173
Selected after reading the title and abstract	114

The relationship between the total number of publications in the databases and the publications selected after reading the title and abstract following the inclusion and exclusion criteria described in the methodology are represented in Figure 3. The database that presented the largest number of selected articles was Scopus with 40.36%, followed by Web of Science with 38.60% and Science Direct with 21.04%.

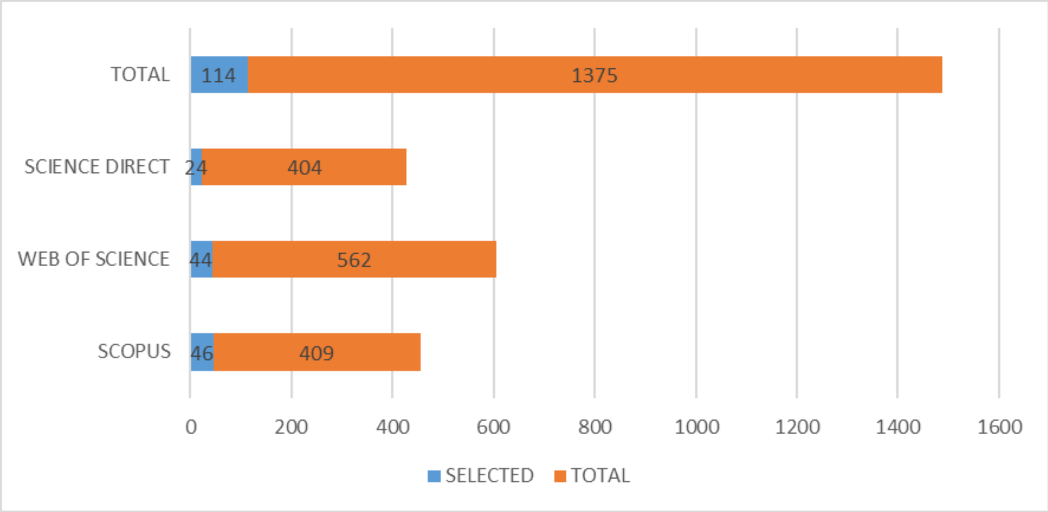

Figure 3: Number of publications selected by database (source: the authors)

Using Power BI, an interactive dashboard was created with a summary of the main results from the analyzes. These started from the analysis of the quantity of publications over the years, shown in Figure 4. The time frame determined in this work was between 2018 and 2022, with the objective of selecting the most recent publications on the proposed topic. Thus, a small variation was observed in the number of works published between the given period, highlighting the years 2020 and 2022 as those with the highest number of publications with 25 and 28 works published, respectively.

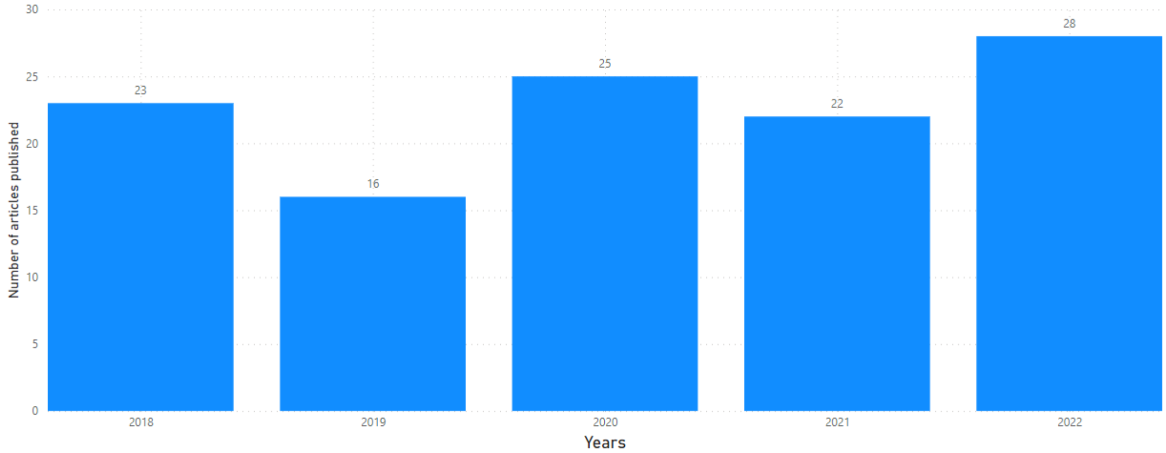

Figure 4: Number of articles published over the years. (source: the authors)

The analyzes continue with the place of publication of the articles. The number of journals which published more than one article from the selected sample was low. Those that had more than 3 publications are shown in graph 3. The Ambiente Construído Journal can be highlighted, which presented 23 publications, corresponding to 20.17% of the total sample. Table 2 describes the importance of the International Group for Lean Construction (IGLC) for the topic by relating the number of publications per journal and the number of publications at the congress in the same time frame as the study (last 4 years), applying the same inclusion and exclusion criteria as the SLR protocol.

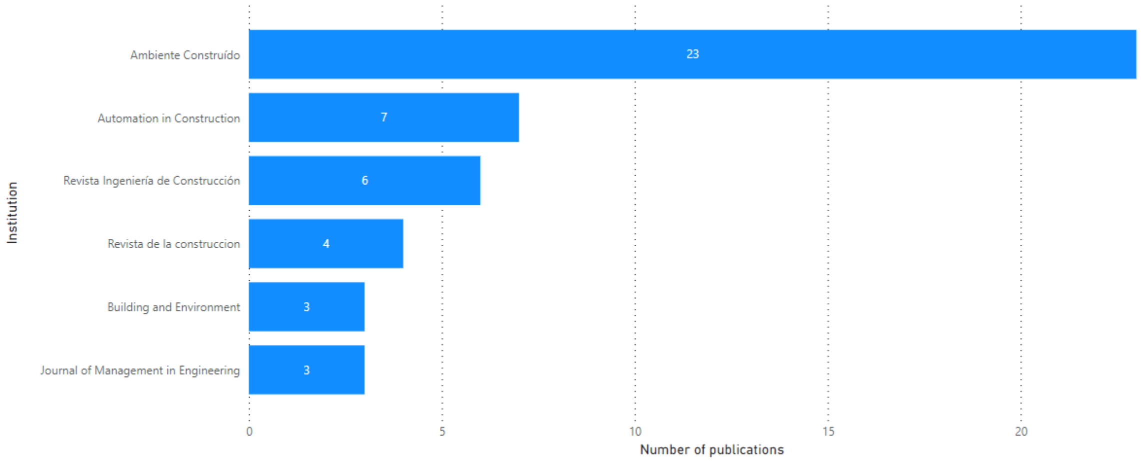

Figure 35: Number of publications by institution (source: the authors)

The recurrence of the main words which appear in the title and summary of the selected articles was analyzed, as represented in the word cloud (Figure 6). It is then possible to identify themes that, despite not being addressed in the string, are present in studies, for example: the centrality is formed by the terms "waste" and "industry", showing that a large part of the publications are related to losses in industries. Relevantly, we have the terms "construction" and "building" highlighting the study topic of this review. Another interesting fact is that even though the terms "BIM" and "Lean" are not present in the string, they were terms of great occurrence in the selected works. This presence demonstrates an integration between the subjects present in the terms of the string, mainly when relating the concepts of these terms with the terms of the string: "feature repeatability" and "performance measurement") since the concepts of the BIM and Lean methodology are directly linked to procedural methodologies with the aim of standardizing processes and increasing performance within the production chain. Thus, these terms can be considered as guiding research when questioning how losses due to making-do are related to BIM and lean methodologies, and how and what is the advantage of integrating these concepts for the decision maker within the construction site.

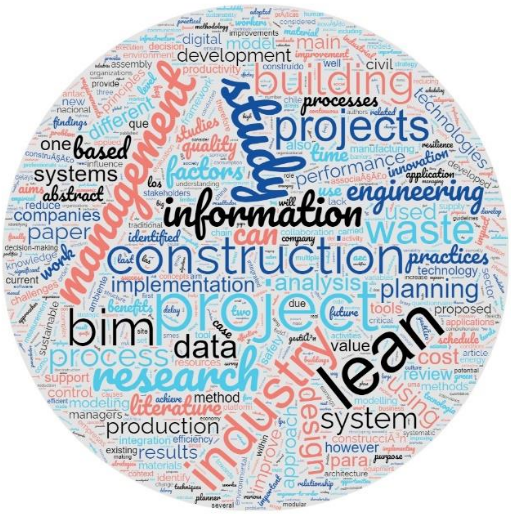

Figure 6: Word cloud. (source: the authors)

Finally, a complete reading of the articles published in 2022 was done in order to identify and understand the most current good management and planning practices and in which phases of the construction life cycle these could be applied. Figure 7 summarizes the life cycle phases of the development of traditional civil construction projects and was adapted from the illustration proposed by Gobin (1993).

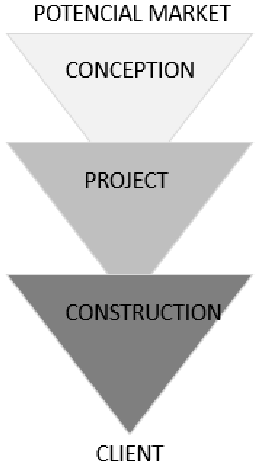

Figure 7: Phases of the traditional life cycle of civil construction projects. (source: Adapted from Gobin (1993)).

The construction life cycle phases for this analysis were divided following the three categories proposed by Gobin (1993), as detailed in Figure 8. However, the programming stage is replaced by "Conception and feasibility" in order to better characterize it. Thus, the results were divided and analyzed following the construction life cycle stages: "Conception and feasibility", "Project" and "Construction". A fourth category was created called "N.A." (not applicable) for articles which analyzed the topic in an industry other than the construction industry.

From a complete reading of the articles, it was possible to identify good management and planning practices used in different types of industries and which can be used within the phases of the construction industry's life cycle. Table 3 and Figure 8 illustrate the distribution of good practices highlighted in the articles in each phase of the construction life cycle, as well as those that were not applied in the construction industry but presented applicability and satisfactory results in other industries.

Figure 8: Distribution of articles selected in the databases in the year 2022 by the life cycle phase of construction management solutions (source: the authors)

Table 3: Distribution of good practices throughout the construction life cycle. (source: the authors)

	CONCEPTION	CONSTRUCTION	PROJECT	NA	TOTAL
BIM	1		4		5
Lean			2	3	5
Supply Chain Management	1	2			3

Standardization Of Services		1			1
TOTAL	4	8	12	12	36

Knowledge gaps related to good management practices within the context of the construction industry were identified (Table 4). These were divided and analyzed into categories, and the works that use literature review as a method were separated into the "Systematic Review" category, since they present several gaps on the topic covered.

The knowledge gaps presented in Table 4 highlight the lack of studies focused on tools which could be instrumental in planning and decision-making in civil construction. The lack of research on the topic of resilience and the industrial revolutions 4.0 and 5.0 is very evident. These themes involve tools which are dedicated to promoting collaboration between humans, resilience, social value, and customer experience, and should be considered as a suggestion for future work. These themes are related to the also absent concepts of big data, multi-criteria decision making and simulation of discrete events, since these are focused on the knowledge area which studies how to treat, analyze and obtain information from a large set of data. Data analysis is very important for defining tools that enable the civil construction industry to evolve to the level of industry 4.0 and 5.0.

Table 4: Category of knowledge gaps and their selection criteria. (Chart 1 source: the authors)

CATEGORY OF KNOWLEDGE GAPS	SELECTION CRITERIA
Industry 4.0 and 5.0	Articles that address tools dedicated to collaboration between humans, resilience and social value. Research on the concepts of industry 4.0 and 5.0 in civil construction.
Big Data	Articles covering Big Data research in construction safety, site management, heritage conservation and project waste minimization and quality improvements.
Multiobjective decision-making	Articles that address decision-making research on the post-disaster topic using hard data.
Discrete event simulation	Articles that evaluate the simultaneous integration of DES, ABM and SD modeling solutions.
Resilience	Research related to the importance of resilience in the organizational structure of companies.
Literature review	Articles which are SLR and present several knowledge gaps on the topics: Lean; BIM; Solutions related to work safety; Multiobjective decision-making; Supply chain management; Materials management; Disruptive technologies (digital).

These tools are linked to the knowledge area that deals with processing, analyzing and obtaining information from sets of presented data sets, and can be applied to BIM and Lean philosophies. These approaches not only extend the principles of lean construction, but also add assertiveness to decision making.

Despite not being explicitly mentioned in the knowledge gap categories, the concept of making-do can be considered a relevant gap. The lack of management techniques in construction can result in tasks being started or continued even in the complete absence of inputs, leading to a reduction in performance and characterizing losses due to making-do. Highlighting this gap is crucial to improving practices and efficiency in the construction sector.

CONCLUSION

From the systematic literature review it was possible to meet the proposed general objective of identifying and understanding the most current good management and planning practices and in which phases of the construction life cycle these could be applied. The search for understanding losses from making-do at construction sites led to the perception that the use of certain good practices imply actions which can be considered beneficial to the process, but that there are still no studies that correlate such good management practices to the concept of losses from making-do, since no works were returned after applying the SLR research protocol in which the term “making-do” was present in their title or abstract. Good management practices lead to the understanding that those which bring benefits to the process must be studied and their applications correlated with the occurrences of losses from making-do in the different development stages of civil construction projects, and so this question requires new research to be conducted.

The number of articles published over the years shows a growing interest in the topic of management solutions for the phases of the civil construction life cycle, reinforcing the current extremely competitive context of civil construction.

The result of distributing the solutions highlighted in the articles in each phase of the construction life cycle made it possible to evaluate in which phase action should be taken to avoid wastes due to making-do. The design phase was the one that presented the greatest number of management solutions, highlighting the importance of this stage for the positive results of construction projects. Among the solutions we can highlight for the project stage: BIM, Lean, Agile project management, Big Data, discrete event simulation and disruptive digital technologies.

However, it was possible to observe concepts that are not explored in the construction industry, such as: industry 4.0 and 5.0 concepts such as resilience and social value, multi-criteria decision making and techniques related to occupational safety, so it is not possible to prove empirically the real effectiveness of the application of these concepts within the development of construction projects.

Many articles entered the "literature review" category highlight a predominant trend of theoretical analyzes and conceptual reviews related to civil construction. In the context of the Brazilian construction industry, it is necessary to advance further with work that relates the concepts of: Lean, BIM, solutions related to workplace safety, multi-criteria decision making, supply chain management, materials management and disruptive (digital) technologies. in practice, demonstrating the effective application of concepts in the construction industry.

In the field of Lean and BIM, it is important to carry out empirical research, with Brazilian case studies, that highlight how these philosophies are implemented in real projects in Brazil, highlighting cases of success and challenges faced, providing relevant data on the effectiveness of these approaches and relating with concepts such as productivity, formal and informal service packages and the occurrence of improvisations and process resilience.

About solutions related to occupational safety, supply chain management, materials management. Collecting this data and analyzing it using methods to support multi-criteria decision-making is crucial, integrating these concepts into everyday practices within the construction site. This would contribute to the consolidation of these methodologies and good practices and would provide data that guided the manager in decision-making and continuous improvement practices.

Considering disruptive technologies, which are those that significantly revolutionize and improve tools, as well as new services and products, it is essential to study them for application within the construction site. Studies that present new technologies such as BIM, internet of things, efficient data management and augmented reality can provide interesting perspectives on the real scenario of technology application within Brazilian construction companies.

Therefore, influencing research applied to case studies is essential to fill the gap between theory and practice in civil construction, therefore, studies that relate wastes due to making-do in civil construction with the concepts of industry 4.0 can be suggested as future work. and 5.0, Big Data, multi-criteria decision-making methods, discrete event simulation and resilience.

METHODOLOGY TO AVOID THE OCCURRENCE OF MAKING-DO WASTE IN CIVIL CONSTRUCTION

Tatiana Gondim do Amaral[1], Rubia Cristina de Souza Pessoni[2],Renato Rafael Del Grosso Filho[3], Nadya Regina Galo[4], Neurielly Ribeiro da Luz[5] and Giovanna Marcelino[6]

ABSTRACT

The scenario of the Civil Construction industry is highlighted by the very high level of production waste, waste generation, and non-value-added activities. Among the array of existing waste types, one significant category is making-do waste, which gives rise to the following consequences: reduced productivity, reduced worker safety and motivation, reduced quality, and rework. The proposed model aims to contribute to efficiency and competitiveness in civil construction by filling gaps in loss management through making-do. Therefore, this study proposes a methodology based on establishing guidelines aimed at avoiding waste due to improvisation by addressing their root causes. To this end, we aimed to analyze a database containing a survey specifically focused on making-do waste at construction sites. A sample of 420 different kinds of waste was obtained, and 47 different guidelines applied to different work stages were created. The guideline with the highest number of occurrences was "Perform verification and inspection from the FVS before, during and after the execution of the service," while the most substantial number of propositions referred to waste whose missing prerequisites were "Information" and "Labor." When applied to the proposed methodology, these guidelines can become a strategic tool combined with production management that is aimed at minimizing waste.

KEYWORDS

Making-do waste; Guidelines; Production management; Civil Construction.

INTRODUCTION

The construction industry has always faced problems regarding deadlines, cost overruns, and waste generation, imposing negative impacts on the environment and excessive consumption of resources (Hussin et al., 2013). In general, it is assumed that there is a very high level of

waste/non-value-added activities in construction. Moreover, several studies have confirmed that waste in the construction industry represents a relatively large percentage of the production cost (Aziz; Hafez, 2013).

However, waste in civil construction extends beyond the waste generated and can be understood as any inefficiency reflected in the use of materials, labor, and equipment in quantities surpassing what is necessary for building production (Santos et al., 1996).

A possible application to improve performance in construction processes while minimizing costs is applying the lean production system (Yücenur; Kaan, 2021). The principles of the Toyota Production System, developed by Ohno (1988), can be considered a major precursor of Lean Manufacturing. Koskela (1992) proposed the application of a new philosophy called Lean Construction in the construction sector.

The philosophy of Lean Construction proposes reducing waste and improvisations in production in search of a product of higher quality and lower cost (Santos; Santos, 2017). As a result, lean construction incorporates many dimensions and techniques that have become synonymous with lean production, such as just-in-time delivery, value stream mapping, and continuous process improvement (Small; Al Hamouri; Al Hamouri, 2017).

Ohno (1988) further expanded this work by identifying and categorizing the types of waste in production, divided into the following categories: waste of overproduction, waste of time on hand (waiting), waste in transportation, waste of processing itself, waste of stock on hand (inventory), waste of movement and waste of making defective products. In the context of civil construction, Koskela (2004) presents a new type of waste called making-do.

The term making-do is defined as the act of starting a task without ensuring that all necessary inputs (materials, tools, machines, people, external conditions, and information) are accessible or when the task continues to be executed despite one of the inputs being missing causing improvisations to occur in the execution of the service (Koskela, 2004).

According to Koskela (2004), among the consequences of making-do waste, the main highlights are reduced productivity, reduced worker safety and motivation, reduced quality, and rework. The investigation of different types of waste and their impact on the cycle time of construction processes has also been studied by other authors, for example, Sommer (2010) and Fireman (2012).

Despite lean philosophies being an emerging phenomenon in manufacturing and construction project management, the construction industry still needs to work on utilizing its full benefits, whether due to a lack of awareness or lack of application of clear strategies (Aslam et al., 2020). Measures to prevent or mitigate making-do waste processes have not yet been identified in the literature.

Previous works by Braga (2018) and Maciel (2020) addressed the identification and analysis of making-do waste. Amaral (2019, 2021, 2022) carried out studies on making-do waste together with a research group; in 2022, the author conducted research on a significant waste database to analyze the relationship between prerequisites, categories, and impacts.

Amaral et al. (2023) pointed out that only surveying losses due to making-do does not provide enough information for managers to completely prevent these losses from occurring in their next undertaking or task. According to the authors, a mere evaluation of impacts caused by 'making-do' waste is insufficient for a manager to prevent such issues in future ventures or tasks. However, it enables a more comprehensive and interactive information analysis to mitigate these different types of waste. The conclusion is that instead of directing efforts towards rectifying all incidents identified onsite, managers could optimize resources by focusing on stages, teams, and processes with the most significant impact, cost, or project delays. These efforts should include workforce retraining, investing in design and selecting materials and components to align with project specifications, adopting medium-planning methods to eliminate constraints, and ensuring continuous flow between interdependent tasks. Furthermore, it is crucial to evaluate risks related to the consequences of rework, which are directly associated with reduced productivity, material waste, unfinished work, and a decline in quality.

By continuing this area of research, the present work aims to fill a significant gap: namely, establishing guidelines to avoid the occurrence of making-do waste associated with a methodology for its application, that is, to define direct strategies to prevent the occurrence of making-do in the Civil Construction cycle. Such a strategy can help decision-making and assist in the production process at construction sites.

METHOD

This research was classified according to its approach, nature, objectives, and procedures.

Regarding the approach, the research is classified as qualitative, as the data will be analyzed and processed initially in a standardized spreadsheet, and subsequently, classifications and guidelines will be suggested.

Regarding the nature of the work, the research is applied because it is aimed at applicability in the construction industry, suggesting improvements in the analysis processes and waste reduction in construction sites.

Regarding the objectives and procedures, the research is classified as exploratory, as it aims to address the phenomenon under study and provide data and analysis to expand on previous and subsequent research.

The data was extracted by a research group comprising experts in production management, working in the construction market as Civil and Production Engineers responsible for on site decisions, as well as master's students from the Production Engineering Postgraduate Program at the Faculty of Science and Technology, and undergraduate students in Civil Engineering from the School of Civil and Environmental Engineering.

RESEARCH DESIGN

The study methodology for developing the work was designed in 5 stages presented in the flowchart in Figure 1.

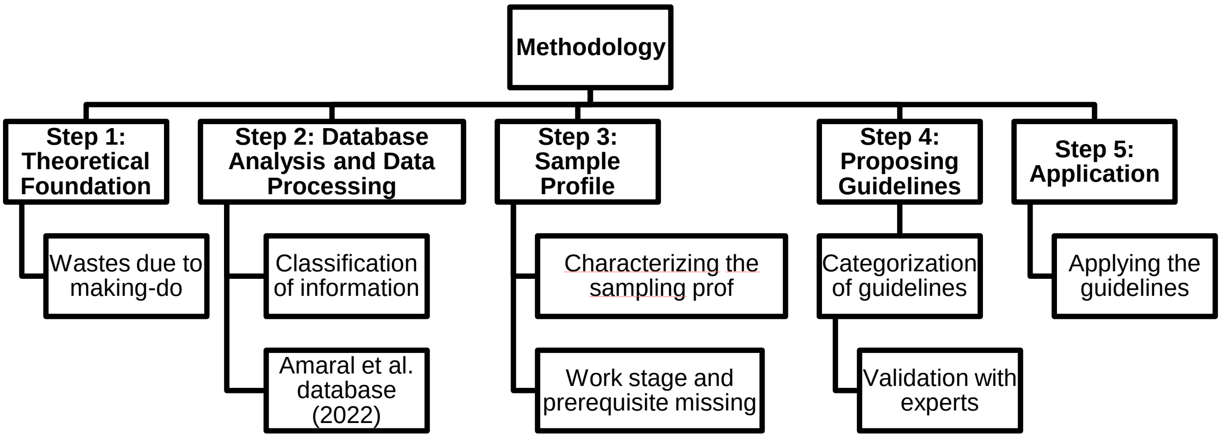

Figure 1: Research execution stages (Figure 1 source: the authors)

In Stage 1, the theoretical basis of the work was addressed, starting by studying the classification of different types of waste in the construction industry, their definitions due to making-do, and the reading of works developed to propose guidelines to minimize waste.

In Stage 2, we sought to process the database to identify the different kinds of making-do waste in 27 projects. The information refers to the database analyzed by Amaral (2022) and the survey carried out by the same research group in 2022.

The different types of waste identified in the projects by the research group encompass several processes, teams, and stages, which involved some research instruments such as questionnaires to characterize the companies, construction sites, and projects; questionnaires to investigate the planning process, semi-structured interviews carried out with production managers, members, directors; as well as document analysis (photos, drawings, drafts, notes, and documents) and web and mobile inspection tools (Amaral et al., 2019, 2022, 2023).

The study database surveyed 7,448 different types of making-do waste, already classified according to the work team involved, prerequisite, category, and impact, in addition to the problem description. To process the information, data lacking clear and complete descriptions of the loss were discarded. This was essential to ensure that the proposed guidelines could effectively manage the causes and impacts generated.

By considering the stage, sub-stage, and category associated with the loss, we were able to identify recurring instances of the same problems in the different studies. Thus, this approach allowed us to focus on analyzing the activities and identifying the missing prerequisites for the loss. As a result, we compiled a sample of 420 instances of waste, each occurring under different stages, sub-stages, and prerequisite conditions, drawn from 19 projects involving 15 companies.

Table 1 presents the characterization of the participating companies, designated by letters “A” to “O.” Information about companies and works from “A” to “K” refers to the database analyzed by Amaral (2022), while the other companies are part of the survey carried out by the research group in 2022.

Table 1: Characterization of companies (Table 1 source: the authors)

Company	City	Time in the market	Certifications	Company size
A	Goiânia -GO	15 years	-	Midsize
B	Goiânia -GO	40 years	PBQPH-level A	Large
W	Goiânia -GO	29 years old	ISO 9001:2015	Large
D	Goiânia -GO	24 years	ISO 9001:2008 and PBQPH- level A	Large
AND	Fortaleza-CE	39 years old	ISO 9001:2015 and PBQPH- level A	Large
F	Fortaleza-CE	40 years	-	Large
G	Goiânia -GO	24 years	ISO 9001:2008, ISO 14001:2004, OHSAS 18001:2007 and PBQPH- level A	Large
H	Goiânia -GO	22 years	ISO 9001:2008 and PBQPH- level A	Large
I	Goiânia -GO	35 years	ISO 9001:2015	Large
J	Tournefeuille - France	20 years	French Standardization Association AFNOR ABNT ISO 9001: 2015 and AFNOR ISO:14001	Midsize
K	Goiânia -GO	19 years old	PBQPH- level A	Large
L	Fortaleza-CE	14 years	-	Large
M	Fortaleza-CE	54 years	-	Large
N	Fortaleza-CE	15 years	PBQPH- level A	Large
O	Fortaleza-CE	-	-	Large

In Stage 3, the sample profile was characterized, observing the construction stage and the missing prerequisite of loss due to making-do. To help identify guidelines at different stages of the development of the work, Table 2 lists the steps considered in the database used with their sub-steps to better understand the scope of each activity analyzed.

Table 2: Steps listed in the database used and their respective sub-steps (source: the authors)

STAGE	SUB-STEPa
Coverings and Linings	Plasterboard Linings and Wooden Structure for Covering.
Hardware and Glass Frames	Smooth Transparent Glass, Wooden Frames, and others.
Structure	Superstructure, Infrastructure, and complementary works.
Facade	Facade Plastering, Ceramic Facade Coating, Facade Plastering, Facade Scaffolding, and Suspended Life-Saving Trays.
Waterproofing and Treatments	Kitchen waterproofing Drain waterproofing.
Infrastructure and Complementary Works	Reinforcements and Consolidations of Foundations, Deep Foundations, and Preparation of Foundations
Fire Fighting Installations	Fire extinguishers.
Installations and appliances	Electrical installations, Additional installations, Appliances and metals, Records, Countertops.
Electrical Installations	Boxes and Control Panels Wires and Cables Conduits Sockets and Switches Piping.
Sanitary, Hydraulic and Gas Installations	Sanitary Sewer Pipes and Connections, Cold Water Pipes and Connections, Piping
Temporary Installations and Machinery	Life Trays, Elevator with Tower/Cabin/Winch, Lifeline, Guardrails Deposits/Office, Temporary Water Installation Facade and Suspended Scaffolding, Work Location, Temporary Power Entry, Rack.
Cleaning and Transport	Permanent Cleaning and Cleaning of the Work.
Carpentry and locksmithing	Closing of Shafts, Fire Doors, Forms, Hood.
Other Facilities	Air Conditioning Installation, Elevator Installation, and Others.
Walls and panels	Masonry and panels, Frames and hardware Block Masonry, Solid Bricks, Plaster Plaster, Mortar Coatings, Contramarco, Internal Plaster Partition, Cobogó.
Skirting and Sill Flooring	Steps and Landings Straightened Concrete Subfloor Ceramic Skirting, Carpets and Rugs Ceramic Coverings/Tile Sills.
Coatings and finishes	Joinery and metalwork, Flooring, Coatings, Linings, and decorative elements.
Coatings and Paintings	Mortar Coatings, Ceramic/Tile Coatings, PVA Painting and Grouting.
Initial Services	Technical services, Machines, and tools.
Preliminary Services	Demolitions Licenses/Fees/Registrations.
Technical services	Architectural Project, Hydrosanitary Project, Structural Project, Electrical/Telephone Project.
Superstructure	Reinforced Concrete and Forms.
Land work	Manual Excavations.

In Stage 4, the guidelines were proposed, in which we sought to consolidate all the results found and define the guidelines. These classifications will support systematic analyses of the guidelines to minimize the causes of wastes.

The guidelines underwent a validation process involving a production management specialist, who addressed queries and suggested improvements. Once the adjustments had been made, the guidelines were taken to a second validation stage, in which the research group was responsible for collecting and organizing the losses that comprise the database used. Four group members took part in a formal validation meeting and suggested adjustments and improvements, which were accepted and, finally, the guidelines were validated. Table 3 below shows the guidelines drawn up for each project stage.

Stage 5 involves applying the guidelines proposed in the construction industry cycle based on a workflow suggestion applied to production management on the construction site

Table 3: Table with examples of guidelines drawn up for each stage of work (source: the authors)

PHASES	SOME SUGGESTED GUIDELINES
Walls and Panels	Training of labor on square, plumb and levels and trims, their checks, tolerances, and limits
Structure	Provide feedback on decision-making regarding the execution of the work. This information must be passed on to the responsible designers and registered as As Built.
Installations and appliances	Carry out training with employees on the use of materials within the quality standards of the service execution procedure, as well as verification by a responsible professional during the execution of the activity.
Coatings and finishes	Perform effective protection of definitive items and finished services
Temporary installations and machinery	The equipment maintenance plan, a daily safety checklist, and operation criteria must be implemented.
Coatings and Paintings	Application of FVM by sampling in all deliveries;
Superstructure	Make sure to carry out not the minimum number but the necessary number of geotechnical tests to obtain the best possible knowledge of the soil.
Flooring, Skirting, and Sills	Monitor FVS, concreting maps, and technological control tests
Electrical installations	Implementation of EPCs and PPE
Initial Services	Create a checklist or use software to list all the official documents required for the work and relate them to their expiration date, renewal period, and revisions.
Facade	Material request planning
Complementation of the Work	Inspect the workplace to allow activities to begin when the impacts of the activity on the work area must be assessed.
Infrastructure and Complementary Works	Carry out verification and inspection from FVS before, during, and after performing the service.
Hydraulic, Sanitary, and Gas Installations	Predict the positioning of all pipes before concreting components

Table 3 (continued): Table with examples of guidelines drawn up for each stage of work (source: the authors)

PHASES	SOME SUGGESTED GUIDELINES
Technical services	Carry out alternative planning for critical cases in which the execution of services is prevented due to unforeseen conditions, listing alternative companies and machinery that could meet the new needs of the work.
Device Installation	Plan an executive service procedure that optimizes the tasks and executive sequence requested in the project.
Cleaning and Transport	Conduct training with employees and implement procedures for ending work, cleaning, and organizing the workplace.
Carpentry and locksmithing	Develop procedures for operating equipment and verify project information and guidelines in accordance with NR18.
Other Facilities	Make sure there is compatibility and clash detection of all subjects
Preliminary Services	Carry out periodic training of the workforce (monthly or bimonthly) according to the greatest needs and execution flaws, promoting qualification and also generating social value for the enterprises.
Frames, Hardware, and Glass	Make sure that the most updated and corrected version of the project is on-site and that it has all the information necessary to carry out the service, site on-site, and that it has all the information necessary to carry out the service before releasing the start of its execution.
Coverings and Linings	Carry out training with employees on the use of materials within the quality standards of the service execution procedure, as well as verification by a responsible professional during the execution of the activity.
Waterproofing and Treatments	Carry out verification and inspection from FVS before, during, and after performing the service.
Fire Fighting Installations	Carry out an inspection before starting activities, check the comfort and safety of the workplace, as well as training to issue the work permit.
Land works	Make sure that the most updated and corrected version of the project is on-site, and that it has all the information necessary to carry out the service before releasing the start of its execution.
Technical services	Carry out alternative planning for critical cases in which the execution of services is prevented due to unforeseen conditions, listing alternative companies and machinery that could meet the new needs of the work.
Device Installation	Plan executive service procedure that optimizes the tasks and executive sequence requested in the project.
Cleaning and Transport	Conduct training with employees and implement procedures for ending work, cleaning, and organizing the workplace.

RESULTS AND DISCUSSIONS

Based on the analysis of 420 different types of making-do waste, it became feasible to verify the work stages with the highest occurrences. Figure 2 shows the steps and number of different types of waste identified.

Based on the approach proposed in characterizing the sampling profile, the missing prerequisite responsible for the occurrence of each loss was verified. Figure 3 presents the prerequisites of the data studied for proposing the guidelines.

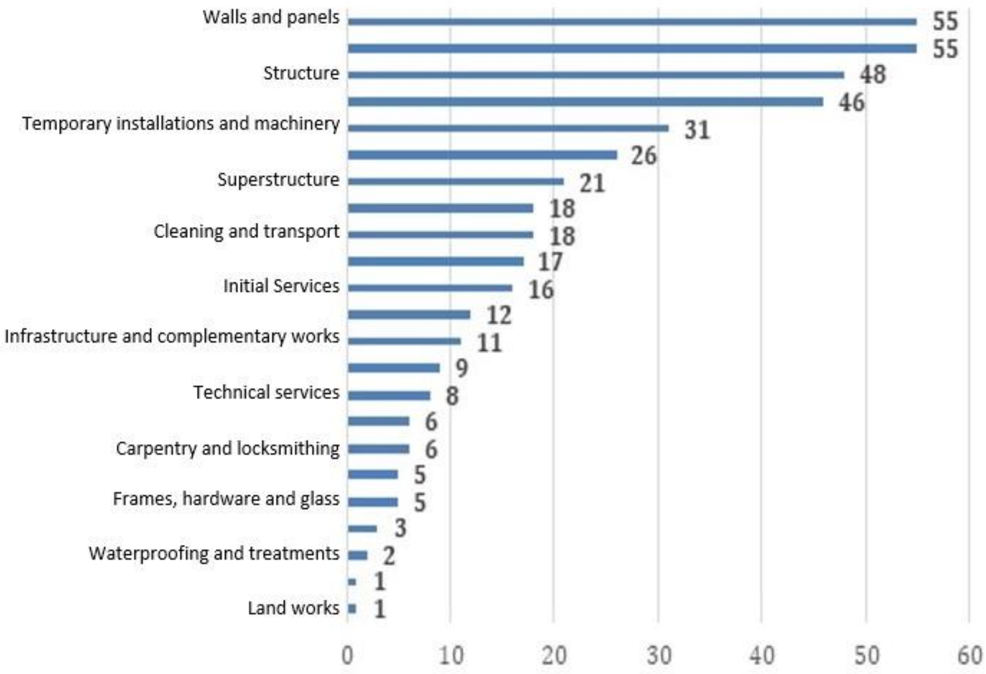

Figure 2: Different types of making-do waste analyzed by the activity stage (Figure 2 source: the authors)

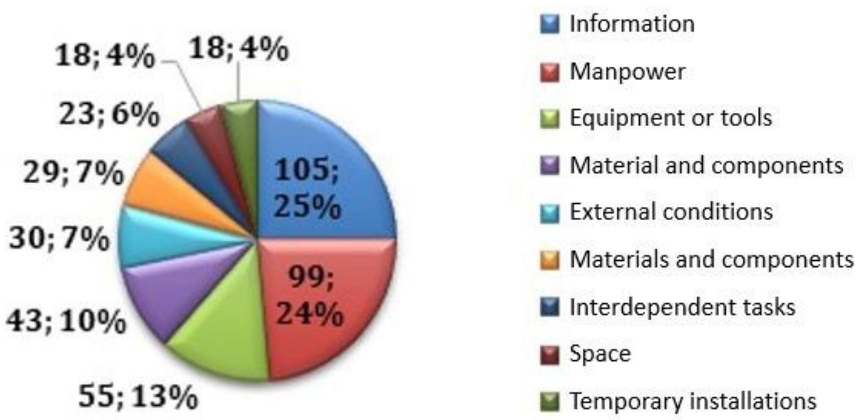

Figure 3: Occurrence of missing prerequisites for different kinds of making-do waste (Figure 3 source: the authors)

In the proposing guidelines stage, the aim was to evaluate all the information provided on the loss occurrence and consolidate all the results found to define the guidelines. These classifications supported the systematic analysis of the guidelines to act on the causes of the loss occurrences. After they were drawn up, the guidelines went through a validation process with a specialist in production management, who suggested improvements and clarified doubts by consulting the guidelines. Once the adjustments suggested by the specialist had been made, the guidelines were taken to a second validation stage, this time with the research group responsible for collecting and classifying the losses that make up the database used in this work. Four group members took part in a focal meeting for discussions and validation and suggested adjustments and improvements, which were carried out, and finally, the guidelines were validated. Thus, one or more guidelines capable of preventing the loss from occurring were proposed. In total, 47 guidelines were created, applied to 420 different types of waste, resulting in 916 propositions in the database. Table 4 presents five guidelines with the highest number of occurrences.

Table 4: Guidelines with the highest number of occurrences in the different types of waste analyzed (Table 4 source: the authors)

PROPOSED GUIDELINE	NUMBER OF OCCURRENCES	PERCENTAGE OF APPLICATIONS AMONG THE PROPOSITIONS
Carry out verification and inspection from FVS before, during, and after performing the service.	203	22.16%
Carry out periodic training of the workforce (monthly or bimonthly) according to the greatest needs and execution flaws, promoting qualification and generating social value for the enterprises.	124	13.54%
Make sure that the most updated and corrected version of the project is on-site, and that it has all the information necessary to carry out the service before starting its execution.	82	8.95%
Perform adequate protection of definitive items and finished services.	44	4.80%

It was observed that the same guideline could be applied to different stages of work to avoid a given loss due to making-do. Given the stages of work with the most significant occurrence of waste, Annex 1 shows an example of a guideline ready for each stage.

As a suggestion to implement the proposed guidelines, Figure 4 presents the application of the developed guidelines in the form of a workflow, that is, a flow of actions that will allow the use of these guidelines. This methodology involves its application from professionals on the service fronts to the management team, which can, in addition to constituting a mechanism for "attacking" the causes of making-do, contribute to forming a preventive and rationalized mentality that will permeate all hierarchical levels of companies.

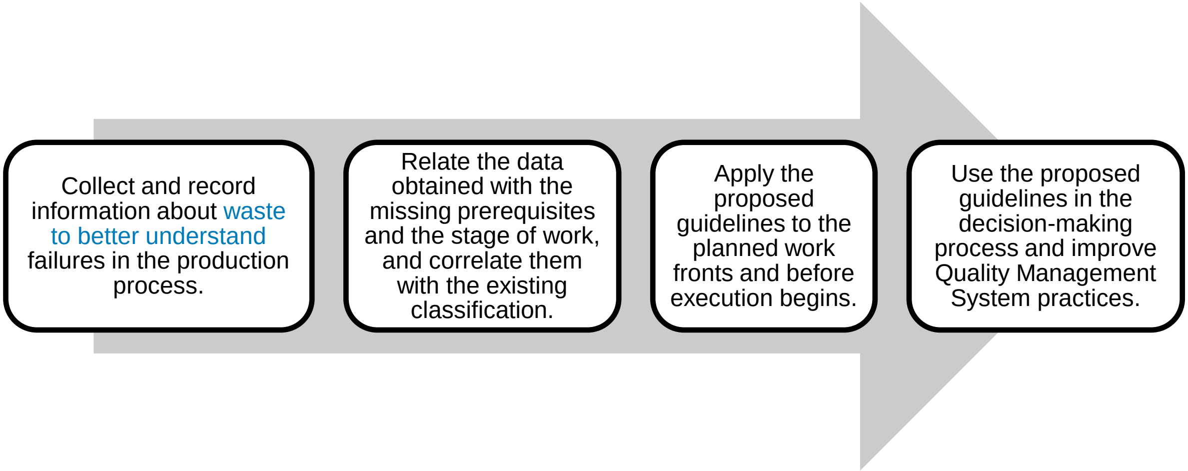

Figure 4: Workflow with a proposed methodology for applying the guidelines developed in this work (Figure 4 source: the authors)

The first step in implementing the proposed methodology involves collecting and recording detailed information about the waste identified during production. This data is essential for an in-depth understanding of the faults that can occur in the process itself. Next, it is necessary to relate the data obtained from the missing prerequisites and identify the specific stage of the construction where these occurred, correlating this information with the existing classification of the identified problems. Next, the obtained data needs to be correlated from the missing prerequisites and the specific stage of the work in which they occurred should be identified. This information is then correlated with the existing classification of the identified problems.

Once the data and correlations have been established, the proposed guidelines must be applied proactively on the planned work fronts before execution begins. This ensures that the recommendations are integrated into the process from the outset, facilitating identifying and preventing potential problems. In addition, the guidelines should be used as part of the decision-making process to improve Quality Management System practices.

CONCLUSION

The present work proposed to outline a methodology capable of preventing the occurrence of making-do waste . Based on data collected at various construction sites, guidelines were drawn up that, when applied, can become a strategic tool combined with production management increasingly free from waste and waste.

Guidelines were developed for 420 types of waste that occurred at the most diverse stages of the work and classified with the most varied missing prerequisites, categories, and impacts. As can be seen in Figure 3, 105 (25%) of the different types of waste with developed guidelines refer to those whose missing prerequisite was Information. The interpretation of this data shows the importance of not only the management team and the construction team having access to all necessary information to carry out each task. This access helps avoid rework, productivity reduction, incomplete tasks, as well as demotivation and other negative impacts (Sommer, 2010; Fireman, 2012).

The guideline with the highest number of occurrences was “Perform verification and inspection from the FVS before, during and after the execution of the service”. This shows the scope that this action can have as the existence of a Management System Effective Quality Management, which includes the assertive application of Service Verification Sheets, permeates all stages of the work, and can eliminate a large amount of waste.

It can also be seen from Figure 2 that 55 (13%) of the types of waste for which guidelines were developed refer to waste that occurred in the Walls and Panels stage, which also highlights the importance of evaluating and applying guidelines in this stage of work. This can contribute to the reduction of inefficiencies or waste during this stage.

Finally, we proposed a methodology tailored to the everyday operations of Civil Construction, drawing from the established guidelines, which were initially validated by a specialist and subsequently by members of the research group responsible for compiling the database used in the present work. This proposed methodology is based on four steps: collecting and recording information about waste during the production process to better understand the failures; then relating this data to missing prerequisites and identifying the stage of the work where they occurred, correlating with the classification of problems; then applying the proposed guidelines before carrying out the work to prevent any type of waste. Finally, the guidelines should be used in the decision-making process to minimize the occurrence of production losses. All this sequencing should be used in the documentary systems of the Quality Management System.

However, it is essential to stress that the management team must also comprehensively analyze the limitations and advantages of the proposed guidelines within their company, recognizing the variation in levels of education, standardized practices and executive processes applied to the context involved. It is also crucial for managers to ensure that the guidelines' viability and effectiveness can be questioned in environments where building systems and procedures differ significantly. For example, adopting certain practices may face obstacles in places where the workforce is less specialized or where procedures are less comprehensive. Therefore, the management team must assess the need to adapt their proposals to local conditions and carefully consider the various factors that influence success.

THE INFLUENCE OF PRECONSTRUCTION PHASE AND LEAN CONSTRUCTION IMPLEMENTATION ON PROJECT PERFORMANCE

Munther Hamaidi [1], Nour Ghandour [2], Mohammad Abdel Hadi [3] and Ayman Naser[4]

ABSTRACT

Effective design management during the preconstruction phase has significant effects on project performance within the Architecture, Engineering, and Construction (AEC) sector. This research examines critical factors that impact the design outcomes at the preconstruction phase in the construction of infrastructure projects which affect the overall project performance. Using a sequential hybrid research approach that combines qualitative interviews and quantitative surveys, this study identifies ten crucial factors that influence project performance during the preconstruction phase. The relative importance index (RII) method is used to prioritise these factors, emphasising the most influential areas for enhancement. This study investigates the use of lean construction (LC) principles and tools to minimize the impact of these factors. These tools include integrated project delivery (IPD), building information modelling (BIM), last planner system (LPS), value stream mapping (VSM), target value design (TVD), set-based design (SBD), and choosing by advantage (CBA). Authors propose a comprehensive Lean Construction-based Risk Mitigation (LC-RM) framework to integrate these methodologies and enhance the design process during the preconstruction phase, thereby improving overall project performance. This research makes a valuable contribution to the field of construction management by providing practical recommendations for effective decision-making and lean practices during the preconstruction phase. It serves as a preliminary step towards improving construction management processes and has the potential to be further explored in future studies.

Lean construction, Design management, Preconstruction, Risk mitigation, Critical factors, Infrastructure construction project

INTRODUCTION

Poor design management (DM) in construction projects can have significant negative impacts on various aspects of the project, including cost, schedule, quality, and overall project success (Pikas et al., 2019). The most effective and efficient method for managing the design during the preconstruction phase is still unclear (Niranjan et al., 2022). The architecture, engineering, and construction (AEC) industry is well-known for its dynamic and unpredictable nature, which presents challenges in achieving effectiveness. Effectiveness, as conceptualised by scholars,

pertains to the efficient allocation of resources necessary for the successful execution of a given task (Gholinezhad Dazmiri & Hamzeh, 2023). According to Koskela (2000), the main objective of improving productivity within the context of LC is to reduce waste and enhance value. The AEC sector generates a substantial quantity of waste. In recent years, the organisation has been utilising lean tools such as the LPS in order to reduce waste (Skaar et al., 2023). Within the framework of lean principles, waste is operationally defined as the suboptimal utilisation of machinery, supplies, personnel, or other valuable resources, leading to the inappropriate allocation of time, financial resources, or other valuable assets (Skaar et al., 2023). As per Koskela (2000), it denotes any task or asset that does not add value to the final product. According to Aslam et al. (2020a), waste in design can be defined as any activity that results in the depletion of resources without providing any value. Time measurement is a crucial metric for assessing waste, particularly when determining the proportion of tasks that do not add value. According to Aslam et al. (2020b), waste during the design phase can arise due to various factors such as delays, waiting times, design flaws, excessive processing, and negative iteration or rework. The presence of these waste materials can significantly affect construction projects, as design errors are the primary factor contributing to the decrease in both cost and value (Tzortzopoulos et al., 2020). Tzortzopoulos et al. (2020) posit that the incorporation of rework and non-value-adding activities within the design process has the potential to prolong the duration of the design phase and give rise to delays. The delays mentioned above can be attributed to various factors, such as the delayed acquisition of design information, frequent modifications to the design, alterations in the timing and order of the implementation, fluctuations in demand, and insufficient design efforts (Naji et al., 2022a; Salam et al., 2023). As a result, it is critical to engage in thorough design management (DM) planning during the preconstruction stage of the infrastructure project in order to ensure its long-term success. This is because DM planning has a significant influence on multiple factors, including client satisfaction and operational and maintenance expenses (Chaize et al., 2022). Hasty designs, design processes, and DM practices are the root causes of many persistent production and construction challenges (Naji et al., 2022b&c). Naji et al. (2022b) identified design errors as the primary cause of structural failures, time and cost overruns, and catastrophic accidents in building construction and maintenance. Inadequate designs may give rise to the need for rework, change orders, and preliminary estimates, thereby potentially resulting in excessive expenditure or project delays. The AEC sector widely acknowledges the aforementioned concerns as prominent contributors to waste (Naji et al., 2022a, b, c)

Previous studies seek to improve the design process during the preconstruction phase in the AEC industry, with particular emphasis on integrating design with advanced technology like BIM to enhance efficiency (Gholinezhad Dazmiri & Hamzeh, 2023; Gunduz et al., 2023), focusing on developing a framework to facilitate early supplier involvement as an approach for reducing construction waste generated during the design process (Othman & El-Saeidy, 2024), investigating only the activities related to early contractor involvement (Memić et al., 2023), targeting preconstruction phase management practices (PCMPs) that can improve labor productivity in multistory building projects (Tarekegn Gurmu, 2023), focusing on the financial aspect of collaboration but undervalued the social dimension which reflects behavioral actions that can lead to goal misalignment (Salam et al., 2023), supporting a visual model with design parameters that are specific to manufacturing to reduce waste in the design stage of a construction project (Cardenas Castaneda et al., 2022), focusing on collaborative decision-making process in the design phase (Schöttle et al., 2018), and developing an initial framing for design process support systems to facilitate the error and knowledge management (Pikas et al., 2019).

According to Lin and Golparvar-Fard (2021), lean is a management methodology that adopts a proactive approach to planning. This approach entails the early identification of constraints to prevent their occurrence during the execution phase. The transformation of the aforementioned limitations into potential risks and inefficiencies significantly impacts the entire lifespan of the construction project (Bajjou & Chafi, 2020). Therefore, various scholarly sources in the field of construction management (Naji et al., 2022b&c) provide a comprehensive analysis of the quantification of performance factors in project management. Construction companies are prioritizing efficient DM and implementing more stringent strategies to evaluate it in order to create preventive measures and improve performance during the preconstruction phase (Naji et al., 2022a). The prompt identification of outcome measures and risk factors linked to DM can aid in mitigating these effects and diminishing the probability of a construction project encountering cost and schedule repercussions.

KNOWLEDGE GAP AND POINT OF DEPARTURE

The literature review reveals that inadequate design management during the preconstruction phase has a significant impact on the overall performance of a project. The authors contend that the current frameworks pertaining to enhancing DM during the preconstruction phase of infrastructure exhibit various limitations. Furthermore, the main reason for these limitations is the absence of a comprehensive lean construction-based risk mitigation framework (LC-RM) that encompasses the global perspective of design management activities during the preconstruction phase (Naji et al., 2022b) (Salam et al., 2023). This framework should encompass the most effective practices, factors contributing to success, and operational procedures that can be implemented in infrastructure projects. Therefore, the primary objective of this study is to investigate the monitoring of performance factors related to design management in order to mitigate the impact of design management during the preconstruction phase and enhance the overall performance of infrastructure projects. Additionally, it aims to explore the potential applications of the study's findings for construction management practitioners, with the goal of proactively addressing and minimising adverse design modifications during the preconstruction phase of infrastructure projects. Hence, the primary aims of this research endeavour encompass the identification of pivotal factors that contribute to suboptimal design outcomes, the evaluation of their significance in impacting project performance, and the proposition of a LC-RM framework to address the existing research gap.

METHODOLOGY

The chosen research methodology is derived from the sequential hybrid approach proposed by Naji et al. (2022c), which involves the collection, interpretation, and modelling of both qualitative and quantitative data. Figure 1 visually represents this approach. The research methodology consists of four phases, namely: (1) identification of the critical factors resulting in poor design outcomes; (2) questionnaire and data collection; (3) data analysis and discussion; and (4) conclusion. Phase one deals with identifying the key factors that contribute to subpar project performance and are associated with unsatisfactory design outcomes; a set of semi-structured interviews with eight construction experts as a pilot-based study (Naji et al., 2022b) to validate the identified factors; and the development of the initial questionnaire of the study. Literature research was undertaken to discover the critical factors, which consisted of three phases: journal selection, article selection, and paper analysis. Using databases such as Scopus, The International Group for Lean Construction (IGLC), the American Society of Civil Engineers (ASCE), Taylor & Francis Online, the International Journal of Project Management (IJPM), IEEE Xplore library, Elsevier, and Emerald, the first stage involved a thorough selection of highly ranked publications in construction engineering and management research.

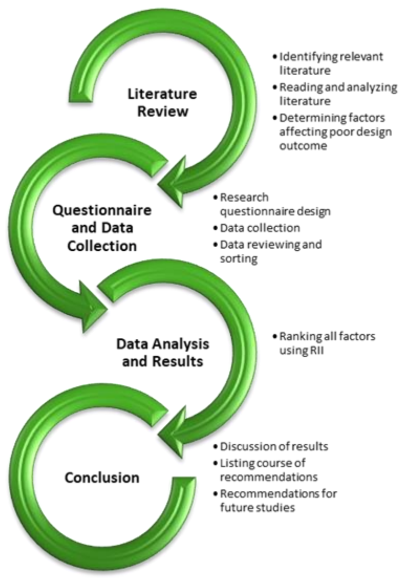

Figure 1: Research Methodology Stages

The second stage involved identifying relevant papers published between 2014 and 2024, based on their titles, abstracts, and keywords. “lean construction”, “design phase”, “infrastructure project”, “lean in design stage”, “successful factors in design stage,” and “design management” were among the terms used in the study. Papers were chosen based on the following criteria: (1) the paper should be specifically related to DM with the goal of mitigating the impact of poor DM; (2) the paper should discuss techniques and tools for controlling and managing DM with an emphasis on application in the field of construction management; and (3) the paper should use a unique assessment technique. Consequently, the review has identified 10 key factors that significantly contribute to the subpar performance of projects. Table 1 displays a comprehensive list of these factors, accompanied by their corresponding references.

The second phase involved the developing the questionnaire and the collecting data. The questionnaire was developed to gather data on the relative significance of the predetermined factors. After finalising the questionnaire design, the sample size was determined, and the data was gathered and organised. The questionnaire was divided into three parts, namely general information, the importance of lean implementation at the preconstruction phase, mainly the design phase and its influence on the project performance, and the level of importance of design management factors influencing the project performance.

Naji et al. (2022b) recommend aiming for a sample size of at least 100, preferably exceeding 200. As per Naji et al. (2022b) findings, the sample size should be sufficiently large to maintain a ratio of observations to estimated parameters of 1:5. In the context of this study, this implies that a minimum sample size of 50 is required. The sample size of the population is determined to be 96, using a confidence interval of 95% and a margin of error of 10%, according to the equation provided below.

$$Sample\ Size = \frac{\frac{z^2 * p\ (1-p)}{e^2}}{1 + (\frac{z^2 * p(1-p)}{e^2 * N})} \qquad (1)$$

Table 1: 10 critical factors that contribute to both poor project performance and a subpar design outcome

Where z is the number of standard deviation a given proportion is away from the mean which is related to the level of confidence, p the population proportion, e the margin of error and N the population size.
The study includes a total of 111 participants, surpassing the minimum requirement in all instances. The questionnaire was disseminated as an online survey in response to limitations on conducting in-person interviews imposed by various organisations. The third stage involved conducting data analysis using the Relative Importance Index method (RII) to identify the primary factors causing poor project performance.

The final phase involved formulating recommendations that could enhance productivity and project delivery, as well as address the triple constraints (i.e., time, cost, and scope) in infrastructure projects. These recommendations pertain to all individuals and groups who are accountable for subpar performance and design results.

DATA COLLECTION AND ANALYSIS

The data was collected through an online questionnaire survey that was distributed using the SurveyMonkey platform. The researchers employed the nonprobability sampling technique to select potential participants, which involves using non-random methods to gather the sample (Naji et al., 2022a). The study employs purposive sampling, a method that involves selecting participants based on specific criteria or their knowledge of particular phenomena. The questionnaire survey was disseminated to over 200 participants in the State of Qatar who possess expertise and familiarity in lean construction, design, engineering, and construction projects through the assistance of industry experts, personal connections, and social media platforms. 116 individuals have participated in the survey, with 5 responses being excluded due to incompleteness. This leaves us with a total of 111 complete responses. The questionnaire was disseminated among various categories of organizations, including clients, designers, consultants, and contractors, to mitigate any potential bias in data collection. In part 1, the respondents were asked to provide information about their backgrounds. In part 2, rate the influence of the lean approach at the design phase on the project performance using a five-point Likert scale with the following numbers and corresponding answers: 1 = not at all important; 2 = slightly important; 3 = moderately important; 4=very important; and 5=extremely important. In the last part of the questionnaire, the respondents were asked to rate the level of importance of design management factors that influence the project performance using the same Likert scale. The ratings were analyzed utilizing a systematic approach employing quantitative statistical results to guide the next step in data collection.

RESULTS

RESPONDENT DEMOGRAPHICS

The responses include executive managers, department managers, project managers, infrastructure facility managers, senior design engineers, construction engineers, and quantity surveyors in the private and public sectors using a variety of parameters, including years of experience, working division, organization type, and position. Most of the respondents were international experts and practitioners from the public and private sectors, representing a wide range of experience and backgrounds in infrastructure projects. For example, the distribution of respondents based on years of experience was nearly equal, except for those with 11 or more years of experience who constituted the majority, accounting for approximately 65%. Figure 2 depicts a summary of the respondents' years of experience. Figure 3 demonstrates that approximately 56% of the respondents were highly or exceedingly knowledgeable about LC, while roughly 33% had a moderate level of familiarity. This demonstrates that the survey respondents were knowledgeable about the subject and were able to understand and respond accurately to the survey questions. As a result, the gathered data are deemed to be sufficient for experienced respondents in this sort of perception study to reach a sound judgment.

DATA ANALYSIS

Using the Relative Importance Index (RII) method, which ranks the influence of various factors on poor project performance, the data were analysed. Afterwards, the five most important factors are selected as the main areas for improvement using the lean approach during the design phase. In their study, Naji et al. (2022a) demonstrated that the RII is a highly efficient approach for analysing questionnaire data and precisely prioritising factors or variables. The RII value, which ranges from 0 to 1, represents the extent of influence on the dependent variable, with higher values indicating a stronger impact. Equation 2 calculates the RII.

$$RII = \frac{\sum W}{A * N} = \frac{5n_5 + 4n_4 + 3n_3 + 2n_2 + 1n_1}{5 * N} \quad (2)$$

Where W is the weight value (ranging from 1 to 5) given by respondents to each factor, in where 1 represents “Not at all Important” and 5 represents “Extremely Important”. A is the highest weight value which is 5 in this case, and N is the total number of responses. However, n is the number of responses to each weight value.

Table 2 presents a summary of the RII value and ranking outcome for the level of significance of the ten identified factors. It has been observed that factors DES9 and DES10 have identical RII values. Further examination revealed that the descriptions of these two factors essentially convey the same point: the insufficient involvement of construction experts during the design phase.

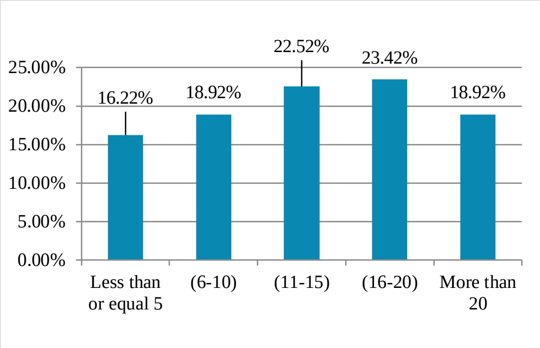

Figure 2: Respondents' years of experience

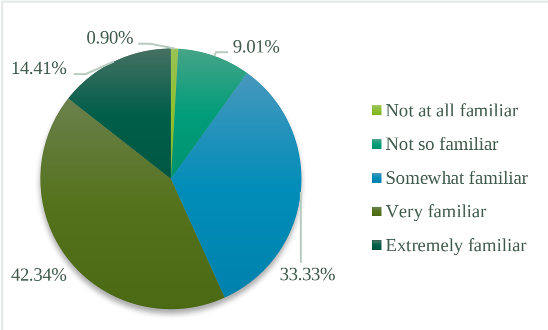

Figure 3: Participant's self-reported level of awareness regarding lean construction

Table 2: RII Value and Ranking Results for DM factors

Code	Factor	RII	Ranking
DES4	Lack of information for project full scope	0.838	1
DES1	Improper defining of client value/ need	0.818	2
DES3	Insufficient and unrealistic constraints on project time	0.811	3
DES9	Lack of constructability review of design	0.810	4
DES10	Inadequate involvement of construction experts during design	0.809	5
DES2	Insufficient and unrealistic constraints on project cost	0.806	6
DES8	Inadequate coordination meeting with other stakeholders	0.798	7
DES6	Individual decision making of design conflicts	0.785	8
DES7	Making design decision based on cost rather than the value of work	0.766	9
DES5	Lack of awareness of local market	0.742	10

DISCUSSION

The result of questionnaire shows the implementing lean practices has a greater impact on project performance during the preconstruction phase, in design phase. Table 3 illustrates the influence degree categorized by various types of organizations. The feedback from the client, consultant, and contractor revealed that the influence of lean principles in design varied from moderate to high. In contrast, the responses from the designers indicated a range of impact from slight to moderate. However, a substantial 76% of all participants hold the belief that integrating lean practices during the design phase has considerable significance, ranging from moderate to extremely crucial. Lack of information for the full scope of the project is the highest RII, which is considered a critical factor to be considered during the development the design in the preconstruction phase to avoid change orders during construction. The outcome is in-line with the outcome of Naji et al. (2022c) study to manage the change-orders. Improper defining of client value is the second RII has been highlighted in Cardenas Castaneda et al. (2022) paper, as one of the wastes during the design phase has to be mitigated. The third RII factor concerns about the inadequate and unrealistic constraints on project time that have been assigned for some activities, which may affect the project duration. The same has been considered a significant and top ranked delay factor in Mahamid (2021) study.

Table 3: The influence of implementing lean principles during the design phase on project performance, with respect to the type of organization

	Level of Impact (%)				
Organization Type	**Extreme Impact**	**Highly Impact**	**Moderate Impact**	**Slightly Impact**	**No Impact at all**
Client	8.33	41.7	41.67	0.00	8.33
Consultant	11.36	40.9	31.82	13.64	2.27
Contractor	5.13	51.3	28.21	12.82	2.56
Designer	0.00	25.0	37.50	37.50	0.00

Moreover, inadequate involvement of construction experts during design phase plays a vital role in minimizing the design error and installation priority. This waste can be avoided and considered during the design phase as highlighted in Gholinezhad Dazmiri & Hamzeh et al. (2023), and Aslam et al. (2020a) as the main lean successful factors to avoid time and cost wastes during the project design. Besides, insufficient and unrealistic constraints on project cost as a sixth RII has a bad impact during the construction that has to be controlled during the design phase as mentioned in Osamudiamen et al. (2022) study.

DEVELOPING A MITIGATION MODEL USING LEAN TOOLS

The processes of the initial two stages, namely initiation and design, have been dissected to fulfil the objective of this research. Figure 4 illustrates the use of process mapping to depict the sequential stages involved in any new construction project. The visual lean tool facilitates the identification of problematic processes that require improvement. Hence, the Kaizen burst icon is utilized to indicate the processes where the six most influential factors affecting project performance are present (highest RII). These processes include identifying the client's needs, developing a comprehensive project cost, creating a detailed project schedule, defining the scope of work for the project, and selecting the project delivery method. This paper aims to identify various lean construction tools and analyze their application to improve the processes. Table 4 provides a summary of various lean construction tools and methods that can effectively mitigate the influence of the six factors.

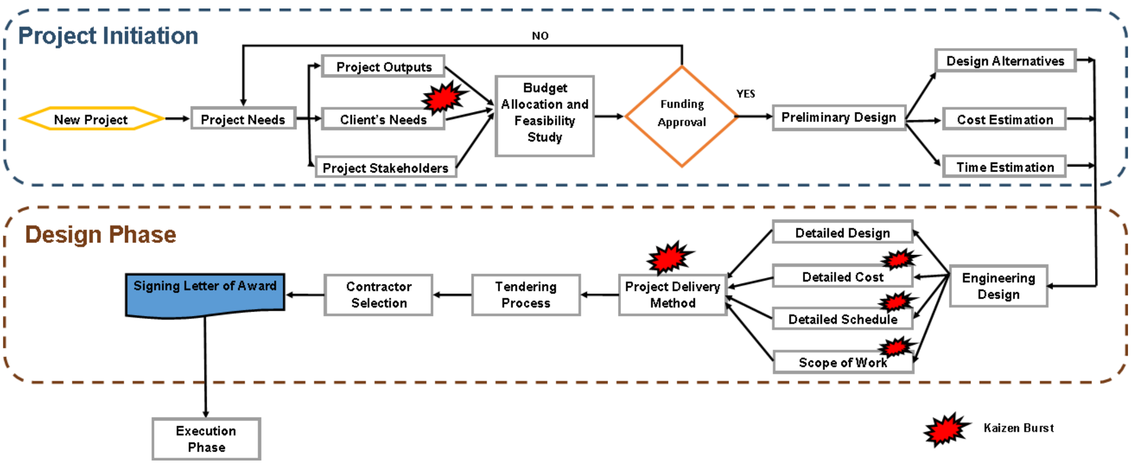

Figure 4: Process map of construction project phases and processes

Each lean tool is utilized and assigned to eliminate the impact factors in Table 4 has the potential to significantly improve the performance of construction projects, during the design phase. That can contribute to mitigating the critical impact factors during the design phase in the following approach:

Table 4: Summary of LC tools for mitigating critical factors affecting the design phase

Lean Tool	Definition	Factors
Integrated Project Delivery (IPD)	A tool that creates a better system of collaboration and communication between the various parties involved in a construction project, from the owner to the designer to the builder and any suppliers involved.	DES 2, DES 3, DES 9 and DES10
Building Information Models (BIM)	A modelling technology and associated set of processes for producing, communicating, and analysing project models.	DES 2, DES 3 and DES 4
Last Planner® System (LPS)	System for project production planning and control, aimed at creating a workflow that achieves reliable execution.	DES 6, DES 8, DES 9 and DES 10
Value Stream Mapping (VSM)	A tool to analyse and identify any weaknesses or waste sources within a complete process.	DES1
Target Value Design (TVD)	A complex system that includes the project definition, design, and construction stages. (Architecture, Engineering, and Construction)	DES1
Choosing by Advantages (CBA)	A tested and effective sound decision-making system to determine the best decision by looking at all the advantages of each option.	DES 6 and DES 7
Set-Based Design (SBD)	A method that keeps requirements and options flexible for as long as possible in design.	DES 5
Lessons Learnt for Continuous Improvement Cycle	Valuable knowledge and experiences gained leveraged for the benefit of future projects.	DES 9 and DES 10

- **Integrated Project Delivery (IPD):** fosters collaboration among key stakeholders (owner, architect, contractor, etc.) from the early stages of a project. It encourages shared risk and rewards, aligning everyone's goals towards project success. By integrating various perspectives and expertise, IPD can lead to more efficient decision-making and problem-solving during the design phase (Assaf et al., 2023).
- **Last Planner System (LPS):** focuses on detailed planning and coordination of tasks, particularly in the construction phase. However, it can also be applied during the design phase to identify dependencies, constraints, and milestones. By breaking down design tasks into manageable chunks and establishing reliable workflows, LPS can improve the efficiency and reliability of the design process (Tzortzopoulos et al., 2020).
- **Building Information Modeling (BIM):** enables the creation of digital representations of a building's physical and functional characteristics. During the design phase, BIM facilitates collaborative design, visualization, and simulation, helping stakeholders better understand the project's scope and requirements. By providing a centralized platform for information exchange, BIM reduces errors, conflicts, and rework, thus improving project performance (Gunduz et al., 2023).
- **Value Stream Mapping (VSM):** is a lean management tool used to analyze and improve processes by identifying value-added and non-value-added activities. Applied

to the design phase, VSM can help identify inefficiencies, bottlenecks, and opportunities for optimization. By streamlining design workflows and eliminating waste, VSM can enhance the overall efficiency and effectiveness of the design process (Gunduz & Fahmi Naser 2017).

- **Target Value Design (TVD):** is a collaborative approach that aims to achieve project goals within a predefined budget. During the design phase, TVD involves setting clear cost targets and continuously evaluating design decisions against these targets. By aligning design decisions with budgetary constraints, TVD helps prevent cost overruns and ensures that the project delivers value to the owner (Kim et al., 2023).
- **Set-Based Design (SBD):** involves exploring multiple design alternatives simultaneously before converging on a final solution. During the design phase, SBD encourages creativity, innovation, and risk management by considering a range of possibilities. By promoting flexibility and adaptability, SBD increases the likelihood of finding optimal design solutions that meet project objectives (Lee et al., 2012).
- **Choosing by Advantage (CBA):** is a decision-making framework that helps prioritize design alternatives based on their advantages and disadvantages. During the design phase, CBA enables stakeholders to evaluate design options systematically, considering factors such as cost, performance, and sustainability. By facilitating informed decision-making, CBA ensures that design choices align with project goals and contribute to overall performance improvement (Dahmani et al., 2023).

Integrating these methodologies throughout the design phase, a lean construction-based risk mitigation model is developed and will enhance the performance of construction projects by fostering collaboration, efficiency, cost-effectiveness, and innovation.

CONCLUSIONS

DM plays a vital role in the AEC industry, particularly during the preconstruction phase, because it has a significant impact on project performance. Preconstruction design management enhances the chances of success in construction projects. A thorough review of the existing literature and an empirical investigation have identified ten critical factors that contribute to poor project performance. The research methodology used a sequential hybrid approach to collect and analyse qualitative and quantitative data. Semi-structured interviews with construction industry experts and practitioners were conducted, as well as an online survey, yielding a comprehensive dataset for analysis. The use of the RII method enabled the identification and prioritization of critical project performance factors, resulting in practical and operational recommendations for improving performance. The study uses LC principles to demonstrate how lean tools and methods can mitigate the identified factors while improving project performance. The proposed framework is a comprehensive approach based on LC principles for risk mitigation during the pre-construction phase, combines lean principles such as VSM, TVD, and SBD with collaborative approaches such as IPD, BIM, and CBA to simplify design processes, maximize resource utilization, and foster innovation. The study enhances construction management by presenting a practical framework for improving project performance through effective decision-making and lean practices during the preconstruction phase, which can be expanded on in future research.

ACKNOWLEDGMENTS

We express our gratitude in advance to all authors and industry partners for their trust in providing us with real construction data and for their ongoing involvement in this research project.

AN AI COPILOT FOR MAKE-READY PLANNING IN THE LAST PLANNER SYSTEM

Camilo I. Lagos[1], Rodrigo F. Herrera [2], Alejandro Mac Cawley[3] and Luis F. Alarcón[4]

ABSTRACT

Many challenges in partial Last Planner System implementations can be attributed to the underutilization of Make-Ready Planning, although other factors also play a role. Failing to identify constraints in time to prevent Reasons for Noncompliance (RNCs) decreases short and long-term performance. Reducing the complexity of identifying, registering, and managing constraints systematically was found as a critical improvement opportunity. This research proposes the use of an artificial intelligence (AI) recommender system to facilitate constraint identification and RNC prevention. The system employs Large Language Model (LLM) embeddings to represent new task descriptions and find the most similar previously seen tasks. Subsequently, it fetches the set of constraints and RNCs belonging to these past tasks, represented in the embedded system, and uses it to produce three prioritized recommendations. Finally, the selected recommendations are categorized using Machine Learning Classification. The model was able to provide three sound recommendations for 69% of tasks and yielded a 60% relative improvement compared to a rule-based frequent pattern probabilistic system. The results pose three benefits for LPS practitioners: Reducing the effort needed to identify and register constraints, alerting probable RNCs needing to be prevented, and enriching data registration, allowing it to be used in future knowledge management.

KEYWORDS

Last Planner System, artificial intelligence, large language models, constraints, reasons for noncompliance.

INTRODUCTION

The Last Planner System (LPS) systematizes the transition from long-term Master Planning to mid-term Lookahead Planning and subsequent Short-term Planning through the Make-Ready Process (Kim, 2019). This process, known as the Make-Ready Process, involves breaking down upcoming activities into manageable work packages typically planned over a variable period that can extend beyond the often-cited four-to-six weeks, especially when dealing with complex materials or detailed design information from engineers, then screened to identify and remove constraints, before selecting constraint-free tasks to commit in the short-term plan and controlling the short-term compliance in search of Reasons for Noncompliance (RNCs)(Ballard & Tommelein, 2016). The process of identifying, managing, and removing constraints to

produce a workable inventory of constraint-free tasks is called make-ready planning (MRP)(Jang & Kim, 2007) (Ballard & Howell, 2003).

Systematic MRP allows to effectively select constraint-free tasks for the short-term plan and carry out short-term commitments efficiently (Javanmardi et al., 2020). Effective constraint removal, captured by the Percent of Constraints Removed (PCR), has a direct positive correlation with sustained short-term compliance, measured by the mean and standard deviation of the Percent Plan Complete (PPC) (Lagos & Alarcón, 2021a). Nevertheless, MRP is one of the least mature components in LPS implementations (Samad et al., 2017) and transversal studies have found that over 70% of constraints are identified less than two weeks before task execution (Pérez et al., 2022) and 55% of constraints are removed later than required (Bellaver et al., 2022). Despite the growing interest in applying AI to project management, there remains a significant gap in its integration with established methodologies like the Last Planner System. Particularly, there is a lack of research on how AI can be effectively implemented to predict and manage task constraints in real time, a gap our study seeks to fill by developing an AI copilot designed for Make-Ready Planning. The primary objective of this study is to develop and validate an AI-based recommender system designed to enhance the Make-Ready Planning process within the Last Planner System by systematically identifying potential constraints and preventing Reasons for Noncompliance (RNCs). The use of past knowledge is powered by an Artificial Intelligence algorithm fitted to a dataset of 1,000 tasks retrieved from 30 projects, the 3,300 constraints identified during MRP, and 4,100 RNCs impacting execution. The algorithm uses the relationships found between the tasks, constraints, and RNC categories and descriptions to find common patterns. These associations allow to predict potential constraints when prompted. Its implementation in LPS support systems can facilitate practitioners to identify and register constraints systematically and more efficiently.

LITERATURE RESEARCH

FACTORS LIMITING MRP AND THEIR IMPACTS

While MRP is key in securing a stable flow of tasks into the short-term plan, thus, increasing short-term plan reliability (Kim, 2019), is often one of the least systematized components of LPS (Lagos et al., 2022). Effective MRP requires allocating time and effort from all last planners to identify constraints with subsequent time in advance, registering in a standardized manner, committing their removal to habilitate task execution, and monitoring their status regularly so that the workable inventory can be updated (Bellaver et al., 2022). Prior transversal LPS adoption studies have found that partial LPS implementations fail to systematize the MRP (Hunt & Gonzalez, 2018). These surveys have found that while short-term planning and control is a widely adopted practice, the selection of short-term tasks is carried out without proper use of a workable-task inventory, active monitoring of constraint status, registering constraint identification and removal, or late constraint identification (Salling et al., 2023).

A Danish survey with over 1,600 responses (Salling et al., 2023) showed that 45% of teams did not know "how the project plan looks 1 month from now" and 44% did not know their upcoming tasks one month in advance. A similar study addressed subsequent increments of IT support for MRP in 162 Brazilian projects (Bellaver et al., 2022). The first iteration, using a cloud-based constraint status table in 38 sites, found that most teams failed to identify and manage constraints using the tools provided, despite it automating constraint management indicators. The second added constraint identification surveys and alerts in 92 sites. These were adopted by only half of the projects and only one-third of the constraints included removal commitment dates. The third iteration added automated guides and a standardized flow, tested in 32 projects. The guiding checklists and the requirement to fulfill them before continuing with the Lookahead Plan improved collection significantly ensuring all constraints were committed and reported. While the study observed an average increase of 50% in identification, 55% were identified late and failed to be removed when required for task execution.

On the other hand, a study covering a sample of 71 high-rise building projects employing IT support for LPS across their entire execution (Pérez et al., 2022) found that the constraint removal time of successful projects was 48% lower than in projects that failed to accomplish the scheduled completion. The same study found statistically significant correlations between constraint identification and removal times, the number of constraints identified, the PCR, and PPC. Finally, another study capturing over 24,000 constraints across 3,700 weeks from 69 projects (Lagos & Alarcón, 2021a) found that teams identify them on average 10 running days before execution and take an average of 16 days to remove them. The same study, which clustered the projects into 37 successful and 32 failed ones according to their schedule accomplishment outcome, observed a 47% difference in constraint removal efficiency and 42% in constraint planning efficiency among the clusters. The differences increased by over 150% when excluding projects with mid-schedule-accomplishment outcomes.

IT-SUPPORT SYSTEMS FOR LPS

The support functions of project management software can be categorized into: Assigning overhead rates to tasks; Job sizing adjustments of overheads; Predictive tender modeling; Work structuring and scheduling; Forecasting resources demand; Unit-based reporting; Load balancing; Task completion monitoring and measuring; and Material laydown planning and logistics (Costa et al., 2023). In addition, the key value propositions of software support have been characterized as Providing systems integrations; registering and consolidating information; standardizing workflows; facilitating analysis; automating updates and notifications; and improving communication and information sharing (Stevens & Olayiwola, 2023). LPS software focuses mainly on the support functions comprised of work structuring and scheduling, and task completion and monitoring (Lagos et al., 2019). Based on the literature findings, LPS support software can be characterized as encompassing a workflow of the master, Lookahead, and short-term planning, is immediately available to other users, consolidated over time, and summarized into reports or indicators captured through short-term control (Daniel et al., 2019; Dave et al., 2016; Faloughi et al., 2014). Therefore, forecasting upcoming Master Plan activities through Lookahead Planning and facilitating resource planning and allocation to bring them into the short-term plan (Heigermoser et al., 2019), as well as allowing short-term control cycles to report the accomplishment of the plan and RNCs are fundamental requirements of LPS-supporting software (Sbiti et al., 2021).

A key distinction is the extent to which they integrate constraints into the workflow. While some systems offer detailed means to register constraint identification, categorize, plan, commit, and report their removal (Lagos et al., 2019), others limit the registration of constraints to representing a blocker status in a task (Faloughi et al., 2014). There are also similar differences in the way in which constraints impact the collaboration workflow. More thorough systems incorporate logic to restrict the movement of tasks from the Lookahead Plan to short-term commitment, while others are limited to the collection of constraints and their status almost independently from task planning, commitment, and execution (Warren, 2019). The minimum viable information found across the systems corresponds to the link between a task belonging to a hierarchical and sequential structure in the WBS, its constraints, and the RNCs experienced by it during its execution (Pérez et al., 2022; Warren, 2019). Tasks can be better characterized considering their dependencies to mother-level activities in the WBS, as sequential pre-requisites, while most RNCs could be considered unforeseen constraints, and system categorization functionalities allow the identification of common types of constraints and RNCs associated with those tasks. Finally, depending on the connections captured by the different database architectures employed, the impact of constraints and RNCs on a given task can be estimated using the schedule differences between the planned and actual start and completion of the task (Lagos & Alarcón, 2021b).

VALUE OF PAST PROJECT INFORMATION FOR PROACTIVE PLANNING

Standardization, knowledge management, data-driven decision-making, benchmarking, and continuous learning are key Lean Construction practices (Castillo, 2015; Kifokeris, 2021). The inherent characteristics of LPS help promote standardization of workflows, data-driven decision-making, and continuous learning and are enriched with the use of IT support to systematize data collection and automate reports (Lagos et al., 2019). Various scientific contributions have shown the value of benchmarking significant LPS project samples to generate and consolidate knowledge (Kim, 2019; Lagos et al., 2019, 2022; Pérez et al., 2022), but its practical use in the industry remains lacking due to the lack of system integrations with data science and Machine Learning(Gondia et al., 2020; Shehab et al., 2022). Such IT contributions would provide value to practitioners in four ways: Information indexing; alerts and forecasting; prescriptive recommendation; and process automation (Cisterna, Lauble, et al., 2022; Cisterna, Seibel, et al., 2022; Kecman, 2001).

Indexing deals with using patterns and similarities found across data to provide structure. For example, unsupervised clustering algorithms can help differentiate groups of projects with different performances and identify quantitative thresholds to divide or benchmark them (Lagos & Alarcón, 2021a). Also, supervised classification algorithms can be trained to automatically sort information based on patterns learned from past data (Y. R. Wang et al., 2012). Among other uses, they can automatically categorize and/or prioritize constraints and RNCs (Lagos & Alarcón, 2021b). Providing alerts and forecasting is another use of the patterns learned through past data observation. For example, fitting a function to explain the behavior of a repetitively measured variable can help forecast the trends of metrics such as the Schedule Performance Index (SPI). A regression prediction model can allow to estimate of the future SPI employing an array of performance variables already captured by LPS such as the PPC, PCR, and RNCs (Jang & Kim, 2007).

Prescriptive recommendation can also employ predictive regression and classification systems to determine or maximize a future state (Wong, 2004). For example, Machine Learning prescription could recommend the most likely constraints or RNCs to be experienced by a task, given its characteristics, recommend corrective actions given a task and RNC tuple or help identify the tasks from the workable inventory with the highest chance of completion in the short-term plan (Shehab et al., 2022). Finally, process automation is simply the use of indexation, forecasting, and prescription to streamline repetitive processes based on previous patterns, predicting the next step, and providing a recommendation accordingly (Cisterna, Seibel, et al., 2022). Since ML systems can employ advanced algorithms and high computing power, they are more likely to identify underlying patterns invisible to a human practitioner and employ them in their predictions (Cisterna, Lauble, et al., 2022).

APPROACHES TO AID CONSTRAINT IDENTIFICATION AND RNC PREVENTION

The literature research yielded three alternative ML approaches to aid in predicting the most likely constraints and RNCs faced by a project task: Fixed rule-based systems; extrapolation models, and generative models (Cisterna, Seibel, et al., 2022; Hatoum & Nassereddine, 2023; Oprach et al., 2019). Fixed rule-based models employ logical conditions and weights to generate predictions, which remain fixed after the model creation. Consequently, these algorithms cannot extrapolate to unseen dimensions or variables (Feng et al., 2019; Wong, 2004). For example, an expert system trained to classify text based on a predetermined set of keywords cannot adapt to new keywords for making predictions.

Extrapolating and reasoning models introduce a degree of flexibility by extrapolating the "meaning" of a token. In NLP, words and statements are the tokens, represented as vectors elucidating their context in an extensive corpus of keywords (Nie et al., 2020). If an unknown word is encountered, the system leverages other embedded tokens to find similar statements. "Synonyms" of the unknown component allow to extrapolate meaning. The extrapolations can range from embedding exact words to high levels of abstraction through stemming, combining, and transforming (Grohe, 2020; Nie et al., 2020). Their robustness depends directly on the size of the corpus and the number of examples used for training, as the embeddings essentially consist of a set of expert rules and transformations applied to the text.

Generative models enhance prediction flexibility by enabling the "creative" use of embedded similarities to generate new text. Systems like Chat GPT employ transformers, which, in turn, utilize embeddings (Hatoum & Nassereddine, 2023). A transformer functions as an encoder-decoder system, to produce and fetch tokens. A large embedding system transforms these tokens into vector representations, preserving their core "meaning" and use. The decoder, trained on a substantial number of input-output statements, utilizes the embedded representations of tokens to select the best set of output tokens for an appropriate response (N. Wang & Issa, 2023). Finally, the degrees of flexibility gained by moving to more advanced systems pose a trade-off between robustness and precision. Robustness depends, among other factors, on the size of the corpus employed, or in other words, the amount and variety of texts employed to train them. As the amount of the corpus increases, so does the embedded space, and, hence, there is a higher chance of finding similarities with words or statements outside the realm of the problem at hand (Nie et al., 2020). Hence, the precision decreases as the predictions obtained might not correspond to constraints and RNCs commonly experienced by LPS projects.

METHODOLOGY

This research employed the Design Science Research Methodology (DSRM) (Venable et al., 2017). DSRM empirically evaluates a solution artifact to validate it and identify key benefits. The artifact resides in the intersection between the Problem Space and the Solution Space, which contrasts the state-of-the-art in the body of knowledge to the state of practice. The body of knowledge captured by the literature research can be summarized as follows:

- Problem Space: Constraint identifying complexity causes late identification and misses. Registering and managing efforts then decreases MRP effectiveness. IT support systems facilitate capture and future use to a limited extent.
- Solution Space: Tasks constraints and RNCs can be retrieved from IT support. ML can detect underlying relations and use them in similarity analyses. LLM embeddings allow similar tasks, and their constraints, and RNCs can retrieved, embedded, and used to produce a new set of recommended constraints for this new task.

The following constructs were produced employing DSRM:

- Solution concept: An input-output predictor producing a prioritized set of recommended constraints, categorized based on their similarities with previously existing ones.
- Proof of Concept (POC): Using embeddings to represent tasks, constraints, and RNCs; K-Nearest-Neighbours to find similar tasks and fetch their constraints and RNCs. Then, employing their embeddings to provide three prioritized and categorized constraints.
- POC validation scope: AI predictions against a deterministic expert prediction model.

DATA COLLECTION

30 projects were randomly selected from a universe of 110 Chilean high-rise building projects that used the same IT support during their complete execution scope. The sample represented almost 30,000 unique construction tasks, filtered to obtain a rich sample of task-constraint and task-RNC (input-output) tuples, based on the following conditions:

- Tasks are limited to a set of 12 superstructure framing categories.

- Exclude tasks without at least one RNC belonging to an MRP-preventable category.
- Exclude tasks that did not contain at least six constraints and/or preventable RNCs.
- Exclude tuples with inputs or outputs with less than five unique stemmed keywords.

Limiting task selection to those with at least six constraints and/or preventable RNCs, as well as five stemmed keywords was required to ensure sufficient data to train, test, and compare the AI and expert systems. A lower threshold could result in failing to predict at least three new constraints. The criteria produced almost 3,000 tasks and 21,000 tuples. The inputs were represented by the name of the task and its mother activities, up to two levels above and excluding the mother activities representing the building's floor levels. The outputs were represented by the category and the description of the constraint or RNC. To ensure clarity, we define 'Mother activities' as tasks that are hierarchically superior or precede the current task in the project schedule. These are activities that need to be completed or significantly progressed before the current task can commence. For example, in the case of constructing a building, if the current task is 'Pouring concrete for the second-floor slab,' its mother activities might include 'Completion of all first-floor structural worksA random sample of 1,000 unique tasks, linked to 3,300 constraints and 4,100 preventable RNCs was retrieved. The input (task categories) and output (constraints or RNCs) taxonomy are presented in Figure 1.

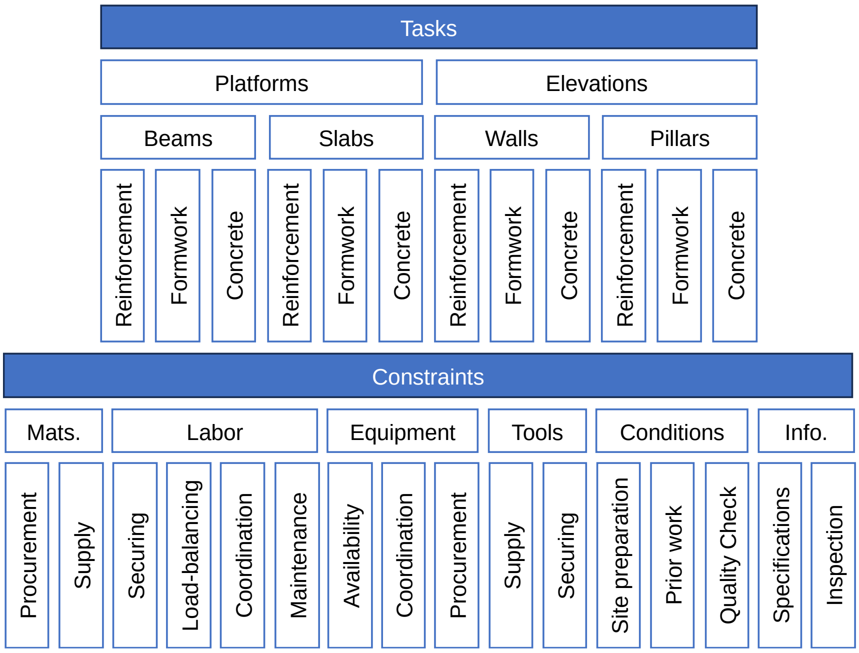

Figure 1. Task and constraint recommendation taxonomy (categories)

AI MODEL

Figure 2 describes the system. The original texts are embedded using the Word2Vec model available in the Python Gensim Library, with default parameters and excluding the use of multiword Ngram embeddings. The vector size was limited to 100 dimensions to avoid overfitting and improve performance. The embedded texts are categorized into input and output statements. A Euclidian distance algorithm computing the sum of squared differences between NumPy arrays is used to measure embedded text similarities for inputs and outputs respectively. A Naive-Bayes text classification algorithm predicts the lowest-level category of any given new task, and the classification results are used to slice the 1,000 task descriptions in the embedded space by removing all who do not belong to the same L2 group as the predicted category. This slicing helps improve performance and avoid unrepresentative similarities in future steps.

Afterward, the new task description enters the embedded space containing only the filtered tasks according to its predicted category. Subsequently, a K-Nearest-Neighbors algorithm fetches the 50 tasks with the minimum Euclidian distance. The ground truth data is then used to describe the constraint descriptions present in all tuples containing the 50 most similar tasks. The embedded representations of these past constraint descriptions are used to predict the three most likely new constraint recommendations. The recommendations are limited to constructing text descriptions using a maximum of five tokens. Since the constraint categories were included in the descriptions when inputting them into the embedding system, the produced outputs are most likely to contain one of the first-level constraint categories (materials, labor, equipment, tools, conditions, and information), and one of the second level categories (16). The remaining tokens are used to construct the specific description, most likely, providing a verb, noun, and adjective to construct the recommended constraint.

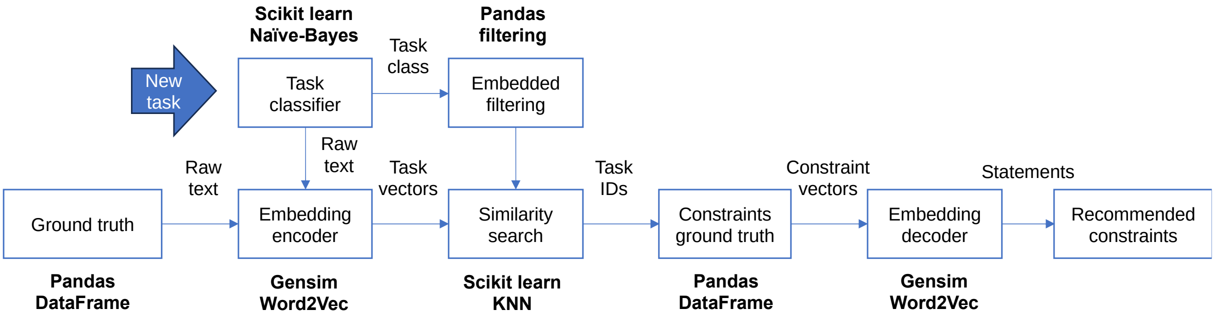

Figure 2. AI model pipeline

MODEL COMPARISON

A rule-based model was employed to benchmark the performance of the recommender system. Since fixed rules cannot be applied to natural language descriptions, the system uses the task-category prediction given by Naive-Bayes as an input to predict constraint categories. The model employs frequent pattern recognition to derive the most-likely class to enter a known set and turns these probabilities into rule-propagation tree using the FP-Growth algorithm. The FP-Growth algorithm, like A-Priori, is an pattern mining algorithm fitted to cases referred to as the supermarket cart problem (Feng et al., 2019). It predicts the most likely N+1 element to be added to a known bundle. The bundle of unique task categories and their linked constraint and RNC categories (ground truth) are passed as association rules. Since tasks contain at least six unique constraints and/or RNCs, the association rules can rank up to six predictions for each task category, the latest being the most frequently observed full set. In this implementation, the FP-Growth predictions were not limited to bundles composed of unique predicted categories, since a task can contain two or more constraints belonging to the same category. Also, the order of the factors in the ground truth bundles did not alter the resulting rules, since the predictions were based on the conditional probability of a new constraint appearing given the frequency of the set's unique components (i.e. constraints and RNCs), structured into a probabilistic frequent patterns tree. As a result, all tasks in the same category received the same ranked sets.

The expert system was implemented employing the FP-Growth model available in the Python MLX tend Library. Both the AI and rule-based systems were trained and tested employing the same 80%-20% sample split. Also, both used the same task category prediction obtained from the Naïve-Bayes algorithm as an input. The cases where the task classification was incorrect were excluded from the subsequent model performance comparison. The outputs produced by both models were contrasted against the ground truth categories of each of the constraints associated with the test tasks to measure the performance. Each model was assigned one point for each predicted constraint present in the ground truth and deducted one point for each prediction that was not present in it.

RESULTS

First, the Naïve-Bayes classification algorithm produced 182 correct task classifications out of the 200-task category ground truth samples employed in the testing set, yielding a recall of 89%. The recall is calculated as the number of correct predictions divided by the test set size. Table 1 presents the prediction recall results. Subsequently, the model comparisons employed a testing subset comprised exclusively of the 178 correctly predicted task categories. It must be noted that FP-Growth results can be directly compared at the category level, but lack a more detailed natural language description, while the AI results give a natural language description but can also not allow the direct identification of a category. In total, 34 out of 600 NLP predictions did not allow for clearly detecting one of the 16 possible constraint categories, 29 of which occurred in the correctly classified tasks. Hence, the maximum theoretical points to achieve with the AI model and FP growth were 505 and 534, respectively.

Table 1. Task categorization results.

	Platforms: Beams			Platforms: Slabs			Elevations: Walls			Elevations: Pillars		
	R	**F**	**C**	**R**	**F**	**C**	**R**	**F**	**C**	**R**	**F**	**C**
G.T.	11	9	10	22	28	23	20	24	25	11	9	8
Pred.	8	8	7	20	26	21	20	23	21	10	8	6
Rec.		77%			92%			93%			86%	

FP growth provided 395 correct recommendations and predicted 139 constraints that were not present in the ground truth data, yielding a net performance of 256 points or 43% predictive capability. On the other hand, the AI model achieved a score of 415 points, with 460 correct predictions, 45 incorrect predictions, and 29 predictions that could not be categorized. Overall, considering that 89% of the task descriptions were misclassified, the AI model showed a consolidated capability to foresee and recommend effective real constraints in 69% of cases when prompted only with the task description and 78% if aided with a human-verified category. Table 2 summarizes this analysis. Furthermore, part of the AI predictions that were not present in the ground truth data could also be explained by the lack of proper registration by the users of the IT support system employed for the data collection.

DISCUSSION

POC LIMITATIONS

This POC was carried out employing 7.400 tuples from 1,000 unique tasks. The data corresponded exclusively to superstructure framing activities and a taxonomy of 16 constraints captured by the single IT-support system in Chilean high-rise building projects, employing Chilean-Spanish dialect and construction terminology when registering information. A hybrid ML architecture was employed instead of state-of-the-art LLMs. Also, the models employed in the POC architecture were not finetuned to further optimize prediction performance, since the results already signaled its benefits over traditional fixed-rule systems and manual identification. Finally, the model was fitted and evaluated using an artificially enriched sample produced by the selection of tasks linked to at least six constraints or preventable RNCs. Enriching the sample was deemed necessary to facilitate prediction outcomes and the existence of constraint-free tasks could be caused simply by the lack of proper registration in the IT support systems. Nevertheless, the POC model should be expanded with a larger corpus to include variance in the tuples and trim unnecessary predictions when a task exhibits a low constraint probability or a reduced set of potential constraints and preventable RNCs.

Table 2. Model performance results.

	Cat. tasks	Constraint preds.	Cat. predictions	Correct predictions	Incorrect predictions	Score
Ground truth	200	1320	1320	600 (aim)	0	600
Expert System	178	534	534	395	139	256 (43%)
AI Model	178	534	505	460	45	415 (69%)

CONTRIBUTIONS

This research shows that even a basic AI pipeline can provide domain-accurate constraint recommendations on 70% of cases based on past project information. This means that 70% of constraints that should be identified during the MRP could now be automatically registered as soon as a task enters the Lookahead Plan. Also, an LPS practitioner employing the IT support systems could quickly validate or modify the predicted task categories and recommended constraints, improving the percentage of use cases covered. Hence, it is estimated that up to 90% of the constraint identification workflow could be streamlined, significantly decreasing the time and effort needed to kickstart the MRP and giving Last Planners a wider time scope to then commit and remove those constraints. Having access to better-registered information facilitates the use of knowledge management for other data-driven decision tasks (Franz et al., 2022), such as improving MRP performance and reducing constraint removal times. Finally, the same concept can be applied to repetitive decisions such as corrective action implementation, RNC registration, and selection of tasks from the workable inventory. The study significantly contributes to the integration of AI in the Last Planner System by providing a validated AI-driven approach to Make-Ready Planning. This contribution not only enhances theoretical understanding but also offers practical tools that can improve efficiency and predictability in construction projects. The implications of these contributions are profound, potentially enabling project managers to reduce delays and better manage resources. While we acknowledge certain limitations in our current model, these should be viewed as starting points for further refinement. The opportunities for future research, such as integrating more advanced algorithms, ultimately aim to build upon the solid foundation this work provides.

OPPORTUNITIES

This POC was carried out employing only 7.400 tuples from 1,000 unique tasks, while the data captured by the single IT support system employed in this study comprises over 290 projects, with over 100,000 unique tasks, 220,000 reasons for noncompliance, and 130,000 constraints. Also, several other LPS support systems have collected similarly sized structured datasets. The results can be further improved by finetuning the existing architecture. Particular examples of finetuning opportunities include (1) the number of neighbors employed by KNN, which was fixed to 50 tasks, (2) the dimension of the embedding vectors, which was limited to 100, (3) the number of tokens employed to produce the outputs, currently fixed to five, (4) adding additional relative value to the tokens describing the constraint category predictions, and (5) employing alternative task classification algorithms instead of NB. State-of-the-art models allow for better embeddings fitted to significantly larger LLM corpora. Open-source LLMs like Large Language Model Meta AI (LLaMA) also offer finetuning and retraining opportunities to better capture the specific LPS task management corpus. Equivalent models like Google's BARD and Bidirectional Encoder Representations from Transformers (BERT) offer end-to-end question-and-answering pipelines, which already incorporate reasoning and generative technologies. State-of-the-art AI research is constantly producing new open-source models and architectures for a wide array of domain-specific challenges, contexts, and corpora.

CONCLUSIONS

This research assessed the use of AI to identify and register constraints early during Lookahead Planning and facilitate Make-Ready Planning. LPS adoption studies found that inefficient MRP impacts short- and long-term performance. Practitioners often fail to identify constraints in time, and they take longer than planned to be removed, 55% of times past planned execution. The hypothesis that task-constraint relationships found on past projects can be used to recommend new ones for a task entering the Lookahead Plan was validated via the Design Science Research Methodology. A Proof-of-Concept AI model was developed using 1,000 tasks connected to 7,400 constraints and preventable RNCs. LLM embeddings helped find similarities among them and use tokens to produce three ranked recommendations. Its performance was compared against an expert recommender based on the FP-Growth algorithm. While FP growth showed a 43% net rate of correct recommendations, the AI model achieved 69%. This rate increases to 78% if the input task is classified beforehand. The model can be finetuned to improve results using a larger sample and the POC can be replaced by state-of-the-art end-to-end question and answering LLM models. The resulting system acts as a copilot for LPS practitioners, helping them kickstart MRP early and more effectively. The same approach can be employed to recommend corrective actions, select tasks to enter short-term plans, or register RNCs. Further research could explore the integration of more advanced machine learning algorithms to improve predictive accuracy and user interaction. Additionally, extending this research to other phases of project management or different industries could provide insights into the broader applicability of AI tools. Long-term studies focusing on the sustained impacts of AI integration in actual project environments would also be invaluable to assess its long-term benefits and challenges.

TAKT AND PULL ZONES IN THE CONSTRUCTION OF LOGISTICS WAREHOUSES

Gustavo Bridi Bellaver[1], Bernardo Martim Beck da Silva Etges[2], Lauro Henrique Alves Rego[3] and Luis Staudt[4].

ABSTRACT

This article will describe how the application of lean philosophy tools in the construction of logistics warehouses can offer new perspectives on project planning, promoting clearer and more visual communication, collaboration, and decision-making processes. this article investigated the use of takt and pull planning methods for the development of an integrated management system for logistics warehouses located in different Brazilian cities. Takt planning of scheduled activities decreased waiting times, leading to a reduction of approximately 8% in the execution time of construction works. Other benefits included greater team engagement and participation in activity planning and sequencing. Two takt zones (repetitive elements) and one pull zone (non-repetitive elements) were demarcated at each construction site, which were planned using line balancing as a unifying element. This strategy facilitated visual management by the field team, ensuring that the entire planning process flowed through the actors actively involved in carrying out the work. In a questionnaire-based survey, construction teams reported great improvements in planning, work comprehension, and coordination between work fronts, as well as improvements in visual management and collaboration. The responses indicated a notable shift in how the field team approached planning and conceptualized their work and demonstrated that the incorporation of takt and pull planning concepts was essential for achieving these results.

INTRODUCTION

The desire to increase construction productivity is driven by the sector's known inefficiency in transforming raw resources into commodities and the importance of building or infrastructure development for economic growth (Hussain & Al-Turjman, 2021), so more than More than ever, strategies to redesign the production chain, analyze internal and operational processes and seek alternatives and opportunities to produce increasingly more efficiently are objectives of organizations seeking to sustain themselves and grow in the market (Sage et al., 2012).

In this context, more recent studies present a wide range of Lean Construction tools to reduce waste and improve production efficiency, which can be used depending on the type of construction or integrated. Zhang and Chen (2016) bring lean techniques and practices that were brought from lean manufacturing, such as daily meetings, Kanban and value stream mapping, in addition to the Pull Planning methodology of the Last Planning System (LPS) concept presented by Silva, Etges and Pereira (2022), which the application in construction brought considerable benefits in meeting deadlines in the construction of buildings.

Takt Planning, Haghsheno et al. (2016) defines it as a methodology that can also result in increasing the stability of the production system in activities with repetitions. It is widely used in various production processes, such as bridge construction, underground construction, tunnel construction and excavations, due to its repetitive work package characteristics, which is why the use of a Takt becomes highly relevant (Haghsheno et al., 2016). Also according to the authors, there are restrictions on the use of this tool in buildings, since often not all floors and the layout of environments are designed identically, and these conditions make greater preparation and planning necessary to integrate the different areas into one. Common takt. In this sense, Formoso et al. (2011) states that the focus should be on the causes of losses, rather than trying to monitor or control the consequences of losses in production, using techniques and tools that have greater adherence to the construction typology and the objectives sought.

Bringing this scenario to the construction of warehouses, Mora (2016) highlights that it is an area that maintains the same concern in the real estate segment, seeking to offer design and construction solutions with appropriate attributes in terms of quality, deadlines and agreement. with the needs of potential customers. Kamaruddeen et al. (2020) presents in their study research results on several modular warehouse construction projects around the world, only 30% of projects can be completed on time, while the rest have experienced delays. In addition to having an impact on excess costs, delays also cause other impacts, such as customer dissatisfaction.

Therefore, this article aims to study the applicability of the Pull and Takt Planning tools in the construction of logistics warehouses as they have previously been identified as the most suitable methods for this type of construction and as the most appropriate alternative to resolve the problem of difficulty in complying with the construction schedule identified, in addition to the perception of a gap that currently exists due to the lack of studies on lean thinking practices in this construction model.

To achieve the research objectives, the work was divided into three main stages, the first being a literature review on the warehouse market in Brazil in order to understand its relevance, and the Takt and Pull planning methodologies. The second stage consisted of structuring the methodology, with the elaboration of strategies for applicability to the phases of building a warehouse, and the third stage, the application of practices in the field in a unified way in works in progress, in order to obtain and evaluate the performance of the work, in addition to the perception of engagement of those involved. The results could be compared to other constructions that do not use the methodology, and, finally, it was possible to conclude that adoption of the practices provided an 8.3% reduction in the total construction time, in addition to contributing to better management, visibility the direction and stability of production.

THE LOGISTICS WAREHOUSE MARKET IN BRAZIL

Poletto (2011) defines that logistics warehouses are enterprises developed in a large area already subdivided, in which these industrial or logistics lots are organized and sold for this purpose, containing infrastructure of paved roads suitable for supporting heavy loads and vehicle traffic, guides , gutters and sidewalks, rainwater galleries, sewage collection and treatment system, drinking water network, electricity and public lighting, signage, and even preserved green areas, where each company or investor is responsible for the construction of their own shed. According to the author, within this type of enterprise, warehouses are commonly built by investors who seek to rent them to an end user.

Mora (2016) observes that currently the development of the Brazilian market for logistics condominiums has adjusted to the new demands and needs of the logistics market, due to the demand for competitiveness and efficiency present in the operation of companies and business segments that rely on large logistics infrastructures, including large storage centers.

Recent data from a survey by specialized consultancy Colliers (2024), concluded that the 51 projects delivered throughout the year added 2.3 million m² to the country's existing inventory, surpassing the mark of 25 million m² of high-end logistics condominiums throughout the national territory, an increase of 10% in the São Paulo region. With the expectation of a fall in interest rates in Brazil throughout 2024, the market is expected to register new acquisitions of logistics assets, making clear the importance of implementing production strategies in this area of construction to monitor the viability of these projects.

TAKT PLANNING

The influence of assembly line principles on building construction was first observed during the construction of the Empire State Building in New York City in 1930. The project emphasized the need to achieve continuous production, accomplishing construction cycles of one pavement per day. This systematic approach not only marked a significant transformation in the construction practices of the time but also established a paradigm for efficiency and productivity in the construction industry. The cost, execution time, and safety indicators of the project were markedly better than those of any comparable enterprise. Thus, the project stood out for its technical innovation and brought significant benefits to civil construction (Kenley and Seppänen, 2010).

As argued by Haghsheno et al. (2016), takt implementation provides increased stability for production systems, contributing to reducing inventories and waiting times between activities, while optimizing transportation through continuous flows. Takt planning is of utmost importance for effective synchronization between different areas, ensuring that individuals operate at an agreed-upon pace. According to Hopp and Spearman (2008), takt time planning provides a standardized time for the execution of each activity in the production line, leading to synchronization of individual deliveries. Adequate definition of the daily production quota provides greater predictability and stability for supporting sectors, while mitigating the influence of variability in customer demands. Frandson, Berghede, and Tommelein (2013) defined takt time as the unit of time within which a product must be produced in order to match the demand rate. Haghsheno et al. (2016) emphasized the importance of understanding the production process and its delivery milestones for defining work packages, including the scope of each action area and the sequencing of activities.

It is possible to determine the takt time of a logistics warehouse project using the equation proposed by Reck and Fireman (2023) (Equation 1). The takt time is mainly influenced by the following three variables: the time available for project execution, the number of slots, and the number of service packages. Additionally, the equation includes a practicability coefficient referring to project-specific uncertainties and characteristics, such as climatic uncertainties. As pointed out by Binninger, Dlouhy, and Haghsheno (2017), the takt time should not be understood as a fixed number applicable to all projects; rather, the takt time should be specific to each project, accounting for its particular characteristics and boundary conditions.

$$\text{Takt time} = \frac{\text{Available time} \times 80\% \text{ Practicability}}{(\text{Repetitions} + \text{Number of activities} - 1)} \qquad \text{Equation 1}$$

A work package, as described by Haghsheno et al. (2016), represents the subdivision of a construction project into smaller areas, which helps to structure and quantify the activities that need to be carried out at each location. The duration of each work package and batch should be similar, thereby providing a stable rhythm to the construction process, with fewer restrictions. Binninger, Dlouhym, and Haghsheno (2017) stated that one of the goals of lean is to reduce batch sizes and individual production times. However, the definition of takt time also depends on the variability and stability of the construction system. Thus, because of the high level of instability of construction processes, a weekly takt is typically adopted. The more refined the takt time, the higher the level of uniformity and control required in the enterprise.

The purpose of lean construction, takt planning, and takt control is to achieve continuous and uniform processes, creating value-generating activities with equal durations throughout the entire process chain (Binninger, Dlouhy, and Haghsheno, 2017). As observed by Haghsheno et al. (2016), takt implementation is particularly relevant for processes that occur frequently and exhibit significant similarity throughout the project. Haghsheno et al. (2016) also underscored that, for the implementation of the takt system to produce positive results, it is essential to ensure that all activities have been completed as planned at the end of each cycle. This enables the uninterrupted execution of subsequent activities, promoting gains in productivity through workflow simplification and transparency.

PULL PLANNING

Pull planning is an LPS tool initially designed to improve productivity. Its conceptual framework was later redirected to creating predictable workflows and fostering rapid learning in various fields associated with civil construction, such as programming, design, construction, documentation, and project delivery (Kalsaas, Grindheim, and Læknes, 2014). Tvedt (2020) described pulled planning as one of the latest additions of the lean thinking toolkit whose function is to create a reliable flow of work across a team of experts.

As noted by Kalsaas, Grindheim, and Læknes (2014), pull planning originates from the master plan, which contains the project's delivery milestones. Similar to takt planning, the project is subdivided into slots, serving as control areas and providing rhythm to work fronts. This approach enables a more efficient and synchronized management of activities throughout the entire project.

As outlined by Tiwari and Sarathy (2012), reverse planning is the subsequent step following the identification of the main project milestones. The method starts from the final delivery and retraces all steps back to the present moment, mapping out the work required for project completion. This approach supports a more detailed understanding of critical steps and activities involved in project development. Kalsaas, Grindheim, and Læknes (2014) complemented the description of the pull planning approach, highlighting the importance of using visual elements in routine management, such as planned start and end dates. These elements generate a clear and accessible representation of the project schedule, making it easier to understand and track planned milestones.

Tsao, Draper, and Howell (2014) described pull planning as a tool that promotes collaborative planning, in which solutions for project execution are reached jointly. Tvedt (2020) underscored that the critical point for success is the collaborative participation of experts, enabling interaction with different perspectives, reducing waste, and anticipating difficulties. Tiwari and Sarathy (2012) argued that pull planning allows building a transparent environment that is empathetic to the difficulties of other team members. This facilitates communication and generates a sense of trust and belonging.

As noted by Silva, Etges, and Pereira (2022), with the development of a transparent environment in which people participate in decision-making and are aware of the team's problems, activities are carried out with greater agility. In this environment, an action plan encompassing the restrictions and potential risks that may impact production is developed. This plan defines deadlines and responsibilities for the solution of the identified points, contributing to efficient management of issues that may arise throughout the project.

Kalsaas, Grindheim, and Læknes (2014) underscored that traditional planning is often long and complex, requiring a large volume of pages and graphics, making it difficult to identify the status of the enterprise with regard to its schedule. Tiwari and Sarathy (2012) reported that pull planning helps the team to build a comprehensive, transparent, flexible, and collaborative planning process in a simplified way. This agile and transparent approach to planning allows for a clearer and more accessible understanding of project progress.

METHODS

Action research was the methodological approach adopted in this paper. Action research focuses on solving real problems (O'Brien 1998) and contributing to the organization's development, being based on simultaneous and collaborative action and research (Coghlan and Brannick 2001). The model was defined on a construction site and replicated in four other warehouse construction sites in Brazil. In each project, the model was adapted to the specific needs of the work site. All figures shown in this work are from the same warehouse, where the pilot was done. Considering the action research, the current paper aims to bring insights from a real case study connecting pull and takt zones for planning of non-repetitive and repetitive activities and the benefits perceived by its participants. After the planning intervention was applied in five work sites, a survey was sent to the involved team members such as managers, engineers, analysts and assistants (n = 43), and 39 individuals completed the questionnaire, representing a 90.7% response rate.

The studied company, herein referred to as Company A, has existed for more than 15 years as one of the largest developers of logistics assets and warehouse rental companies in Brazil. Currently, it has more than 1 million m² of built logistics warehouses in 16 states and 34 cities in the country. The company has eight ongoing developments, corresponding to 365 thousand m2, and delivered 600 thousand m2 of gross leasable area in the last two years. Company A constantly invests in improving product quality, using the best market practices to offer an integrated operation to its customers. Several solutions based on technology and innovation are provided. Nevertheless, up to the beginning of this study, the company had not had contact with lean philosophy or LPS tools. Project planning was carried out in the central office using Gantt charts and sent to worksites.

RESULTS AND DISCUSSION

A typical logistics warehouse facility includes the warehouse itself, which can be modularized to meet specific customer needs, auxiliary facilities for warehouse operation, such as cafeteria, changing room, and guardhouse, and infrastructure networks (INs) for the warehouse and auxiliary facilities. Thus, aiming to promote integrated management based on lean and LPS principles, we defined a model for the planning and management of tasks carried out in the warehouse, outdoor environments, and auxiliary facilities.

The first stage in the development and implementation of the lean management model was defining the macroflow of activities in the three lines (warehouse, INs, and auxiliary facilities). For this, a construction team comprising engineers, analysts, master builder, and construction coordinator was formed for the sequencing of activities and definition of work packages. This step was carried out collaboratively, using sticky notes to promote team engagement and facilitate visual management of the activity. After work package sequences were defined, the tasks included in each work package were described in detail to enhance the understanding of the process and sequencing. Each work package became a line in a line of balance (LOB) and the sequence of those packages served as the sequence of lines in the LOB in the activity planning stage.

Having analyzed in depth the projects of the different ventures of the company, it was understood that takt time was applicable to logistics warehouse and IN activities, which have repetitive elements in their design. Previous works using takt planning in non-repetititve labour have shown a high risk of losing effectiveness in field due to a lack of knowledge of information about productivities, means and methods, defining identical labor content for the trades (Linnik, Berghede and Ballard, 2013; Tommelein, 2017). Therefore, for auxiliary facilities, the focus would be to apply pull planning strategies, given that activities were slightly repetitive and slots differed greatly in workload, for that reason, we could treat them as non-repetitive elements in a pull planning section.

The company had a very large focus on the warehouse and had good control over its activities; however, the other areas received less attention and planning. With the advancement of planning, an integrated vision of all areas was developed, aiming toward work assertiveness. Table 1 depicts the factors evaluated in this study.

Table 1: Evaluation of work zones

Criterion	Takt zone: warehouse	Takt zone: IN	Pull zone: auxiliary facilities
Repetitive unit	Yes	Yes	No
Clear constructive sequence	Yes	Yes	Yes
Possible to determine the rhythm of each slot	Yes	Yes	No
Integrated view of the project (before/after)	Yes / Yes	No / Yes	No / Yes

TAKT ZONE

Takt was applied to enhance production stability, maintain the rhythm of activities, reduce waste, and reduce the total time of project execution. This section explains the repetitive elements aspects in constructing a logistics warehouse.

Takt Zone: Warehouse

The first line to be planned was the warehouse, as it is the core of the project and must be delivered as soon as possible for customers to adapt the facility to their needs to being operation. Logistics warehouses are designed for modularization, so that they can be rented to more than one customer. According to the project designs, warehouses are created as repetitive modules (for rental purposes) that can be compartmentalized in the future if needed. Each module consists of a leasable storage area, reception, and loading docks. It was clear to the project team that the leasable lots would be takted. However, the lots were too small for some activities (e.g., subbase and base execution); therefore, two leasable lots were used for the planning of one slot. When estimating the takt time for the activities (Equation 1), it was observed that dividing by two lots was relevant for several ventures in the company. With this method, the takt time was close to one working week, representing an easy time measure for everyone on the project. The standard slot was defined as 4 lots and 2 sublots for leasing, two receptions, and part of a mezzanine.

The first stage of the process was to prepare the list of quantities for each slot. The list of quantities was not detailed in this step, corresponding to large volumes of work. This was made so as to identify the workload of each work package within slots in the established takt time. This method allowed obtaining the metrics to be controlled on a day-to-day basis. Subsequently, a scheme was drawn on the warehouse layout containing all lots and the quantities of all work packages to be managed (Figure 1).

Takt Zone: INs

The environment surrounding the warehouse, comprising underground and aboveground networks, pavement, and landscaping, posed challenges, primarily contributing to the failure to meet the delivery deadline. IN always differs across worksites because of differences in land type, land size, neighborhood, number of auxiliary facilities, state legislation, and many other factors that influence the project. To identify the rhythm required to meet the client's deadline, it was first necessary to determine the division of areas for takt.

The team decided that areas should be divided so as to meet an attack plan focused on a single work front (designing a train of activities passing through the lots). Lots were designed with area divisions as similar as possible. The aim was to create the most homogenous possible quantity of work for activities passing through lots within a week. Activities would pass to the following lot only after being completed to guarantee adequate starting conditions for the following team. This division ensured a very effective allotment of activities from construction of the subbase onward, given that work quantities were divided by area. Another positive outcome was the good division of lots in underground networks, as many networks run parallel to the warehouse, generating a similar workload to be managed under a takt approach. Therefore, the repetitiveness aspect of the project was satisfied again and takt time would be the methodology to go for. The lot division is shown in Figure 2. The lot layout was drawn and the list of quantities was prepared to obtain monitoring metrics and allow the sizing of teams and equipment.

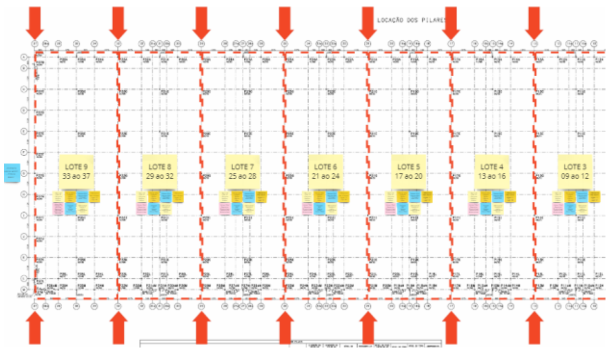

Figure 1: Warehouse layout and lists of quantities for takt time implementation

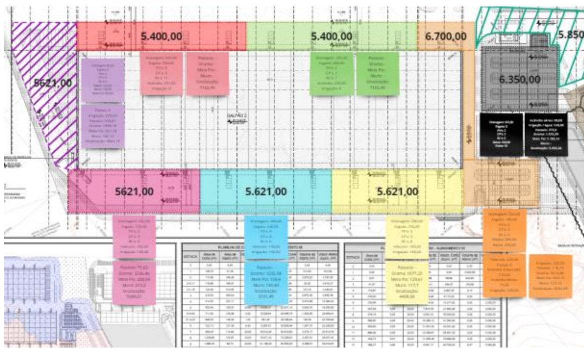

Figure 2: IN Layout and list of quantities of external areas for takt time implementation

PULL ZONE: AUXILIARY FACILITIES

The design of auxiliary facilities (comprising cafeteria/leisure area, changing rooms, reception, truck driver support, water tower, pumping station, measuring booth, and reuse water station) was approached differently. The first step was to prepare all lists of quantities for tasks defined in the macroflow of auxiliary facilities, per building. Not all work tasks were carried out in all buildings (e.g., installing ceramic flooring in the water tower); therefore, takt implementation would be difficult because of the non-repetitive aspect of this activities. As a result, it was decided to apply pull planning for auxiliary facilities, in a collaborative way with the team.

The sequences of work packages were defined by the team. Milestones for the delivery of materials with long lead time and the final work deadline were defined. With this information, the pull planning session began. On the basis of estimated team productivity rates, the necessary deadlines for each work package were determined, defining the work plans of the facilities.

INTEGRATED MANAGEMENT MODEL

Given that two different methodologies were used for planning, it was essential to unify them into a single model for integrated management of the entire project. Visual management is crucial to increase team engagement, communication, understanding of goals, and general alignment of teams to meet deadlines and customer demands. Thus, a LOB was used for unification of plans and visual management of lines.

The union of these methodologies and the definition of visual tools, increasing the transparency of the process, considering the takt phase and the pull phase, proved to be a great gain for the project and a new methodology that can provide a new way of visualizing planning. Not following just one methodology, but using the best of both and generating concise information that adds value to the construction team.

For this, a grid panel was mounted on the wall, and sticky notes were used to construct the lines of balance, being visible to everyone in the room. The columns represented weekly time horizons. The vertical axis was divided into three lines: warehouse (green notes), IN (red notes), and auxiliary facilities (yellow notes). Slots were distinguished by an additional axis used for writing dates. Thus, takt planning was unified with pull planning (Figure 3). The lower part of the panel shows activities differing in the degree of sequencing.

Figure 3: Lines of balance contemplating takt and pull planning zones

SATISFACTION SURVEY WITH THE CONSTRUCTION TEAM

At three months after the beginning of the last project, the construction team was asked to answer a questionnaire to evaluate their perception of value of planning based on lean, takt, and pull methods. The survey contained seven questions rated on a 5-point Likert (1 = lowest level; 5 = highest level). Table 2 presents the questions, their score frequency, and their mean score. An additional item (multiple choice) was used to evaluate whether participants believed the proposed planning tool, together with its philosophy and methodology, to have contributed to other areas of their day-to-day work. The answers are shown in Figure 4.

Table 2: Questions and answers about the process of implementing collaborative planning with takt and pull zones in logistics warehouse construction

Question	Score frequency (%)					Mean
	1	2	3	4	5	
Rate your participation and use of the proposed tools	0%	0%	10.3%	33.3%	56.4%	4.46
Rate your level of understanding of lean construction	0%	2.6%	7.7%	43.6%	46.2%	4.33
Rate the improvement in your understanding of project planning	0%	0%	2.6%	33.3%	64.1%	4.62
Rate the improvement in your understanding of possible interferences between different work packages	0%	2.6%	5.1%	35.9%	56.4%	4.46
Rate the importance of takt planning for collaborative planning	0%	0%	20.5%	28.2%	51.3%	4.31
Rate the importance of pull planning for collaborative planning	0%	0%	17.9%	38.5%	43.6%	4.26
Rate the benefit of viewing warehouse, infrastructure network, and support facility plans in the same tool	0%	0%	2.6%	25.6%	71.8%	4.69

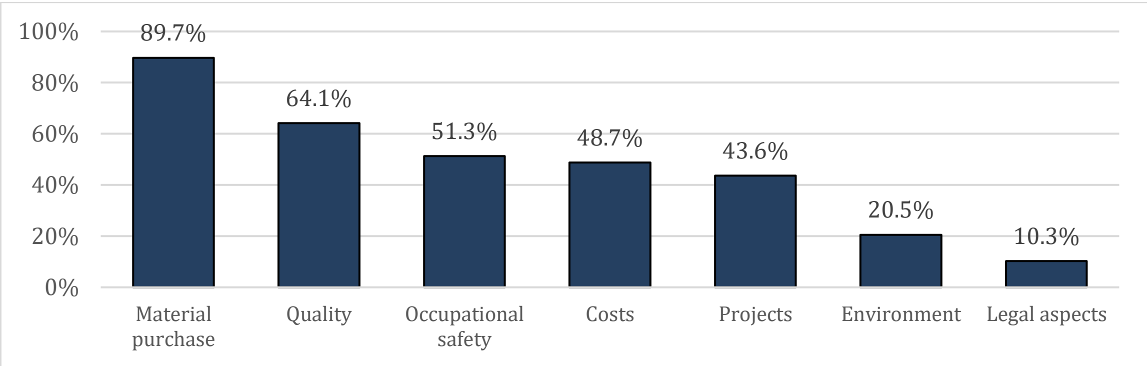

Figure 4: Areas that benefited from integrated planning, as identified by participants

The results showed that the construction team valued the planning strategy. The highest score (5) was attributed to all questions by many participants. The team reported a significant improvement in the planning and understanding of the construction project, as evidenced by question 3: 97% of participants rated the item with a score of 4 or 5. In question 4, concerning the improvement in participants' understanding of interference between work packages, 91% of respondents attributed a score of 4 or 5. The concepts of takt and pull planning were essential for the development of lean, collaborative, easy-to-understand plans. Takt and pull planning concepts were deemed very important (score of 4 or 5) by 80% and 82% of respondents, respectively. Finally, 97% of the team gave high importance (score of 4 or 5) to being able to visualize the different plans in the same visual management tool.

The majority of respondents (35 out of 39) reported improvements in material purchase with the use of integrated management plans. This assertive, visual, collaborative planning method allowed anticipating purchases and visually identifying needs when working together with other routines implemented in the project. The planning technique was also reported to improve quality and occupational safety. The importance of knowing how to identify what is needed to perform a given activity in its fullness, coupled with routines of activity monitoring, was valued by the team. Benefits to cost control were also perceived by participants. Knowing what was happening, what would happen, when, and why improved the understanding of the current situation and the possibility of obtaining better results. Regarding projects, identification of deadline dates well beforehand and their discussion with the multidisciplinary team were valued by participants. The other possible benefits were given minor importance. Therefore, it can be said that lean, takt, and pull concepts not only contributed to project management but also added value to several other areas of the construction project.

The mean scores for planning improvement criteria, represented by items 3, 4, and 7, were 4.62, 4.46, and 4.69, respectively. The overall score of the three items was 4.59, demonstrating that the team had a completely different perception about the way of thinking and executing the work. Questions regarding takt and pull planning concepts had mean scores of 4.31 and 4.26, respectively, demonstrating the importance of these concepts to the team, greatly changing the way of planning and thinking about the project. The findings confirm the importance of these planning tools for construction management.

CONCLUSIONS

Before the implementation of the integrated planning and management system based on takt and pull planning, the team used the Gantt chart as the sole planning tool. All efforts were concentrated on the warehouse, in detriment of external areas and auxiliary facilities. As a result, the company faced average delays of 3.8 months in the delivery of these additional areas after warehouse delivery. With the application of the proposed techniques, the team had a greater engagement with planning goals and metrics and there was a greater involvement of front-line actors. Participants gained understanding of the steps to be executed and greater commitment to the plan because they felt included in its development, not perceiving it as something imposed by another sector or board. The use of the LOB as a centralizing tool of information and guidance for the field team was of great value and increased the clarity of goals, constructive sequences, and future steps. Furthermore, the LOB served as a basis for the planning of medium- and short-term routines in LPS, which were developed on site for better production management and stability.

As a result of the proposed planning, the first executed project had a 4-week shorter delivery date than the previous project (12 months). This is equivalent to a reduction of 8.3% in the total project schedule. For this type of enterprise, there are three major projects occurring in parallel that need to be executed to meet the client's short deadlines. Their visualization helped improve the team's understanding of what is and should be happening on site. The concepts have been applied in other projects. Takt planning proved to be very effective for lots with similar workloads, facilitating the understanding of what was expected by teams on a daily and weekly basis. In activities that varied greatly in quantities between lots, the method did not provide good results, because their planning was not feasible. In these cases, pull planning was a good strategy to ensure compliance with the deadline, engage teams, and plan collaboratively and assertively.

The questionnaire aimed to provide insight into the perceived value and comprehension of the proposed concepts by the construction team. The results indicated an enhancement in the team's understanding of project planning. The method made it easy to understand the influence of a work front on other fronts. It improved visual management, collaboration, and understanding of subsequent steps, goals, and the required rhythm of each work front to meet the client's deadline. In addition to planning, the proposed method brought benefits to material purchase, work quality, occupational safety, cost control, and adherence to time schedules.

EXPLORING THE LIMITATIONS AND OPPORTUNITIES OF INDUSTRIALIZED CONSTRUCTION IN COLOMBIA FROM A LEAN PERSPECTIVE

William León[1], Jose Guevara[2] and Nelly García-López[3]

ABSTRACT

Despite the significant impact that industrialized construction (IC) has on the project production chain and its clear influence on productivity levels across the industry, multiple limitations hinder its suitable implementation worldwide. Existing research has identified synergies between the implementation of Lean Principles (LP) and the adequate implementation of IC processes. However, most of these studies have been carried out in markets with a high maturity and implementation levels of both IC and LP. This paper aims to explore the synergies between the implementation of LP and opportunities for improvement for the effective implementation of IC in Colombia. This article presents a qualitative analysis of twenty semi-structured interviews with construction professionals from some of the largest construction companies in Colombia. The analysis revealed that despite growing interest in applying IC by leading companies in Colombia, the current implementation of IC principles is still low. Additionally, the application of LP such as continuous improvement, variability reduction, value generation, and waste reduction are identified as key enablers for IC.

Industrialized Construction, Lean Principles, Productivity, Developing Countries, Semi-structured Interviews, and Literature Review.

INTRODUCTION

The implementation of industrialized construction (IC) has been recognized as a viable approach to enhance project performance (Andersson & Lessing, 2017). IC implementation implies a significant shift in the construction paradigm, indicating a fundamental restructuring of organizational frameworks and methods (Smith et al., 2018). Despite its benefits, the implementation and adoption of IC are still in their early stages, as the market and industry continue to pose substantial challenges (Lessing et al., 2005). In developing countries, these challenges include skilled labor shortages, rising labor costs, low productivity, and a lack of standardization. Interestingly, these issues can be mitigated through the implementation of industrialization processes (Vásquez-Hernández et al., 2022).

On the other hand, construction management literature shows that Lean Principles (LPs) allow for improved integration by fostering long-term relationships among stakeholders. This is beneficial for implementing IC, as LPs facilitate sophisticated supply chain management, simplify design for manufacturing and installation, and enable experience capture and knowledge management for continuous improvement. Consequently, an increasing body of literature recognizes that LPs offer tools that strengthen and support the implementation of IC practices (Zhou et al., 2023).

This paper aims to gain insight into the dynamics between the concepts of IC and LP in Colombia, serving as an initial reference for the maturity level in developing countries (Smith et al., 2018). The goal is to provide a preliminary diagnosis of the status of IC implementation and identify strategies that can facilitate and enhance its implementation(Vásquez-Hernández et al., 2023).

POINTS OF DEPARTURE

INDUSTRIALIZED CONSTRUCTION

Standardization of processes, mass manufacturing, and reduced unpredictability are the main goals of industrialized construction (Dave et al., 2016). This approach differs from conventional construction methods, which frequently exhibit considerable variability and depend heavily on the subjective judgment and experience of the contractor (Hairstans & Smith, 2018). Industrialized construction seeks to create a consistent production model that guarantees punctual delivery, resource stability, and quality assurance. Its objective is to integrate repeatable production cycles and transparent processes, thereby enhancing predictability and reliability in construction project planning (Ji et al., 2017).

In the construction sector, there is no universally agreed-upon definition for the term “industrialization” (Liu et al., 2019). Depending on the specific guidelines and features of construction processes, it encompasses various developmental phases and maturity levels, ranging from in-situ production systems to fully prefabricated systems (Andersson & Lessing, 2017). In the context of this research, we based our interviews on the industrialized construction framework developed by Lessing (Lessing, 2015), that views industrialized construction as a system composed of eight IC practices: planning process and control, supply chain management, technical systems development, customer focus, factory-based component manufacturing, information and communication technology utilization, performance measurement and integration of prior experiences.

LEAN PRINCIPLES

According to Koskela (Koskela et al., 2002), Lean Construction is a concept based on production theory that is crucial for the advancement of economical, sustainable, and effective practices in the Architectural Engineering and Construction (AEC) industry. This approach focuses on maximizing the final value of the building product for the client, reducing waste, and continuously improving processes to enhance management of construction projects (Koskela et al., 2002). When this concept is applied, processes become more productive, leading to increased project profitability and a reduction in wasteful practices that result in value loss for the project (Aslam et al., 2021). Consequently, LC is viewed as an essential tool for maximizing value and eliminating waste (Igwe et al., 2020).

This general definition of Lean Construction incorporates some implementation principles, such as identifying the value of the product from the customer's point of view, establishing a value chain for each product, characterizing a value stream, eliminating waste, implementing a pull workflow (Pull System), ensuring continuous process improvement, maintaining transparency, and providing training (Bajjou et al., 2019).

RESEARCH METHODOLOGY

Using a mixed methods approach, this study combines a literature survey with a qualitative analysis based on the perspectives of professionals in Colombia's construction industry. The goal is to cross-validate the interview findings with theoretical foundations of the global state of the art in IC and LP. This specific methodology was chosen because it provides a strong synergy between qualitative data gathered from ongoing project experience in Colombia and the assessment of literature that supports or explains IC behavior. It offers a thorough review of the state of continuous improvement in specific work contexts, examining constraints and obstacles from a Lean perspective. These opposing and reliable points of view make it possible to critically assess the situation and identify areas for further improvement.

Using this data, a cross-analysis of the benefits of industrialization and lean principles is conducted, with a particular emphasis on the relatively new industrialized construction sector and its unique risks and problems. In conclusion, a list of constraints and opportunities for development in the industrialized construction sector in countries with low levels of industrialized construction maturity is established.

FIRST STEP – PAPER SELECTION STRATEGY

This step involved searching the Web of Science database for relevant articles. Key ideas were extracted from the selected articles to establish a reference framework for understanding the concept of global IC and its implications for the construction process (Doerfel & Barnett, 1999). In addition to this general search, a focused investigation was carried out to identify Lean principles in the construction sector, exploring their implications, advantages, restrictions, and consequences on the production chain in construction projects. Concepts such as Lean Construction, Industrialized Construction, Last Planner System, and Productivity served as the foundation for this specific search.

SECOND STEP –INITIAL QUALITATIVE ANALYSIS

The authors adopted a qualitative approach, conducting over 20 hours of expert interviews to analyze the qualitative data. These interviews were recorded, transcribed verbatim using NVivo software, and subsequently synthesized into a coherent narrative that encapsulated the significance of LP within the realm of IC (Biygautane et al., 2019). Before conducting the interviews, interviewers explained key concepts to ensure respondents were aware of proper definitions of IC practices and LP with the aim of reducing the risk of bias or interviewer-induced partiality.

THIRD STEP – MULTICATEGORY UNIT ANALYSIS

This phase involved summarizing the data gathered from the 20 hours of interviews and initiating the process of distilling the key ideas covered (Yin, 2018). To achieve this, it was essential to identify the analytical categories with the greatest influence and generality. These categories were subject to further examination during the results discussion (Yin, 2003). According to Taylor (Taylor et al., 2011), utilizing these categories or units of analysis helps highlight key ideas, facilitating a better understanding of how IC and LP synergize in nations with low IC maturity. Key topics of discussion include efficiency, rework, information flow, productivity, and collaborative work settings. Throughout this discussion, these ideas will be referred to as units of analysis or categories.

FOURTH STEP – COMPARISON, LIMITATIONS AND OPPORTUNITIES ANALYSIS

To validate and assess the findings comparatively, data from qualitative interviews related to LP and IC are juxtaposed with an examination of relevant literature. This process involves aligning qualitative classifications and interview data with conclusions drawn from a global body of research on lean construction. Through a comparative analysis, a precise point of reference can be established to identify constraints, opportunities, and potential areas for continuous improvement in nations with low IC maturity (Yin, 2003). Figure 1 presents the methodological approach.

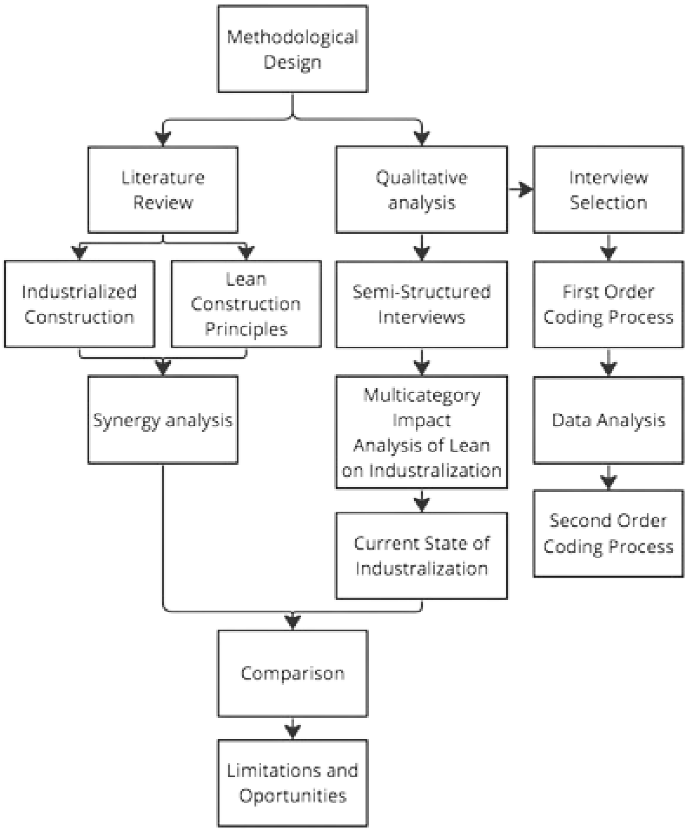

Figure 1: Methodology

RESULTS

A comprehensive profile of the respondents, including their years of experience and area of work in the construction industry, is presented in Table 1. These profiles serve as the basis for conducting semi-structured interviews, information processing, and extracting categories for analysis.

Table *1*: Interviewees

Interview	Sector	Years of experience	Field of experience
1	Design and construction execution	3	Design
2	Design and construction execution	3	Coordination
3	Design and construction execution	7	Construction
4	Design and construction execution	4	Design
5	BIM Manager	7	Model
6	BIM Manager	7	Model
7	BIM Manager	3	Coordination
8	BIM Manager	4	Coordination
9	Construction Manager	3	Construction / Industrialization
10	Construction Manager	3	Construction / Industrialization
11	Construction Manager	3	Construction / Industrialization
12	Construction Manager	4	Construction / Industrialization
13	Lean Manager	5	Productivity
14	Lean Manager	4	Processes
15	Lean Manager	3	Scheduling
16	Lean Manager	7	Scheduling
17	Project Manager	5	Productivity
18	Project Manager	5	Scheduling
19	Project Manager	5	Budget
20	Project Manager	6	Scheduling

Table 2 provides a summary of IC practices derived from the literature review, interviews, international references, and selected quotes illustrating Colombia's current adoption status.

Table *2*: IC practices

IC Practices	Literature-based description	Colombia-based description
Planning and Control	Effective management and organization throughout the design, fabrication, assembly, and other related operations are essential to achieving goals and providing customers with the best value define the concept of planning and control. (Lessing et al., 2005).	"Initiatives focused on process optimization at various stages of the project life cycle are increasingly being observed, including the early implementation stages of systems such as the Last Planner System."
Supply chain management	This concept refers to the optimization of construction activities, from the construction site to the factories where pre-assembly takes place. The aim is to improve logistics and supply management at all stages. (Erik Eriksson, 2010).	"Prefabricated building solutions can only be employed on-site with a specific number of components on specific projects."
Technical systems development	This idea involves integrating technical production systems throughout every stage of the project to enhance the quality of the final product and standardize processes. (Lessing et al., 2005).	"It is considered acceptable at present the development of technological systems focused on continuous improvement of quality and process standardization."
Customer focus	This concept refers to a managerial vision where there is a production focus based on the customer, understanding that it is necessary to ensure that products are delivered to the end consumer with the appropriate cost and quality. (Lessing et al., 2005).	"Strong connections exist between the builder and the client. Items are crafted with the customer and the market in mind."
Factory-based component manufacturing	Building components are manufactured with state-of-the-art equipment in comfortable working environments that promote efficient manufacturing (Abdel-Jaber et al., 2022).	"The construction techniques are by no means entirely prefabricated and preassembled. Most procedures are carried out on-site."
Information and communication technology utilization	This concept refers to a working structure where accurate and reliable data exist to make operations more industrialized. Current Information and Communication Technology should provide tools for effectively managing updates and revisions of digital content, along with solutions for data interchange and storage (Sacks, Koskela, et al., 2010; Sacks, Radosavljevic, et al., 2010; Sami Ur Rehman et al., 2022).	"The implementation of the Common Data Environment is progressing through many of the key stages of the construction process, alongside efficient collaborative processes."
Participant relationships	This concept refers to the development of adequate relationships among participants focused on enhanced performance and the production of effective outcomes that optimize value. Fostering sustained engagement with the processes. (Koskela et al., 2002).	"Discipline coordination is continuously improving and favoring standardization, resulting in fruitful outcomes for process optimization."
Performance measurement	This concept refers to the use and improvement of methods aimed at optimizing construction processes through industrialization strategies. (Ballard, 1993).	"It is observed that strategies for mass construction involve standardized procedures, ensuring consistency across processes, schedules, and resources."

A summary of LP based on interviews, literature review, and selected quotes illustrating Colombia's present potential for improvement is shown in Table 3.

Table *3*: Lean Principles (LP)

LP	Literature-based description	Colombia-based description
Continuous improvement	Organizational guidelines emphasizing continuous process enhancement (Koskela et al., 2019).	"The Last Planner System is being implemented alongside methodical meetings as the fundamental tools to foster an environment of continuous process improvement."
Improving flow and reducing variability	Strategies focus on controlling time deviations in the execution of activities and ensuring a continuous flow of processes (Salhab et al., 2022) (Garcia-Lopez & Fischer, 2024).	"A significant variability is observed in the execution of activities at all stages of the project life cycle."
Value generation	Long-term projects that add value for the client (Koskela et al., 2019; Sacks, Koskela, et al., 2010.	"The creation of value for the client is the foundation of project design, ensuring the production of goods suited to the market."
Waste reduction	A methodical and ongoing approach to waste reduction (Igwe et al., 2020; Womack, 1996).	"Preliminary, experience-based attempts are observed to reduce waste, but with many opportunities for improvement. There is no standardization in waste reduction practices."

In Table 4, the primary LP are listed, along with their direct impact on IC practices. These serve as instruments for continuous improvement and as means of facilitating implementation, particularly in emerging nations.

Table 4: LP and IC practices interaction

2nd-Order Codes (LP)	1st-Order Codes (IC practices)	References	Illustrative Quotes
Continuous improvement	Supply chain management	(Aslam et al., 2020, 2021; Ballard, 1993; Koskela et al., 2002, 2019)	"There is no culture of continuous process improvement or learning from past experiences. The production system and project stages are consistently developed in the same manner. A shift in the learning paradigm would facilitate the implementation of more efficient processes."
	Information and communication technology utilization	(Eastman, 2008; Sacks, Koskela, et al., 2010; Sacks, Radosavljevic, et al., 2010; Sami Ur Rehman et al., 2022; Sharma & Trivedi, 2021; L. Zhang et al., 2017)	"In terms of technology, we remain quite traditional. We don't learn from past mistakes and avoid adopting new tools due to a fear of change."

Table 4 (Continued): LP and IC practices interaction

2nd-Order Codes (LP)	1st-Order Codes (IC practices)	References	Illustrative Quotes
Improving flow and reducing variability	Planning and Control	(Chauhan et al., 2018; Gonzalez et al., 2008; Hamzeh et al., 2016a, 2016b; Kenley, 2004; Laufer et al., 1994) (Garcia-Lopez & Fischer, 2024)	"Project planning and process variability often result from inadequate information management. The absence of effective channels hinders the standardization of processes."
	Technical systems development	(Cândido et al., 2014; Pasquire & Ebbs, 2017; Tatum, 2005; Vásquez-Hernández et al., 2023; F. Zhang et al., 2019)	"There is a lack of standardization in our processes, leading to variations in execution and an inability to control uncertainty. The absence of standardized technical systems hampers productivity. It is crucial to implement standardization and eliminate variability."
	Participant relationships	(Ballesteros-Pérez et al., 2020; Fischer et al., 2021; Gonzalez et al., 2008; Lindhard et al., 2019; Poshdar et al., 2014; Salhab et al., 2022; Thomas et al., 2002; Tommelein, 1997)	"It is common to encounter information silos. Poor integration of disciplines hinders effective communication and decision-making efficiency. The flow of information is consistently disrupted, making process optimization unattainable."
Value added	Customer focus	(Freeman et al., 1991; Gomez & Rameson, 2019; Igwe et al., 2020; Kim & Ballard, 2010a, 2010b)	"I believe the current construction industry recognizes the significance of the end customer. Value creation is intricately tied to establishing a direct relationship with the client and understanding their needs and expectations."
	Factory-based component manufacturing	(Abdel-Jaber et al., 2022; Bajjou et al., 2019)	"In the context of prefabrication, significant information gaps exist. We lack effective implementation of these technologies and an understanding of their added value. There is considerable resistance to change. If viewed from the perspective of value creation, people would likely embrace these new trends more readily."
Waste reduction	Performance measurement	(Igwe et al., 2020; Maraqa et al., 2020; Womack, 1996)	"Undoubtedly, waste poses a challenge for project managers. While we are aware of its presence, finding effective ways to mitigate this problem remains elusive. Implementing active and radical measures against this issue could significantly enhance project performance."
	Planning and Control	(Chauhan et al., 2018; Gonzalez et al., 2008; Hamzeh et al., 2016a, 2016b; Kenley, 2004; Laufer et al., 1994)	"Once again, planning and time control in construction are influenced by nearly all variables. Surprisingly, the matter of waste has not been forcefully addressed as a mitigation measure. It is crucial to acknowledge the necessity of responsibly managing waste as a means to enhance the reliability of planning."

DISCUSSION

EXPLORATION OF IC MATURITY IN COLOMBIA

Based on Table 2, the maturity of IC in Colombia is still incipient in certain enumerated categories. Interview responses show that construction projects in Colombia implement many industrialization practices, but their level of development is still in early stages. The implementation of prefabrication, technology in construction systems, coordination, process standardization, and planning relationships between the developer and contractors present clear improvement opportunities for a comprehensive and efficient implementation of industrialization initiatives according to the parameters obtained from Lessing (Lessing, 2015).

As shown in Table 2 and 3, the areas with the relative highest degree of implementation are not directly related to prefabrication or the development of technical systems, as areas focused on information management, collaborative work environments, and coordination between the developer and the client demonstrate a more advanced level of development. The categories of customer focus, utilization of information and communication technology, and performance measurement reflect a more positive perception of development according to the interviewees.

Results show that the primary focus of industrialization in Colombia is on strategies that facilitate the integration of key industry players and optimize project life cycle processes and management techniques. For instance, value generation from customer integration and waste reduction within the implementation efforts associated with LPs outperforms technological implementation or prefabrication shown in Table 2. Accordingly, it is noteworthy to emphasize that, based on the semi-structured interviews, only two of the eight IC practices have reached an advanced level of maturity. Furthermore, both the literature study and the respondents' perspectives indicate that none of the four LPs discussed in this research currently effectively support the application of real-world IC in Colombia.

LIMITATIONS IN THE INDUSTRIALIZATION PROCESS

The challenges associated with performance metrics primarily involve increased overall project costs, higher early-stage expenses, and elevated technological expenditures. This includes greater economic risk, higher labor expenses, increased transportation costs, and longer timeframes during the planning and design stages. Most of these obstacles are linked to circumstances that would change if LP were implemented—essentially, focusing on value generation and continuous process improvement (Andersson & Lessing, 2017).

Furthermore, the lack of integration and process modifications are typically associated with hurdles in process flow (Qi et al., 2021). The primary causes of integration barriers include disjointed supply chains, inadequate short-term business partnerships, unsuitable project delivery models, and contracts, as well as insufficient cooperation and communication among involved parties (Ekanayake et al., 2021a). Once again, applying LP, centered on creating cooperative work environments that optimize information flow and discipline integration, could help overcome these obstacles (Ekanayake et al., 2021b). The result is that many of the IC practices may potentially benefit from the improvement of flow and reduction of variability.

Additionally, there are noted obstacles related to planning and design. A clear absence of a planning and control framework tailored to the specific market requirements is observed within these barriers (Vásquez-Hernández et al., 2023). Incompatibilities between conventional and industrialized designs are apparent, as are constraints on customization, the failure to specify or decide on the design in a timely manner, the inflexibility of applying changes to the design later, the absence of design standardization, and minimal investment in the design stage (Qi et al., 2020).

Finally, inadequate change management, low motivation, and a lack of experience, training, and knowledge in construction firms are impediments related to knowledge management. This includes a lack of process documentation, low levels of research in the industry, insufficient collaboration between academia and industry, inadequate planning capabilities, a lack of skill techniques, a shortage of skilled labor, an inability to objectively assess the benefits of industrialization, inadequate education and training, an inability to synchronize off-site and on-site activities, and a lack of prior design, on-site management, and on-site experience as some of the barriers related to knowledge, skills, and experience (Kedir & Hall, 2021).

IMPLICATIONS AND OPPORTUNITIES

This study integrates literature review with the collection of empirical information from semi-structured interviews with experts in the Colombian industry. This combined methodology helps identify fundamental LP associated with opportunities for improvement in the construction sector, fostering synergy and facilitating their proper implementation.

Results suggest that the construction industry in Colombia has embarked on a significant transition toward industrialization, but still has ample room for continuous improvement and significant opportunities for development in many IC practices. This presents significant challenges in terms of productivity, efficiency, and value generation. Therefore, the simultaneous application of LP in each of the previously analyzed categories holds great potential to expedite the implementation of industrialization and its seamless integration with construction paradigms in Colombia.

The four main LP identified in the results phase demonstrate substantial potential for improvement across the eight IC practices addressed in this study. This approach can bring about significant changes in the industry, promoting process standardization, enhancing information flow, increasing productivity, integrating multidisciplinary groups, and creating streamlined processes to accelerate the production chain. The combined impact of LP and IC practices facilitates the effective implementation of an acceptable level of maturity of industrialization in the short term in Colombia and offers a valuable pathway to accelerate efficient IC practices in other countries with a low IC maturity.

Finally, this study, structured from construction projects in Colombia, provides valuable information about the current state of industrialization in developing countries, which constitute a significant sector in global construction. This study also enables understanding of improvement opportunities in the development of industrialization in countries with initial stages of maturity. The analysis is useful to other Latin American countries with similar industrialization conditions and Lean implementation efforts.

CONCLUSION

Through semi-structured interviews and a comparison with the literature in the Scopus and Web of Science (WoS) databases, this study conducted an analysis of the influence of LP in IC practices in Colombia. Based on the results of the literature review, four LP were identified. These principles have the potential to mitigate the impact of adoption barriers by modifying critical conditions that are considered to have a high and very high impact on the adoption of IC practices in the Colombian context.

Various criteria were used to assess how much the application of LP contributed to the examples under study. First, it is observed that the identification and reduction of waste contribute to the improvement of performance metrics (cost, time, quality, and productivity), thereby mitigating the negative perception associated with unsuccessful attempts and inconsistent outcomes. Second, the reduction of information silos is associated with enhanced communication and teamwork, increased early integration, and improved phase synchronization—both between design and external production and among production, external installation, and internal processes. Third, knowledge, value creation, continuous improvement, and change management are crucial aspects. Research efforts in LP within the context of project management are particularly focused on the external production phase. A substantial body of research and the consulted experts agree that incorporating LP at an early stage enhances the adoption and implementation of IC practices in the construction industry.

There are limited studies focusing on the application of LP in both construction management and integrated design management in countries with low IC maturity. Practices aimed at reducing project fragmentation are not well-documented. However, integration-based approaches involve collaboration among project stakeholders within a phase and across different project phases. To manage their production system and associated subsystems, oversee current operations, and execute construction projects, construction companies require an integrated vision of work across disciplines. This strategy, which integrates discrete projects with continuous activities, requires different technical systems, organizational structures, procedures, and supply chains compared to traditional construction enterprises.

By examining the utilization of LP and their role in reducing adoption barriers, the current paper offers a practical contribution by identifying specific Lean strategies that can be integrated into various stages of the continuous improvement process and linking them to outcomes that modify circumstances related to adoption obstacles in IC practices implementation. These findings serve as input for transformations based on the LP, which, through process flow, knowledge management, performance enhancement, and value generation, helps reduce the uncertainty surrounding the enhanced utility perception of coordinating fitted work units compared to conventional construction practices, thereby lowering adoption barriers.

QUANTIFYING AND PLANNING CARBON EMISSIONS IN CONSTRUCTION WITH LOCATION-BASED SCHEDULING

Kristian Birch Pedersen[1], Glória Stefankovics[2], Stefan Plamenov Nachev[3], and Søren Wandahl[4]

ABSTRACT

Many countries focus on limiting greenhouse gas (GHG) emissions, such as carbon dioxide, which also impacts the construction industry. The most forward-thinking countries have already enforced regulations on the maximum allowed emission from new buildings. Regarding building lifecycle stages after EN15978, the regulations primarily target product and usage stages, neglecting construction process emissions. This oversight is concerning as material innovations reduce product emissions, shifting the need for optimization to the construction stage.

This study quantifies construction emissions, optimizing GHG during construction using the Location-Based Management System (LBMS) method. It incorporates construction-related emissions and uses a Location-Based Schedule, calculating anticipated kilowatt-hours (kWh) usage per location with data from various sources. Tested on three cases—residential building, office renovation, and medical facility—the method shows varied results based on project size, complexity, and LBMS introduction time.

Findings indicate a potential 42% CO_2 reduction in the scenario with the longest construction time. The study identifies site emission rates surpassing the 2023 limit over 30 years, underscoring the importance of comparing planned and realized schedules. Given climate regulations until 2050, the research deems the quantification method crucial for accurately addressing construction site emissions.

KEYWORDS

Location-based Management System (LBMS), Takt Planning (TP), environment, greenhouse gas emissions (GHG), planning

INTRODUCTION

The Climate Act in Denmark, where the research is conducted, aligns with the Paris Agreement's aim to limit the rise in global temperature. Denmark targets a 50-54% emission reduction by 2025, 70% by 2030, and climate neutrality by 2050. However, the building industry, responsible for approximately 39% of global greenhouse gases (GHG) (UNEIEA, 2017), is often overseen in the green transition, which poses a challenge to achieving the

ambitious targets. Historically, efforts to reduce GHG from buildings have mainly been focused on the use face, i.e., Operational Energy (OE), as it constitutes the majority of lifecycle energy use. However, in recent years, the emissions due to Embodied Energy (EE), i.e., the energy used for extraction of raw materials, processing into building materials, transportation, and on-site construction, have started to gain focus (Wandahl et al., 2021). Recognizing the slow pace of industry change, strategies and tools must be promptly discussed, tested, and implemented to meet targets concerning EE.

In 2011, the European Committee for Standardization (CEN) released a new standard for measuring the environmental sustainability of buildings. Figure 1 illustrates the diagram used for the LCA method in 'EN15978:2011 Sustainability of construction works' (CEN, 2011).

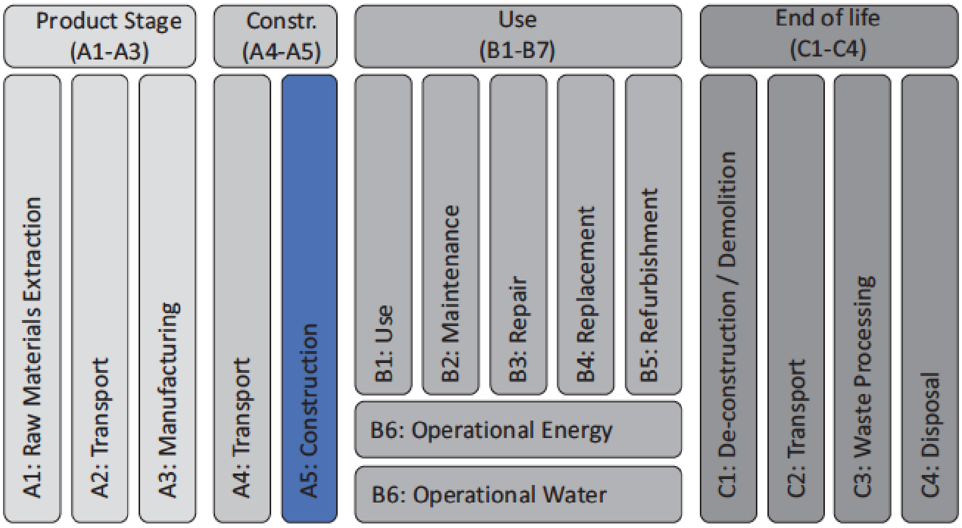

Figure 1: Life Cycle phases according to CEN (2011).

Today, many emissions arise from producing building materials (phases A1-A3), prompting a shift to more sustainable materials with lower life-cycle emissions. Architects and engineers will increasingly be responsible for proving the carbon footprint calculations, aided by tools like EC3 (CLF, 2023). Transportation emissions (phase A4) are challenging to quantify, but it is imperative to acknowledge their significance in the broader context of sustainable construction. Despite its complexities, efforts to address A4 emissions should not be sidelined. Meanwhile, energy consumption for heating, drying, lighting, and processing electricity on construction sites (phase A5) can more easily be monitored and quantified. Construction site-related emissions (phase A5) remain relatively undiscovered, studies on how scheduling can impact emissions are scarce (Lim et al., 2016), and suitable quantification tools are absent, leaving stakeholders in the dark.

This study explores how schedule changes impact energy consumption at construction sites (phase A5), caused by delays or schedule optimization using a Location-Based Management System (LBMS). Initially centered on A5 and leveraging LBMS for measurement, our research will prioritize A4 emissions in continuous sustainability assessments. This shift aims to provide a comprehensive understanding of construction-related emissions, thereby improving decision-making for sustainable practices.

Due to limited empirical data, this study relies on reports, some over five years old, using average values for analysis, making the methodology somewhat experimental.

METHOD

This paper presents a research work classified as an explorative case study (Yin, 2003). This research strategy was chosen because it enabled the present authors to investigate a phenomenon characterized by a lack of detailed preliminary research (Yin, 2003). The study's phenomenon comprises understanding how schedule changes positively or negatively affect construction site energy consumption.

As a starting point, a literature review is conducted to identify A5 energy consumption from actual cases. It is not easy to identify the necessary data, as many studies assume that the energy consumption in A5 is limited and, therefore, negligible (Hendrickson and Horvath, 2000; Lemay, 2011). In general, reported research on EE of construction is limited, and when said, it is often for the accumulated production stage only (A1 to A3) or occasionally as accumulated production and construction (A1 to A5). Very few case studies report designated A5 values, cf. Table. 1. This lack of data for A5 constitutes a critical knowledge gap in reducing lifecycle CO_2 emissions from buildings during the construction phase.

Table 1: Consumption of energy in A5 for different projects (values in kWh/m2)

Project	Heating of building (A5.1)	Drying (A5.2)	Process & lightning (A5.3)	Sum A5
DK1 – commercial (Sommer et al., 2013)	121.96	0.00	34.79	157
DK2 – commercial (Sommer et al., 2013)	12.86	67.50	24.74	105
DK3 – commercial (Sommer et al., 2013)	107.20	0.86	16.91	125
DK4 – residential (Sommer et al., 2013)	34.00	0.00	30.39	64
DK5 – commercial (Sommer et al., 2013)	154.22	17.33	25.85	197
TYR1 – residential (Bozdag & Secer, 2007)	na	na	na	148
TYR1 – residential (Bozdag & Secer, 2007)	na	na	na	159
TYR2 – residential (Bozdag & Secer, 2007)	na	na	na	143
Averages	86	17	27	130

As argued earlier, the focus of this study will be only on point phase A5. A5 can be split further into sub-groups, cf. equation 1, which are the most demanding energy sources during the construction phase - (A5.1) Heating, (A5.2) Drying, (A5.3) Lighting and Process (Sommer et al., 2013).

$$E_{construction} = E_{heating} + E_{drying} + (E_{lighting} + E_{process}) \quad (1)$$

Where:

$E_{construction}$ = Energy consumption in A5 in total [kWh/m2]

$E_{heating}$ = Energy consumption for heating of building [kWh/m2]

E_{drying} = Energy consumption for drying of building [kWh/m2]

$E_{lighting}$ = Energy consumption for lighting of the site [kWh/m2]

$E_{process}$ = Energy consumption for processes on the site [kWh/m2]

Table 1 includes five Danish cases, DK1 to DK5. For these cases, diesel-powered machines are not included, as the data is limited to machinery using on-site electricity, including lighting. Secondly, three Turkish case studies, TYR1 to TYR3, are included. In the Danish studies, the average energy consumption is 129.72 kWh/m2, while theoretical values from the early 90s suggest 150 kWh/m2 for the "Erection" phase (Bozdag & Secer, 2007), indicating a 15%

difference. Technological advancements may explain this gap, with site equipment improvements over the last 20 years. Notably, the Danish report excludes diesel-powered machinery, potentially contributing to lower numbers than the Turkish report. Despite variations, the Danish measurements align with literature expectations, justifying their use as a calculation base.

Although relevant, other aspects that impact the overall CO_2-Emission, such as changes to the project and materials, will be disregarded for this paper's focus.

As a result of exploratory work, the authors suggest 10 important parameters to estimate the base consumption factors called $C_{heating}$, C_{drying}, ($C_{lighting + process}$): The parameters are explained below:

1. **Construction period for the project.** How long does the project run for? It is relevant for calculating the number of workdays requiring lighting and construction process electricity. It is determined with the Start date of the first activity and the End date of the last activity and circled with purple below.
2. **Full construction period per location**. The start and End dates for activities within the location are used to determine operational days in the location. This is relevant to determining the days when lighting and construction process electricity will be required per location and marked with red below.
3. **Winter period definition**. Defining the Start and End date of a winter period. In this research, it is assumed to be from the 1st of October to the 31st of March.
4. **Number of winter periods**. Determining the number of winter periods during ongoing work, impacting heating energy consumption (highlighted in blue in Figure 2).

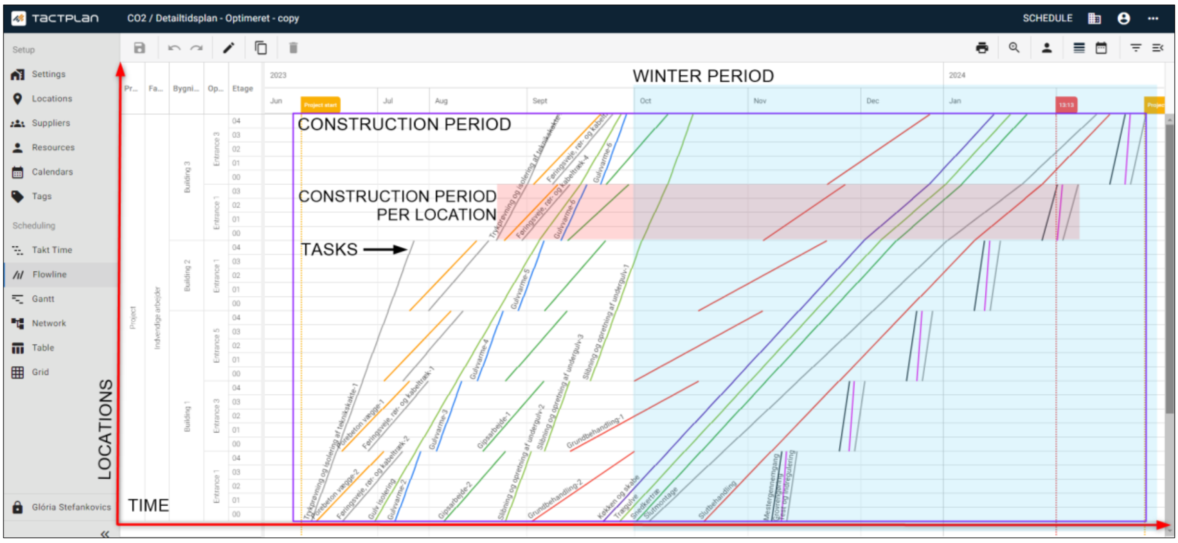

Figure 2: Location-based schedule illustrating full construction period, period per location, and winter period.

5. **Multiple construction periods within a location** – Investigating energy waste during idle periods in a location with starts and stops (marked in green in Figure 3) where no work is executed. The location must be segmented into multiple work periods to facilitate this calculation.

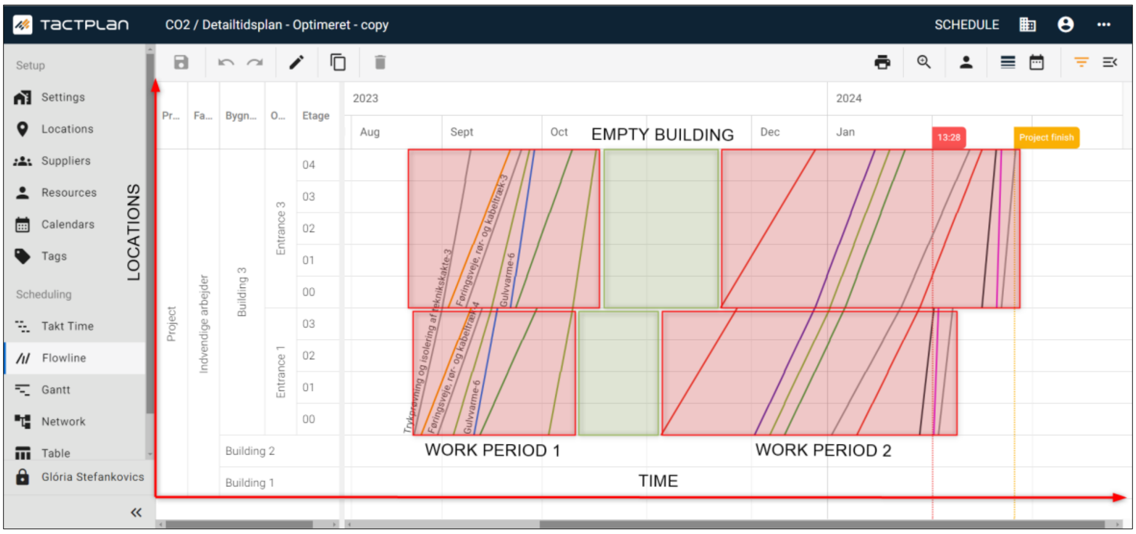

Figure 3: Possible break periods within a location during no work periods.

6. **Number of winter workdays (N_{wdays}).** Only the working days have been taken to calculate the energy consumption.
7. **Area per location (A**). The size of each location. It is essential as the base values described earlier are measured in kWh/m2.
8. **Type of heating**. Identifying the heating method employed (e.g., district heating, calorifiers). This paper and the two referenced reports utilize district heating.
9. **Type of installation**. Determining if the electricity and heating for the construction site has one common installation or if each building has its own installation. This is important because if there is a period when there is an empty building, there needs to be a method to turn off the electricity and heating for that building without stopping it for the other parts of the project. It is understood that having such installation per floor might be very complicated to achieve, so this is limited to per building within a project.
10. **$kgCO_2$/kWh produced (I)**. Based on the production method for energy, this number varies depending on the country for which the calculations are made.

With the base consumption factors (Table 1) and the relevant parameters listed above, plus the use of Tactplan (Tactplan, 2024), a software designed to streamline location-based planning, which provides a seamless workflow, enabling efficient data collection for analysis, it is possible to calculate the consumption per location. The next section will present the results based on equations 2, 3, 4, and 5 below. Other software tools, such as Vico Schedule Planner, could also have been used. However, it is important that the scheduling tool show and utilize both task and location dependencies, which makes traditional CPM/Gantt-based tools unsuitable for this method and analysis.

$$E_{heating} = N_{wdays} * A * C_{heating} \quad (2)$$

$$E_{drying} = N_{wdays} * A * C_{drying} \quad (3)$$

$$(E_{lighting} + E_{process}) = Day * A * C_{lighting +process} \quad (4)$$

$$Q = \sum E * I \quad (5)$$

$E_{heating}$ = Energy consumption for heating of building [kWh]
E_{drying} = Energy consumption for drying of building [kWh]
$E_{lighting}$ = Energy consumption for lighting of the site [kWh]
$E_{process}$ = Energy consumption for processes on the site [kWh]
N_{wdays} = Number of winter days [days]
A =Area per location [m^2]
$C_{heating}$ = Base consumption for heating of building / day =86 kWh/m^2
C_{drying} = Base consumption for drying of building / day = 17 kWh/m^2
$C_{lighting + process}$ = Base consumption for lightning and process / day = 27 kWh/m^2
Day = Construction time [days]
Q = total quantity of CO_2 emissions [$kgCO_2$]
I = CO_2 intensity of the produced electricity [$kgCO_2$/kWh]

The total energy consumption for each scenario within every case study is determined by combining the kWh usage for lighting, process energy, and heating. Heating is calculated by summing up the square meters under construction, multiplied by the number of winter days in the building period, and multiplied by the heating consumption rate in kWh/m2. Similarly, the estimate for lighting and process energy involves multiplying the number of workdays in all work periods by the square meters of the areas under construction and the lightning + process electricity consumption rate in kWh. No additional drying equipment is planned, as temperature-sensitive internal works coincide with internal heating, resulting in an E_{drying} value of 0,2, which can then be disregarded.

CASE STUDIES AND RESULTS

This research examines three real-life cases, each described with preconditions, results, and conclusions. To maintain confidentiality, project names and details are undisclosed. The cases involve different building types, introduction periods for Location-Based Scheduling (LBS), and optimization tasks, aiming to mitigate single random good results and assess outcomes without bias towards single projects with the best results. Location-Based Scheduling is today widely adopted in construction (Lerche et al., 2019) and known for its ability to optimize the schedule (Kenley & Harfield, 2015; Seppänen et al., 2010).

CASE STUDY A – 9,000 M² NEW RESIDENTIAL

The task for this project from the management team was to create a Location-Based Schedule with given constraints for resources and start and end dates.

Preconditions

The project's management team adopted LBS exclusively for internal works, with energy consumption calculations covering the period from June 14, 2023, to February 23, 2024. The case study involves three buildings with varying entrances and five floors.

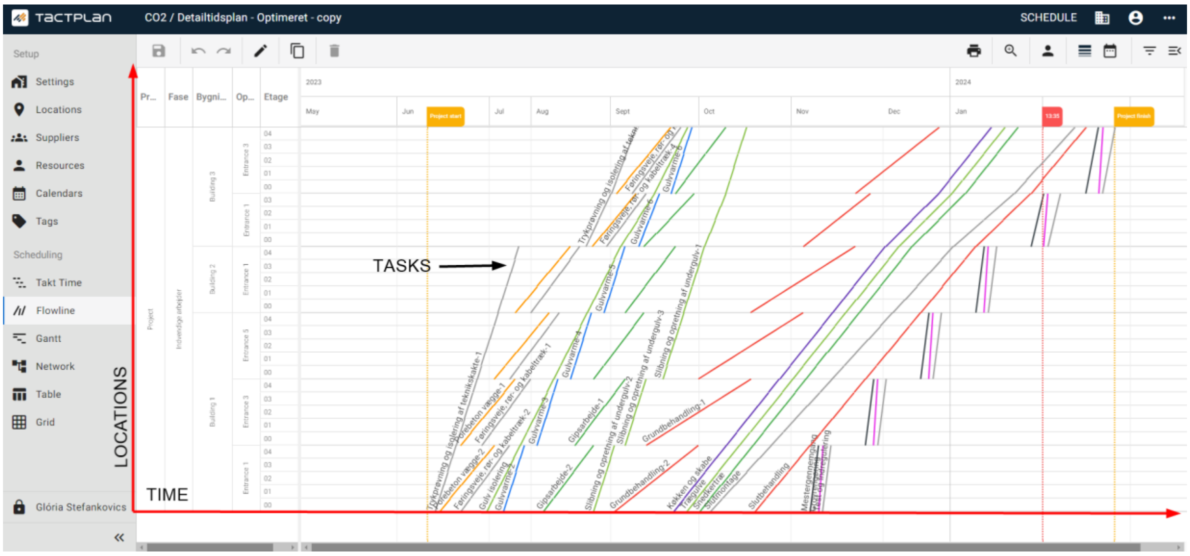

Figure 4: Schedule for Case Study A

- ***Scenario 1*** **-** Common heating and electricity installation for the entire construction site without the option to isolate empty buildings. Traditional practices involve continuous internal lighting and heating during the winter, serving as a benchmark for comparison.
- ***Scenario 2*** **-** Heating and electricity installation with the option to isolate empty buildings. Stricter emission control requires enhanced project management during construction, potentially prompting operational changes. This scenario explores optimizing heating and lighting schedules, proposing their shutdown during pauses of at least two weeks between two finish-to-start activities in the same building, as illustrated in Figure 3 (marked with green). Maintaining a minimum indoor temperature in colder climates is crucial for preventing materials from freezing or deteriorating, which could affect their quality and integrity. Completely turning off the heating could lead to issues, which could cause delays and additional costs to rectify. But continuously running heating systems during periods when no work is taking place can be costly in terms of energy consumption, so even though it is not the current practice, the point of the scenario is to see if the CO_2 emission savings justify further investigation into the feasibility of minimal or no heating strategies.
- ***Scenario 3*** **-** Shifting work to non-winter months. Results from previous cases highlight heating as a significant contributor to energy consumption. To determine potential energy savings, the project start is shifted to the first non-winter day (April 1, 2023) while maintaining other preconditions, resources, and durations, resulting in a project end date of December 5, 2024.

Case A - Conclusions

Table 2: Results for Case Study A.

Scenario 1			**Scenario 2**			**Scenario 3**		
Energy kWh	*CO_2 tons*	*CO_2 kg/m^2*year for 30 years*	*Energy kWh*	*CO_2 tons*	*CO_2 kg/m^2*year for 30 years*	*Energy kWh*	*CO_2 tons*	*CO_2 kg/m^2*year for 30 years*
219,002	36	0.161	178,454	30	0.131	68,445	11	0.050

Transitioning from traditional site operations to a more sustainable process presents an opportunity to reduce emissions. In this case study, a potential improvement of 17% is demonstrated. For shorter projects lasting less than a year, minimizing internal work during winter can result in a 69% improvement in emissions without additional effort.

CASE STUDY B – 8,000 M2 OFFICE RENOVATION

Tasked with minimizing project extension in a delayed project, the management team aimed to address significant delay costs after initial milestones. Despite having a Location Based Schedule, commissioning works at the project's end overlapped, assuming contractors could share locations during that period. However, detailed analysis revealed finish-to-start relations among various activities, hindering simultaneous execution. The initially reserved time was insufficient, leading to a 3-month project extension and a potential one-year delay.

Preconditions

Due to tight deadlines, project complexity, and continuous work, a scenario like turning off heating in inactive locations is not feasible.

- ***Scenario 1* -** Lighting + process energy usage at all times and heating usage during winter periods – 12-month delay
- ***Scenario 2* -** Lighting + process energy usage at all times and heating usage during winter periods - Optimized 3-month delay.

Case B - Conclusions

Table 3: Results for Case Study B.

Scenario 1			Scenario 2		
Energy kWh	*CO_2 tons*	*CO_2 kg/m^2*year for 30 years*	*Energy kWh*	*CO_2 tons*	*CO_2 kg/m^2*year for 30 years*
1,544,112	256	1.187	1,323,216	220	1.017

The results highlight a potential correlation between project duration and energy consumption, a logical inference given the expectation of higher energy usage in longer projects. The transparency and detailed construction process provided by LBMS underscore its importance. As regulations evolve, the need for methods to quantify the energy implications of delays is anticipated.

CASE STUDY C – 50,000 M2 NEW MEDICAL FACILITY

The project's management team initiated LBMS from the project's inception. The available information includes start and end dates for the tender schedule and actual execution, allowing for an investigation into how time impacts energy consumption and emissions in the context of delays.

This case study compares actual project end dates with the industry average delay for medical buildings. A 2022 report by the Ministry of Health in Denmark indicates an average delay of 2.3 years for 16 medical facilities. Since structural works are typically on time while delays often occur during internal works, the 2.3-year delay is proportionally added to the planned duration of interior works.

Preconditions

Due to tight deadlines, project complexity, and continuous activity, creating a similar scenario to turn off heating in inactive locations is not feasible.

- ***Scenario 1*** - Tender Schedule: Lighting + construction process electricity usage at all times and Heating usage during winter periods.
- ***Scenario 2*** – Actual Schedule: Lighting + construction process electricity usage at all times and Heating usage during winter periods. Compared to the tender schedule, there is a delay of approximately 5 months.
- ***Scenario 3*** – Theoretical industry delay (+2.3 years): Lighting + process electricity usage at all times and Heating usage during winter periods.

Case C - Conclusions

Table 4: Results for case study C.

Scenario 1			**Scenario 2**			**Scenario 3**		
Energy kWh	*CO_2 tons*	*CO_2 kg/m²* year for 30 years*	*Energy kWh*	*CO_2 tons*	*CO_2 kg/m²* year for 30 years*	*Energy kWh*	*CO_2 tons*	*CO_2 kg/m²* year for 30 years*
6,552,733	1,088	0.725	8,336,426	1,384	0.923	11,839,282	1,965	1.310

As can be seen, there is a big difference between the actual (scenario 2) and the theoretical industry delay (scenario 3), amounting to 581 tons (42%) of extra CO_2 emissions. The amount has been converted to other equivalents in Table 5 to understand better what that means.

Table 5: Conversion to illustrate the amount of CO_2 emissions.

581 tons of CO_2	274 family homes' electricity for one year
	216,044 liters of diesel consumed
	2,396,992 km driven by an average gasoline-powered car
	70,674,377 smartphones charged

The results indicate that delays significantly impact energy consumption. Complex projects with a history of overrun risk face penalties for excess emissions, further adding to the already exceeded budgets due to delays.

CURRENT LIMITATIONS OF THE METHOD

The method relies on data from reports dating five or more years back, potentially underestimating efficiency gains in energy consumption due to technological advancements. However, the developed method allows quick parameter changes, automatically adjusting results with updated information.

The challenge lies in obtaining updated, reliable data, requiring cooperation from building owners, management teams, equipment vendors, and contractors willing to track and share relevant consumption numbers. Detailed research could be pursued with the involvement of interested parties sharing information.

Such factors are: 1) kWh used for electricity on site, 2) kWh used for heating on site, 3) kWh used for warm water, 4) kWh used for heating the temporary offices, 5) kWh used for heating the changing rooms for workers, and 5) Emissions from diesel-powered heavy machinery.

Another limitation is that the calculations are made with average values from different types of projects. A better approach would be if there were an extensive library of projects where the most similar one could be chosen based on the parameters listed in Section 2. In that way, the correlation between historic projects and new estimates will be stronger. However, such reliable data currently doesn’t exist.

DISCUSSION

Based on the results across the three case studies and examined scenarios, it is evident that the quantification method applies to various situations.

What is the ratio between the emissions from Production and Use compared to Construction process emissions?

Currently, material production (phases A1 to A3) and building operation (phases B1 to B7) contribute the most to emission production (Wandahl et al., 2021).

The construction phase (phase A5) accounts for approximately 10% of GHG emissions from buildings (Klimapartnerskab, 2020). Upcoming Danish regulations targeting 12 $kgCO_2$ per m^2 per year will decrease values for materials and occupancy, the most significant contributors. As these values decrease, the attention will shift to the construction phase as a substantial area for emissions reduction demands. Notably, the 12 $kgCO_2$ per m^2 per year regulations exclude the construction process but results from case study C demonstrates a potential reduction of over 1 $kgCO_2$ per m2 per year, constituting 8% of the threshold value solely from energy consumption. This 8% could increase by including transportation and diesel-powered machinery.

Additionally, the initial threshold of 12 $kgCO_2$ per m2 per year is just a starting point. As regulations become stricter, by 2050, there will be a growing need for a quantification method for emissions produced by construction sites, along with a requirement to document A5 and reduce A5 GHG.

Possibilities for future development

More recent data

Similar to Sommer et al. (2013), new research can validate if technological advancements have reduced overall energy consumption. Comparing calculations from study cases using this quantification method with actual metered consumption on construction sites can yield more accurate conclusions.

Resources – Manning linked to energy consumption

The simplest improvement entails considering heating consumption for temporary offices and worker changing rooms. By utilizing resource counts from a graph, one can determine the necessary work crews and their areas during different project phases. This calculation method, utilizing average numbers from Table 1, becomes applicable.

Resources - Diesel-powered machinery energy consumption

Addressing the limitations, the calculations did not consider energy use and GHG from diesel-powered construction equipment. However, by creating a catalogue of commonly used heavy machinery brands and examining their technical specifications for hourly consumption, it's feasible to multiply the number of resources by their consumption and convert it to CO_2 emissions. Fossil fuels are a significant source of CO_2 emissions, and the LBMS method facilitates efficient planning for heavy machinery use. The European Rental Association's "Equipment CO_2 Calculator" (ERA, 2024) is a potential source of inspiration.

Automated calculation method integrated into software

The calculations in this research are time-consuming, done in spreadsheets, and should be integrated directly into a scheduling tool, automating the process. With an LBMS engine, the software could extract start/end dates, identify winter periods, and apply base values for heating/lighting, requiring only user input for area per location. Resources, including heating and diesel-powered machinery emission factors, should be part of any future construction schedule. Background calculations would enable rapid estimation updates with each schedule change, allowing users to evaluate the environmental impact of strategic moves in seconds.

CONCLUSIONS

Results from all study cases underscore that the primary correlation with CO_2 production is tied to duration and scale. Larger areas require more heating energy, and expansive projects often lead to longer construction periods, increasing winter periods and energy usage for heating. Given that heating is the primary energy consumer, building types prone to delays and cost overruns face a higher risk of surpassing CO_2 limits once regulations are in place.

The core reason for utilizing location-based planning methods such as Location-Based Scheduling or Takt planning (TP) in projects is to minimize the risk of time overruns, leveraging their superior overview and coordination capabilities. As also stated by (Ballard & Tommelein, 2021), when projects can be divided spatially, it is recommended to use a form of location-based planning method. Larger and more complex projects stand to gain significantly from LBMS, reducing risks in the planning phase and ensuring a healthier schedule.

LBMS enables pinpointing schedule problem areas by considering both time and location, a capability lacking in the Critical Path Method (CPM) due to its omission of task placement data. A CPM/Gantt-based schedule lacks the ability to show and optimize non-working zones which have been found critical for reducing CO_2 emissions. By highlighting location, LBMS facilitates analysis of electricity, lighting, drying, and other processes, allowing for consumption calculation based on area and time.

Another location-based method available is Takt planning (TP). This planning form is somewhat similar to LBMS apart from its rigidity, which stems from operating on fixed time intervals and relying heavily on completing preceding tasks within the allocated time frame. That is all to say, that bearing in mind the disadvantage of TP, the method could also be used to help quantify CO_2 emissions on site, as it also entails the necessary data (area and time).

In summary, optimizing schedules for time and resources doesn't necessarily equate to reduced CO_2 emissions. Sometimes, optimizing for time may inadvertently lead to increased energy consumption and emissions, particularly if activities are shifted to winter periods without prior heating plans. However, project management can make informed decisions by quantifying the impacts of schedule changes. They can evaluate the extra emissions and costs, compare them with the initial optimization, and choose between schedules aligned with milestones or delayed schedules.

SYNERGY BETWEEN LPS AND SLACK: A CASE STUDY IN BRAZILIAN HORIZONTAL HOUSING DEVELOPMENTS

João P. P Vieira[1], Bernardo M. B. S. Etges[2], Fernando P. Vasconcelos[3], Gustavo B. Bellaver[4] and Hugo R. C. Nogueira[5]

ABSTRACT

Construction projects are remarkably unique, given the specific nature in which their production processes are organized and the high levels of variability and uncertainty that permeate their entire life cycle. Several initiatives can be implemented to mitigate the effects associated with unpredictability in construction projects. The Last Planner System has emerged as a valuable tool to provide greater confidence in the planning of construction projects. Another practice that has been increasingly adopted in the sector is the use of buffers. Despite the incipient perception that buffers may be associated with waste, studies conducted in airports and logistics centers have suggested their use as a valuable ally in combating uncertainties and protecting the production system. Research also points to the combined use of buffers with pull planning to reduce the effects of variability. In view of the foregoing, this study aimed to investigate the use of slack practices together with the long-, medium-, and short-term plans of the Last Planner System. The investigation used as a reference the following classifications of time off practices mapped in the literature: Redundancy, work-in-progress and margins of manoeuvre. The research was based on a case study of Brazilian horizontal housing developments. The main finding highlights the synergy between the categories of time off practices found and the objectives established by each of the horizons of the Last Planner System. Furthermore, other dimensions of analysis, such as logistics, supplies, security, may arise due to the nature of the project typology, and the need for practices that mitigate the uncertainties inherent in the execution of these projects.

KEYWORDS

Lean Construction, slack, last planner system.

INTRODUCTION

Construction projects have a unique nature, characterized by distinct products, temporary mobilization of production teams, local production conditions, and the need to meet pre-established criteria of cost, execution time, quality, and risk (Ballard and Howell, 1998; Limmer,

2008). In addition to these factors, construction projects are commonly associated with high variability and high levels of uncertainty (Formoso et al., 2021). However, as noted by Onho (1988), the basis of a well-balanced production system lies in its stability.

In the field of construction projects, the Last Planner System (LPS) has emerged as a valuable tool to ensure that the work that should be done can be done. With LPS, it is possible to manage an inventory of available work, from which teams commit to what they will do, improving workflow and increasing the reliability of construction planning (Samad et al., 2017; Ballard 2000).

In parallel, studies have proposed the use of buffers as protection measures against variability (Fireman et al., 2022). Traditionally, buffers have been viewed as a form of waste because of the lack of a clear recognition of their potential to add value to production processes. Nevertheless, their consistent application has proved to be an important ally in combating uncertainty and increasing predictability (Horman et al., 2003).

Buffers can be defined as a set of resources implemented to protect the production system against unforeseen events, fluctuations, and delays in resource availability (Alves and Tommlein, 2003). Formoso et al. (2021) and Saurin (2017) introduced the concept of slack. Although related to the buffer approach, slack practices, in addition to addressing uncertainty aspects, contribute to meeting demands or actions at a more strategic level. Buffers are mostly recommended for dealing with random variability that can undermine production goals (Büchmann-Slorup, 2014).

Previous studies described slack as a leading element in combating variability. Fireman (2018) assessed the influence of slack on work standardization in the construction environment. Saurin et al. (2021) discussed practical applications, requirements, and consequences of using slack according to strategic orientation and resource availability.

Recent studies have explored the application of slack resources and practices in construction, focusing on large-scale projects such as airport terminals and logistics centers. The investigations aimed to establish an association between slack and LPS-based planning and control methods, particularly in the context of pull planning, to effectively manage variability (Fireman et al., 2022).

Based on the study of Fireman et al. (2022), who proposed the slack practices and resources (SPR) model, this research aims to investigate the use of slack concepts and their consonance with LPS practices for reducing variability and protecting production systems in the context of horizontal housing developments in Central-Western Brazil.

SLACK

Lean construction focuses on minimizing non-transformative steps (waiting, inspection, handling), especially through reduction of variability (Koskela, 2000). As pointed out by Hopp and Spearman (1996), variability is defined as the lack of uniformity of a class of entities, which can be random (equipment downtime) or systematically observed in a given system (product diversity).

The literature contains some discussions on the subject. Ballard (2001) discussed the impacts of slack on cycle times, underscoring gains in reliability and, consequently, reduced variability. Saurin et al. (2013), in studying guidelines for managing complex systems, noted that slack contributes to absorbing the impacts of variability. Slack can take various forms, such as redundant equipment, underutilized space, excess labor, and time margins; however, it may potentially mask problems and obscure system inefficiencies.

The role of slack practices in supporting organizations to deal with variability has been discussed and associated with different managerial processes (Fireman et al., 2022). Saurin and Werle (2017), in a literature review, analyzed slack in sociotechnical systems and proposed a structured framework to better understand slack practices, their uses, and categories (Table 1).

Based on the framework of Saurin and Werle (2017), Fireman et al. (2022) investigated how slack practices and/or resources can be used in production planning, demonstrating their positive effects in mitigating variability at different hierarchical levels (long-, medium-, and short-term planning).

LPS

LPS improves the reliability of activities in the short term, functioning as a shield against variability in planned work and promoting workforce engagement through increased collaboration of the work teams that integrate the decision process (Ballard, 1994). In LPS, planning is structured on three levels. At the lowest level, what will be done is the result of the planning process that best aligns what should be executed (planned) with what is possible to be executed based on constraints imposed by the scenario (Ballard, 1994). The medium-term plan (six-week look-ahead) determines the path to achieve these objectives, identifying and removing constraints and ensuring that resources (materials, information, and equipment) are available for task execution (Ballard, 1994). The master plan focuses on global objectives and constraints, addressing the project as a whole and describing what should be done.

Table 1: Slack practices (Saurin and Werle, 2017)

Practice	Definition	Subcategory	Definition
Redundancy	Resources in addition to the minimum necessary to perform a function (Nonaka, 1990) or more than one resource performing the required function (Azadeh et al., 2016).	Standby	The redundant resource is not immediately involved in the task at hand, and is typically not present in the operator's immediate environment (Clarke, 2005).
		Active resource	The redundant resource is involved in the task at hand (Clarke, 2005).
		Redundant procedures	Redundant checks are made to detect failures, usually involving different professionals and types of inspection (Ong and Coeira, 2010) and alternative procedures to execute an activity (Saurin and Werle, 2017).
Work-in-progress	Resources waiting to be processed in between process steps and stages.	Simultaneous work zones	Number of simultaneous work zones in a construction site. They offer alternative activities to keep the teams busy in case of temporary stoppages in one or more work zones (Bashford et al., 2003; Sacks et al., 2010).
		Stock of materials	Stocks of semi-processed products, raw materials, and finished products (Saurin and Werle, 2017). The latter two types are interpreted here from an expanded view of work-in-progress (i.e., raw materials are waiting to be processed, whereas finished products are waiting to be delivered to customers).
Margins of maneuver	Practices that create or maintain margins that allow the system to function despite unexpected demands (Saurin and Werle, 2017).	Defensive practices	Practices that create or maintain margins that allow the system to function despite unexpected demands (Saurin and Werle, 2017).
		Autonomous practices	Practices restricting other units' actions or borrowing other units' margin (Stephens et al., 2011).
		Coordinated practices	Practices that recognize or create a common-pool resource from which two or more units can draw (Stephens et al., 2011), such as multifunctional workers or general-purpose machines (Fireman et al., 2018).

RESEARCH METHOD

METHOD DESCRIPTION

Certain factors must be considered when selecting the research strategy. These include the type of research question, the extent of control the researcher has over events, and the emphasis on historical or contemporary events (Yin, 2003). According to Yin (2003), a case study approach is recommended for research with exploratory characteristics or descriptive aspects in a real and contemporary context. It should be noted that this research method has some inherent limitations regarding result generalization, as its focus lies on seeking an analytical understanding and interpreting facts within the studied context (Costa, 2010). This study aims to understand how slack practices and resources are applied in the context of horizontal housing developments. Thus, a case study approach aligns well with the research theme.

The data were collected by an auxiliary researcher, who acted as a consultant in the studied project. The company where the study was carried out had no previous experience with LPS. The consultant provided guidance on the development of long-, medium-, and short-term plans, logistics plans, and control routines and offered training and workshops for indirect workers. The consultant's role in the project was not that of a decision-maker; rather, the role focused on ensuring the implementation of core LPS practices and facilitating the identification of waste during planning phases. The consultant remained in the project for approximately 9 months, being 4 months for the development of long-term and logistics plans and 5 months for the formulation of medium- and short-term work routines.

The content of this study is divided into four parts: (i) a brief contextualization of the theme, (ii) a description of the chosen company and its characteristics in the context of lean implementation, (iii) an overview of the data collection process and the researchers' contributions to the project, and (iv) a presentation of the findings from the case study.

THE SELECTED COMPANY AND CONSTRUCTION PROJECT

The research was conducted in a Brazilian construction company founded in 1986. The company specializes in residential civil construction, specifically in medium- and high-end buildings and horizontal developments (residential lots) (Figure 1). The company has launched 37 projects, resulting in the construction of 22 million m^2 over its 35 years of history. Recently, the company has expanded its operations to include house construction projects.

Figure 1: Illustrative image of the horizontal housing project (source: the authors)

The project selected for the case study is a horizontal housing development with 626 units and 37,000 m^2 built. The project has a total duration of 25 months, starting in October 2022 and predicted for completion in December 2024.

DATA COLLECTION

The data used in the research were acquired by the auxiliary researcher during the consulting process of the study project. The data sources included documents generated in the period and participant and non-participant observations. There were no major difficulties in data collection, as the consultant had direct access to project plans, control documents, and work routines.

The **analyzed documents** included long-, medium-, and short-term plans; minutes of meeting with contractors; logistics plans, including site layout and zoning studies of inventory areas and equipment; constraints identified in weekly meetings for medium-term planning; weekly plan spreadsheets and daily monitoring spreadsheets of production leaders' goals.

Participant observations were conducted by the consultant, who integrated the planning team responsible for drafting all stages of long-term and logistics plans for the project. Although actively engaged in discussions, the consultant lacked decision-making authority. The consultant also took part in about 20 medium-term planning meetings addressing issues related to the construction staff and support sectors, and participated in approximately 60 daily meetings for monitoring weekly goals.

Non-participant observations were carried out weekly during visits to the site. These observations involved monitoring practical aspects in progress, such as instances when a supplier truck was used to transport material kits. Observations also included reviewing documents produced during the consultant's absence. Of note, the consultant did not partake in all short-term planning meetings where weekly goals were defined.

From this, the time off practices consolidated by Fireman et al. were used as a reference. (2022) seeking to identify the action, map the practice of time off and classify the variability and resources involved.

RESULTS

LEAN IMPLEMENTATION

The lean implementation process began in April 2022 with the structuring of the long-term strategy and logistics plan for a single project. Lean planning introduced the concept of work packages, whereby it is possible to create work scenarios that take into account pace variations, activity durations, and labor histograms. A total of five scenarios were created, with participation of about 15 professionals from Operations, Planning, Budget, Projects, and Strategy departments. The company's top management ultimately chose the optimum version in terms of time and cost.

Scenarios were generated using the time path tool in zoomed view and the line balance tool in the most detailed version. Each version incorporated variations in productivity based on the rainy periods of the city. The site is situated in a region prone to intense rainy periods lasting up to 5 months per year. This reduction in productivity was subsequently transformed into time spaces between work packages. At this point, the first slack was identified, categorized as redundancy (standby).

After the long-term plan was developed, the next step was to promote the diffusion of lean concepts within the organization and create work planning and monitoring routines. LPS served as the basis for unfolding the masterplan into medium-term, short-term, and daily routines. Medium-term routines involved collaborative planning with the company's support sectors, with goals and restrictions defined over an 8-week horizon. Short-term routines, referring both to weekly schedules and daily hurdles for goal monitoring, were prepared by the production team together with outsourcing labor supervisors.

An important component of the work planning routines was the inclusion of work logistics as an essential part of the production process. Given that the project is a horizontal development, the logistics of supplying work fronts played a key role in ensuring productivity. The horizontal displacement of production leaders was physically demanding, making it challenging to effectively manage materials and staff across all fronts. Therefore, logistics leaders were involved in the formulation of medium-term plans, weekly work planning routines, and daily monitoring routines.

Currently, lean implementation has become a significant pillar within the company's restructuring process. Placed under the coordination of the planning sector, it encompasses all five ongoing projects of the company and is centered on reducing variability, enhancing the stability of the production system, and meeting deadlines.

CASE STUDY

The study included team members who had participated in the project since the development of the long-term plan. The production manager, production engineer, engineer, and planning assistant and logistics coordinator also participated in this study. Therefore, it can be said that the team was highly qualified to identify and evaluate opportunities for slack practices in all planning horizons (long, medium, and short term) and the logistics of the project.

The key element of medium- and short-term planning was work packages. All work fronts were designed to allow observation of package evolution, as well as supply and kitification routines. This view was essential for decision-making by site managers when identifying priorities and points to be strengthened in day-to-day management.

Thus, in this research, the analysis was segmented into LPS horizons, namely long, medium, and short terms. Furthermore, a separate analysis was carried out for on-site logistics, given the importance of its integration with planning.

LONG-TERM PLANNING

Long-term breaks were mainly associated with periods of intense rainfall during project execution (Table 2). In this scenario, protection against time variability was achieved by the insertion of waiting times between work packages to ensure that work fronts would not be interrupted by incomplete predecessor tasks.

Table 2: Description of slack practices in long-term planning (source: the authors)

ID	Instantiations of slack practices	Slack practices	Variability tackled by slack practice	Slack resources	Unintentional consequences
1	Use of a generator to cover power shortages	Redundancy – active	Possibility of receiving more energy from the supplier	Financial	None
2	Insertion of waiting times between work packages in long-term planning	Redundancy – standby	Delays in predecessor tasks negatively affect successor tasks, delaying the schedule	Time	None
3	Worker accommodation camp larger than necessary to meet a potentially greater labor demand than initially planned in the resource histogram	Margins of maneuver – autonomous	Lack of dining area infrastructure could result in last-minute mobilization of labor	Space	Increase in worker camp infrastructure
4	Schedule final deliveries before the customer's deadline	Work-in-progress – stock of materials	Protection against unforeseen events that could influence the delivery date	Time	None
5	Project coordinator acting as the resident engineer for the training of new members	Redundancy – active	The project coordinator worked together with the resident engineer to develop technical tasks for the new team member	People	None
6	Use of productivity estimates lower than the historical average in the masterplan	Margins of maneuver – defensive	Possible low performance of the production team	People	None
7	The purchase of extra production equipment was considered in the budget to replace contractor equipment	Redundancy – active	Ensure that third-party labor does not remain idle due to equipment shortage	Equipment	Extra space for equipment storage

Aiming to protect against time variability, the planning team decided to use productivity indicators below the company's historical series, foreseeing the potential waste that would occur in these periods. In another scenario, early delivery dates were set as a goal for the production team to generate a greater sense of urgency in decision-making.

Two other slack practices were adopted by the company with the aim of (i) ensuring quick actions against time variability (e.g., by designing a worker accommodation camp with a greater capacity than that estimated by the initial labor histogram to ensure quick mobilizations, if necessary) and (ii) preventing or eliminating idleness at work fronts (e.g., by having own inventory of tools to equip third-party labor teams when they, for some reason, had a shortage of equipment).

MEDIUM-TERM PLANNING

For the medium-term horizon, slack practices were mainly characterized by production protection (Table 3). For instance, third-party labor teams were mobilized from other projects to compensate for newly integrated teams during their learning cycle.

Table 3: Description of slack practices in medium-term planning (source: the authors)

ID	Instantiations of slack practices	Slack practices	Variability tackled by slack practice	Slack resources	Unintentional consequences
1	Preemptive kit assembly	Work-in-progress – stock of materials	Delays could impact tasks requiring these resources (kits)	Materials	Increase in the area for kit storage
2	Resident engineer acting as a backup front-line production leader	Redundancy – standby	Engineer acting as production leader to compensate for the lack of front-line supervisors	People	None
3	Spare third-party teams mobilized from other worksites to support the learning curve of new teams	Redundancy – standby	Spare teams to support the possibly low productivity of new teams	People	Temporary increase in logistics demand
4	Company designer developed a formwork plan because the contract designer delayed plan delivery	Redundancy – active	A delay in plan delivery could delay the beginning of the work	People	None
5	Purchase of raw material from secondary supplier to cover delays in delivery from the main supplier	Redundancy – active	Delay in material delivery could lead to idleness on work fronts	Materials	None
6	Integration training carried out together with labor teams from other construction sites to speed up possible future mobilizations	Redundancy – standby	Delays in work tasks that would require team mobilization	People	None
7	Alteration of wooden formwork plans for columns to facilitate assembly at the work front	Margins of maneuver – autonomous	Low productivity of the carpentry team	Projects	Additional demand placed on the design team
8	Alteration of the prestressed beam layout to facilitate the assembly of electrical installations embedded in the slab	Margins of maneuver – autonomous	Low productivity of the electrical team	Projects	Additional demand placed on the design team
9	Intended accumulation of concrete tasks to achieve the minimum volume of the concrete mixer truck	Margins of maneuver – autonomous	Achieve the minimum volume for concrete delivery	Materials	None

In another situation, because of a delay in material supply by the primary supplier, the procurement team purchased materials in duplicate from another supplier to ensure that successor work packages would not be penalized by a shortage of resources. In both cases, resource redundancy was deliberate to maintain the production pace.

As a margin of maneuver and to protect production, the company's project team had unscheduled demands when a layout plan did not have sufficient efficiency in production. As a result, plans had to be revised to increase labor productivity, as was the case when column layout plans were revised to increase the productivity of carpentry teams and when layout plans for prestressed beams were revised to increase the productivity of the slab installation team.

SHORT-TERM PLANNING

Short-term breaks were taken mainly to ensure the uninterrupted flow of teams and the rhythm of work packages scheduled in weekly meetings with production leaders (Table 4). The practices categorized as margins of maneuver had greater prominence. For instance, a team of masons was allocated to a carpentry front to prevent idleness. Also for this purpose, the excavation backhoe originally used for digging infiltration wells was mobilized to the bobcat front, as the latter had to undergo unscheduled maintenance.

Table 4: Description of slack practices in short-term planning (source: the authors)

ID	Instantiations of slack practices	Slack practices	Variability tackled by slack practice	Slack resourc e-es	Un-intentional consequen-ces
1	Implement Saturday work schedules	Margins of maneuver – autonomous	Low productivity during weekdays	Time	Direct and indirect overtime costs
2	Plan alternative activities to prevent teams from idling in the event of delays in the predecessor task	Work-in-progress – simultaneous work sites	Delay in the predecessor task	People	None
3	Carpentry teams from column production fronts redirected to the slab front to offset any delays	Redundancy – standby	Carpentry teams working on columns are used as reinforcement for the slab team to compensate for delays	People	None
4	Backhoe for digging infiltration wells being used to replace work carried out by bobcat on foundations	Margins of maneuver – coordinated	Backhoe being used to replace equipment under maintenance	Equip-ment	None
5	Mobilization of a concrete truck from a third-party supplier to make up for unavailability of the company's concrete plant	Margins of maneuver – autonomous	Third-party supplier providing concrete during maintenance of the local plant	Materials	None
6	Resident engineer inspected the quality of tasks carried out after the production leader verified the service	Redundancy – redundant procedures	Tasks completed without being inspected for quality	People	None
7	Deployment of mason teams to the column carpentry service to offset delays	Margins of maneuver – coordinated	Idle workers	People	None

Slack practices were also carried out to ensure compliance with short-term goals, as noncompliance could lead to delays in medium- and long-term goals. For example, work was scheduled on Saturdays to recover goals not reached during the week. A third-party concrete mixer truck was deployed to compensate for the absence of the construction company's own truck, thereby ensuring the supply of concrete to the work fronts.

LOGISTICS

The adoption of slack practices was observed in processes depending on supply logistics, particularly margins of maneuver involving equipment used to transport materials. For example, a ¾-ton truck supplying kits was used to supply steel column starters. A backhoe digging infiltration wells was used to move earth from other work fronts.

Slack practices related to work in progress (stock of materials) were also identified. A buffer area was planned for the storage of raw materials, and material kits were delivered before the planned deadline. These slack practices were adopted to ensure that labor teams or work fronts would not run out of materials, protecting production against equipment failures and delivery of third-party raw materials (Table 5).

Table 5: Description of slack practices in construction site logistics (source: the authors)

ID	Instantiations of slack practices	Slack practices	Variability tackled by slack practice	Slack resources	Unintentional consequences
1	¾-Ton truck adapted for installation kits being used to supply steel column starter	Margins of maneuver – coordinated	Mobilization of new equipment for unloading at new work sites	Equipment	None
2	Use of supplier's pick-up truck to transport small volume materials	Margins of maneuver – autonomous	Mobilization of new equipment for unloading at new work sites	Equipment	None
3	Storage areas designed with buffer zones for the delivery of raw materials	Work-in-progress – stock of materials	Delays in the delivery of raw materials by suppliers could impact work sites	Space	Increase in the storage space for raw materials
4	Forklift adapted to assist in unloading raw materials delivered by the supplier	Margins of maneuver – autonomous	Equipment can speed up the unloading of materials from suppliers	Equipment	None
5	Workers aiding the Munck truck mobilized to the assembly of steel column starter kits	Margins of maneuver – autonomous	Support labor used in the absence of supplier labor	People	None
6	Backhoe for excavating infiltration wells allocated to moving excavated soil from other work sites	Margins of maneuver– autonomous	Equipment being used in the absence of supplier labor	Equipment	None
7	Preemptive provision of kits to work fronts to safeguard against unforeseen logistics equipment issues	Work-in-progress – stock of materials	Equipment-related unforeseen events can result in shortage of materials at work fronts	Materials	None
8	Deduct one hour when calculating the productivity of supply logistics equipment	Margins of maneuver – defensive	Possible unscheduled downtime of machines and equipment and possible low performance in meeting demands	Equipment	None
9	Construction leader verifies the number of material kits delivered and checked by the warehouse team	Redundancy – redundant procedures	Delivery of kits with missing components	Materials	None

CONCLUSIONS

This research portrayed how slack practices and resources can be used to reduce the impact of variability in the context of horizontal residential developments. On the basis of the classification proposed by Fireman et al. (2022), a case study was conducted for the identification, classification, and analysis of slack practices and resources.

The following chart shows all slack practices mapped in this study for each LPS horizon and logistics (Figure 2). The LPS production planning tool allowed structuring the analysis into three planning horizons. Horizons comprised slack practices of different natures.

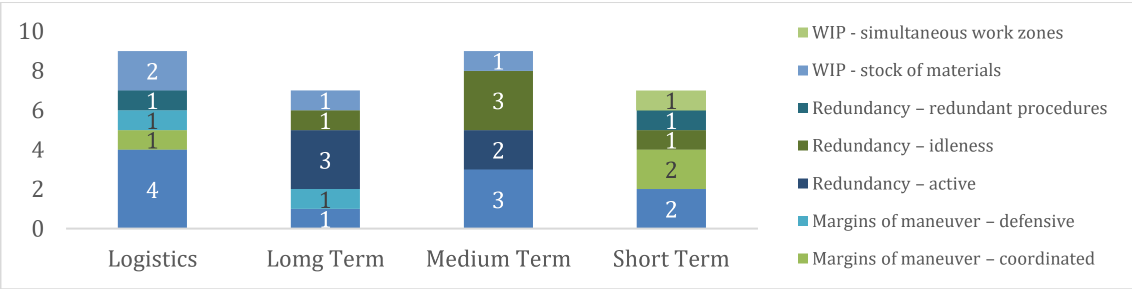

Figure 2: General distribution of slack practices mapped in this study (source: the authors)

In the long term, redundancy slack practices were the most prominent, used to ensure the continuous flow of labor teams. In this horizon, the main slack resources were time and people. The medium-term horizon was characterized by a variety of slack practices. The main practices were redundancy (active and standby) and margins for maneuver. This scenario converges directly with the main objectives of the planning horizon, as its focus is to provide greater reliability to the production system and protect production via resource availability. People and materials were the major slack resources. In the short-term horizon, autonomous and coordinated margins of maneuver were the main slack practices. This finding suggests prior alignment towards safeguarding field teams by taking immediate actions to address daily unforeseen events, avoiding the loss of short-term work packages.

Finally, according to the characteristics of the studied project, logistics was identified as a key element for the effectiveness of long-, medium-, and short-term slack practices adopted to protect production. Therefore, we conducted a more in-depth analysis of this area. There was a greater focus on the acquisition, organization, and distribution of materials and/or equipment, as evidenced by autonomous margins of maneuver and work-in-progress (stock of materials). Another concern of logistics was ensuring availability of equipment in all distribution operations. Such concern was evident by the various actions focused on optimizing equipment use in the supply of materials and inputs.

This study demonstrated how LPS and slack practices and resources interact to protect variability, and how other dimensions of analysis can arise depending on project characteristics, such as logistics, safety, and supply. The uniqueness of this case study is a limitation of the research. The stage of maturity of LPS implementation might have hindered the clarity of horizon objectives by construction teams. Furthermore, because it is an ongoing project, it was not possible to clearly evaluate the results and impacts of slack practices and resources identified in project planning.

Future research should analyze a greater number of developments with similar characteristics to gain a deeper understanding of the use of specific slack practices and resources, leading to more reliable recommendations and improved project outcomes. Furthermore, comparing these results with other similar studies can provide good considerations regarding the use of SPRs for the management of construction projects.

Additionally, there is an opportunity to investigate the infrastructure stage of the project, as our study focused solely on the housing execution phase. A quantitative/qualitative analysis of the impact of slack practices and resources should be carried out to investigate the effectiveness of actions. Finally, given that logistics played a significant role in slack practices and resources, further studies should assess their impacts on LPS horizons.

It was possible to observe that slack practices span across all LPS horizons; depending on the nature and typology of the project, other relevant horizons may arise to protect production against variability. Logistics emerged as a critical element, given the characteristics of the studied construction project and the strong influence of logistics actions on the horizons of the production system as a whole.

SCRUM'S DISTINCT ROLE DEFINITION COMPLEMENTING LPS & TAKT IMPLEMENTATION

William Power[1], Derek Sinnott[2] and Patrick Lynch[3].

ABSTRACT

LPS and Takt are lauded for their potential to transform construction's approach to planning and execution. However, more explicit specification of the roles and responsibilities of different levels of management would be helpful towards more effective functioning of the methods. Scrum offers distinct role, responsibility, and accountability definition and this paper examines the applicability of such disciplined role clarity to assist LPS and Takt implementations.

This mixed-methods research uses case study design and data from purposeful semi-structured interviews, observation, a literature review, and project documentation review from four projects in three different construction sectors.

Findings posit that the adoption of role definition of Product Owner, Scrum Master, and Developers from Scrum could bring greater clarity and effectiveness to site management team's delivery. Eliminating duplication of effort and crossover of duties allows greater focus on executing work, preparing work, and stakeholder engagement.

KEYWORDS

Lean construction, scrum, agile, last planner system, takt.

INTRODUCTION & LITERATURE REVIEW

Last Planner® System (LPS) has brought distinct change and advantage to construction delivery over the past 30 years and much research is available to showcase this (Hamzeh et al., 2008; Liu et al., 2010). In the past decade, case studies of successful Takt planning implementation have increased (Frandson et al., 2013; Binninger et al., 2017; Dlouhy et al., 2018), as well as growing interest in the application of Scrum and Agile from the software industry to aspects of construction delivery (Poudel et al., 2020; Engineer-Manriquez, 2021; Power et al., 2022).

In the 2020 LPS Benchmark, Ballard and Tommelein (2021, p.55) ask if Agile methods could enhance LPS implementation and suggest a rigorous description and evaluation of methods that fall under the Agile umbrella should be conducted to assess if they should be incorporated into future LPS Benchmarks. This paper examines role definition as espoused in Scrum and how that could address an identified gap in both LPS and Takt implementation.

Again, Ballard and Tommelein (2021, p. 54) ask if more definitive specification of the managerial roles above the crew level Last Planners would assist more effect implementation of LPS. Literature and practice fall short of clearly identifying the roles required by participants

to ensure effective implementation of both LPS and Takt. Table 1 presents how this 'gap' has been highlighted and suggestions for addressing it.

Table 1 – LPS Facilitator or Champion or Process Manager or Scrum Master or PMO [Adapted from Power et al. (2021)

Publication	Reference to the facilitation / champion / process manager / scrum master / PMO role
Thomassen, et al. (2003, p.65)	Process Manager - An organiser of collaborative planning between the subcontractors. Doesn't hold any formal management responsibilities so can focus on coaching and facilitating effective communication across project teams.
Daniel et al. (2016, p.29)	Internal Facilitator – On two case projects the LPS implementation was internally facilitated. If left to the team themselves it was felt no one would be accountable.
Daniel and Pasquire (2017, p.7)	Lean Champion and Internal Facilitator – Effective facilitation is a prerequisite for effective LPS implementation. Competent Facilitators and Lean Champions, supported with proactive Lean Leadership involvement, increases wider engagement.
Ebbs et al. (2018, p.725, 731)	External Facilitator – Senior management must encourage and support the Project / Site Manager to implement LPS and sustain the effort once the external facilitator departs the project. If the LPS Facilitator has design and / or construction experience it helps build authority and engagement.
Poudel et al. (2020, p.13)	Scrum Master – Having a person like a Scrum Master role in the LPS implementation would assist adherence to the principles and ensure consistent implementation over the duration of the project.
Power et al. (2021, p. 153)	LPS Facilitator – By introducing and ensuring a consistent weekly LPS structure, the LPS Facilitator focuses on implementing all LPS functions which contributes to higher PPC and productivity by stabilising workflow.
Power et al. (2022, p.185)	Scrum Master – The Scrum Masters coordinated the implementation of LPS and Scrum and brought an extra layer of support to site management by coordinating the daily and weekly planning process.
Riekki et al (2023, p.1187)	PMO – The success of the Takt implementation was specifically due to the leadership and enforcement provided by the PMO. If left to the team, Takt would not have contributed as much.

Despite the role definition advanced in Table 1, except for Riekki et al. (2023), it is only a singular leadership role that is being described as opposed to prescribing how a 'Team' should interact and coordinate together. Leaving implementation on the shoulders of a single 'expert' is not going to create or sustain sector wide LPS or Takt embedment. Additionally, the PMO input as described in Riekki et al. (2023) may struggle to achieve requisite voluntary internal collaboration and the implementation may become reliant on full-time PMO oversight. Riekki et al (2023, p.1189) noted the PMO mandated daily contractor attendance at the planning huddles. This emphasised the need for ownership and accountability for daily huddle implementation in Takt planning. A more distinct definition of all roles involved in deployment of LPS and Takt should be considered. Poudel et al. (2020) suggested using Scrum as a benchmark for clearly defining LPS roles and responsibilities. A brief introduction of LPS, Takt, and Scrum follows.

Last Planner System – A word search in IGLC database for 'Last Planner' shows 368 papers, therefore much literature exists to explain LPS. The key concepts of LPS are to assist with construction controlling and planning and has been extended to setting and seeking production targets for project planning and control in the 2020 Current Process Benchmark (Ballard and Tommelein, 2021). Ballard and Tommelein (2016, p.59) state that LPS addresses the high variability which causes low workflow reliability on construction projects. A critical step was to help project participants improve their commitments and to appreciate the need to deliver on what they said they would do.

Takt Planning - A word search on 'Takt' in IGLC database highlights 97 papers, indicating the increasing popularity of Takt as a production planning process in construction projects. Takt time aligns the output rates of various trades by setting a consistent pace to allow continuous workflow through pre-defined zones. It prioritises flow of work dictated by the pace of the labour crews (Frandson et al., 2013) and as well as promoting continuous workflow, Takt also seeks more reliable handoffs, and strives to enhance the design of the production system. According to Frandson et al. (2014) using LPS with Takt offers greater control and stability. Additionally, Takt's continuous planning and system design creates a steadier atmosphere for LPS implementation (Frandson et al., 2014)

Scrum - A search on 'Scrum' on the IGLC database shows only 8 papers up to IGLC 31. Even though Koskela and Howell (2002) and Owen et al. (2006) posited both LPS and Scrum had the potential to improve the coordination of construction operations, practitioner and academic focus has predominantly been on improving LPS. The Scrum Guide (2020) proposes Scrum helps teams generate value by seeking adaptive solutions to complex problems and thus is called a lightweight framework. Scrum relies on autonomous, empowered, and self-sufficient teams which can make their own decisions to progress towards their objectives. Small batches of valuable work are developed within 'sprints' of one to two weeks duration. Daily Huddles and regular demonstrations allow implementation of change if required. This restricts the chance of miscommunication or misunderstanding of where the true value lies (Sutherland, 2014; Layton et al., 2020; Engineer-Manriquez, 2021).

Construction planning - Construction's approach to planning is confined to transformation of inputs to outputs (Sacks, 2016; Daniel et al., 2020); this limits the collaborative environment needed for efficient and orderly task execution (Demir and Theis, 2016; Ballard et al., 2020). Traditional construction management falls short in the 'flow' and 'value' concepts; Daniel et al. (2020) suggests LPS and Scrum addresses these shortfalls by promoting a more collaborative environment for construction planning. A more complete construction production system is offered with LPS (short term planning, execution, and control – Koskela and Howell, 2002, p.6) and Scrum (focusing on Minimum Viable Product through Sprints – Layton et al. 2020, p.438) complementing the 'transformation' of inputs to a continuous workflow of value outcomes.

While LPS and Takt are lauded and widely publicised as having the potential to transform construction execution effectiveness, there are aspects of Agile and Scrum can also bring distinct advantages to production planning and control (Poudel et al., 2020; Power et al., 2022).

This research poses three questions to address the following hypothesis: A clearer definition of construction management team roles and responsibilities, as defined in Scrum, will assist LPS and Takt to enhance construction delivery.

RQ1 – What are the roles and tasks of construction management teams?

RQ2 – How do construction management teams perceive their roles and responsibilities?

RQ3 – How can the role definitions in Scrum benefit construction management?

METHODOLOGY

Mixed methods were adopted with case study design in accordance with Yin (2009). The first author worked as LPS Facilitator across the four projects: two residential, one commercial, and one pharmaceutical. Dissimilar roles and responsibilities were witnessed between different sectors and from project to project. This impacted the effectiveness of the LPS implementation and therefore it became important to examine the disparity in roles and responsibilities. Table 2 presents the research sequence and participants.

Table 2 - Research sequence and participants

Steps	Source	Project and Participants
1	Integrative Literature Review	Construction, Lean, Lean Construction, Agile, Scrum Literature. Scrum Guide 2022.
2	Project Documentation	LPS documentation & data; Lessons Learned; Meeting Minutes; Procurement Logs; Safety & Quality Registers.
3	Direct Observation	Direct Observation / Shadowing of Site Management personnel on 4 projects over 8 months.
4	Purposeful Interviews	Interviews with Site Management teams on four projects (4 X PMs, 4 X Superintendents, 3 X Site Supervisors). N = 11.

A mixed-methods approach was selected as both quantitative and qualitative models can complement and compensate each other's weaknesses (Steckler et al. (1992). The resulting triangulation adds to the validity of the findings (Bogdan and Biklen, 2006). In accordance with Creswell (2009) a sequential explanatory approach was adopted. The quantitative data was gathered over an 8-month observation period and the qualitative data gathering followed. The quantitative data was analysed and influenced the approach to the qualitative data gathering (Creswell et al., 2003).

Four projects across different sectors were deliberately selected to increase validity and to offer a broader perspective, as advocated by Yin (2009) and Stake (1995). The researcher visited the projects weekly over a period of 8 months and accompanied and observed site management executing their daily duties on the projects. The project managers, superintendents, site supervisors, and crew leaders were the focus of the observation. Interviews were conducted with four project managers, four site superintendents, and three supervisors from the four different projects.

FINDINGS & DISCUSSION

Table 3 takes the definition of Scrum roles from the 2020 Scrum Guide and, while maintaining Scrum terminology, proposes how these could align with current construction management roles. It is important to distinguish between a Product Owner (PO) and a Project Manager (PM). Layton et al. (2023) state the Product Owners primary job is to take care of the business side of the product or service and is responsible for maximising the value of the product resulting from the Scrum team's work (p.32). However, in traditional project management, the Project Manager carries huge responsibilities, which are broad, all inclusive, and often too much for one person to deliver effectively (p.173).

Table 3 - Scrum roles applied in construction (adapted from Scrum Guide, 2020).

Scrum title / Construction title	Responsibilities	Accountabilities
Product Owner (PO) / Project Manager (PM)	Ensures overall project progression. Owns the backlog, breaks it down, and prioritises the order and sequence. Owns Sprint Planning and Stakeholder Reviews.	Managing the product backlog. Keeping the product goal to the fore. Creating, ordering, and communicating the product backlog. Ensuring the product backlog is transparent, visible, and understood by all. Being available to the team to resolve escalated impediments.
Scrum Master (SM) / Superintendent	Connects interested parties and ensures backlog items are called into the sprint backlog. Holds daily huddles with team, tracks work progression, highlights blockers and constraints.	Coaching and mentoring team members to become self-managing. Assisting the scrum team focus on progressing highest value items to defined completion. Removal of constraints and any challenges to the scrum team's progress. Adhering to the scrum framework process while developing and improving scrum adoption. Helping the scrum team understand the need for precise product backlog items, facilitating stakeholder collaboration as requested and as needed.
Developers / Supervisor & Crew leaders, Designers, Engineers, Inspectors	Implementing effective and value-creating work methodologies that remove wasteful practices. Decides what work gets done in each sprint. Own getting the planned work completed. Demonstrate the completed work is ready for the next user.	Creating a plan for the Sprint from the Sprint backlog. Instilling quality by ensuring the definition of done is adhered to. Adapting the plan each day towards the Sprint goal. Ensuring any constraints are raised as early as possible. Holding team members accountable for progressing the plan.

RQ1 – What are the roles and tasks of construction management teams?

A Direct Observation (DO) exercise was carried out with the site management team members as they carried out their duties. Table 4 presents a collation of the observations and notes gathered from both the DO and the documentation review. This highlights that the project managers duties involved much liaison and coordination with subcontractors along with involvement in fixing day-to-day problems. A key observation was the impact of the competence and experience of the Superintendents on where the PM could focus their time. Inexperienced and less qualified Superintendents necessitated PMs to become more involved in day-to-day issues which left less bandwidth for higher level lookaheads and client liaison. The middle management role of the Superintendent finds itself pulled towards more face-to-face and day-to-day 'firefighting' and coordination of subcontractor's work. The extent of this depends on the ability of the site supervisor to execute their role and on the personality of the

PM. If the PM tends towards micromanagement and more face-to-face engagement with those executing the work, the function of the Superintendent can become confused and frustrated.

Table 4 – Current site management duties.

Project	What are management doing?		
	Project Manager	Superintendent	Site Supervisor
Project A - Residential	Upward reporting; coordinating external inputs; weekly meetings and reports.	Solving issues; uploading inspections & audits; meetings; safety & quality issues	Ensuring materials are available; ensuring next work zone was available to crews.
Project B - Commercial	Involved in day-to-day problem solving; status meetings; liaising with utility companies and external bodies.	Resolving design issues; ordering materials; responding to subcontractor queries.	Ensuring safety & quality inspections occur and any actions are closed out. Assisting crews with problems.
Project C - Residential	Coordinating subcontractors; scheduling; communicating with cost control; meetings; status reports for clients and senior leadership; Liaise with utility providers, client visits, senior management visits.	Providing inputs for reports; running production, safety, and quality meetings; managing subcontractor's work; coordinating design requests & site raised RFIs; Value Engineering exercises.	Directing crews to locations; resolving daily issues; coordinating plant and managing deliveries.
Project D - Pharmaceutical	Client liaison; reports; meetings; lookaheads; team update meetings.	Attending safety and quality briefings; meetings; liaising with design teams; signoffs.	Day to day safety, quality, and production visits and signoffs; escalating issues for resolution.

From table 4 the Superintendent role duplicates aspects of both the PM and Supervisors roles while its own key duties are unclear. Rather than having defined boundaries the Superintendents role can cross into the PM realm and cross on in some cases completely overlay the role of the Supervisor.

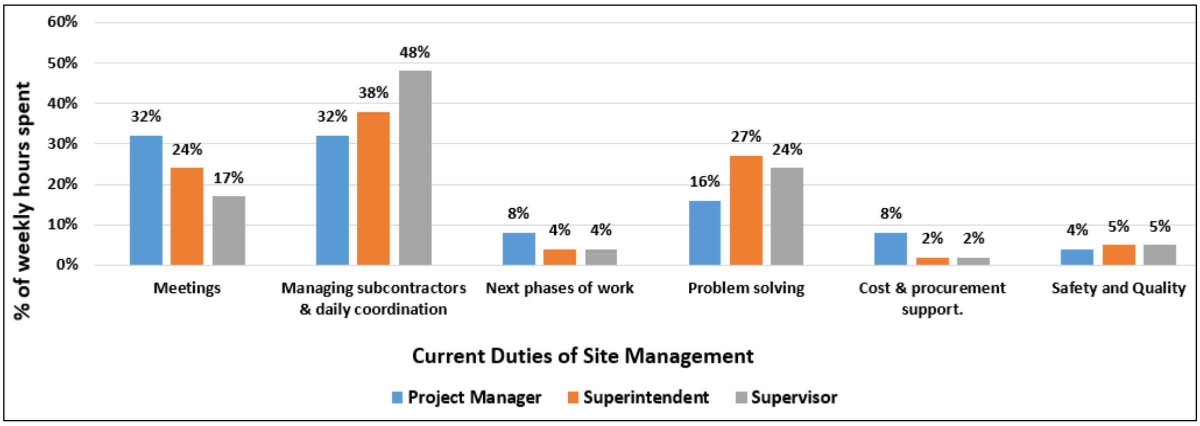

Figure 1 – Current duties of Site Management.

The Supervisor appears to be executing tasks that are helping the crews deliver their work. However, there is inconsistency in the ability of Supervisors – some are competent enough to deliver excellent management, while others are drawn to micromanagement of subcontractors to compensate for both poor contractor management and the Supervisor's own 'comfort' of being close to the work and away from management duties. Key standout points from figure 1 are the amount of time spent in meetings, managing subcontractors and daily coordination, and problem solving. Additionally, it is obvious there is duplication of effort across the PM, Superintendent, and Supervisors as all three expend a similar amount of time attending meetings, managing subcontractors and daily coordination, and problem solving.

In answering RQ 1 the research finds significant crossover of roles and responsibilities and a distinct lack of structure and definition across the levels of construction site management.

RQ2 – How do construction management teams perceive their roles and responsibilities?

After analysis of the quantitative data, semi-structured interviews were conducted with the site management team. These interviews were transcribed and merged with the themes presented in table 5.

Table 5 - Collated interview findings

Theme	Project Managers	Superintendents	Site Supervisors
Meetings	Some days are end-to-end meetings purely because the organisations mandate specific reviews must be held. Preparation and follow up takes a lot of time.	Noted that PMs almost always request Superintendents to attend the same meetings in case a specific answer is required.	Supervisors feel they have nothing to contribute to most meetings they are requested to attend. More effective communication and updates would keep them informed.
Subcontractor coordination	Subcontractors prefer to discuss issues directly with senior site management	Are involved in too much coordination with PMs reaching across them and Supervisors escalating every issue.	Are involved but are fearful of making an error as ultimately the PM or Superintendent will have the last say.
Problem solving	So many issues are escalated to PM level for resolution and verification.	Don't feel adequately empowered to decide as the PM needs to know to be aware of any impacts and may impose an alternative solution.	Will escalate every issue to Superintendent and PM level for decision. They see themselves and 'carriers' of the problems to be solved. Very little decisions are made at their level.

Analysis of table 5 and the interview texts reinforces the crossover of roles and responsibilities and the absence of structure and definition across the levels of construction site management. PMs stated they are constantly 'pulled' towards coordination and problem solving. Some stated they were 'good' at this when they were in Superintendent roles and now find it difficult to delegate responsibility and empower others to develop in the role themselves. Past relationships with subcontractors mean it is easy for subcontractor leadership to bypass other levels of site management and come directly to the PM – this adds to the workload as unforeseen issues that could have been resolved at Supervisor and Superintendent level are now burdened on the PM. This adds to frustrations at Superintendent and Supervisor level and reinforces the siloed mentality when the team should be fostering a collaborative planning environment. The absence of a visual plan of upcoming tasks means that Superintendents keep their own lookahead in their head as two stated in the interviews. None of the Superintendents or Supervisors referred to the master schedule. They noted that was the job of the project scheduler and the PM to manage the schedule. However, only two PMs referred to the schedule with two others attending a weekly meeting with the scheduler to review progress and update the schedule. In answering RQ 2 the research finds an absence of role definition and no hierarchical management structure that would keep resolution of issues at the lowest levels to protect the PMs capacity. An absence of clear responsibilities for Superintendents and Supervisors highlights underutilisation of their talent and capability. Inconsistency could be addressed with specific training to ensure standardisation of the roles.

RQ3 – How can the role definitions in Scrum benefit construction management?

From RQs 1 and 2 the following issues emerged:

- Unclear roles and responsibilities for the levels of construction management.
- No tiered work execution and impediment escalation process to filtered out issues as they rise through levels of management.
- Poor discipline around, and protection of, access to PMs time and calendar.
- Lack of standardisation of competency expectation for roles leads to gaps requiring to be filled by others in the team.
- No specific, short-term, lookahead planning process results in firefighting to resolve impending issues.

LPS and Takt bring order and structure to construction delivery. When used in conjunction with Agile and Scrum approaches there is an opportunity to create a more stable environment to assist construction teams. This stability aligns with Koskela and Howell (2002) and Owen et al. (2006) who identified the advantages Scrum and LPS brough to traditional practices.

Table 6 - Phases of Agile and Scrum, LPS, and Takt planning practices.

Agile & Scrum practices	Last Planner System	Takt
Product Goal – The goal of the initiative and how that supports the company's strategy		
Product Roadmap – Broad list of features that assist achieve the product goal.	High-level Milestone Plan.	Overall Process Analysis
Release Planning – Timescale for release of increments of value	Phase Pull Plan & 6 week lookahead.	Takt Analysis & Takt Planning
Sprint Planning – establish specific iteration goals and tasks.	Make Ready Planning & Commitment Planning	Process Planning
Sprint – fixed-length timeboxes designed so Developers can create a development rhythm.	Execute Weekly Work Plan	Weekly Work Plan
Daily Scrum – Coordinate work for the day.	Daily Huddles	
Sprint Review – demonstration of working product and receiving feedback from stakeholders.	Learning from PPC & RNC report.	
Sprint Retrospective – Team improvement of environment and processes to optimise efficiency.	Implementing improvements.	

Table 6 presents the phases of Agile and Scrum, LPS, and Takt planning practices and how they equate to each other within each method. Takt is precise, fragile, and needs LPS to support its implementation. LPS is a broader, more accommodating framework but the literature has specifically stated that better definition of the roles and responsibilities would assist improving LPS. Scrum is more general, all-encompassing, and being the least structured, can be used to manage any type of work or project. It is flexible and adaptable to almost any scale of problem.

In addressing Ballard and Tommelein's (2021, p. 54) request for clarity regarding the LPS specific or supporting roles and responsibilities of management above the crew-level Last Planners, the research presents the following role descriptions as an antidote to the current issues highlighted in RQs 1 and 2, and in research and practice. The role descriptions contribute to a more supportive management structure for LPS and Takt implementation.

Construction Scrum Master (CSM): This research proposes the Scrum Master role as the key facilitator of production in construction. They are accountable for the team's effectiveness and in construction this can be specifically measured by PPC. The critical roles can be listed as:

- Coaching the supervisors and construction crew leaders in self-management and engaging cross-functionally at crew level.
- Assisting the team define high-value releases of work that progresses the project towards the product goal.
- Facilitating and encouraging the identification of constraints / impediments to the team's progress as early as possible (includes procurement, resource, equipment, design lookaheads). Owning the removal of these constraints / impediments.
- Ensuring all weekly events take place, whether Scrum framework, LPS, or Takt; must have daily huddles, weekly planning sessions to lookahead, identify constraints, make tasks ready, agree weekly work plan, generate PPC and reasons for non-completion of tasks to promote new learning.

The Scrum Guide (2020, p.3) proposes the Scrum Master must create a working atmosphere for success where:

1. A Product Owner organises the proposed work into a Product Backlog.
2. The Scrum Team progresses through a batch of work and turns it into a value deliverable during a Sprint.
3. The Scrum Team and stakeholders review the output and consider and amendments to carry into the next Sprint.
4. Repeat.

If the equivalent role in construction is the Superintendent it therefore infers that this person holds key and pivotal accountabilities for the project's progression. The Superintendent therefore should hold the competencies and soft skills that include a deep knowledge of the construction process plus servant leadership skills to serve both the Product Owner (Project Manager) and the Developers (Supervisors and Crew leaders). The Scrum Guide (2020, p.6) adds the Scrum Master is 'accountable', 'serves', and most importantly are '…true leaders who serve the Scrum Team and the larger organisation'. This would be like the 'facilitator' role as described by Power et al. (2021, p.150) and the 'process manager' as suggested by Thomassen et al. (2003, p.65).

Construction Product Owner (CPO): It is important to remember the distinction between Product Owner and Project Manager. The construction PM role addresses many aspects of management, and we propose it additionally uses aspects of the Scrum Product Owner responsibilities to better 'serve' the Scrum Master and Developers. Critically, we require the CPO to empower the CSM and the Developers to execute their own roles and responsibilities while knowing where and when to distance themselves from the day-to-day running of construction production. Before listing the proposed CPO roles and responsibilities it is important to note that support must be available from higher management levels to ensure the CPO is not overburdened and has the capacity to serve the CSM and the Developers. In aligning with the role as defined in scrum, the CPO should focus on the 'What' and the 'When' – what value needs to be delivered by when? The critical roles are:

- Developing and communicating the Product Goal – value to be delivered, scope, schedule, budget, stakeholder management.
- Creating the Product Roadmap and Product Backlog items – project phases, execution strategy, sequencing.
- Sequencing the backlog before handing off to the CSM and Developers for refinement and execution.
- Ensure clarity around the backlog items so the value required is understood by everyone.

The CPO represents the company and stakeholders, and any scope addition can only be with the CPO's agreement. If capacity allows, the CPO can also work with the CSM and Developers, but roles and responsibilities must be clear, or all will revert to the status quo.

Construction Developer (CD): The Developers consist of the construction supervisor, design team members, quality inspectors, safety auditors, and crew supervisors. These are the Last Planners who are at the point of work planning and execution and deliver the real value on projects. It is therefore critical that those doing the work are working on the correct tasks in the correct order and that all distractions and constraints / impediments are removed to allow smooth flow of inputs. An effective CSM will facilitate this environment and the CD's will be excused from unnecessary meetings and non-value adding 'time-stealing' events – they can focus totally on production, safety, and quality. The CD's will be accountable for:

- Collaborating on building a Sprint Backlog, effectively make-ready planning and commitment planning in LPS and Process Planning as in Takt.
- Ensuring quality completions by agreement on Definition of Done.
- Reviewing and adapting daily at the Huddle to ensure focus on the Sprint Goal.
- Expecting ambitious standards and accountability from others on the Team.

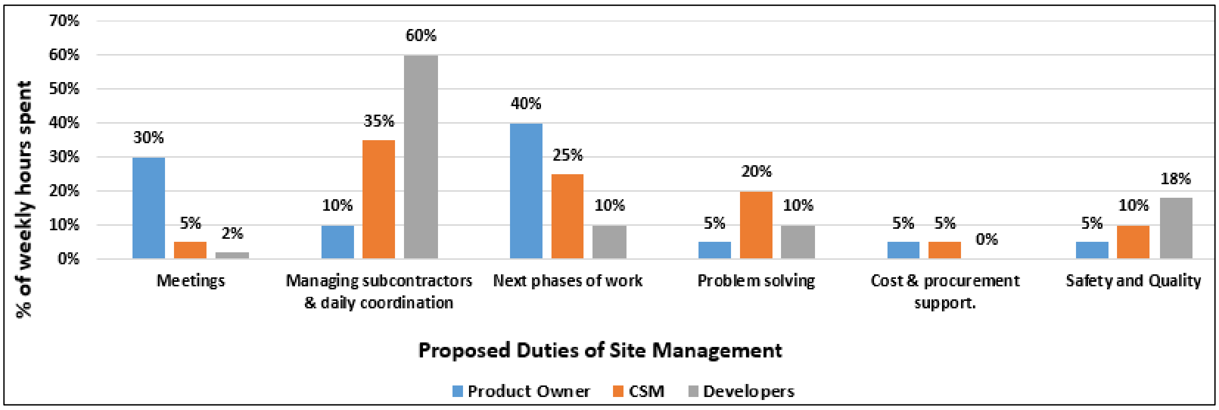

Figure 2 – Proposed duties when aligning to Scrum roles.

Figure 2 proposes how weekly duties should be reordered to allow each role focus on their highest value items. In comparison with figure 1, Project Manager equates to Product Owner, Superintendent equates to Scrum Master, and Supervisor equates to Developer. The CPO focuses on the next phases of work and ordering the backlog while shielding the CSM and Developers from unnecessary meetings. The CSM runs the weekly and monthly operations, coordinating all inputs are in place by ensuring all tasks are constraint free. The Developers execute the daily work in accordance with the weekly work plan and contribute to the look ahead planning sessions. All problem solving is kept closest to the workface if possible.

CONCLUSION & RECOMMENDATIONS

The paper demonstrates the critical role of the CSM in ensuring a flow of ready works is available for weekly execution. This differs from the ad-hoc current state of PM's and team member's planning processes and specifically addresses a gap in current LPS and Takt execution. The value add of the new role brings clarity and definition to all management teams responsibilities relating to site production planning and control. Other benefits accrue from coaching and mentoring supervisors and crew leaders, releasing the CPO / PM to shield the execution team, prioritising highest value tasks to be worked on, and provides oversight of an effective constraint identification and resolution process. Adhering to the proposed roles would bring better order and structure to the construction management team – the CPO / PM could focus on managing the project without distraction; the supervisors and crew leaders could focus on progressing through weekly lists of constraint-free tasks to be executed. Companies should develop and codify the role of the CSM allowing a pathway of career progression towards more effective CPOs. The role takes the ordered backlog from the CPO / PM and supports the Developers in executing each phase of project execution. The CPO / PM shields the CSM and Developers from all unnecessary distractions like meetings and longer-term planning.

Next steps would be the testing of this proposal on a project and to examine what findings can be brought forward to better support current LPS and Takt implementation practices.

RELATIONSHIP BETWEEN TIME SPENT IN PRODUCTION WORK ACTIVITIES AND PRODUCTION WORKSPACES.

Cristina T. Pérez.[1], Søren Wandahl[2] and Mathias Arildsen[3]

ABSTRACT

The study presented in this paper is part of an ongoing research project that addresses the absence of established procedures for automatically measuring the distribution of time workers spend on Value-adding (VA) activities. To understand the relationship between workers' time spent on VA activities and VA workspaces, the activities conducted by a carpenter trade were studied during the realization of a Case Study on a renovation building project. The carpenters were divided into three groups regarding the activities that they conducted: interior, façade, and roof activities. The authors used two sources of evidence to compare the time that workers spent in production work categories and workspaces: (1) the work sampling technique to obtain time spent in work categories and (2) smartwatches to collect time spent in different workspaces. The authors used geographic data points provided by smartwatches worn by the carpenter trade to collect their location within the job site and developed a Python script to automatically group the data points into workspaces. Correlation analysis reveals a strong correlation (R^2=0.2473) and very strong correlation (R^2=0.7886) between time spent in VA workspaces and time spent on VA activities when the workers worked on interior and exterior activities, respectively.

Workspaces, construction site, production work, value-adding work.

INTRODUCTION

Automating the activity recognition process on construction sites has been the first step in numerous studies in the last decades that aimed to automatize the Work Sampling (WS) technique. The WS technique quantifies shares of time using a set of activity categories, classified into the Lean activity categorization of Value-Adding (VA) and Non-Value-Adding (NVA) activities (Dozzi & AbouRizk, 1993). Researchers have approached the issue from different angles, from exploring the use of bodyworn sensors to applying vision- or audio-based technologies either in a laboratory setting or on-site. Some studies have combined multiple technologies, and most use machine learning algorithms to analyze and classify data (Pérez et al., 2023).

Most of the papers found in the literature are part of a long-term research project conducted by researchers from the Indian Institute of Technology Madras (Joshua & Varghese, 2010, 2011, 2013, 2014). Joshua and Varghese conducted a series of studies focusing on recognizing masonry work activities using bodyworn accelerometers. Accelerometers measure acceleration, which in practical terms means human changes in speed or direction. These data streams are

collected from sensors, for instance, inertial measurement units (Jacobsen et al. 2023). The first study (Joshua & Varghese, 2010) involved a subject posing as a mason performing instructed activities in a lab environment. Encouraging results led to an expanded study, where a mason performed productive tasks in both an instructed and uninstructed data collection mode. The accelerometer data patterns were observed to be repetitive and distinct for a particular class of activity, and supervised classifiers – in particular, neural network classifiers – confirmed a significant potential to classify masons' productive work activities using accelerometer data. This potential was then tested in a field situation studying iron workers and carpenters (Joshua & Varghese, 2014). The results showed a better classifying performance of iron worker activities than of carpentry, with an overall classification accuracy obtained for iron workers of 90.07% and for carpenters 77.74%.

Another approach was studied by Akhavian and Behzadan (2016), who used smartphones secured with a band on workers' upper arms to identify different construction tasks such as hammering and handling a wheelbarrow. Data from the built-in accelerometer and gyroscope in the smartphones were then analyzed through supervised machine learning algorithms to identify when workers were performing an activity and when they were being idle, achieving an accuracy of up to 97%.

Researchers from the Finnish University of Aalto (Görsch et al., 2022; Zhao et al., 2019) have explored the use of different technologies to track indoor workers' location and associate the positions with Direct Work (DW) or Indirect Work (ID) activities. Zhao et al. (2019) applied various tracking device placement strategies in three different cases to explore coverage and accuracy. Results showed that it is possible to obtain a real-time presence index using Bluetooth Low Energy (BLE) on construction sites when paired with heuristic rules, and suggested that uninterrupted presence is strongly correlated with time spent on VA activities. Görsch et al. (2022) continued this work through carrying out a time-motion study, combining the video data from head-mounted cameras and location data from indoor positioning BLE technology to understand the time spent in VA work when uninterrupted presence is detected by indoor positioning. However, the classification of the activities into DW, IW, and Waste Work (WW) was conducted manually based on the analysis of the recorded video.

Overall, it is evident that digital approaches to automizing the WS process have shown great potential, and this potential will increase as technology develops. In general, the literature review points to the existence of two approaches primarily used for activity recognition: sensor-based and video-based technologies. However, a significant limitation of both approaches exists in the data labelling process. Researchers need to select and classify a limited number of activities. Those activities are mainly associated with the specific activities of the construction process that the participants are doing (e.g., sawing, hammering, etc.) rather than a more generic classification into DW, ID or WW. In most cases, the activities are manually classified or classified using machine learning tools.

The literature about video-based technologies reveals that these technologies are based on monocular cameras or stereo cameras. Vision-based tracking of workers refers to retrieving the worker trajectories from recorded videos, which is a fundamental step for activity recognition (Jacobsen et al. 2023). In most of the studies, video annotation was used as an additional source of evidence to compare the results obtained from the sensors rather than using deep learning detection methods.

Lastly, these studies were applied on a reduced number of workers, involving between one and ten workers at maximum. In some cases, the subjects were academic participants simulating construction workers' activities in laboratories. So, the actual application on job sites and how practitioners could adopt the technologies have yet to be explored.

Regarding the studies that adopted tracking systems, they were conducted exclusively inside buildings. Other workspaces, such as material storage areas, transportation paths, and preparation workspaces, were not taken into consideration. So, these studies are limited to classifying work activities conducted in the production workspaces, avoiding the rest of job site areas.

In conclusion, there are currently three research gaps in the published studies concerning automation of the WS technique: (1) sensor-based technologies are limited to identify direct work activities previously labeled; (2) the activity recognition has mainly been conducted in delimited training areas; and (3) the studies were conducted with a limited number of participants, in most of the cases, subjects simulating workers' activities. Thus, a novel approach for automating WS is needed in job sites to deal with the abovementioned challenges based on indirect measurements.

To further investigate the possibilities of using sensor-based technologies in the construction industry to gain a better understanding of how workers spend their time, it was chosen to use smartwatches with Global Positioning System (GPS) sensors for the investigation. By using a GPS-signal the presence of the workers can be determined, which will give an insight into the workers presence at a construction site. Therefore, the following research question has been created to investigate the phenomenon:

- What is the possible relationship between the time spent in value-adding work found and the time in value-adding workspaces?

To address this question, the authors conducted a case study on a renovation project.

RESEARCH METHODOLOGY

The present paper adopts a Case Study (Yin, 2003) as the primary research method. The phenomenon of the study comprised construction workers' activities and locations. The real-life context is represented by the building project studied. The Case Study was carried out on a construction site in Fredericia, Denmark. The project studied is a social housing project consisting of 84 single-story apartments and a common house that are undergoing renovation. The apartments are divided into blocks, where there are three to six apartments in each block. The apartments were built in 1955 and the total building area is 8.600 m2. Ten of the blocks were under renovation when the data collection occurred. The focus of the data collection was on the carpenter trade. Their work consisted of internal and external activities in and around apartment blocks. The exterior work consisted of renovating the facade and roof.

The Case Study was conducted in week 9 and 10 in 2023. Data was collected for 10 workdays, where a full workday for the carpenters was from 06:30 to either 15:00 or 15:30. The carpenter observed mainly designed to perform three kinds of activities (Figure 1): (1) interior walls and ceilings; (2) façade; and (3) roof activities.

a b c

Figure 1: Carpenter main activities studied: (a) interior; (b) façade; and (c) roof activities

The authors used two sources of evidence to compare the time that workers spent in work categories and workspaces, those being (Figure 2): (1) the work sampling technique to obtain time spent in work categories and (2) smartwatches to collect time spent in different workspaces.

Activities	Collecting time in work categories	Collecting time in workspaces
Source of evidence/tool	Work Sampling Technique	Smartwatches
Steps	1) clarifying the work activities; 2) developing forms; 3) data collection; 4) deciding the accuracy desired; 5) data analysis.	1) clarifying the workspace categories; 2) data collection; 3) data extraction, aggregation and cleaning; 4) data classification and 5) data analysis.
Output	Time spent in Production work activities	Time spent in Production Workspaces
Analysis	Correlation analysis

COLLECTING TIME SPENT IN WORK CATEGORIES

In this research, the WS procedure consisted of five steps previously developed by the present research team (Salling et al., 2022). The authors adopted that procedure to keep consistent with previous WS studies as part of a long-term research project. The steps are: (1) clarifying the categories of the activities to be measured; (2) developing data collection forms; (3) data collection; (4) deciding the confidence interval and the accuracy desired and calculating the number of observations needed; and (5) data analysis. Due to length limitations, this research methodology section will focus on describing steps 1 and 3. The other steps present the same structure as described in Salling et al. (2022).

During Step 1 – Clarifying the work categories, the authors classified the activities of the carpenter trade observed on the job site during the first day of job site visits, named as Day 0. In this study, a six-work categories classification was adopted, those are: (1) production; (2) talking; (3) preparation; (4) transportation; (5) walking; and (6) waiting.

During Step 3 – Data collection, the observations were made from the start of the carpenter's workday until the end (Figure 3a). The observations were collected in a general way in all the carpenters called "All activities" in Figure 3b. In addition, specific observations were made in three groups of workers. A stabilization curve of the share of observations of the production observation was created to provide a visual check of the accuracy of the collected data. The curve stabilizes at 28% after around 500 observations. Upon completion of ten days of data collection, a total of 1,661 samples (n) were recorded and distributed: 437 observations for the interior; 568 observations for the façade, and 663 observations in the roof activities.

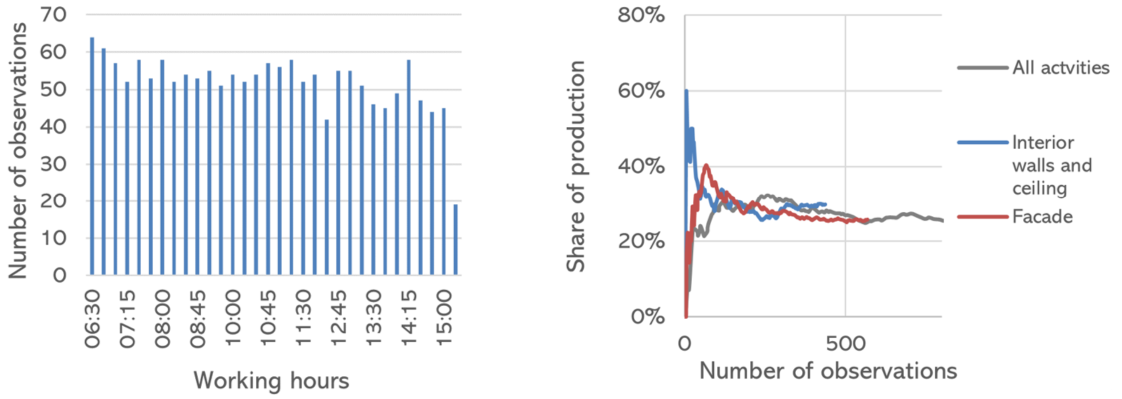

Figure 3: Sample characterization: (a) Distribution throughout the day; (b) curve stabilization.

COLLECTING TIME SPENT IN WORKSPACES

The procedure to collect the time spent in workspaces was previously proposed by the Pérez et al. (2022). The same procedure was adopted in this Case Study, which presents five steps: (1) clarifying the workspace categories; (2) data collection; (3) data extraction, aggregation and cleaning; (4) data classification and (5) data analysis.

Step 1: Clarifying The Workspace Categories

This study adopted a five-workspace categories classification for diving the job site (Figure 4), those being: (1) production; (2) preparation; (3) transportation; (4) storage; and (5) containers. It was chosen to consider all apartment blocks production workspace because the carpenters will only be able to perform VA work there. Since there is work being done on the facade it was chosen to extend the production zone one metre out from the building, so they also had some space to roam around in for their productive activities. The existing roads of the construction site were set to a transport workspace because the carpenters will be mainly transporting material and walking. The remaining zones of the construction site are the storage and container zones. The container zone is used for the breaks of the carpenters. The storage contained most of the tools and materials.

The classification of the job site areas into those five workspace categories used as an assumption that each zone has one single main purpose. For example, the storage workspace is mainly destined for storing material; however, talking and walking activities can be conducted in that area. A similar assumption can be made for the production workspace. The purpose of that area is to do VA activities. The behavior of the workers could not affect one of the categories of the workspace. It means the work activity conducted by the workers does not affect the purpose of the workspace.

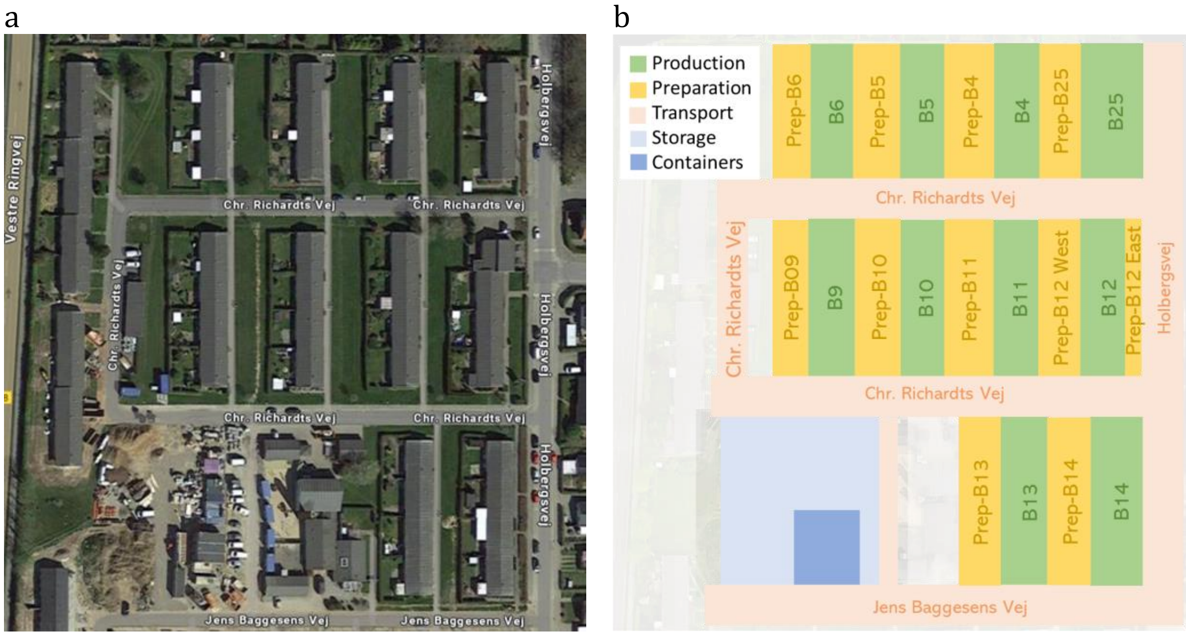

Figure 4: Jobsite (a) Aerial view; and (b) workspaces division into five categories

Step 2: Data Collection

To collect the time spent in the workspaces, ten carpenters were equipped with a Garmin Forerunner 255 smartwatch (named SW11 to SW20). The smartwatch collected carpenters GPS-positions throughout the day. The smartwatches collected data with a frequency of 1 to 30 seconds depending on whether they detected movement or not. Each smartwatch was marked with the carpenter's initials, so they would be wearing the same smartwatch throughout the data collection period. This allowed the authors to associate the data from each smartwatch with the activities conducted by each carpenter. The carpenters were classified into three groups according to the main activities that they conducted, those being: (1) interior walls and ceiling (SW 18 and 19); façade (SW 12, 13, 14 and 17); and roof activities (SW 15 and 20).

Step 3: Data Extraction, Aggregation and Cleaning

The data extraction consists of obtaining the datapoints collected by the smartwatches. For that, the smartwatches were collected at the end of the workday and synchronized to Garmin Connect using a USB-cable so that the data were stored for later analysis. The collected data can be exported from Garmin Connect in .gpx format (a GPS exchange file). The .gpx file is run through the "TCX converter"-program, which converts the .gpx file into a .csv-file. The .csv file is then transferred into an Excel sheet that cleans the data.

During the data aggregation, a dataset of each smartwatch for each day of collection (named SW11Day 1 to SW11Day 7) was created. The information that is stored in the .csv file is the latitudinal and longitudinal coordinates together with the time in Unix time format.

The data from the smartwatches are cleaned from breaks, which are from 09:00 to 09:30 and from 12:00 to 12:30. To clean the dataset from potential GPS errors, the following assumption have been used. If the speed travelling from two consecutive data is lower than 0,5 m/s, the worker is still standing, or higher than 1,5 m/s, the worker is running or caused by a GPS error (Pérez et al., 2022). If a datapoint exceeds these limits, the point is removed . The dataset was reduced greatly by using the speed assumptions. The datapoints still lie within the same region as can be seen in Figure 5, where the red points are the points discarded from the speed assumption and the blue points are the remaining in the dataset after the cleaning process. Most of the deleted datapoints seem to lie in a cloud around the remaining datapoints. Some of the datapoints removed are when SW18 is walking from one location to another, for example, on day 5 in Figure 5b.

Finally, it was decided to remove the first day of data collection since it does not reflect a full day of data collection. This entire data cleaning process resulted in the dataset going from a total of 414.997 raw datapoints to a total of 108.281 cleaned datapoints. The cleaned data files are transferred into a .csv-file so that the datapoints can be classified into a zone of the construction site using a Python script.

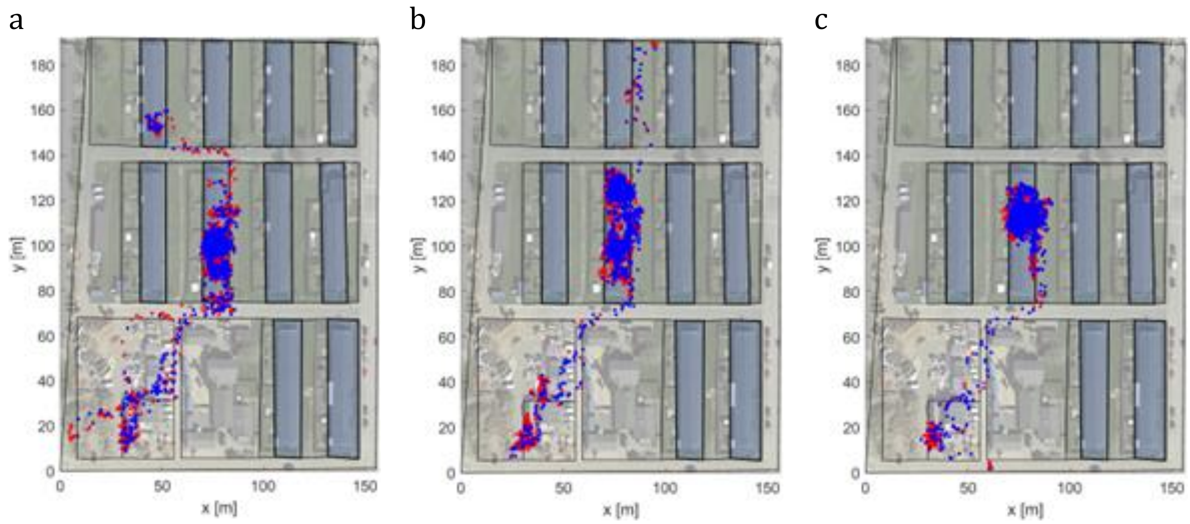

Figure 5: Data cleaned for SW18: (a) Day 5; (b) Day 6; and (c) Day7

Step 4: Data Classification

A Python script was created to sort the data points obtained by the smartwatches into the different workspaces of the job site. Python is a programming language that has many user-generated libraries, which give Python many uses and possibilities (python.org, n.d.). The script was written in Spyder version 5.1.5 which was accessed through Anaconda. The developed Python script was based on a script previously developed by the research team (Pérez et al., 2022). The developed Python script consists of nine steps: (1) Import packages i.e. numpy, pandas, shapely.geometry and matplotlib.pyplot; (2) Create a function to import the datapoints from the zones of the construction site and smartwatches; (3) Import the zones and smartwatches datapoints; (4) Create empty arrays to store the filtered datapoints; (5) Classify the datapoints into the right zones of the construction site; (6) Convert the data points into a "metric" system for the plot; (7) Plot the data points and zones; (8) Convert Unix time into a readable time stamp; and (9) Export the sorted data points into a .csv-file.

Step 5: Data analysis

The data analysis aimed to first visually present the data of time spent on work categories and time spent in workspaces to understand, compare, and validate the data. The analysis is based on three different types of work observed and monitored: (1) interior walls and ceiling; (2) façade; and (3) roof activities. Both the WS data, presenting data on time spent on work activities, and the SW data, presenting time spent in workspaces, apply to these three types of work.

Secondly, to analyze the relationship between time spent in VA workspaces and time spent on VA work activities. The data analysis aimed to test whether a possible relationship exists and is statistically significant. VA workspace is the production workspace, and VA activity is the production activity. The analysis was applied to the three types of works observed. The authors used the Statistical Package for the Social Sciences (SPSS) software for statistical analysis. This analysis was conducted as a linear regression analysis providing a linear regression and further an ANOVA analysis to reveal the statistical significance of the linear regression model's predictive capabilities. Common for the two tests are that they rely on interpreting the correlation coefficient (R). Previous recommendations (Cohen, 1988) outline that $R > 0.5$ reflects a large effect size. Research in the same area as this has previously used $R = 0.318$ as an acceptable level (Liu et al., 2011; Nevet et al., 2020; Wandal et al., 2023). Nonetheless, in this research, $R = 0.5$ is chosen as the minimum limit for accepting any relationship established through the statistical analysis. The R-value can be squared (R^2) to reflect the predictive capabilities of the independent variable in the analysis instead. The R^2 value corresponding to $R = 0.5$ is 0.25; thus, $R^2 = 0.25$ is the lower acceptance limit.

RESULTS AND DISCUSSION

The findings are divided into three main parts. First, the results from the WS application are presented regarding the kind of work conducted by the carpenter. Second, the smartwatch results concerning the location of workers in the different workspaces are analyzed. The last part comprises the comparison analysis considering the WS observations and the location data.

WORK TIME SPENT IN WORK CATEGORIES

The distribution of time spent into work categories is illustrated in Figure 6. The total number of observations (n=437) on the carpenters doing interior walls and ceiling activities are distributed with 30% on production, 16% on talking, 28% on preparation, 13% on transport, 12% on walking, and 1% on waiting. Those numbers are similar to the distribution obtained for the roofers. However, the main difference in their time allocation can be seen in the "gone" activity. The authors added that category because, in 6% of the observations made, they could not find the workers on the roof. Regarding the workers involved in the façade activities, the research team observed them doing preparation activities in 36% of the 568 observations registered. Those are the workers spending more time in this kind of work category.

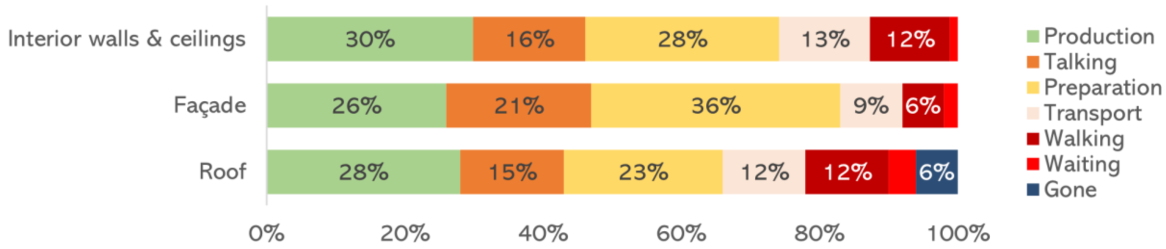

Figure 6: Distribution of time spent into work categories.

WORK TIME SPENT IN WORKSPACES

The developed script enables the classification of GPS data points from each worker into the specified workspaces (Figure 7). The analysis of the time spent in workspaces revealed that carpenters who worked on the interior walls and ceilings were the workers who spent more time in production workspaces. Those workers spent around 78% of their time in production workspaces in comparison to 50% spent by roofers. In contracts, the carpenters who worked on the façade had a wider range for their share of time in production zones, ranging from 25-60%.

The workers destined to conduct roof and facade activities spent more time in the preparation zones compared to the interior walls and ceiling activity. This can be caused because the carpenters who work on the interior walls and ceiling mainly did their preparation work within the production work zones, which is not necessarily possible for the other activities. The roofers spent most time outside of the site compared to the other carpenters. Most carpenters have roughly the same share of time in the transportation, containers, and storage zones.

	SW18	SW19	SW12	SW13	SW14	SW17	SW15	SW20
	Interior		Facade				Roof	
Production	78%	78%	61%	44%	60%	25%	50%	54%
Preperation	10%	7%	27%	42%	24%	56%	26%	19%
Transport	2%	2%	2%	3%	2%	3%	6%	6%
Containers	8%	12%	8%	6%	12%	13%	14%	14%
Storage	2%	1%	2%	4%	2%	3%	4%	4%
Outside site	0%	0%	0%	0%	0%	0%	1%	4%

Figure 7: Time spent in the different workspaces by the different smartwatches

Understanding the distribution of workers' time in the different workspaces can be useful to see where potential problems are, thus forming the starting point for discussion. For example, if workers spend a large quantity of time on transportation workspaces possible logistics and job site layout issues could be causing that situation.

CORRELATION OF DATA

The correlation analysis aimed to illustrate the relationship between the two datasets: (1) the time allocated to VA activities recorded by the WS application and (2) the time spent in VA workspaces tracked by the smartwatches. Figure 8 shows a visual interpretation of a possible correlation between the time spent in VA activities and the time spent on VA workspaces in which workers are involved in the interior (Figure 8a) and roof activities (Figure 8b).

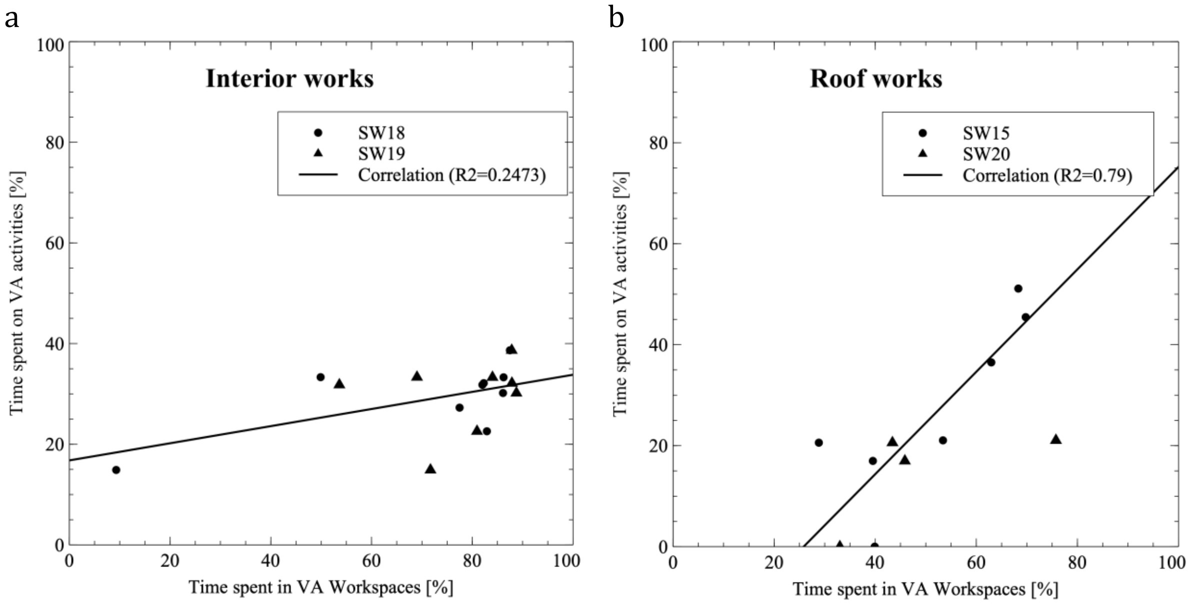

Figure 8: Comparison of time in Prod. Activities and Workspaces: (a) interiors; and (b) roof

In Figure 8, it can be seen that there is a medium to strong correlation between time spent in VA workspaces and time spent on VA activities for both interior works and roof works. For the facade work, no statistically valid correlation could be found. The result of the linear regression analysis can be found in Table 1.

Table 1: Correlation analysis between time spent in VA workspaces and on VA activities

Type of Work	Linear regression equation	R^2	correlation
Interior	y=0.1702x+16.792	0.2473	Medium/Strong
SW18	y=0.1702x+16.792	0.4699	Strong
SW19	y=0.1191x+20.336	0.0392	Low
Roof	=1.0138x-26.19	0.7886	Strong
SW15	=0.9192x-20.248	0.6798	Strong
SW20	=1.1415x-34.329	0.9690	Strong
Façade	=-0.013x+27.752	0.0019	Low
SW12	=-0.2241x+41.383	0.1307	Low
SW13	=0.1232x+21.917	0.1127	Low
SW14	=-0.0272x+28.749	0.0027	Low
SW17	=-0.2874x+34.210	0.2332	Medium

Interior work has an R^2 value of 0.2473, which is very close to the outlined threshold of 0.25 for a strong correlation. Roof work shows an R^2 value of 0.7886, which is a very strong correlation where it can predict almost all the independent variables. The relation analysis conducted in the time spent in VA activities and VA workspaces in the workers doing activities on the façade was unclear with a low to almost non-existent R^2 value of R^2=0.0019. The time that three of the four carpenters working on the facade (SW12, SW13 and SW14) spent in the production zone is not close to the share of time they spent on the production work category, which had an average of 26% during the two weeks. While their time in production zones range from 44% to 61%.

A plausible justification for the low correlation identified for the façade activities can be related to the boundaries definition of the zones created for classifying the GPS data points into workspaces. The authors used the same division of the job site into workspaces for the three groups of carpenters. That division into workspaces worked well when studying the interior (Figure 9a) and exterior activities (Figure 9c). However, when the workers conducted the façade activities, they worked on the boundary division into production and preparation spaces (Figure

9b). That situation could have impacted the distribution of data points identified in the preparation workspace.

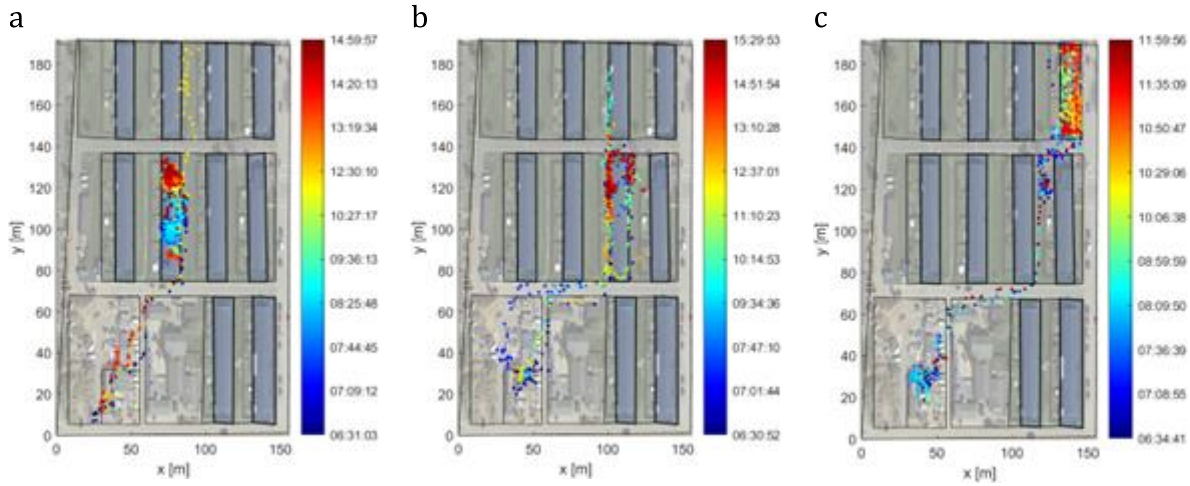

Figure 9: Example of GPS data points on: (a) interior; (b) façade; and (c) roof activities

CONCLUSION

The Case Study presented in this paper is part of an ongoing research project that aims to address the absence of established procedures for automatically measuring the distribution of time spent by workers on VA activities. This project is focused on the identification of workers' locations at the job site using smartwatches as an indirect way to understand how workers spend their time.

This paper aims to understand the relationship between workers' time spent on VA activities and time spent on VA workspaces. For that, the authors studied the activities conducted by a carpenter trade during the realization of a Case Study on a renovation building project. The carpenters were divided into three groups regarding the activities that they conducted (interior; façade, and roof activities). The authors collected their distribution of time on VA activities by the application of the WS technique and the distribution of time in VA workspaces by smartwatches. Correlation analysis reveals a strong correlation and a very strong correlation between time spent in VA workspaces and time spent in VA when the workers worked on interior and exterior activities, respectively. The correlation could not be proved when working on façade activities.

Hence, the primary contribution of this paper lies in the use of smartwatches to understand how workers spend their time indirectly by collecting their locations on the job site. The study results showed that, in traditional processes as studied in this paper, the amount of time workers spend in VA increases when there is an increase in time spent in VA workspaces. Previous studies stated that although presence in production workspaces is not equivalent to time spent on VA activities, it is a prerequisite. From the present study, the authors can conclude that it is true. The more time spent in production workspaces, the more time spent on productive activities, as concluded from the comparison analysis. However, the nature of the activity will impact workers' presence in the production workspace directly.

The primary limitation of this study is associated with the adopted workspace categorization used to classify zones into VA or non-VA. The authors opted for a three-workspace classification, and the assignment of certain locations to one category or another might have influenced the distribution of time analysis. An illustrative example was presented for the façade activities. Future studies should adopt different classifications of job sites for each activity. Lastly, the correlation analysis is limited to one single study. Thus, caution is necessary when generalizing findings to other contexts and other construction processes.

ACKNOWLEDGMENTS

This research was funded by the Independent Research Fund Denmark grant number 0217-00020B. The authors are also grateful for the contractor who opened their door for this study.

LAST PLANNER SYSTEM IN THE OWNER'S PERSPECTIVE: CASE STUDY IN ONSHORE WIND ENERGY PROJECTS

Marcus C.T. Fireman[1], Lucas B. Bizarro[2], Bruno G. Antonini[3], Giuliano Silva de Campos[4], Celso Denardi Junior[5] and Bernardo M.B.S. Etges[6]

ABSTRACT

The race to reduce countries' carbon footprints has increased pressure to shorten the timelines of projects related to the construction of renewable energy parks. Projects of this scale require greater involvement between the representatives of the owner, who act in project management, and companies contracted to perform different scopes of the project. This study presents, through two case studies, the adoption of a model based on the Last Planner System from the perspective of the owner in onshore wind energy projects. It discusses current challenges within the management model of these projects and addresses tools and routines to be considered by companies participating in onshore wind energy construction. Among the main contributions of the research is the highlighted importance of the owner in the dissemination of lean within contracted companies, as well as the role of rituals such as control tower meetings and lookahead planning in improving communication and collaboration between sectors.

KEYWORDS

Lean construction, Last Planner System, owner, onshore wind energy project, collaboration.

INTRODUCTION

Energy supply has always been considered a critical aspect of modern life, playing a central role in the economic landscape of most countries and serving as the primary input to enhance social well-being and global development (Lima et al., 2013). In recent decades, concerned with total Greenhouse Gas emissions, an international alliance of countries has treated the global decarbonization process as a key element in addressing climate change (Souza, 2017). This initiative has led to an increasingly growing expansion in the search for renewable energy use (Irena, 2019).

Regarded as clean energy in terms of its final product, wind energy has seen strong growth in Brazil in recent years. According to the Brazilian Wind Energy Association (ABEE), the first wind parks were installed in Brazilian territory in 2011, and last year, the country reached a milestone of 890 wind parks with about 25 GW of installed capacity, all produced in the onshore model. However, the current scenario presents more challenging aspects regarding the construction of new parks: (i) increased competitiveness, the global race for renewable energies has created challenges for the supply chain; (ii) tighter deadlines; (iii) parks in more inhospitable locations with significant infrastructure challenges; and (iv) complexity in the production and assembly of wind turbines, which are larger and with a generation capacity well above the initial models.

Aiming to improve their efficiency and competitiveness, companies involved in the construction of new wind parks have sought the adoption of planning methods that bring better reliability to the management of deadlines and costs (Lima et al, 2023). This movement is also identified outside Brazil, where a series of research demonstrates the advances in the adoption of methods such as the Last Planner System and Takt planning in offshore wind energy projects (Lerche et al., 2019; Lerche, 2020; Lerche et al., 2020; Lerche et al., 2022; Tommelein & Lerche, 2023). The Last Planner system (LPS) is a construction planning and control methodology that emphasizes collaboration and team commitment to improve project schedule reliability. It aims to enhance predictability and reduce waste by involving multidisciplinary teams in defining realistic work plans and proactively identifying constraints. However, it is possible to identify as a limitation of these studies the fact that the adoption of these methods from the Owner's perspective is scarcely discussed.

The construction of onshore wind parks holds great complexity and interface between different work scopes, including from obtaining licenses to the creation of road access, civil construction of tower bases and the substation, foundations, assembly of electrical transmission cables, and the assembly of wind towers and rotors (Gouveia, 2013). Normally, each work scope is the responsibility of different companies, according to competencies and expertise, which are contracted in the Engineering, Procurement and Construction (EPC) format. On a regular basis, the owner in these types of capital projects presents an in-house team responsible for contractual management, managing the owner's constraints, and supervision of issues related to service quality, occupational health and safety, and environmental aspects.

In the IGLC database, it is possible to notice the existence of articles that addressed the involvement of the owner in lean initiatives (Drysdale 2013; Knapp et al., 2014; Wirahadikusumah; Sulistyaningsih, 2013; Mota et al., 2019; Christensen et al. 2023). Knapp et al. (2014) highlighted that the owner plays a crucial role in facilitating the decision-making process in IPD projects. Toledo et al. (2014) presents a proposal for Bim-Lean implementation to improve the quality of information for project progress control and constraint management of the owner. Drysdale (2013) described the British highway agency's strategy for deploying lean improvement across the supply chain. Recently, Schöttle; Bocker (2023) proposes new integrations to the Last Planner System to increase common understanding of the project scope and goals within the owner, project teams, and stakeholders as the basis for reliable megaprojects delivery. However, there is still a gap regarding how to structure an owner planning model based on the Last Planner.

This paper presents a case study of lean construction implementation in major wind power projects in Brazil. The authors present the benefits, limitations, and opportunities identified from the development of lean construction in this case study. As the main contribution of this paper, it presents an adaptation of the Last Planner model from the owner's perspective.

METHOD

This research adopts a design science research methodology, and the artifact created is a planning method based on the Last Planner system, incorporating the perspective of the owner in a wind power project. The study was structured around three main phases: (i) diagnosis; (ii) development; (iii) evaluation. The diagnosis and development phases were conducted through two case studies within an onshore wind power project developed by Company X. The first three authors participated as consultants responsible for implementing lean concepts, and the last authors represented the company's planning sector.

Company X is an energy management firm which is responsible for managing land issues such as leasing and purchasing areas for the park's execution, monitoring environmental issues regarding fauna and flora, the approval and compatibility of engineering designs, and, finally, monitoring the execution of production through planning in collaboration with the quality and occupational safety sector, according to the norms established in contracts with contractors.

The diagnosis phase occurred in the first case study, located in the northeast region of Brazil, comprising 70 wind turbines. This phase began in September 2022 and concluded in November 2022. During this period, the authors conducted a Swimlane workshop, analyzed planning documents, performed direct observations of management routines, and interviewed representatives from Company X and its stakeholders. The purpose of the diagnosis phase was to understand the planning model utilized by Company X and identify the primary gaps.

The development phase spanned from March to December 2023 in the second case study, also situated in the northeast of Brazil and involving 188 wind turbines. For the construction of the Wind Complex, Company X hired four companies to execute the main work scopes. Contractor C was responsible for Civil and Earthmoving scopes; Contractor S handled the construction of the Power Substation and Medium Voltage Networks; Contractor O was in charge of the Transmission Lines; and Contractor V supplied and assembled the wind turbines. Figure 1 illustrates the organizational chart showing the principal responsibilities of each company.

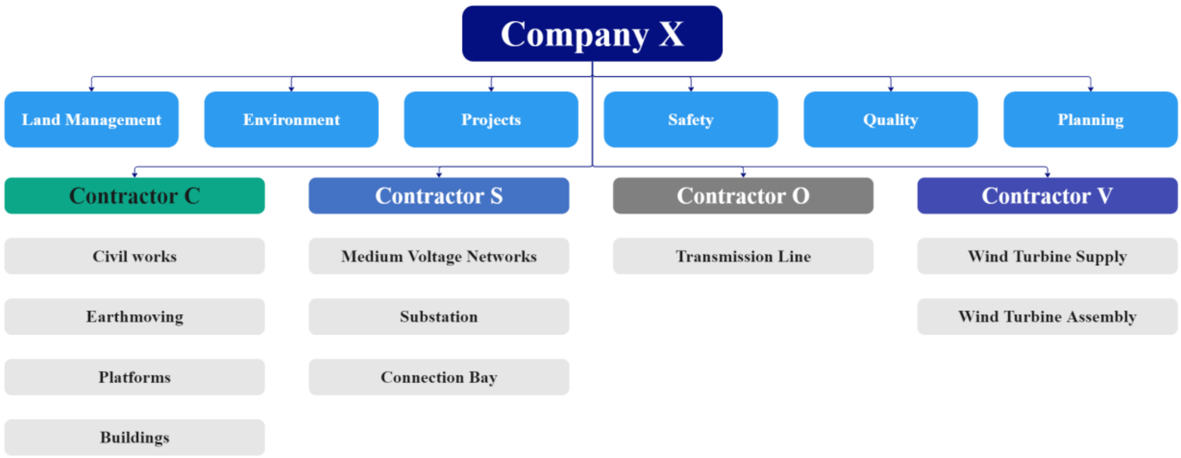

Figure 1: Organizational chart of Company X and the service scope of each company.

RESULTS

The findings are structured around the research's three phases: Diagnosis, Development, and Evaluation.

DIAGNOSIS – CASE STUDY 1

The project initiated with an in-depth diagnostic analysis of the company's current operational landscape, with the application of interviews with key department heads to identify critical issues and areas for potential enhancement. This process enabled the construction of a comprehensive swimlane diagram, delineating processes and responsibilities across various departments, including Business Development, Environmental, Land Management, Engineering, Planning, and Production, and proposed targeted improvements for each activity area. Figure 2 showcases the detailed swimlane diagram, illustrating the collaborative workflow and inter-departmental responsibilities.

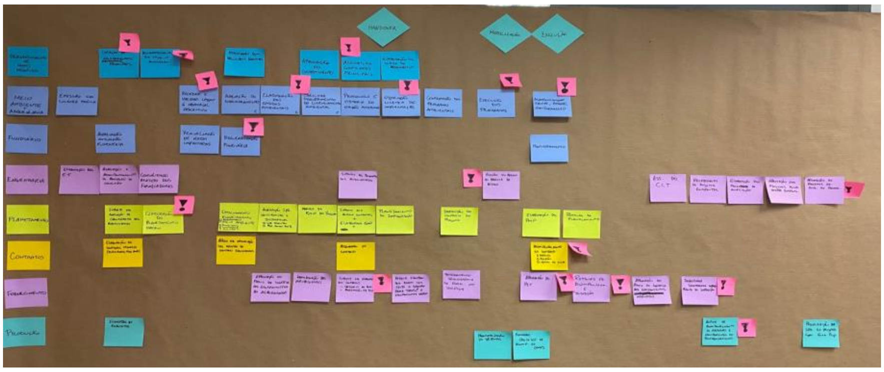

Figure 2: Project Development Flow

The consolidation of identified challenges revealed 63 areas for potential improvement, categorized by project phases. The Execution phase emerged as the most problematic, accounting for approximately 44% of the issues, followed by the Project Development phase at 35%, and the Commissioning phase at 21%.

The analysis of the execution phase pinpointed key concerns among the teams, predominantly centered around: (i) communication breakdowns with contractors; (ii) mismatches between weekly schedules and monthly replanning in the contractors' field planning; (iii) discrepancies between the agreed-upon timelines and contractors' actual scheduling efforts.

The planning department routinely faced the challenge of synthesizing progress updates from various contractors into coherent trend analysis reports. This task was complicated by the necessity to handle data from disparate sources, including MS Project, Excel, and WhatsApp, into a unified system, leading to inefficiencies and redundancies. Updated reports were then generated for executive management, providing insights into contractor performance. In instances of schedule delays, contractors were requested to submit action plans for review and incorporation into the project's master schedule, utilizing the critical path method for strategic adjustments.

Direct observation of management practices highlighted two main meetings: (i) the weekly contract meeting, focusing on contractual and procedural discussions with contractors and Company X's departmental representatives (safety, planning, environment, quality, production); and (ii) the monthly coordination meeting, serving a similar purpose but extending participation to contractors' directors and the client's executive team. These sessions, conducted separately with each contractor, were crucial for Company X to manage the interface between contractors' project scopes. Meeting minutes were meticulously prepared, encapsulating discussions and action items with each contractor.

A meticulous review of these meeting minutes revealed a dual categorization of discussion topics: operational constraints and contractual procedure adjustments. Analysis of resolution timelines for identified constraints showed a significant variance, ranging from 1 to 6.5 weeks across different areas, with outliers extending up to 18 weeks. Although data did not conclusively indicate the timeliness of constraint resolution, feedback from meeting participants suggested a reactive, firefighting approach to addressing issues, often aiming for resolution within the week.

DEVELOPMENT - CASE STUDY 2

The initial diagnostic phase provided insights into the operational dynamics of the company and identified key focus areas for development in the second case study. The development phase started with the creation of phase scheduling workshop to strategically visualize project phases and map out potential interferences and constraints with a broader anticipation horizon (12 to 21 weeks). For a more intuitive grasp of potential service scope interferences throughout the sub-parks, the Time-Location technique was employed.

The Time-Location tool, a form of location-based scheduling, utilizes the x-axis for production lots (park paths) and the y-axis for project time. This tool was instrumental in visualizing execution interferences in the field for Civil and Medium Voltage Networks activities, particularly due to the high number of rock detonations required throughout the project, which could impact nearby service executions within a 500 meters radius due to the need for temporary halts. Figure 3 illustrates the Time-location developed collaboratively with planning and production departments of the contracted companies and Company X.

Figure 3: Time-location for contractor C and S scopes.

After completing the time location chart, it was possible to pinpoint areas and times where interferences or a high volume of simultaneous services occurred. Table 1 lists the main points of concern identified in the planning.

Table 1- Time-location attention points

Id	Attention Points
1	Possible detonations for pole excavation concurrent with Base execution
2	Possible detonations for pole excavation concurrent with Platform Base execution
3	Possible detonations for pole excavation concurrent with Access Earthmoving
4	Possible detonations for pole excavation concurrent with Access Earthmoving
5	Services of RMT Suppression concurrent with Access Earthmoving

Only Contractor C was aligned with Lean culture, having embarked on their Lean journey in 2020 and adopting planning rituals based on the Last Planner system. Rounds of training and education on Lean Construction, Last Planner System, Takt Planning, and waste were conducted for both Company X employees and the other Contractors. Beyond theoretical discussions, the game Takt Planning - Wind Turbines was applied to practically implement Takt planning and develop the Time-location for a mini-park of 10 wind turbines. This activity involved 11 employees, 3 from Contractor C, 5 from Contractor S, and 3 from Contractor O (Figure 4).

Figure 4: Practical Application of Takt Planning and Time-location Concepts.

To enhance internal communication within Company X and establish a specific forum for discussing schedules and constraints, a Lookahead planning routine was implemented with a 6-week planning horizon and bi-weekly control meetings. These meetings involved planning departments of each Contractor and Company X, where Contractors were responsible for presenting their 6-week activity schedules and reporting constraints related to their scopes and those of Company X.

The constrains related to Company X were mainly due to land issues, such as land release that could impact the planned execution site or land embargoes; environmental issues, including wildlife, flora, and archaeological sites; factory inspections regarding the quality of products supplied by contractors, among other project management constrains. Additionally, constrains on the mobilization of labor and machinery by contractors were important for Company X to anticipate the necessary workforce for the swifter release of documentation. Furthermore, given the complexity of constructing a wind park, constrains related to the wind window for tower and wind turbine assembly were significant concerns, alongside the requisite training for workforce qualification in working at heights. Logistic constraints were also critical factors due to the large volume and magnitude of equipment involved.

The planning department of Company X critically evaluated the plans against the time-location, contractual items, and procedures. After these lookahead meetings, an internal session was held with the Safety, Environment, Quality, Land Management, and Production departments to review the contractors' proposed plans and identify potential sector-specific constraints (Figure 5).

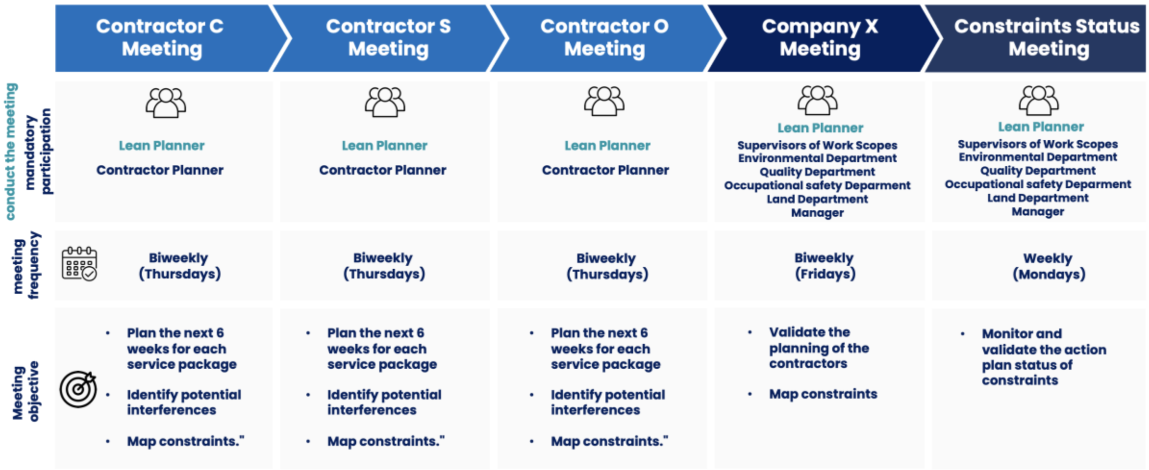

Figure 5 – Medium-term rituals workflow.

Lookahead planning meetings utilized visual management boards (Figure 6), where each contractor had a designated space for their 6-week plan. Activities were represented with post-its, and those with constraints were marked with a coded sticker indicating a constraint needing resolution. Action plans for removing identified constraints were highlighted on visual boards, specifying responsible individuals and deadlines for each Contractor. This approach emphasized constraint management, improving visibility and transparency of potential project impacts compared to the text-heavy minutes of weekly meetings.

Figure 6- Lookahead Management Panels (left) and Constraint Removal Plan (right)

The final element of the lookahead meeting was the constraint removal status routine, conducted alongside the Control Tower routine. The Control Tower was a weekly ritual involving representatives from the internal areas of Safety, Environment, Land Management, Quality, Planning, and Production, where each presented predefined indicators to the project manager and colleagues. This routine was crucial for aligning all company sectors, facilitating discussion, and presenting key elements for the project manager's decision-making. Furthermore, the weekly Control Tower meetings allowed for periodic monitoring of each department's indicators, fostering discussion and action plan formulation to achieve targets (Figure 9).

Figure 9: Control tower panels

EVALUATION

The initiative by Company X, the project owner, to implement the Lookahead planning routine along with its contractors led to the internal adoption of this practice by contractors S and O. For Company O, the adoption was voluntary, as the company's senior management and planning departments saw value in the ritual. However, Company S faced initial challenges in adopting the routine, largely because its leadership did not fully support the initiative, viewing it as beyond their contractual obligations, which affected the quality of the lookahead plans due to a lack of engagement and cooperation from support departments in creating more feasible plans.

To assess the maturity gained by the companies, analyses of key medium-term planning indicators were conducted: (i) Percentage of Constraint Removal (PCR) – evaluating the number of constraints removed on time against the total number of constraints for the period under review; (ii) Bi-weekly Adherence – assessing the number of completed packages compared to the planned work packages within a fortnight.

Figure 8 demonstrates the maturity level achieved by each contractor throughout the project, evidencing the effectiveness of the Lookahead routine in early constraint identification. The analysis covers two periods: the first from 03/07/23 to 14/08/23, and the second from 21/08/23 to 02/10/23, calculating the average Percentage of Constraint Removal (PCR) for each contractor across these periods.

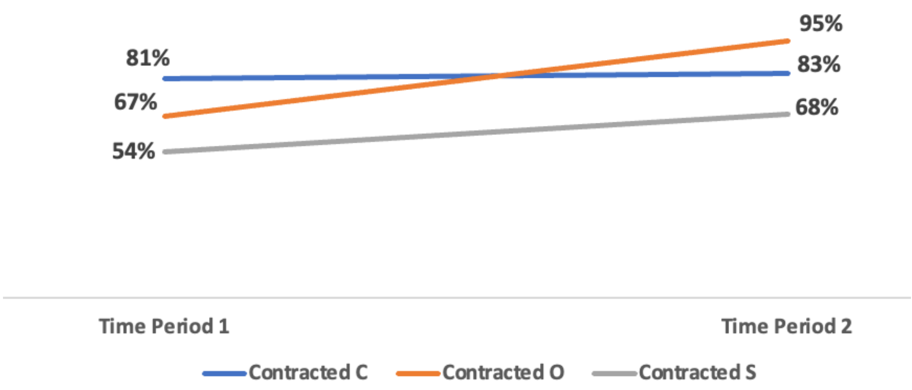

Figure 10- Evolution of Contractors' PCR Indicators

From Figure 8, it is clear that all three contractors improved in identifying and removing constraints on time. Contractor C's consistent performance was expected due to its internal adoption of the routine, leading to greater experience and maturity with the process over the project. Contractor O showed significant improvement, starting with an initial average of 67% and reaching 95% PCR in the last period analyzed. Contractor S also improved its Percentage of Constraint Removal, although it remained lower than the other contractors.

The Bi-weekly Adherence indicator for the defined medium-term plan packages showed a stable adherence rate across the project (Figure 11). Consolidating the packages from all three contractors yielded an average overall adherence of 78% for Contractor C, 77% for Contractor O, and 70% for Contractor S. A specific dip was noted in week 32, impacted by local holidays not initially accounted for, indicating a potential planning oversight for that week.

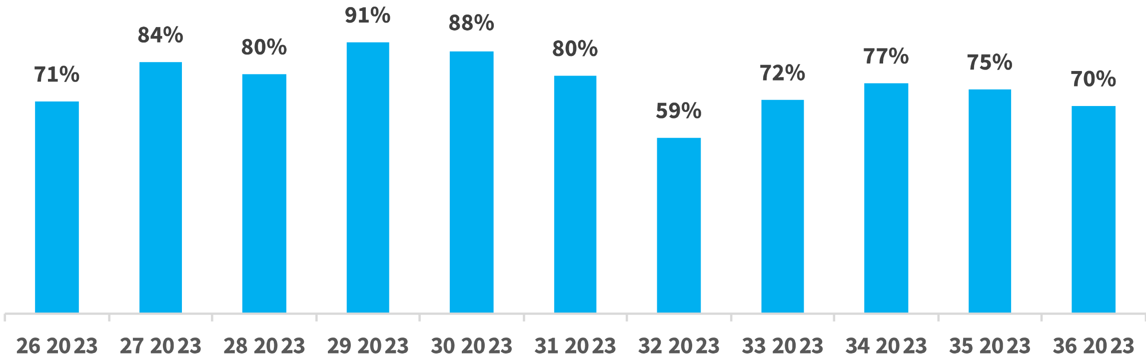

Figure 11- General Adherence Indicator

At the end of the project, in order to better understand and comprehend potential gains in the perception of those involved from Company X, a survey was developed and shared with the planning coordinator, who also was the main sponsor of the lean implementation journey. The questionnaire was designed with 6 open-ended questions, which can be viewed in Table 2.

Table 2- Post-implementation Lean Perception Questionnaire

Questions	Answers
How would you describe the effectiveness of communication between the contracted companies and the Company X team prior to the implementation of the Last Planner System?"	The communication was based on weekly meetings and highly reactive, focusing on project issues.
In your opinion, how has the Last Planner System improved planning transparency between the contracted companies and the Company X team? If so, provide examples if possible.	The LPS aided in the forward-looking view of activities, focusing on resolving problems and constraints before they impacted operations. An example is the approval of health and safety procedures and documentation prior to commencing activities.
Did the Last Planner System help identify and solve conflicts or obstacles more efficiently and with greater predictability during project execution? If so, provide an example if possible.	Yes, one example was with the contractor S, where we conducted a workshop and task force to identify issues and deviations from the planning in the final phase of the project, aiming to not impact commissioning activities.
In your experience, did the Last Planner System facilitate adaptation to unforeseen changes during project execution? If so, how?	Yes, the LPS proved to be a very useful tool for analysing scenarios and providing responses to changes and unforeseen events in the project.
What were the main perceived benefits of implementing the Last Planner System in the construction of the wind farm?	Increased predictability, greater integration between project areas, and improved communication with contractors were the main perceived benefits.
Did you notice an improvement in communication and transparency of relevant information among Engie's internal sectors for the project after the implementation of Lean? If so, provide examples if possible.	Yes, and the involvement of all areas in the lookahaed meetings greatly assisted in communication and understanding of constraints and critical points between the areas.

CONCLUSION

This study aimed to explore a planning and management model based on the Last Planner System from the owner's perspective in onshore wind energy projects through two case studies. The first case study shed light on the current challenges faced by the owner in managing onshore wind projects. One challenge stem from the traditional management and contract model, where the owner relies on an internal team for contractual management and coordination of interfaces between contractors, giving contractors full autonomy for planning and executing the project. This model has been questioned in literature and industry for not fostering collaboration among contractors, often prioritizing local optimization over global efficiency. Another challenge is the low maturity of contractors in adopting efficient planning practices based on Lean, such as the Last Planner System, and the third challenge relates to internal communication failures within the owner's team, with departments sometimes operating independently without aligning with project priorities.

The second case study showcased the adaptation of the Last Planner System from the project owner's viewpoint, implementing elements like Phase scheduling and Lookahead planning meetings. While phase scheduling aimed to identify hand-offs and potential risks to meeting deadlines using the time-location tool, the Lookahead meetings established structured sessions with contractors to proactively address constraints, whether from the contractors or the owner (Company X). This model created separate focal points for discussing each contractor's 6-week plan, followed by an internal alignment meeting to identify constraints, avoiding lengthy meetings and maintaining the quality of discussions despite varying Lean maturity levels among contractors.

A key outcome of the second case study was the enhanced Lean maturity among contractors, supported by internal training cycles and the structured Lookahead planning rituals implemented by the owner, which were disseminated among the contractors, improving their planning processes and proactive constraint management. This maturation was evidenced by indicators such as the Percentage of Constraint Removal and Bi-weekly Adherence of planned packages.

Another outcome was the implementation of the Control Tower ritual, aimed at fostering collaboration across departments, indicator-based management, and monitoring the status of departmental constraints. This ritual successfully integrated various aspects (land management, environment, safety, projects, quality) into production control.

Future research suggestions include exploring the adoption of BIM and 4D planning in onshore wind energy projects as mechanisms for identifying spatial constraints and conflicts. Another potential research area is the relationship between the implementation of integrated project delivery in onshore wind energy projects and the increased maturity in adopting Lean practices among contractors and the owner.

AGILE RAMP-UP: A METHOD TO REDUCE PREMATURE CONSTRUCTION START

Caio M. Lima[1], Marcus C. T. Fireman[2], Lucas H. Nascimento[3], Bernardo M. B. S. Etges[4], Bruno G. Antonini[5], Bruno B. Bluhm[6], Denilson P. Silva[7] and Fabiano C. O. Rocha[8]

ABSTRACT

It is understood that one of the main contributing factors to stagnant productivity in the construction sector is the haste of project teams to start construction without a thorough readiness assessment. With the aim of improving the sector's performance, recent research has turned to analyzing the consequences and challenges associated with the premature start of projects, showing a direction in the search for effective solutions to these issues. The purpose of this work was to present the application of an agile ramp-up method developed to mitigate cases of premature construction start in onshore wind projects. The method used in this article was Design Science Research and covers the following phases: awareness of the problem through understanding the concepts involved; artifact suggestion through the development of a diagnosis; development from the choice of appropriate tools for constructing the "Starting Right" method; evaluation through the impact, transparency, and statistical variance analysis in 16 projects, of which 6 applied the method; conclusion through the systematization of the main learnings. The "Starting Right" method significantly improved the performance of projects during the initial phases, with strategic tool use proving essential for effective responses to various scenarios.

KEYWORDS

Agile Ramp-Up, Lean construction, Wind Farm, LPS.

INTRODUCTION

The construction sector faces persistent productivity challenges, often compounded by the premature start of projects without a thorough assessment of construction readiness. This research, initially focused on onshore wind projects, reveals issues that are universally relevant across various types of construction, such as civil infrastructure, commercial buildings, and industrial developments. In this context, investigating the premature start of construction has

proven critical to understanding how the pressures of deadlines and perceived benefits by stakeholders can compromise the success of a project in any of these areas.

In pursuit of enhancing the performance of the sector, some studies have shifted their research focus towards understanding the premature start of construction projects. (Griego;Leite, 2017; Abotaleb et al., 2019; Radzi et al., 2020; Ibrahim, et al. 2021). In this point, Ibrahim et al. (2021) suggest as a major reason of the stagnant productivity in the sector is that project teams often rush into construction without adequately assessing construction readiness.

Determining the right time to start construction is pointed out by Griego; Leite (2017) as one of the most important planning decisions on a major capital project. According to the same authors, this decision in many times is influenced by the fact of at least one stakeholder perceives a benefit from an early start construction, as result, project teams face pressure to begin construction, whether or not they are ready. The consequences of this decision could negatively impact a project outcome through frequent interruptions, rework, litigations, claims, disputes, out-of-sequence work, delays (Griego; Leite, 2017; Aboutaleb et al., 2019; Ibrahim et al., 2021).

This new line of research is led by the Construction Industry Institute (CII), which present two key terms: (i) premature construction start; (ii) construction readiness. The premature construction start is defined as "a decision, by at least one party, to start construction with at least one risk that exceeds an acceptable tolerance to a party, and which can result in an interruption to construction" (Griego; Leite, 2017). While construction readiness is defined as "a series of activities and procedures that should be completed or substantially completed prior to construction to productively start and sustain construction operations" (Ibrahim, et al. 2021). Despite the different definitions, it is implicit that the main purpose of both terms is to bring more clarity to the importance of avoiding interruptions right from the beginning of the projects.

It is possible to identify in the literature some research that has already addressed similar topics, but without the specific focus on the start of projects. For example, Koskela (2004) introduce the term making-do as a situation where the activity is started even without all prerequisites available. The relevance of the line of research led by CII is that when an organization experiences an interruption in the start, project teams react by spending additional capital on increased labor and speedier engineering documentation delivery in order to get the project back on track (Griego; Leite, 2017). In this point, the studies of Griego; Leite (2017) identified drivers, lead indicators and impact of premature construction start while Ibrahim et al. (2021) propose a model to assess the construction readiness. But even though advances have been observed in the respective research, there are still alternatives of methods that help companies reduce the cases of premature construction start.

In Lean construction, which highlights collaboration among teams to minimize waste and maximize value for stakeholders (LCI), the Last Planner System (LPS) stands out as a method that aligns closely with these goals. The main idea behind LPS is to establish a reliable and stable workflow through the preparation process (Ballard; Howell, 1998). Another aspect related to the Last Planner System tool is that it allows a global view of the project through three levels of planning: short, medium, and long-term (VIEIRA; BORGE; BARROS NETO, 2020). In this sense, the preparation process works to ensure that all prerequisites are available when the task is initiated, thus avoiding interruptions and lack of productivity. But, although this is the ideal to be pursued, in practice, some studies have shown that due the complexity of construction, unexpected contexts emerge that require adaptive decision-making, and the go/no-go decision to start an activity need to be applied (Pikas et al., 2012). These natural manifestations of resilience by team to respond an unexpected event require the appropriate support from the organization to create conditions to encouraging the diversity of perspectives when making decision, design slack, monitoring gaps between prescription and practice, or even anticipating and monitoring of small changes (Saurin; Sanches, 2014). Yet, although the benefits related to the application of the LPS, it is not exclusive to the construction start phase, requiring adaptations to its peculiarities.

In other industries, the Ramp-up phases presents similarities with the construction start phase, since the interruptions and the uncertainty are a common theme. The Ramp-up begins when the process is scale up from zero and ends at the stable production of full-volume (Christensen; Rymaszewska, 2016). This phase also encompasses the cases of manufacturing "start-ups" of new production lines or new factories, where the production output increase gradually (Glock; Grosse, 2015). Recently, a new way of managing the Ramp-up phase has emerged. This includes agile principles as an asset to combat the growth volatile and uncertainty of business environment (Kremsmayr et al., 2016; Mamaghani; Medini, 2021). According to DeVor et al (1997), agile manufacturing is described as the ability of a company to adapt and thrive amidst constant changes, including those in markets, technologies, and business relationships.

Historically, production management can be viewed from different perspectives, with the traditional approach linked to conversion, prioritizing aspects related to the transformation of inputs into the final product (COELHO, 2003). One important criterion of lean management is achieving the customer's needs. By entering lean management into the construction industry to reduce wastes in each process. Many innovative techniques developed by different individuals can be used for lean production, lean construction or agile methods in such a way that identifies wastes and tries to eliminate or minimize their impact (RASHID, HERAVI, 2012).

Therefore, understanding the complete production flow and identifying value-adding activities is crucial. One of the primary objectives of Lean Construction is the reduction of non-value-adding activities, further optimizing the production process.

The present study seeks to present the results of the application of an agile ramp-up method developed to mitigate cases of premature construction start in onshore wind projects. The methodology was developed based on 6 case studies.

AGILE RAMP-UP

Managing Ramp-up phase is a challenging task, due the complexity related to high uncertainty, resource availability, lack of process maturity and the involvement of several stakeholders from different backgrounds (Heraud et al., 2023). Another characteristic with negative impact is that the ramp-up process is normally designed based only on experiences from an existing production line (Mueller et el. 2020).

Recently several studies have presented agility as one of the main drivers of ramp-up management (Kremsmayr et al., 2016; Bergs et al., 2021; Mamaghani; Medini, 2021; Heuraud et al., 2023; Kadkhoda-Ahmadi et al.,2023). These studies highlight that the agile principles enable the companies to respond quickly to changes and to support continuous development and quality improvement during ramp-up phase.

Kremsmayr et al. (2016) allowed an advancement on the application of agility principles in ramp-up management. According to them, the agile ramp-ups could be characterized according four criteria (Figure 1):

- Proactive task prescheduling – Considers the principle of proactive through the application of possible scenarios as well as their effects on a Ramp-up phase. It also presents the concerns with mitigate risk and achieve time advantages.
- Acceleration of upscaling phase – The acceleration principle is achieved with transparent decision-making process and simplification of the major Ramp-up processes. The main idea is to remove unnecessary process steps and interion loops and organize efficiently the experience gained from previous ramp-ups.

- Flexible capacity adjustment – Involves the ability to undertake flexible capacity adjustment even shortly before starting or during Ramp-up activities. It highlights the necessity to determine and monitoring certain performance levels.
- Rapid response to change – Here there is a focus on the reduction of recovery time, since the system need to be able to quickly respond to unexpected disruptions and recovery to the initial schedule as soon as possible. Here the importance of an structured help chain in organization is implicit.

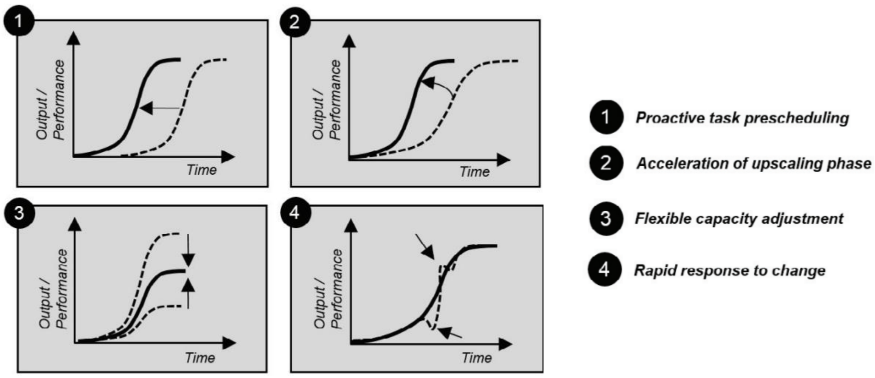

Figure 1: Four Criteria to Agile Ramp-up according Kremsmayr et al. (2016)

METHOD

For the development of the present study, the Design Science Research (DSR) methodology was employed. As highlighted by Bax (2014), the focus of DSR lies in the creation, investigation, validation, and evaluation of new artifacts, including constructs, frameworks, models, methods, and instances of information systems. The artifact developed in this article can be understood as a method for the accelerated initiation of wind farm projects, termed "Starting Right".

The aim of DSR is to create outputs that serve human purposes, and the critical point is to design a system that will address new challenges Kasanen et al. (1993) and create new perspectives for the current time (Lukka, 2003). DSR seeks to devise solution concepts, name artifacts, solve classes of problems (Van Aken, 2004; Holmstrom et al.2009), and, at the same time, provide a theoretical contribution to the field of knowledge (Kasanen et al., 1993).

The "Starting Right" methodology was developed based on the Agile Ramp Up structures used in the work of Kremsmayr et al., (2016), where these authors devised an artifact aimed at a hybrid industry of high-quality powder metallurgy. With this in mind, the "Starting Right" method, aimed at accelerating wind farm projects, utilized the Lean construction management philosophy, as well as tools such as the Last Planner System (LPS), visual management (Control Tower), risk matrix, and mobilization control spreadsheets. For this study, the LPS was integrated with key planning instruments: the Line of Balance for long-term planning, Six-week ahead planning for medium-term objectives, and Check Out meetings for short-term progress monitoring.

In this context, DSR played a crucial role in the design of this artifact, guiding its development through the steps outlined in Figure 02.

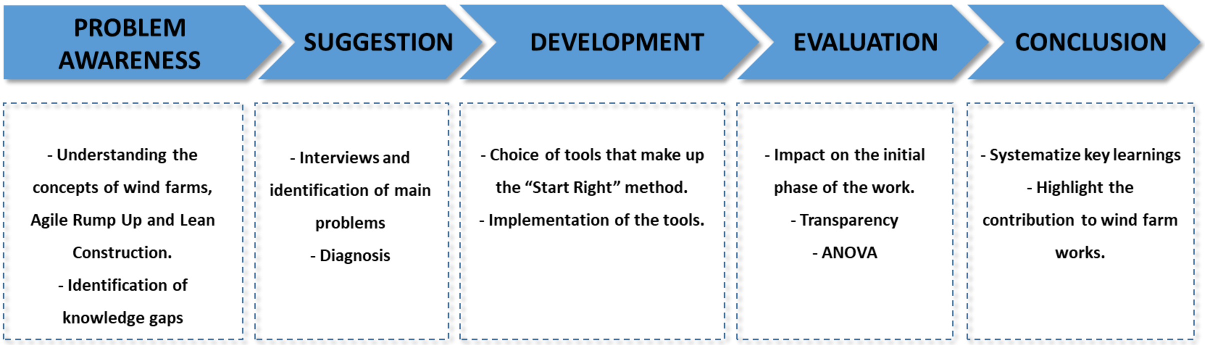

Figure 2: Methodological design

The development and implementation of the "Starting Right" method, as well as its deployment, were carried out by a management consultancy that began in 2020 at a wind farm construction company located in the northeast of Brazil. The Problem Awareness stage involved understanding the construction process of wind farms, studies on Agile Ramp Up, and studies on Lean principles. Furthermore, gaps in knowledge regarding these topics were identified. The selection criteria for the projects analyzed in this article required the project to involve the construction of wind farms, specifically the construction of access roads and concrete foundations (Table 1). Although there were other ongoing projects, such as building constructions and highways, the "Starting Right" method was applied exclusively to wind farm constructions, reflecting the constructor’s strategic decision to focus on this sector.

Subsequently, the Artifact Suggestion stage was carried out, in which the consulting firm conducted interviews with the engineers involved in the project "Project 11" (Table 1). The objective was to identify the main obstacles related to efficient management, culminating in the formulation of a diagnosis to be addressed.

Table 1: List of works analyzed

PROJECT	YEAR	TOWERS	METHOD	PROJECT	YEAR	TOWERS	METHOD
Project 01	2015	31	Conventional	**Project 09**	2019	121	Conventional
Project 02	2015	153	Conventional	**Project 10**	2019	49	Conventional
Project 03	2015	47	Conventional	**Project 11**	2020	120	*Start Right*
Project 04	2016	98	Conventional	**Project 12**	2021	76	*Start Right*
Project 05	2017	65	Conventional	**Project 13**	2021	93	*Start Right*
Project 06	2018	230	Conventional	**Project 14**	2021	70	*Start Right*
Project 07	2018	36	Conventional	**Project 15**	2021	123	*Start Right*
Project 08	2019	36	Conventional	**Project 16**	2022	188	*Start Right*

The Development phase involved selecting the most appropriate tools, taking into account the context identified during the diagnosis, followed by their implementation in "Project 11". This development process was subdivided into four parts, which were outlined as the initial guidelines of the "Starting Right" method. It is important to highlight that, after the implementation in "Project 11", this method was extended and applied to subsequent projects.

"STARTING RIGHT" RAMP UP METHOD

The "Starting Right" method encompassed 4 main pillars, which are: (1) Anticipating possible scenarios and mitigating risks as early as possible; (2) simplifying processes using a mobilization checklist; (3) making capacity adjustments before starting or during the initiation of activities; (4) reacting quickly to unexpected events through a structured support chain.

To facilitate the implementation of these guidelines, it was essential to determine the ideal timing for their application and identify the necessary tools for each situation, as described below:

Anticipate possible scenarios and mitigate risks as quickly as possible

Anticipating possible scenarios and mitigating risks are crucial elements for the success of any venture, especially in the field of wind farm construction. To address this challenge, two strategic tools were adopted: the Risk Matrix and Scenario Simulation. The Risk Matrix provides a comprehensive view of the potential challenges and opportunities that may arise throughout the project, allowing for proactive identification and an anticipatory approach. The Scenario Simulation, on the other hand, offered a global view of the project through long-term planning. For this purpose, the Critical Path Method and Line of Balance spreadsheets were used, which provided a clear visualization of milestone dates and resource allocation. Moreover, the combination of Scenario Simulation with the Risk Matrix contributed to better formulation and refinement of analysis at this stage.

Simplify processes using a mobilization checklist

The simplification of processes in the mobilization stage was crucial for the efficiency of the "Starting Right" methodology, being proactively incorporated through the use of a mobilization checklist spreadsheet. This spreadsheet not only simplifies the management of mobilization but also provides an effective channel to document and track new items that apply to a new project. The records obtained can be used in identifying patterns in the process. Thus, this simplification boosts operational efficiency and contributes to building a solid foundation for future ventures.

Make capacity adjustments before starting or during the start of activities

At this stage, the Carousel of Works control spreadsheet was employed, which facilitated the process of transferring a resource from one project to another. This approach aims to optimize the use of resources, ensuring proper allocation according to the needs of each project, providing greater flexibility and efficiency in the execution of simultaneous or sequential projects. For this purpose, mid-term meetings known as "Six Weeks Look Ahead" were utilized. These meetings were held periodically, occurring weekly or bi-weekly, with the goal of anticipating potential constraints in the planned activities over a six-week period.

React quickly to unexpected events from structured help chain

For effective management of emergency situations, it is essential to promptly address unforeseen events through a structured support chain. For this, Project Schedule Meetings, Check Out, Control Tower, and Management Meetings were utilized. The Project Control meeting involves discussions regarding the approvals and releases of executive projects, as well as analyzing specific aspects of the construction. This meeting takes place before the construction starts. On the other hand, Check Out, Control Tower, and Management Meetings occur at the beginning of the construction. The Check Out meeting provides a dedicated environment where operational teams meet with leadership daily to review critical events, share information, and make decisions, eliminating constraints for the next day. The weekly meeting called Control Tower presents an overview of all the project's information, with the participation of key leadership involved in the project's execution, aiming to present tactical indicators to the management. Concluding the support chain, a strategic meeting is held weekly, summarizing the main indicators and events for the board of directors. These four meetings enable quick and coordinated responses to minimize negative impacts, mitigate risks, and restore operational normality as quickly as possible.

Continuing with the DSR stages, the evaluation of the artifact took into account the Impact of the Starting Right method in the initial phase of the projects and the Transparency of the processes (Figure 02). The analysis of this impact is quantified by two aspects, first by the degree of deviation observed during the contractual progress of 25%, as exemplified in Figure 03, and by the level of challenges faced during implementation, classified as low, medium, and high.

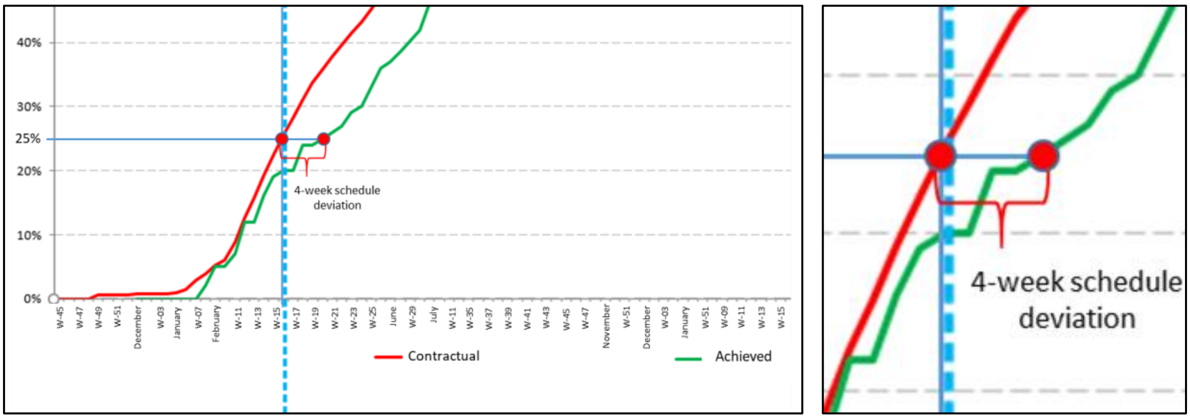

Figure 3: Example of S Curve for Project 7 Monitoring (left) and Zoom in on the 4-week schedule deviation (right)

Still pertaining to the Analysis phase, in addition to considering transparency as the ability of the production process (or its components) to facilitate communication with people (Formoso et al., 2002), robust statistical analyses were conducted to assess the effectiveness of the "Starting Right" method. According to Kerzner (2013), the technique of Analysis of Variance (ANOVA) is essential for comparing groups in project management studies. This technique was employed to quantify the schedule deviations during the Ramp-Up phase, comparing the performance of projects that used the conventional method with those that implemented "Starting Right".

In the final stage, the conclusion consisted of systematizing the main learnings, aiming to clearly highlight the method's contribution to wind farm projects.

RESULTS

In this section, we will discuss the results related to the development and evaluation phase of the artifact, presenting a representation of the method's structure, as well as analyses focused on the impact on the initial phases of the projects and the perception of the transparency of the implemented processes.

STRUCTURE OF THE "START RIGHT" METHOD

The "Starting Right" artifact represents an effective approach to the agile initiation of projects in wind farms. As illustrated in Figure 04, tools such as the Risk Matrix, Scenario Simulation, Mobilization Worksheets, LPS, "six weeks look ahead" meeting, Carousel of Works, Project schedule meeting, Check out, Control Tower, and Board meetings should be applied, especially in the initial phases of the project, until it reaches its production stability. It is worth noting that the continued use of these tools (1, 3, and 4) beyond the stability phase is indispensable, as they play fundamental roles in the ongoing management of the project.

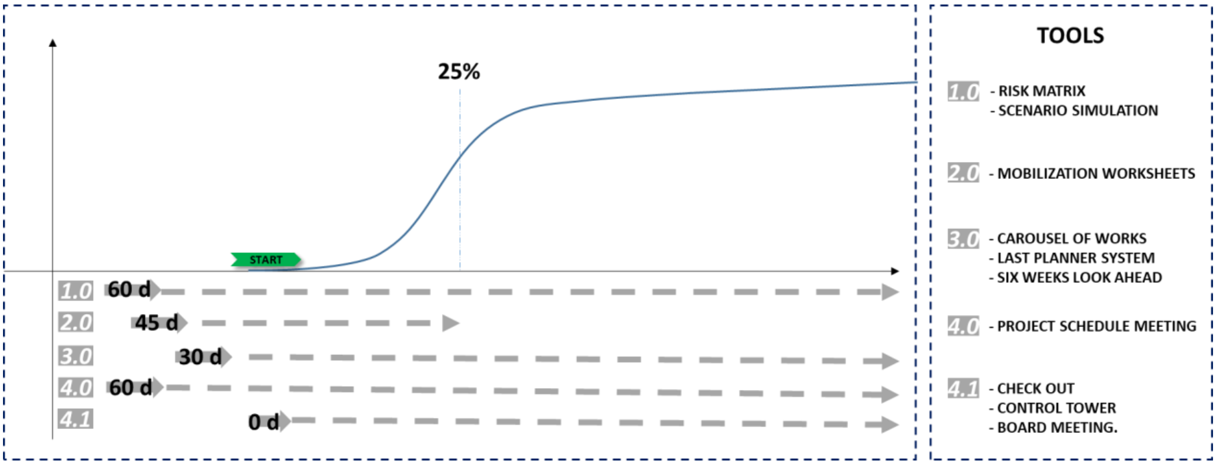

Figure 4: Representation of the Application of the method

Figure 03 also shows that each group of tools is initiated at a specific moment in the development of the project. This cadence is essential to ensure the success of the rapid startup of the venture.

Wind farm projects often occur in previously uninhabited locations, requiring the construction of accommodations, advanced campsites, and appropriate infrastructure. These constructions are necessary to ensure that the project can be started on schedule.

Details of the cadence for starting the tool groups:

- 60 days before the start of the project, the first group of tools is initiated
- 45 days before the start of the project, the second group of tools is initiated.
- 30 days before the start of the project, the third group of tools is initiated.
- 60 and 0 days before the start of the project, the fourth group of tools is initiated.

ANALYSIS OF THE METHOD'S IMPACT ON THE INITIAL PHASE OF THE PROJECT

Based on the analysis of the 16 projects monitored (Figure 04), it is observed that, in the period preceding the implementation, the occurrence of schedule deviations, resulting in delays in the initial phase of the projects, was more frequent. However, upon examining the period following implementation, it is noticed that the projects began to exhibit a superior performance pattern in their initial phase.

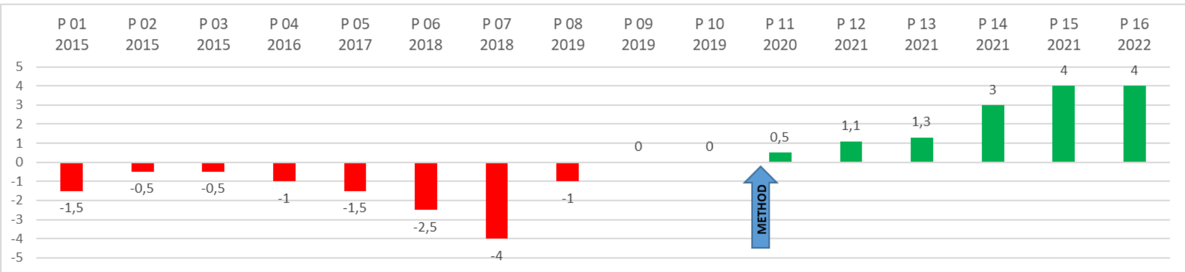

Figure 4: Timeline of the initial Ramp Up of ventures.

Considering this, an advancement in the method's maturity over the time of its application is noted. This progress is evidenced by the increase in the effectiveness of the "Ramp Ups" observed in the projects after the method's implementation (Figure 04). However, it is relevant to highlight the difficulties encountered during the implementation period, as can be seen in the initial performances of projects 11, 12, and 13. Among the difficulties that initially impacted the performance of the projects (Table 02), delays in the application of the tools and the lack of a database stand out.

Table 2: Impacts identified

Impact on Implementation	Level
Delay in applying tools	High
Customer Involvement in the Ramp-up process	High
Database shortage	Average

From this analysis, it was observed that the delay in the implementation of the tools had a significant impact on the adoption process of the new method. This situation arose mainly because the company's standard operational model did not anticipate a 60-day lead time for the start of these follow-ups. As a result, projects 11 and 12 started with only 30 days, compromising the available period for effective responses and identification of constraints, which ended up being identified too late. Despite these setbacks, projects 11 and 12 achieved positive outcomes. However, it is important to highlight that their performance, although satisfactory, did not reach the performance levels observed in projects 14, 15, and 16.

The presence and engagement of the client in the planning process and constraint removal are of vital importance, especially considering that various constraints emerge directly from their participation, such as license releases, project approvals, among other essential items for the construction's progress. In this context, the case of project 13 stands out, which, despite adhering to the 60-day advance preparation recommendation and achieving positive results, failed to replicate the high performance observed in projects 14, 15, and 16. This situation highlights the importance of effective collaboration with the client to overcome challenges and avoid delays, thus ensuring the smoothness and success of the construction process.

Another aspect that had a moderate impact was the lack of a comprehensive database on interferences and risk analyses, leading to a continuous refinement process. As the methodology was perfected over time, a notable improvement in the results of subsequent projects was observed, highlighting the continuous evolution of the method.

INFORMATION TRANSPARENCY AND THE VARIANCE ANALYSIS TECHNIQUE

When analyzing the tools implemented in the "Starting Right" method from the aspect of transparency, it is noted that, in general, all of them have the capacity to enhance communication among the involved parties. Particularly noteworthy is the integration observed between groups 3 and 4, as the support network structured by these tools continuously consulted the information surveys developed by tool groups 1 and 2. The discussions and analyses conducted through the support network played a crucial role, allowing the project to react agilely to unexpected events through active communication. However, during the implementation period, significant challenges were faced in attempting to establish a new culture within the company with the new routines. Many employees did not fully understand the proposed changes and, as a result, did not adhere to them as expected. It was essential for the construction engineers to provide regular guidance to their supervisors to ensure the adoption of the new practices until they could apply them independently.

It is important to highlight that, despite the initial positive results presented by the projects, it was essential to maintain the continuous use of the tools for the most part. This aimed to perpetuate transparency among the sectors, ensuring the sustainment of monitoring and control of the venture beyond the initial implementation period. It is worth noting that the tools were reused throughout the project, incorporating new analyses, risk identification, and proposition of solutions.

Moreover, a statistical analysis of variance was also conducted to further elucidate the effectiveness of the 'Starting Right' method. This analysis compared the schedule performances between two distinct groups of projects: those that did not implement the 'Starting Right' method and those that did. The data presented in Table 3 reveal a significant contrast between the groups, with the average of schedule deviations being negative for the group that followed the conventional method, indicating frequent delays, and positive for the group that adopted the 'Starting Right' method, reflecting earlier deliveries compared to the planned schedule.

Table 3: Variance analysis

Group	**Average**	**Variance**
Conventional	-1,25	1,51
Start Right	2,32	2,39

Interestingly, greater variance was observed in the projects that used 'Starting Right', particularly due to a substantial leap in performance between projects 11 and 15, where an improvement in schedule deviation from 0.5 to 4 weeks was recorded. This increased variance does not obscure the fact that, as evidenced by Figure 4, projects with the 'Starting Right' method consistently demonstrate superior results, underlining the method's potential to improve delivery during the Ramp-Up stage.

CONCLUSIONS

The "Start Right" method combines Lean construction principles with agile approaches, aiming to prevent premature project starts and achieve significant improvements in initial performance. Its application demonstrates the importance of strategically using tools for effective responses to various scenarios. The case studies addressed in this work showed that the application of the agile ramp-up methods, yielded positive results. The analysis encompassed 16 ventures, of which 6 adopted the new method. It became evident that determining the appropriate moment to start monitoring the constructions is of fundamental importance, highlighting the relevance of avoiding interruptions from the beginning of the projects.

The development of a database to document interferences and risks proved to be highly beneficial. Such a practice not only facilitated risk management but also significantly contributed to the enhancement and maturity of the method's implementation. However, it is important to note that, despite satisfactory results, the effectiveness of the method may be compromised in the absence of effective collaboration and joint planning with the client. This limitation was particularly evident in project 13, indicating that greater integration and alignment among all involved parties could have elevated the achieved results.

In this context, for the implementation of the Starting Right method, it is recommended to train employees on the presented tools, as well as to respect the appropriate time for the start of each phase. It is important to emphasize that the challenges faced by the construction sector vary according to its constructive characteristics, which can generate variations in the results. Therefore, it is suggested to expand the application of the method to other types of constructions in order to evaluate its performance. Additionally, fostering effective collaboration and joint planning with all stakeholders is essential for enhancing integration and alignment of th implementation. Continual evaluation and adaptation of the method should be carried out to align with the unique challenges and characteristics of each construction sector, accommodating variations in results and ensuring maximum efficacy.

The "Start Right" method combines Lean construction principles with agile approaches, aiming to prevent premature project starts and achieve significant improvements in initial performance. Its application demonstrates the importance of strategically using tools for effective responses to various scenarios.

LEAN CONSTRUCTION IMPLEMENTATION IN THE CONSTRUCTION OF AN AIRPORT RUNWAY

Lucas M. Moura[1], Bruno G. Antonini[2], Marcus C. T. Fireman[3], Bernardo M. B. S. Etges[4], Frederico R. Campos[5] and Bárbara K. Kronbauer[6]

ABSTRACT

This study explores the application of Lean Construction in the expansion and restoration of an airport runway, a project marked by complexities and high demands. The aim of this paper is to address the following research question: "What is the effectiveness of the daily scheduling approach compared to the weekly horizon approach for short-term scheduling in complex and variable infrastructure projects?". To answer this question, an extensive literature review was conducted, anchored in the action research method. It was found that the adoption of daily schedules may be more efficient, as it allows for greater agility in responding to client needs, accommodating constant changes requested by stakeholders, and managing uncertainties inherent in infrastructure projects of this nature. The results highlight significant advances in long-term adherence and project management effectiveness, despite encountered obstacles such as coordination among different stakeholders and adaptation to variabilities. The Percentage of Constraint Removal (PCR) improved by 22% from the start to the end of the project, while maintaining a 93% adherence to the Master Planning.

KEYWORDS

Lean construction, Last Planner® System, variability, constraint analysis, lookahead planning.

INTRODUCTION

It is estimated that in Brazil, there will be an investment of over 10 billion reais in airport infrastructure over the next 30 years (Brazil, 2022). Specifically, for the year 2024, an investment of 3 billion is expected, which would represent an increase of 65% compared to previous years. This scenario of significant investment highlights the necessity and feasibility of applying Lean Construction techniques and the Last Planner System to optimize costs, meet deadlines (Mohan & Iyer, 2005), and ensure operational efficiency (Castillo et al., 2014) in large-scale projects.

Lean Construction seeks to eliminate waste and maximize the value delivered to the client throughout the construction process (Koskela, 1992). The Last Planner System (LPS), in turn, is a methodology that integrates Lean principles for planning and controlling production in construction (Ballard & Howell, 2004). Both approaches have been successful in various sectors, however, when applied to infrastructure projects, they face specific challenges.

The present article aims to present a case in which Lean Construction and the Last Planner system were applied in an airport pavement project. Therefore, it intends to contribute to the development of Lean methodology in infrastructure projects. Thus, it seeks to answer the following research question: What is the effectiveness of the daily scheduling approach compared to the weekly horizon approach for short-term scheduling in complex and variable infrastructure projects?

LITERATURE REVIEW

For the diagnostic phase of the study, a comprehensive review of articles in the IGLC database was conducted to identify research addressing the challenges encountered in implementing Lean Construction and the Last Planner System (LPS) specifically within airport pavement projects. However, the search conducted on 05/04/2024 yielded no results for the term "Airport Runway". Upon broadening the search to the term "Airport", only seven results were returned. Of these, only one article (Herrera, 2018) directly addressed the challenges, while another (Tribelsky & Sacks, 2010) discussed waste management, emphasizing adaptability as a primary requirement and project issues such as "project overrun". These findings underscore the existing gap in the literature regarding the application of Lean Construction and the Last Planner System in infrastructure projects, as previously highlighted by Formoso et al. (2022) and Kassab et al. (2020).

Faced with this limitation, it was necessary to broaden the scope of the research, considering the similarities between airport pavement projects and complex infrastructure projects. Such projects encounter common challenges, including the presence of multiple stakeholders, varying levels of expertise, underground conditions, and the need for intensive coordination. Therefore, articles addressing the main challenges encountered in complex infrastructure projects were sought, aiming to develop a comprehensive strategy that meets all requirements and empowers the team in adopting the Lean philosophy. Existing literature highlights barriers such as the lack of support from senior management (Demirksen, 2019), communication problems (Opsahl et al., 2015), a lack of common understanding of the project's scope and objectives (Schöttle & Böker, 2023), and cultural resistance from those involved (Wandahl, 2014), were found in the literature.

Throughout the research, not only were the issues highlighted in the literature observed, but also successful aspects in projects. Authors such as Opsahl et al. (2015) emphasize the importance of engaging both employees and clients to ensure effective communication and trust development. Kassab et al. (2020) highlight the significance of maintaining commitment from all involved parties. The recommendations found in the literature were essential in guiding the implementation of Lean Construction and the Last Planner System in the journey presented in this article.

METHOD

This paper presents a methodological approach based on action research to assess the implementation of Lean Construction and the Last Planner System in an airport pavement project. The choice of action research as a method of investigation is grounded in the need for a practical and collaborative approach to solving specific problems in a real-world context (Eden & Huxham, 1996). By involving both researchers and action participants, this method allows for continuous assessment, iterative adjustments, and direct feedback, ensuring a thorough understanding of the implementation of Lean Construction and Last Planner System practices in the project.

The Action Research method is based on five main steps: Diagnosis, conducted during the literature review phase; Action Planning, evidenced in the pre-construction phase with the time location technique; Action taking, basing the work's success on Lean and LPS tools and routines; Evaluating, based on the indicators presented in the Results section; and Specifying learning, discussed in the Conclusion section.

BACKGROUND OF STUDY

PROJECT DESCRIPTION

The project carried out at Ministro Victor Konder Airport in Navegantes, Santa Catarina, Brazil, involved the expansion of the landing strip and the restoration of the existing pavement. Originally measuring 1700 meters in length and 45 meters in width, the runway underwent an extension to 1800 meters towards threshold 25. Additionally, threshold 07 was relocated, and Runway End Safety Areas (RESAs) were implemented at both ends. The runway, primarily composed of flexible pavement and rigid pavement at the ends, was adapted to support higher loads by replacing the flexible pavement with a greater thickness along the runway and widening the existing shoulder.

The scope also included the update of horizontal and vertical signage, lighting for low visibility operations, improvements in the drainage system, and a runway strip. Figure 1 presents a comparison between the existing runway and the proposed runway after the improvements are executed.

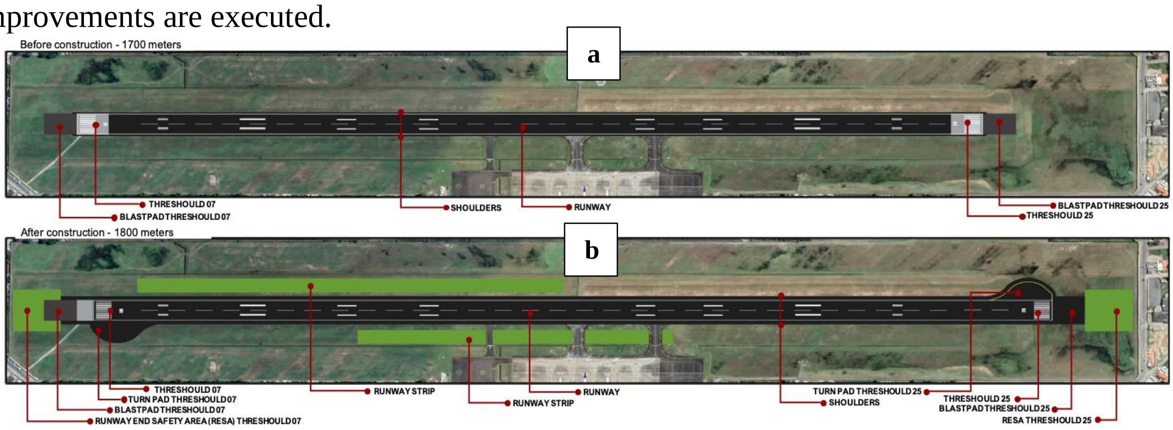

Figure 1: (a) Existing Runway; (b) Runway after the proposed improvements.

LEAN CONSTRUCTION JOURNEY

The Lean Construction implementation journey took place from May to November 2023. An implementation schedule for tools was conceived to introduce Lean Construction principles to project collaborators, as well as their practical application, monitoring, and continuous improvement. Figure 2 presents the timeline of Lean implementation in the Navegantes International Airport project.

In the first month the journey began with the execution of mobilization planning and priority plan studies. In the second month, the Last Planner System (LPS) was applied, integrating planning horizons and visual management tools, which were sustained throughout the entire project. In the third month, emphasis was placed on training and interactive activities about Takt Planning and focus on lessons learned and kaizens, more specifically on the definitive accreditation of collaborators and equipment. In the final months of implementation (four to seven) efforts were made for Pull Planning of drainage and lighting systems and detailed planning of micro-activities and commissioning.

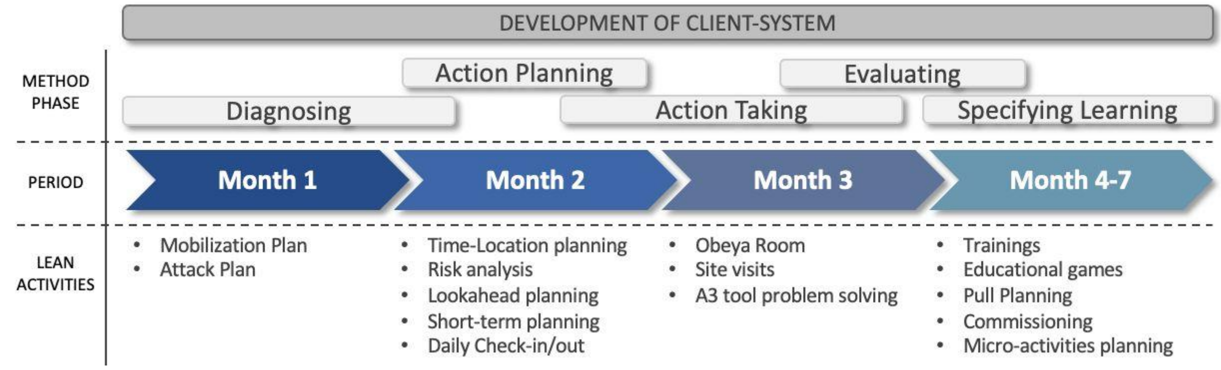

Figure 2: Timeline for LC implementation in the airport project

LEAN CONSTRUCTION IMPLEMENTATION

MONTH 1 – PRE WORKS

From the outset, the project was shown to be of high complexity due to the urgent need for mobilization to meet the contractual milestone with the client. Thus, a swimlane diagram was developed to map all activities (arranged chronologically) to be undertaken by the involved sectors (separated into lanes). These activities ranged from documentation and hiring of collaborators to the establishment of temporary facilities on site. This visual tool delineates the distribution of tasks and facilitates synchronized teamwork, ensuring transparency and cooperation among sectors, as demonstrated in Figure 3.

Figure 3: Swimlane diagram of activities for team mobilization; (a) routine execution; (b) final board

Simultaneously, a priority plan was developed aiming to establish a logical and efficient sequence of activities, with strategic allocation of resources to maximize productivity and reduce waste. This attack plan was developed using the Time-Location methodology to preliminarily map the temporal sequence and location of macro activities, offering clarity in understanding the project flow and facilitating the identification of potential conflicts and overlaps.

MONTH 2– LPS AND VM IMPLEMENTATION

The main challenge of the project was related to the restricted work window from 11:30 PM to 5:30 AM, due to the airport runway's operation during opposite hours. Any delay in production could interfere with the airport operations, making team efficiency a challenge due to time constraints and the need for daily mobilization to the airside of the airport. Recognizing that standard productivity rates in road projects would not be directly applicable in this scenario, studies of daily activities were necessary, focusing specifically on Hot Mix Asphalt (HMA) resurfacing service. The project demanded the application of HMA with different mixes and thicknesses, each presenting its own demands and challenges. Through scheduling scenarios, it was possible to identify an estimated daily productivity, considering time constraints and the processes of mobilization and demobilization. Figure 4 illustrates a pessimistic scenario of the daily schedule for asphalt resurfacing, considering the time constraints due to the continuous operation of the airport runway during opposite hours.

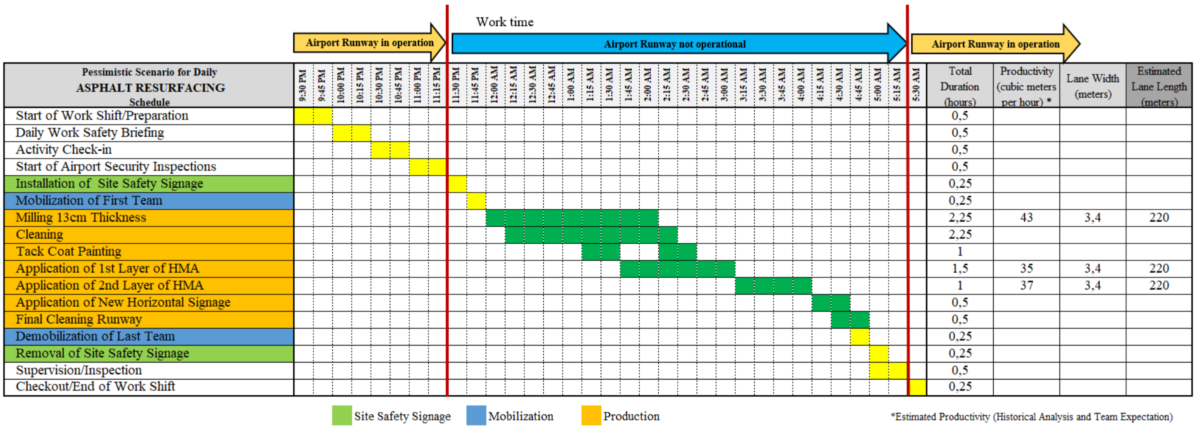

Figure 4: Daily schedule for asphalt resurfacing: pessimistic scenario

A workshop focused on risk identification was also conducted. This collaborative workshop allowed for the mapping of potential uncertainties, which, combined with the daily variation in productivity, was essential for constructing the master plan in a time-location format, integrating buffers into the schedule, and creating scenarios varying according to the identified risks and challenges. The strategy involved setting up macro work packages, as any service initiated had to be completed the same night. This master schedule was posted on the big room wall, as shown in Figure 5, to facilitate the visualization of the proposed attack plan by collaborators.

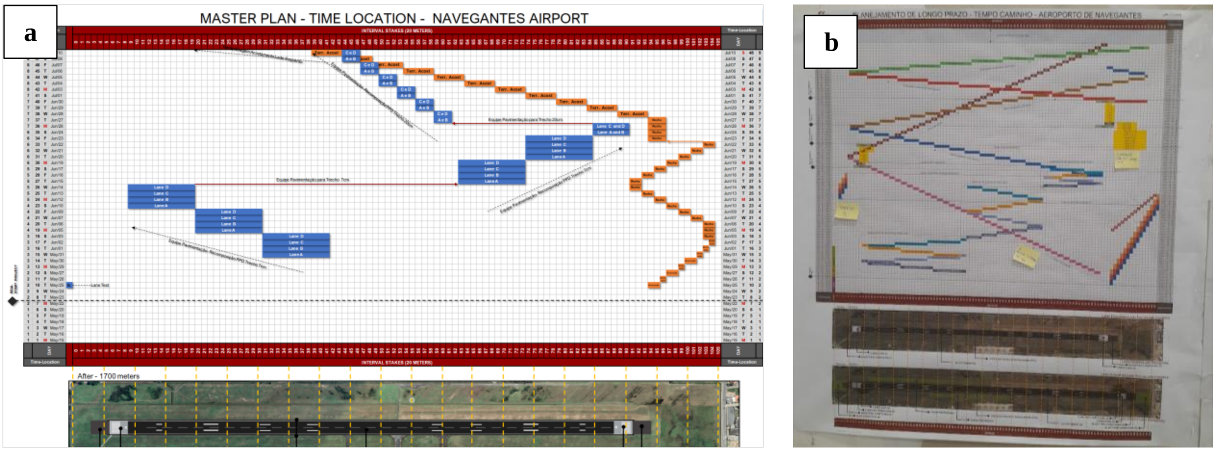

Figure 5: Time-Location master planning: (a) digital version; (b) printed version.

Within the implementation of LPS as a planning and production control system, medium-term, short-term, and learning dimensions were implemented, here represented by the Check-in/out routines as proposed by Ballard & Tommelein (2021). The Lookahead Planning was implemented with a six-week horizon, aiming for proactive identification of constraints and the generation of effective action plans to ensure uninterrupted workflows. From this medium-term routine, the Percentage of Constraint Removal (PCR) indicator was collected. The short-term, developed weekly in collaboration with production leaders, included the weekly activity plan. In this routine, the Percentage of Plans Completed (PPC) and adherence to production in quantity produced were collected. For daily control, daily check-in/out meetings were held for continuous monitoring of progress against the weekly plan, allowing for agile identification of deviations and interruptions for workflow efficiency.

These indicators, along with those developed with other sectors, were continuously presented in the Big Room or Obeya Room once a week for weekly performance evaluation, allowing the team to identify and prioritize the most critical issues. This approach enabled an improvement in collaboration between sectors, strengthening the support chain and its effective communication. All these control mechanisms were implemented due to the unique nature of this project, with constant plan changes from the client, continuity of Airport use during the day, and high variability of thickness with the removal of the asphalt layer. Figure 6 presents the high level of engagement and collaboration across all planning levels.

Figure 6: LPS meetings: (a) Lookahead planning; (b) Short-term planning; (c) Daily Check in/out

MONTH 3 – LESSONS LEARNED AND KAIZEN

Due to the expiration of the temporary accreditation deadline given by the airport administrator to the company, the definitive accreditation of collaborators and equipment became the main reason for the non-completion of scheduled activities. The critical period occurred between weeks 3 to 6, during which there was a peak in expirations resulting in up to 24% of workers being unavailable, as shown in Figure 7. This situation became particularly problematic because the unavailability of key operators from work fronts, such as paving, hindered the progression of activities.

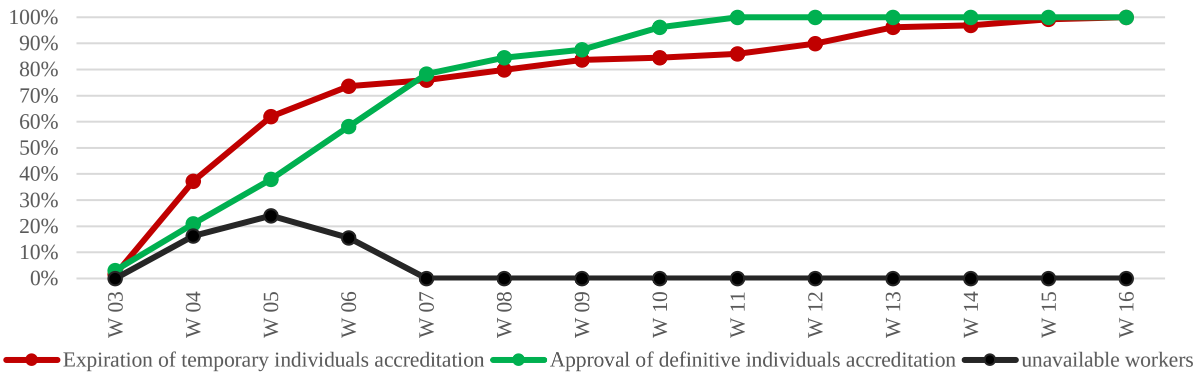

Figure 7: Expirations and Approvals of individual accreditation

Faced with the challenges of the temporary accreditation expiration and the subsequent need for definitive accreditation, the project team adopted proactive measures in August and September. The focus was directed towards training in problem-solving and the effective use of the A3 Tool for analysis and communication. This effort aimed not only to address the immediate issue of accreditation but also to strengthen the team's capacity to deal with future operational challenges. The client's uncertainty regarding accreditation processes exacerbated the situation, highlighting the need for a clear and effective action plan. To mitigate the negative impacts and optimize the accreditation process for the future, a detailed flowchart was developed, as shown in Figure 8, serving as an essential guide to simplify and expedite the accreditation procedure, demonstrating the commitment to continuous improvement and operational efficiency in the challenging context of airport projects.

Figure 8: Process mapping for individuals and vehicles airport accreditation: (a) digital version; (b) printed version.

MONTH 4 – 7 – PULL PLANNING SESSIONS

As the final step in the implementation of LPS, Pull Planning Workshops were conducted for training alongside third-party teams to study activities that were further removed from the long-term schedule. This approach involved teams responsible for the execution, aiming to map necessary tasks and their dependencies, identifying milestones, and establishing a logical sequence of activities to ensure efficiency in the workflow and meet the project deadline. In November, in the final phase, detailed planning of micro-activities focused on delivery and commissioning, tailored for the last three weeks. This meticulous elaboration ensured the identification, planning, and execution of critical tasks, guaranteeing an effective final inspection and the successful completion of the project. This slightly more detailed focus may deviate from the level of detail portrayed by the LPS literature, yet demonstrates that for this type of work, with high variability, it may be necessary to review the short-term planning horizon in order to enhance the predictability of service fronts.

DISCUSSION AND RESULTS

CHALLENGES DURING IMPLEMENTATION

Among the main challenges faced during the Lean Construction (LC) and Last Planner System (LPS) implementation journey, two stand out: the low performance of the Percentage of Constraint Removal (PCR) indicator and the low performance of the Percentage of Plans Concluded (PPC). Regarding the PCR, an average indicator of 54% was observed over the first 3 months of the project (June to August), a number also noted by Jang & Kim (2007) and Torre et al. (2021) in paving projects. This result can be explained by the various changes in the daily execution plan by the client. Despite the high climatic variability inherent to the region where the Airport is located, the change of plan corresponded to 22% of the reasons for non-completion of the week's activities, as presented in Figure 9. Such plan changes also led to an increase in the complexity of the service front (11%) and the lack of projects (10%), as there was not enough time for the prior study of the service front and the execution of the project. These difficulties are corroborated by Demirksen et al. (2019) who identified the main challenge for effective Lean implementation as the communication barrier among stakeholders, whether it be the difficulty in engaging the client or even the lack of effective information sharing and an integrated control of changes.

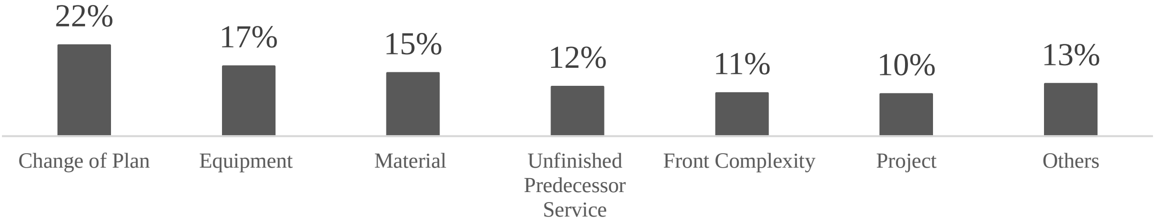

Figure 9: Main causes of interferences in the activities

This change of plan also resulted in not having enough time to identify and solve constraints in time. During the implementation, it was found that 69% of action plans in the lookahead planning were scheduled for the week following the identification date, as shown in Figure 10, indicating a challenge in effectively anticipating constraints. The six-week anticipation strategy, although implemented, proved to be potentially inadequate due to the high level of project uncertainties.

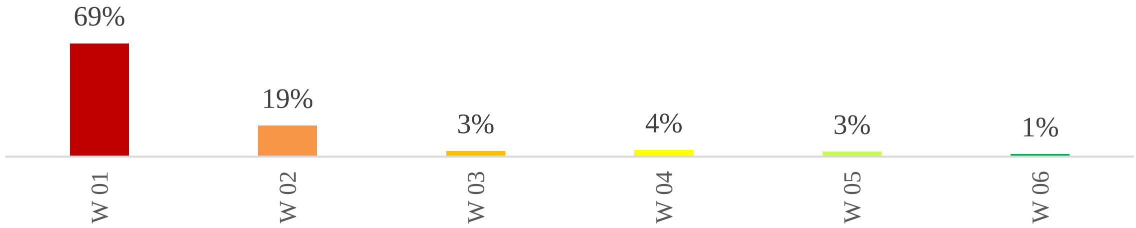

Figure 10: Average time of constraint identification in the lookahead planning routine

In light of this scenario, efforts were made to involve the client in the weekly lookahead planning meetings held in the Big Room. The room and the periodic meetings played a key role in engaging the client due to the transparency and visual management of the main pains felt by the service fronts. Thus, from month 5, a 22% improvement in the PCR indicator was noted, as shown in Figure 11.

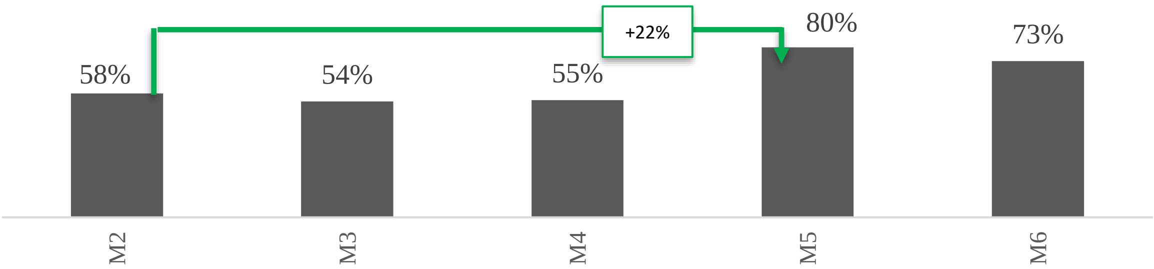

Figure 11: Monthly average PCR

Despite the correlation between PCR and PPC cited by Torre et al. (2021), the PPC did not follow the expected evolution, remaining at 41%, below the average found in the literature for paving works, namely 64% (Torre et al., 2021), 67% (Jang & Kim, 2007), and even 85% (Tezel et al., 2016). As mentioned earlier, most of the causes of non-completion are presented in the change of plan, demonstrating the high variability of the project.

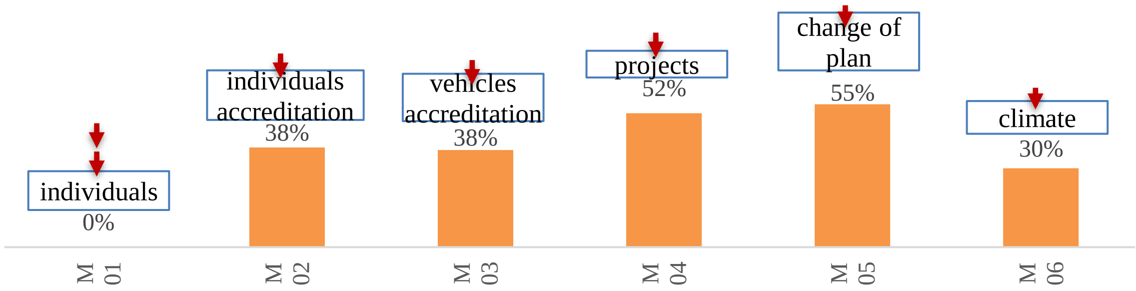

Figure 12: Weekly average PPC and problems

The low PPC indicator itself, coupled with satisfactory adherence to long-term planning, affected team morale. Therefore, a collection of weekly adherence based on the total quantity produced per day was initiated, which ended up raising team morale and maintaining satisfactory performance throughout the project. This adherence indicator showed an average performance of 75% throughout the project and also had an apparent correlation with the PCR indicator, as demonstrated in Figure 13.

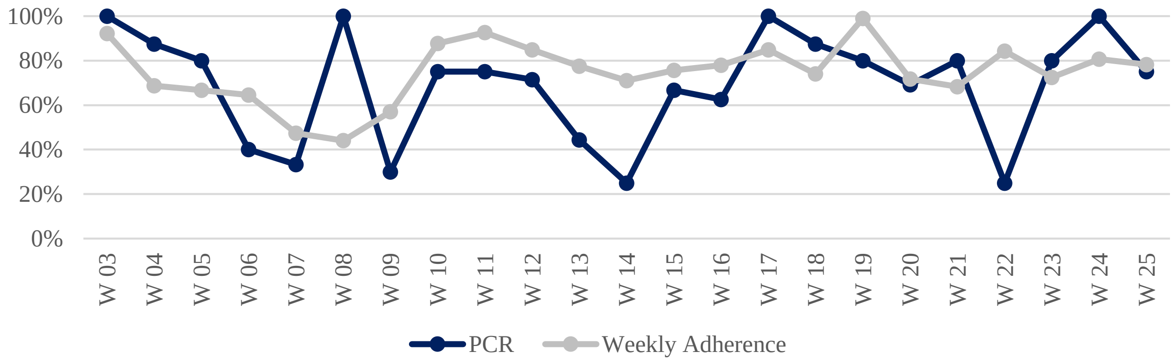

Figure 13: PCR and Weekly Adherence

OVERALL INDICATORS

Overall, the project was successful in the main long-term indicators, achieving 93% adherence to the planned long-term schedule and staying ahead of schedule in 27 of 29 project weeks. During the project, delays were identified only in weeks 2 and 9, with airport accreditation being pointed out as the main cause of these delays. However, the recovery plan effectively brought the project back on track after just one week. Week 21 marked the maximum advancement of the project, reaching 9% ahead of the planned schedule, as shown in Figure 14.

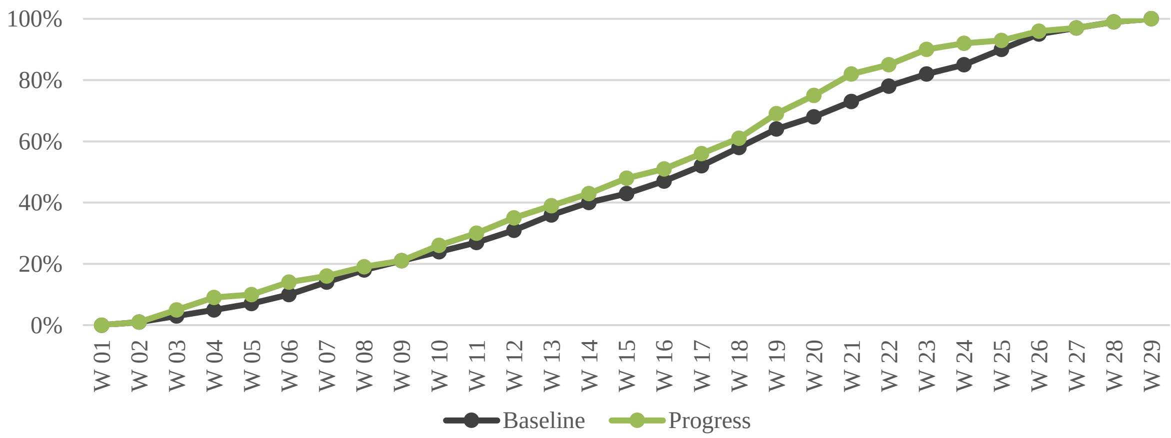

Figure 14: Physical progress chart of the project

CONCLUSIONS

The application of Lean Construction principles in an airport runway expansion and resurfacing project demonstrated significant improvements in schedule adherence and operational efficiency. The integration of strategies such as the Last Planner System and Pull Planning, complemented by visual management tools and collaborative work, resulted in more agile and adaptable project execution. Overcoming challenges such as accreditation constraints and climate variations highlights the importance of flexible planning and rapid response. The success achieved, marked by significant progress in scheduling and reduced variability in constraint removal, reinforces the value of Lean Construction in optimizing complex projects and promoting a culture of continuous improvement.

Analyzing the challenges faced during the project implementation, such as the low Percentage of Constraint Removal (PCR) and the Percentage of Complete Plan (PPC), resulting from low client engagement in routines, frequent plan changes, uncertainties related to accreditation, and local climate variations, questions the effectiveness of the weekly horizon approach for short-term scheduling in projects characterized by high complexity and variability, as addressed in this study. The analysis of the various stages developed over seven months addresses the research question proposed in this study, since that the adoption of daily schedules may be more efficient, as it better adjusts to the agility required by the client, considering the constant changes requested by all stakeholders and the uncertainties inherent to such infrastructure projects. It is also important to emphasize the need to seek mechanisms to engage the client throughout the project, as the active participation of all stakeholders is fundamental to ensuring the successful completion of the implementation journey.

PRINCIPLES AND PRESCRIPTIONS FOR THE DEVELOPMENT AND IMPLEMENTATION OF PERFORMANCE DASHBOARDS

Karina Barth[1] and Carlos Formoso[2]

ABSTRACT

Lean Production implementation in construction creates additional demands for Performance Measurement Systems (PMS), beyond what is typically suggested in general performance measurement literature. A PMS can support the implementation of Lean Production by evaluating the impacts of changes and providing information to guide organizations through this process. Some companies have adopted additional metrics during Lean implementation, but often limited to indicators related to the Last Planner System. Most companies still use traditional production control metrics, like cost, time deviation and project progress. There are opportunities for enhance performance measurement in Lean implementation programs, especially by incorporating leading indicators related to fundamental concepts and principles, such as pull production, work-in-progress, and continuous flow. Performance dashboards play a key role in achieving those objectives, facilitating information distribution across managerial levels, enhancing stakeholder communication, and encouraging participation. The main outcome of this investigation is a set of design principles (i.e. general recommendations that support decision-making in the design of a solution) and design prescriptions (i.e. suggested course of action for a given circumstance to achieve a certain effect) to guide the development and implementation of performance dashboards. This research is based on two empirical studies conducted in construction companies implementing lean production.

KEYWORDS

Dashboard, Performance Measurement, Indicator, Metric, Visual Management.

INTRODUCTION

The implementation of the Lean Production philosophy in construction creates additional demands for Performance Measurement Systems (PMS), in relation to what is suggested in general literature on performance measurement (PM) (Maskel, 1991). In fact, the literature suggests that the development of a PMS can play a major role in the introduction of any new managerial approaches, such as the Lean philosophy (Sarhan and Fox, 2013). PMS can support the implementation of Lean concepts and principles, by evaluating the impact of changes (Zanon et al., 2020) and providing information to guide organizations through this implementation process (Teh and Pang, 1999). A well-balanced PMS that contains a combination of leading and lagging indicators can contribute to cultural changes, reinforcing desired behaviours, values, and beliefs (Bourne et al., 2000; Naslund and Norrman, 2019). It also connects continuous improvement initiatives to strategic objectives, indicating

opportunities for improvement or the need for changes (Kennerley and Neely, 2003). Most importantly, PMS can be used to highlight intermediate benefits, such as increased management capacity, reduced work-in-progress (WIP), faster identification of problems and a greater willingness to change (Crawford and Cox, 1990). It is important to highlight these improvements in order to maintain the motivation and support of different stakeholders in the change process, as some goals normally established in these programs, such as improving costs and time performance, require a long time to be achieved.

In general, construction companies face many problems related to PM: (1) most metrics are focused on results, being ineffective to support real-time decisions (Sarhan and Fox, 2013) (2) some PMS contain too many metrics, mostly focused on supporting rather than critical processes (Costa and Formoso, 2004); (3) the conception of PMS is often limited to the selection of isolated metrics (Beatham et al., 2004); and (4) PMS are poorly integrated into continuous improvement initiatives (Kennerley and Neely, 2003). Moreover, the inappropriate use of PMS is a critical factor in the failure of Lean implementation programmes in construction (Sarhan and Fox, 2013). Some still use traditional production control metrics, such as cost and time deviation, which are strongly based on the thermostat model; in that context control means to meet a predefined standard by correcting deviations, without putting much effort into identifying and eliminating the root causes of these deviations (Koskela and Howell, 2002). By contrast, PM in Lean Production systems should point out different types of problems and support a deep understanding of the main problems (Koskela and Howell, 2002), which can be considered as sources of creative tension for continuous improvement (Spear and Bowen, 1999). Moreover, PMS should provide information that will be used as a reference for improving and learning (Pavlov and Bourne, 2011).

Some companies often adopt additional metrics during the implementation of Lean Construction, but these are often limited to indicators related to the Last Planner System (LPS) (España et al., 2012; Sacks et al., 2017), such as PPC, effectiveness in constraint removal, and causes for the non-completion of plans. Therefore, there are opportunities for improving PM in Lean implementation programs, especially by using some leading indicators related to fundamental concepts and principles, such as pull production, WIP, and continuous flow. Performance Dashboards (PDs) also play a key role in the achievement of those objectives as they create information fields that support the distribution of information among different managerial levels (Waal and Counet, 2008), improve communication between stakeholders (Bititci et al., 2016), and foster people's participation (Greif, 1991). Through the combined analysis of indicators, PDs make it possible to carry out more consistent evaluations and scenario projections (Pauwels et al., 2009).

The research question that guided this investigation is "How to develop and implement PDs as a visual management device that supports Lean implementation in construction companies?". This investigation is focused on the performance of construction production systems which can be assessed considering different dimensions: efficiency, lead-time, quality, safety, environmental impact, etc. The main outcome of this investigation is a set of design principles and prescriptions that can provide guidance for the development and implementation of PDs. This study is part of a doctoral research study that aimed to propose a prescriptive knowledge framework that consists of a set of preliminary propositions for design principles and prescriptions for the development of PMS to support the implementation of the Lean philosophy in construction companies (Barth, 2023).

PERFORMANCE DASHBOARDS

The purpose of a PMS is to quantify the efficiency and effectiveness of the actions established (Neely et al., 2005). This objective can be analyzed in relation to the achievement of corporate strategies, in relation to improvement programs, or in terms of local improvements (Bourne et al., 2000). Besides, a PMS has the purpose of supporting decision-making and fostering learning and continuous improvement (Franco-Santos et al., 2007). In addition, PMS can contribute to increase process transparency, a core Lean principle, by making visible some invisible process attributes.

PDs are visual management artefacts that bring together important information to support the achievement of one or more objectives, consolidated and organized in a single interface, so that the information can be combined and quickly analysed by users (Yigitbasioglu and Velcu, 2012; Vilarinho et al., 2018). Visual devices are considered as a means for improving the performance of production systems (Valente et al., 2019), but it is through their effective use that this mechanism can achieve its full potential (Parry and Turner, 2006). As a visual device that supports PMS (Bititci et al., 2016; Eckerson, 2011), a PD has the functions of: (i) support decision-making process (DeBusk et al., 2003; Sarikaya et al., 2019); (ii) allow monitoring of projects toward goals and strategies (DeBusk et al., 2003; Cahyadi and Prananto, 2015); (iii) promote a flow of information supporting communication within the company (Pauwels et al., 2009; Vázquez-Ingelmo et al., 2020); (iv) facilitate prioritization (Yigitbasioglu and Velcu, 2012); (v) support improvement and learning (Parry and Turner, 2006; Cahyadi and Prananto, 2015; Vilarinho et al., 2018); and (vi) encourage the delivery of consistent information (Pauwels et al 2009; Yigitbasioglu and Velcu, 2012).

Like any visual management device, the development of a PD includes a visual and a non-visual portion (Nicolini, 2007). Developing a visual management system involves much more than just designing the device itself (Valente et al., 2019). Some authors use the image of an iceberg to illustrate that the visual device itself (PD) is the small portion of ice that arises above water, while most of the work remains submerged (Eckerson, 2011; Valente et al., 2019). In fact, Valente et al. (2019) suggests that the development of a visual management practice should start by the analysing of the process (identifying main problems, potential causes, and who is involved), then identify users' needs (which information is relevant and what is the purpose of the tool), integrate the visual device into the process or routine (whether it is necessary to perform coordination tasks and promote collaboration), and conclude by defining the attributes of the visual device (the only stage that involves visual work).

Knowing those attributes helps to design visual devices that are in line with the needs of users and the company (Cahyadi and Prananto, 2015). In terms of visual elements, PDs should communicate ideas clearly and effectively. The use of colours, signs, symbols, and graphs can support prioritisation, alerting the user to what needs more attention (Yigitbasioglu and Velcu, 2012). Visual elements should draw the user's attention to the content of the data, avoiding redundant or unnecessary information. Dynamic PDs can be used to show different levels of data granularity for users at different hierarchical levels (Cahyadi and Prananto, 2015). Lower-level PDs should provide additional information (details, views, and perspectives) that enable users to understand problems in more detail (Eckerson, 2011).

Regarding non-visual elements, it is important to devise a database that allows data to be properly organised in order to keep a historical report on the company (Cahyadi and Prananto, 2015). PDs must be integrated with this database so that users can access the information when necessary (Yigitbasioglu and Velcu, 2012). One important concern is the IT system to be used (Cahyadi and Prananto, 2015). Business Intelligence (BI) systems are often used to detail information and analyse scenarios (Eckerson, 2011). However, the wrong use of IT can lead to a loss of focus on what is most important and hinder the use of PDs (Nicolini, 2007).

Although PDs have become popular as management tools, the literature does not reflect this trend. Various publications aimed at professionals, such as articles in the business press (Miller and Cioffi, 2004) and textbooks (e.g., Eckerson, 2011 and Few, 2006) discuss the format for visualising information on PDs, how to monitor and measure business with PDs and how PDs should be designed. However, only a few studies on the use of PDs to support PM can be found in academic journals (e.g. Bititci et al., 2016; Cahyadi and Prananto, 2015; Pauwels et al., 2009; Vilarinho et al., 2018; Yigitbasioglu and Velcu, 2012), and even fewer studies related to construction companies. Only 5 papers discussing PDs have been found in the IGLC proceedings (Barth & Formoso, 2008; Wong et al., 2009; Bølviken et al., 2017; Amaral et al., 2020; Amaral et al., 2022), and only three of them deal directly with the development of PDs.

RESEARCH METHOD

Design Science Research (DSR) was the methodological approach adopted in this investigation. This approach has a prescriptive character, and consists of developing solution concepts, called "artefacts", to solve classes of problems (van Aken, 2004; Holmstrom and Ketokivi, 2009). The artefact proposed in this research consists of a set of *preliminary propositions for design principles and prescriptions* for the development and implementation of PDs. This research has explored the development of PMS to support Lean implementation programs, considering production management in construction companies as the application context. A *design prescription* can be defined as a suggested course of action for a given circumstance to achieve a certain effect (Ropohl, 1997), while *design principles* are categories of prescriptions, i.e., general recommendations that support decision-making in the design of a solution or artefact (Vaishnavi and Kuechler, 2007). The artefact was developed as the result of two empirical studies, through collaborative work with two companies. Therefore, the research method can be positioned as *action design research*, i.e., design, implementation, and evaluation of an artefact collaboratively with potential users (Sein et al., 2011).

The two companies (Company A and B) were chosen because both had been involved in long-term programmes for implementing Lean concepts and practices in production management and also due to their interest in improving their PMS. Company A, founded in 1922, is one of Brazil's largest retailers, specialised in the sale of apparel, and acts as a client for commercial building projects. Annually, this company has 40 to 60 small-sized, fast projects, most of them refurbishments. Company B, founded in 1965, is a large firm that develops and builds residential building projects for lower-, middle-, and upper middle-class markets in Chile. Power BI was the IT platform chosen by Company A to support PM and the use of PDs, while Company B managed their metrics by using MS Excel.

The two empirical studies were divided into three stages: understanding the problem in its context; developing and implementing the PMS; and analysing and evaluating the PMS. There were some iterations between those stages, as in any DSR project. Besides understanding the real problem, the first stage had the objective of raising awareness and formalise a plan to develop a PMS to support the Lean improvement programme. Development and implementation stage was made up of several cycles for the creation of the artefact: planning, action (gradual implementation of the artefact), evaluation and reflection, which are typical of the iterative cycles of action design research (Holmstrom and Ketokivi, 2009). In practice, there was no separation between development and implementation. Rather, there was an initial emphasis on the development (construction) of the PMS when it was being conceived. When the team felt that the prototype was ready to be tested, the emphasis shifted to action, evaluation, and reflection. What divided the development from the implementation was the decision by each of the companies to allocate an internal team in charge of implementing the PMS. The "analysis and evaluation" stage was carried out individually for each company, considering the prototype implemented.

At the beginning of each empirical study, a working group, named "PMS Group" was created, to support the development of this research. This group was made up of representatives from different departments of the organization and the first author of this paper. There were meetings every other week during the development of each empirical study. Occasionally, other company representatives were invited to support the discussion on specific topics.

The set of requirements for PMS proposed by Barth and Formoso (2021) was used as the basis for the development of the PMS Group's work. It began with the development of **maps of objectives and strategic actions** for the Lean implementation program in each company, with the aim of explaining and prioritizing implementation actions in the development of the PMS. From the elaboration of those maps, the PMS Group proceeded with defining the elements of PMS, which encompass not only the indicators themselves, but also PDs and cycles of learning and continuous improvement within the PMS. These cycles involve decision-making instances, reports, assigned responsibilities, frequency, and inputs and outputs for each stage. After several discussions among the PMS Group, a proposal of PMS emerged and was presented to representatives of each company. The proposal was refined based on the suggestions made from those professionals and moved on to implementation. The PMS Group continued to refine the PMS proposal along the implementation process.

In both empirical studies, the PDs were partially implemented due to time and human resource constraints on the part of the companies. At Company B, the **planning** and **operational PDs** were tested, but the proposed **tactical** and **strategic PDs** were presented to the company representatives in a mock-up format. At Company A, the **planning PD** was tested, and the **operational** and **tactical PDs** proposals were delivered in mock-up format. Strategic **PD** was not part of the research at Company A.

Multiple sources of evidence were used, including participant observation (LPS meetings, PMS Group meetings, and meetings with professionals from the companies studied), direct observation during visits to construction sites, individual and group interviews, document analysis, analysis of existing software tools and existing company databases. Table 1 summarises the time spent in each source of evidence for different research stages.

Table 1: Summary of hours spent in each source of evidence for different research stages.

Stage	Source of Evidence	Company A	Company B
Understanding	Participant observation	23,8hr	26,5hr
	Direct observation	6,0hr	13,5hr
	Individual and group interviews	12,5hr	5,0hr
Development and implementation	Participant observation	61,5hr	106,5hr
	Individual and group interviews	2,0hr	-
Analysis and evaluation	Participant observation	15,8hr	1,5hr
	Individual and group interviews	-	6,3hr
Total		121,5hr	159,3hr

RESULTS

MAPS FOR THE LEAN IMPLEMENTATION PROGRAM

The PMS Group developed maps of goals and strategic actions for the Lean implementation program, in the short, medium, and long term (Figure 1). Intermediate goals were defined based on long-term strategic goals, which were the point of departure to establish actions connected to the Lean implementation program. Those actions were distributed across seven managerial processes: (1) production, (2) quality, (3) design and BIM, (4) people, (5) costs, (6) supply chain, and (7) performance measurement and learning.

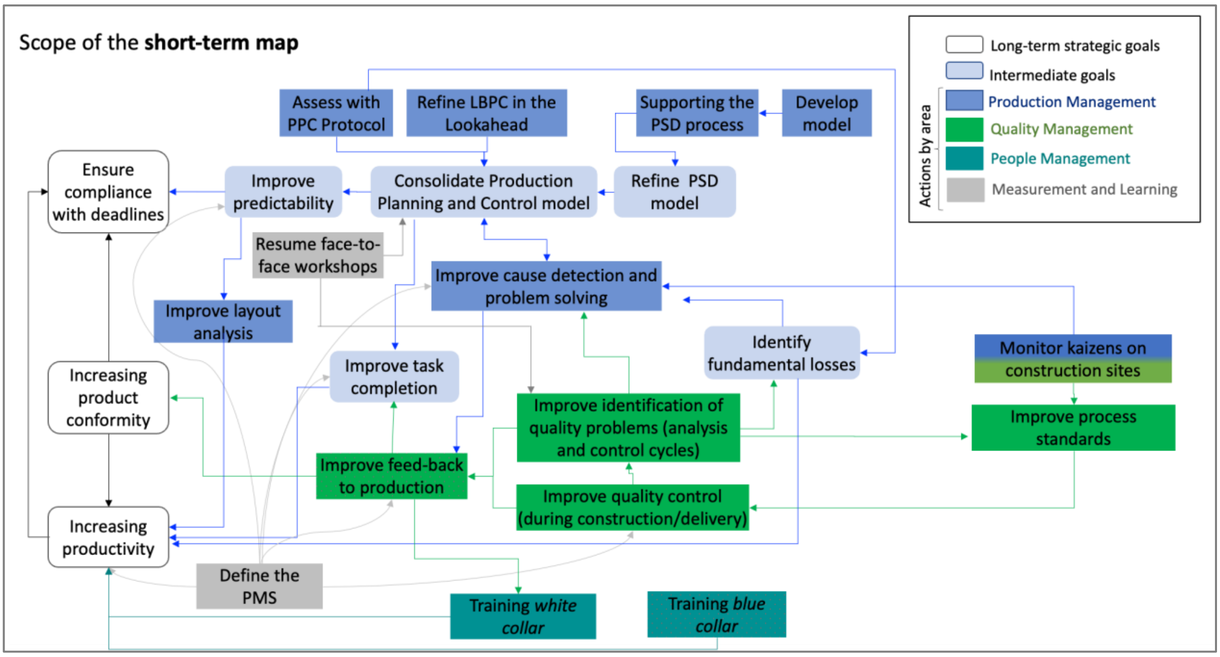

Figure 1: Example map of goals and strategic actions for the Lean program.

INCLUSION OF NEW INDICATORS

In an effort to assess the performance of production management, considering some core Lean principles, the PMS Group suggested the inclusion of new indicators. Adherence to planned batches, cycle time and tagging differentiated work packages (e.g. rework, non-planned work packages, etc.) were proposed to monitor WIP. Indicators were also proposed to assess the status of production, based on a tool named production status matrix, and to monitor the rhythm of activities being carried out (control of batch completion rhythm) (Barth and Formoso, 2021), as well as metrics for projecting the conclusion of the construction stage.

The planned batch adherence graph compares the planned start and finish of each batch with the actual start and finish. This graph also makes a projection of the expected start and finish dates on the basis of the data obtained on the same batch, allowing improvement actions to be taken in time to change unwanted results. The cycle time graph complements this information, in which variations can be monitored. Tagging differentiated work packages graph is a stratification of the work packages planned and executed in the short-term plan, which are labelled according to their nature (informal activities, rework activities, percentage of backlog activities that are executed, etc.). A high volume of informal work indicates that part of the workforce capacity is being planned informally and may be being used to execute activities that do not add value.

The development and implementation of these indicators was carried out in collaboration with its representatives of each company, in pilot projects. During those pilot projects, the need to develop a database to organize the information generated by the PMS was identified. The PMS Group was in charge of developing a database by using MS Excel spreadsheets, seeking to automate data collection based on existing controls. It is important to emphasise that most of the indicators proposed in this research work can be obtained from a small number of control tools, as there was a concern with limiting the data collection effort. Adherence to planned batches, cycle time, control of batch completion rhythm, project completion projection can be obtained from the status control matrix. Differentiated work packages can be identified in short-term plans.

PERFORMANCE DASHBOARDS

Based on the definition of new indicators and the construction of the database, each PMS Group devised a set of **planning PDs**, which evolved throughout discussions with representatives of different areas of the company. PDs were developed for the operational, tactical, and strategic levels. Moreover, some specific PDs were developed according to requirements of each company. Company A, for instance, chose to use a PD that grouped together short- and medium-term SLP indicators, while Company B chose to use a PD for each planning horizon. In Company B, in addition to the typical LPS indicators, the medium-term PD had a strong emphasis on location-based planning and control (LBPC) indicators (adherence to planned batches and cycle time). Due to space limitations, only operational and tactical PDs developed for Company B are presented in this paper. A complete description of all PDs is presented in Barth (2023).

The **operational PD** (Figure 2) groups together the indicators of one project divided into five zones: cost, labour efficiency, quality, project deadline and planning. A second interface of the operational PD also contains graphs of LBPC indicators for some processes considered critical to the projects. Moreover, the **production status matrix** is presented as part of the operational PD in company B (Figure 3), where it is possible to monitor fully completed batches, WIP, rework and interrupted work.

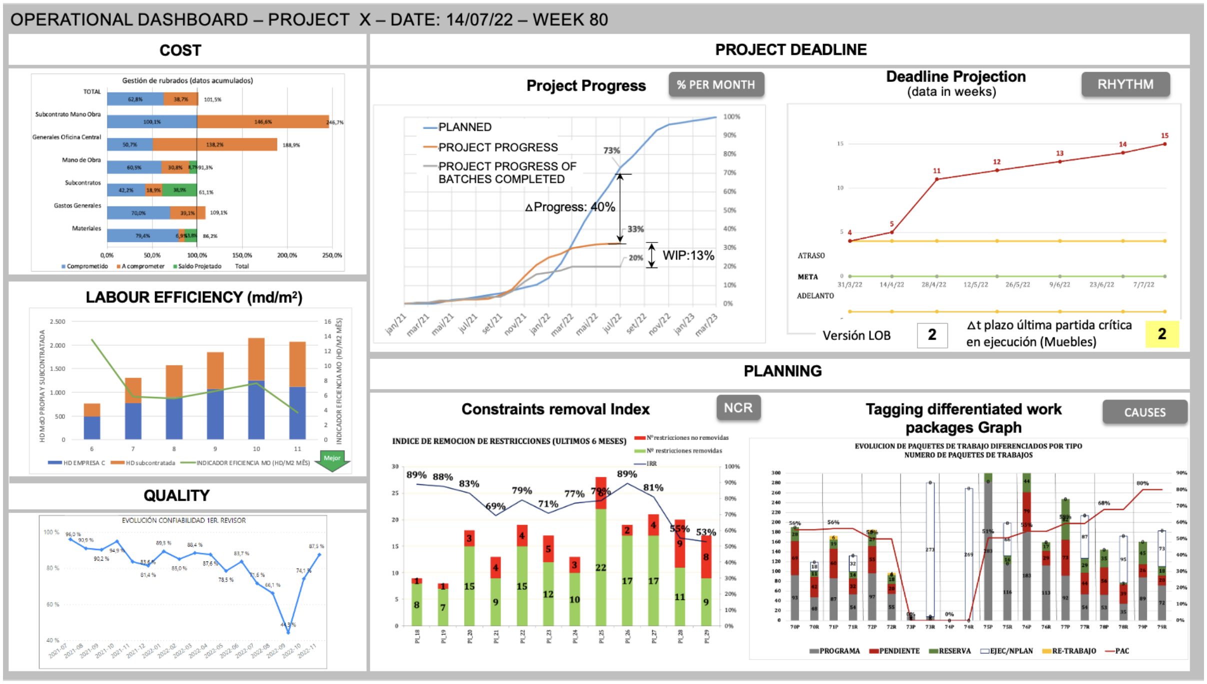

Figure 2: Example of Operational PD for residential building project.

Figure 3: Extract of the Production Status Matrix: part of the operational PD.

The tactical PD (Figure 4) enables comparisons between projects to be made, supporting meetings involving the whole production management staff, in which information is exchanged between site managers from different projects and the top production manager. The **tactical PD** was divided into six areas: cost, project progress, project duration, quality, labour productivity and safety management. The **strategic PD** was divided into four zones: planning (including time deviation, and project progress with and without batch completion), cost (cost deviation), quality conformance, and labour utilisation metrics (outcomes measured by area and monetary units).

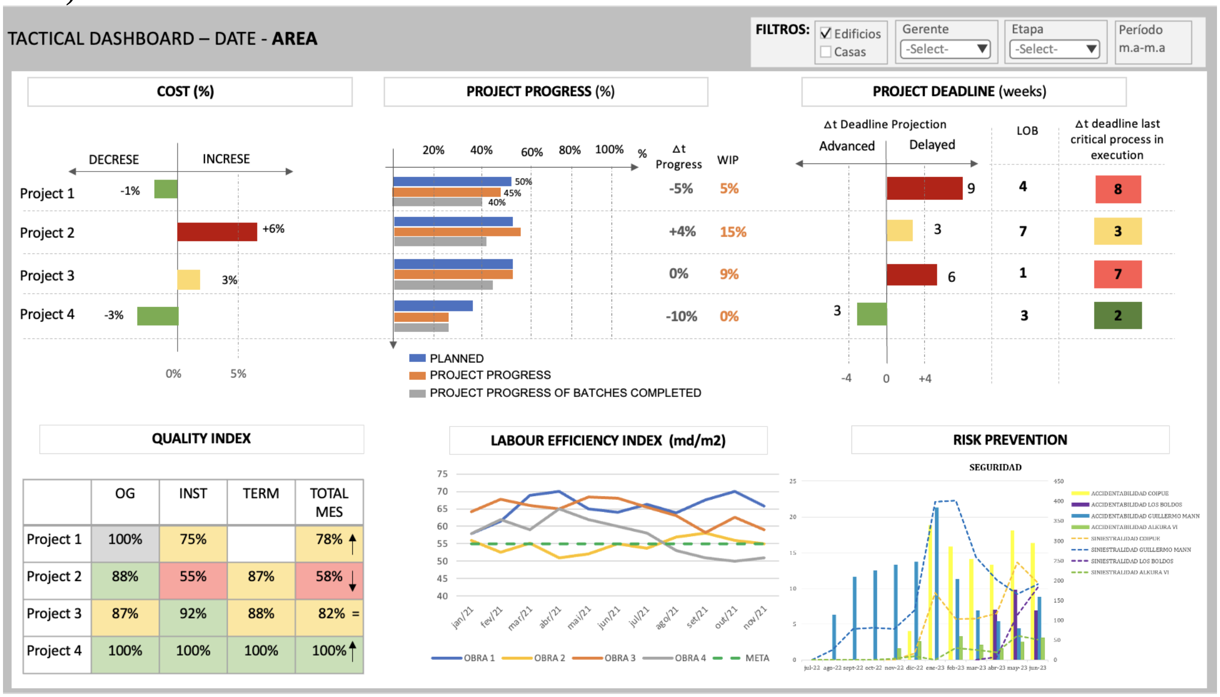

Figure 4: Example of Tactical PD for residential building project.

ESTABLISHMENT OF DECISION-MAKING INSTANCES

Some decision-making formal instances were defined in order to formally define control points and learning cycles for continuous improvement. Those control points must be regarded as moments for analysis and reflection, based on indicators connected via PDs. In fact, some regular meetings that already existed in the companies were adapted to include PD analysis. In Company B, the short-term planning PD was used to discuss the results at the weekly commitment planning meeting, whereas the medium-term planning PD was used in look-ahead meetings every fortnight. The operational PD was connected to a monthly meeting between the Site Manager and the Project Manager, named operational meeting. The tactical PD was used for a monthly meeting between each Project Manager and the company Overall Construction Manager, to present the results of the projects under the responsibility of the former. In addition, a lessons-learned meeting was held three times a year, in which Project Managers presented good practices and improvement opportunities identified in the projects completed during the period.

NON-VISUAL ELEMENTS

For each proposed PD, the PMS Group defined a person in charge for compiling the indicators and generating the reports. This is concern with the non-visual part of the PMS, that is necessary to generate an update version of the visual device (Valente et al., 2019). The flow of information generated by the PDs had to be made clear, to make reliable connections between operational, tactical, and strategic PDs. In this flow, the goals are broken down from the strategic level, through the tactical PD, up to the operational level. This allows a user at the strategic level to access detailed information by using the tactical and operational PDs, when necessary, as suggested by Eckerson (2011) and Cahyadi and Prananto (2015). At the operational level, goals and feedback are also disseminated among the construction site teams. The information generated by PM at the operational level, feeds back into the tactical and strategic levels, creating a bottom-up and top-down flow, as suggested by Bhasin (2012).

DESIGN PRINCIPLES AND PRESCRIPTIONS

Based on the literature review and the two empirical studies, five design principles and 8 prescriptions for developing and implementing PDs to support production management in construction companies was proposed. Some of the observed practices involved in the implementation of PMSs of the two empirical studies are presented as examples of the application of the set of principles and prescriptions.

Principle 1: Include a set of leading and lagging indicators that complement each other and help overcoming limitations of individual metrics.

Prescription: Use combined controls to anticipate future results. Practice identified: analysis of project progress (lagging indicators) combined with plan reliability (PPC), status of WIP and delivery projections (leading indicators) and rhythm curves.

Principle 2: Promote improvement and learning.

Prescription: Identify emergent connections between indicators as a way of learning. Practice identified: the users of the PD identified that the higher the degree of completeness of batches, the better the quality of the final product, considering that fewer assessment and finishing tasks needs to be carried out.

Principle 3: Support decision-making by providing meaningful and timely feedback to users.

Prescription: Identify the information needs of different stakeholders. The choice of indicators and the way they are displayed depend on the specific needs and knowledge of each user (e.g., managers, workers, and subcontractors). *Practice identified:* PDs were designed to include both the information required by their direct users and the information considered important by those who assess performance at different managerial levels.

Prescription: *Use PDs as visual management devices*. Visual devices must be designed for users and made available so that the necessary information is accessible (Valente et al., 2017). *Practice identified*: the use of dashboards to monitor production status, giving visibility to the situation in each production batch, and at the same time providing data on cycle time, WIP, and task completeness.

Prescription: *Connect PD analyses to a decision-making instance. Practice identified*: PDs need to be connected to formal meetings (e.g. LPS meetings), otherwise they are not systematically used. Note that this is a requirement, but simply connecting PDs to instances of analysis and reflection does not guarantee that they will be used for decision-making. The combination of different design principles is what makes it possible to achieve the desired effects.

Prescription: *Use IT to develop PDs and automate data collection and processing, and define the human resources for implementation.* IT helps to reduce the time and effort needed to collect and process data (Bhasin, 2012), but it is also important to assign tasks to those responsible for conducting this process. *Practice identified:* use of business intelligence software or spreadsheets to introduce automation in the generation of PDs. This prescription was partially implemented in the two empirical studies.

Principle 4: Show production status.

Prescription: Monitor production status by using the status control matrix. Monitoring the system status makes it possible to apply pull production, defined by Hopp and Spearman (1996) as authorising the release of work based on the status of the system, in order to avoid WIP. Practice identified: Use of leading indicators and visual devices (production status matrix) to monitor production status.

Principle 5: Provide information to deal with variability that cannot be removed.

Prescription: Give visibility to processes and results. Construction projects, like other complex systems, are characterised by a high degree of variability that cannot be fully removed (Williams, 1999). The PMS must provide information that makes complexity visible so that people can learn from information about anomalies and informal practices. *Practices identified:* Measurement of informal practices, represented in the differentiated work packages chart at the operational PD; making explicit non-visual work in the process of generating PDs and the staff responsible for that.

Some of the proposed prescriptions are related to the conception of PD, whereas others are concerned with their implementation, such as "identify emergent connections between indicators as a way of learning", "use PD as visual management devices", and "connect PD analyses to a decision-making instance".

CONCLUSIONS

The main outcome of this research work is a set of 5 design principles and 8 prescriptions for the development and implementation of PDs to support production management in construction companies. Those PDs have played an important role in the Lean implementation programs of the companies involved in this research study, as they have made the use of PM more systematic, and introduced a number of metrics related to Lean concepts, which are not usually adopted in construction companies. The implementation of the PDs required explicit planning of the non-visual activities needed to generate the necessary metrics, as well as the establishment of formal meetings for analysis and reflection. The use of these visual management devices made it possible to explore connections between the indicators, resulting in analyses more consistent with the reality of the projects. The use of PDs was promoted by connecting them to decision-making instances (LPS and other formal meetings), which encouraged the frequent updating of the indicators that were part of the PMS. In addition, the PDs made it possible to make the flow of information between the different hierarchical levels transparent.

Further work is necessary in the assessment and refinement of the proposed knowledge framework (design principles, prescriptions, and practices) so that it can be widely used in the implementation of Lean Construction. This is considered the main limitation of the proposed artefact.

PROPOSAL FOR A DEADLINE DEVIATION INDEX BASED ON LINE OF BALANCE AND RHYTHM DEVIATION DATA

Marcus P. Sterzi[1] and Fabiana Bonesi[2]

ABSTRACT

The line of balance (LOB) plays an important role in the implementation of Location-Based Planning and Control (LBPC), inducing most activities to be carried out at only one production rate and enabling the established deadlines to be met. Monitoring deviations from these deadlines is essential for project success, particularly in the construction industry. Rhythm deviation, an indicator rooted in Lean Construction principles and closely linked to LBPC, reveals the interference of critical tasks with other project activities and enables the analysis of how rhythm deviation of critical activities affects the project's deadline deviation. Analysing deadlines using the LOB technique in combination with rhythm deviation helps identify which activities are associated with project delays and advancements, allowing for corrective actions to improve workflow. However, this topic receives limited attention in the literature. The aim of this research is to propose a Deadline Deviation Index for monitoring and projecting delays and advancements in construction projects based on LOB and rhythm deviation data. This paper adopts an Action-Research methodology within a Case Study Approach. It presents findings from a case study involving 12 residential building projects that utilized location-based methods for scheduling and control, alongside rhythm deviation for monitoring critical processes. The results underscore how integrating the LOB technique with rhythm deviation enhances workflow and deadline management, thereby refining the sector's ability to estimate delays and advancements.

KEYWORDS

Location-Based Planning and Control (LBPC), Takt planning (TP), Line-of-Balance, Rhythm Deviation, Deadline Deviation.

INTRODUCTION

Traditionally, companies in the construction industry have relied on physical progress (a metric based on the Earned Value Management) as an indicator to measure project performance and progress (in terms of the volume of work carried out) over time (Kim & Ballard, 2002). However, result indicators, such as physical progress, tend to be reactive, focusing on the past and inefficient for supporting decision-making (Sarhan and Fox, 2013). Additionally, this indicator does not reflect time deviation, or a deadline projection based on Lean principles. Analysing the performance and progress of a project based on Lean principles should consider a set of factors: causes of problems, waste elimination, continuous improvement, zero defects,

[2] MSc, Building Innovation Research Unit (NORIE), Federal University of Rio Grande do Sul (UFRGS), Porto Alegre, Brazil. Consultant and Managing Partner at LD Consulting, fabiana@ldconsulting.com.br, orcid.org/0000-0002-9899-7798

just-in-time, multifunctional teams, variability, and cycle time of critical processes (Karlsson & Åhlstrom, 1996; Koskela, 1992). In this way, process indicators can enhance the reliability of result indicators, as they focus on assessing performance at intermediate stages while providing information during execution to identify possible losses and problems (Braglia et al., 2019).

In this context, LBPC can address the shortcomings of traditional models. LBPC can be defined as a planning and control approach that allows for: (i) identifying critical construction processes in a time-location-context relationship; (ii) explicitly managing workflows on-site; (iii) supporting decision-making at different planning levels (Lucko et al., 2014). LBPC involves a set of techniques, including the line of balance (LOB), which represents the master plan (Ballard & Tommelein, 2021).

Adopting the Location Breakdown Structure (Kenley & Seppänen, 2010) and applying the LOB technique enables a better understanding of a project composed of repetitive activities because it allows for adjusting activities' production rates. It facilitates a smooth and efficient flow of resources and requires less time and effort to produce than network schedules (Arditi & Albulak, 1986). The LOB technique provides a clear overview of the project's overall status by quantitatively representing the cumulative completions of activities associated with a planned number at a given time (Suhail & Neale, 1994). It graphically reveals any imbalances that suggest a deviation from the plan due to the uneven progress of activities, enabling management to focus on assessing the deviation quantitatively (Khisty, 1970). The major benefits of the LOB are that several concepts related to Lean Production Philosophy are explicitly used, such as batch size, work-in-progress, cycle time, and the rhythm of processes (Schramm et al., 2006).

The rhythm deviation of critical activities is a performance indicator that incorporates lean concepts, strongly related to LBPC, specifically to Takt Time Planning (TTP) (Barth et al., 2019). According to Barth et al. (2019), the rhythm deviation control represents a form of critical process control, considering only fully accomplished tasks (batches). Each team must complete their work in a specified batch within a certain amount of time, also called takt time (Frandson et al., 2013; 2014). In this context, monitoring the rhythms of critical activities and their impacts on other activities can provide the trend of completing the last critical process (Barth et al., 2019), and consequently, the deadline projection.

Studies on LBPC (Kala et al., 2012; Seppänen et al., 2013; Frandson et al., 2013; 2014) have not extensively explored integrating LOB technique with performance indicators, such as the rhythm deviation of critical processes, to analyse deadline control in construction projects. Managing workflow through LOB technique alongside analysing rhythm deviations has the potential to proactively control delays and overruns in a production planning and control system based on Lean principles. So, this research aims to propose the application of a Deadline Deviation Index for monitoring delays and advancements in construction projects, as well as to establish a graphical representation indicating deadlines based on LOB and rhythm deviation data.

CASE STUDY

With 60 years of history, the company under study is currently the largest real estate group in Chile and one of the largest in South America. It is a fully integrated company that acquires land, designs, and constructs projects, and sells the end products. Most of residential building projects delivered by the company exhibit a high degree of repetitiveness, such as horizontal housing estates and vertical buildings. This company operates in 13 out of the 15 regions of Chile and sells more than 3,000 units per year. The company initiated a significant transformation process that resulted in a larger corporation with different brands focusing on distinct customer segments.

PREVIOUS RESEARCH AND PRACTICE

A Lean Implementation Program has been carried out in the company with the support of a consultancy firm and a research institution, both from Brazil. Previous research (Barth et al. 2019; Barth et al. 2020) reported the implementation process and presents a preliminary assessment of the impacts of the Lean implementation program.

RESEARCH METHOD

The methodological approach adopted in this investigation was Action-Research, based on a Case Study Approach. Action-Research is an approach that allows the active participation of the researcher in the observed phenomenon (Thiollent, 2005). Thiollent (2005) defines action research as a specific type of empirical-based research that is conceived and carried out through action in which researchers and some participants in the situation or problem are involved cooperatively. According to Dick (1993), action research has two objectives: action to bring about change in organizations and research to increase understanding of the topic under study.

A Lean Implementation Program was conducted within the company with the assistance of a consultancy firm. The researchers, who also acted as consultants and facilitators, were actively engaged in executing interventions or modifications based on the research findings, collaborating closely with company stakeholders to drive change. Additionally, the researchers maintained a continuous process of reflection to refine the research methodology and gain deeper insights into the identified challenges and potential solutions. Lastly, they disseminated the findings of the action research to pertinent employees, thereby enriching the collective knowledge base and potentially catalysing further initiatives.

The proposed Deadline Deviation Index has been tested and refined in 12 projects undertaken by the company. Ten out of the twelve projects had implemented Last Planner System (LPS) and LBPC, as well as the rhythm deviation of critical activities for analysis of the project deadline. Multiple sources of evidence were utilized in each project: interviews with site engineers and project managers, participant observations in (LPS) meetings, direct observations of the construction site, and analysis of planning documents.

The steps used to implement this Index are as follows: (a) train individuals to comprehend the significance of measuring rhythm deviation based on Lean concepts and principles; (b) designate responsibility for data collection and analysis; (c) create a rhythm deviation matrix and charts; (d) gather data; (e) utilize visual aids to disseminate information; (f) generate the Deadline Deviation Index; (g) analyse data, discuss rhythm deviations, deadline deviations, and establish corrective actions; and (h) report to various hierarchical levels within the company.

DISCUSSION AND RESULTS

LINE OF BALANCE DELIVERY STAGES

One of the fundamental stages in the development of LOB is the identification of Delivery Stages or milestones of the construction project. These Delivery Stages play a crucial role in referencing and predicting potential project delays or advancements in relation to the existing Master Plan. Therefore, the LOB model implemented in the studies must effectively demonstrate the different stages of delivery. The first delivery stage was associated with rough construction; the second delivery stage involved raw finishes. The third delivery stage addressed punch list items, and the fourth delivery stage focused on client delivery. The Figure 1 illustrates the workflows and delivery stages (both partial and final) using the LOB technique.

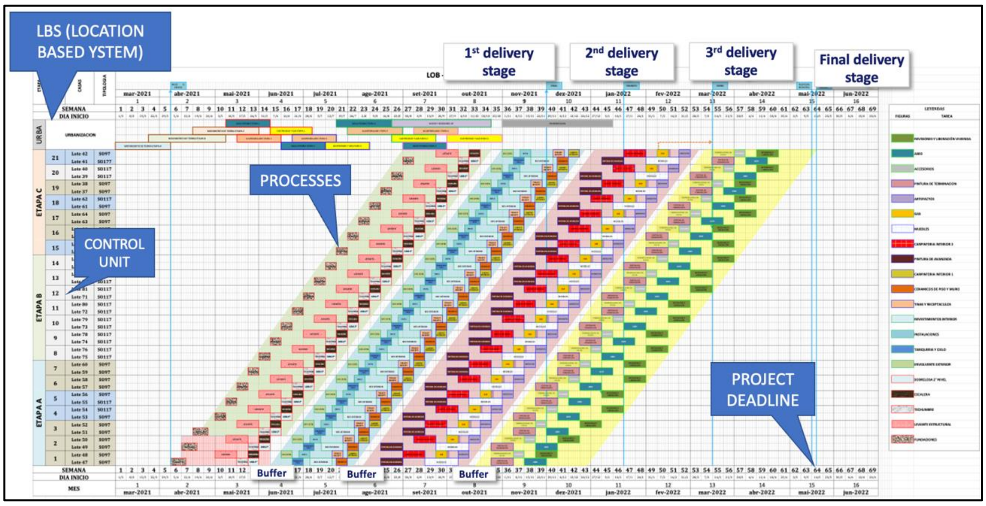

Figure 1: Example of Definition of workflows (whole project) and Delivery Stages (partial and final) through the LOB technique

RHYTHM DEVIATION FOR CRITICAL PROCESSES

The LOB developed for the construction projects under study, along with their respective delivery stages, provided the data that served as input for the creation of rhythm deviation control charts. In this context, planned and real completion dates, as well as the corresponding quantity of planned and real batches completed within a specific period, were compiled into an integrated database that allowed for the generation of rhythm deviation control charts. The rhythm deviation encourages the entire team, including subcontractors, to prioritize batch completion alongside integrated quality control measures. In this study, all 12 residential construction projects analysed applied the rhythm deviation in monitoring critical activities.

Figure 2 illustrates the rhythm deviation chart developed for a critical activity. The rhythm deviation is represented by the difference (in weeks) between the planned date in the current LOB and the real execution date of the critical activity. This allows monitoring the actual pace of the activity in relation to the planned pace in the current LOB, as well as projecting the execution pace until the completion of the activity based on resource analysis and constraints of each critical activity. The data enable the analysis of strategies and resources needed to reduce pace deviation in future weeks.

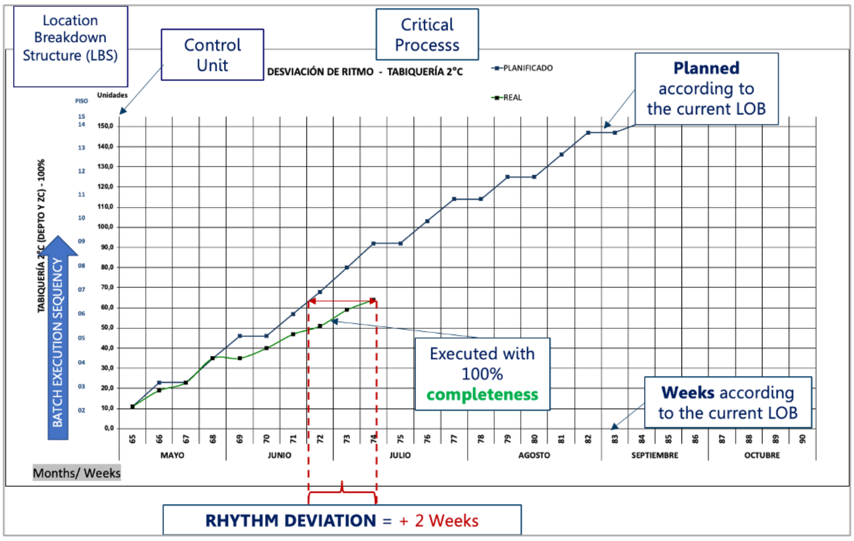

Figure 2: Example of a chart to monitor the rhythm deviation of one critical construction process.

Figure 3 illustrates the integrated rhythm deviation chart of different critical activities, enabling monitoring of the effects that critical tasks have on other activities. The following analyses can be conducted: (a) checking for possible clashes between critical activities based on real paces and projections, (b) analysing the paces of projections in a consolidated manner, and (c) examining the impact of real paces and projections on the intermediate plan. Considering the pivotal role many of these activities play in production, both in terms of time and cost, any adjustment in the pace of a process line justifies a comprehensive analysis of its impact on others.

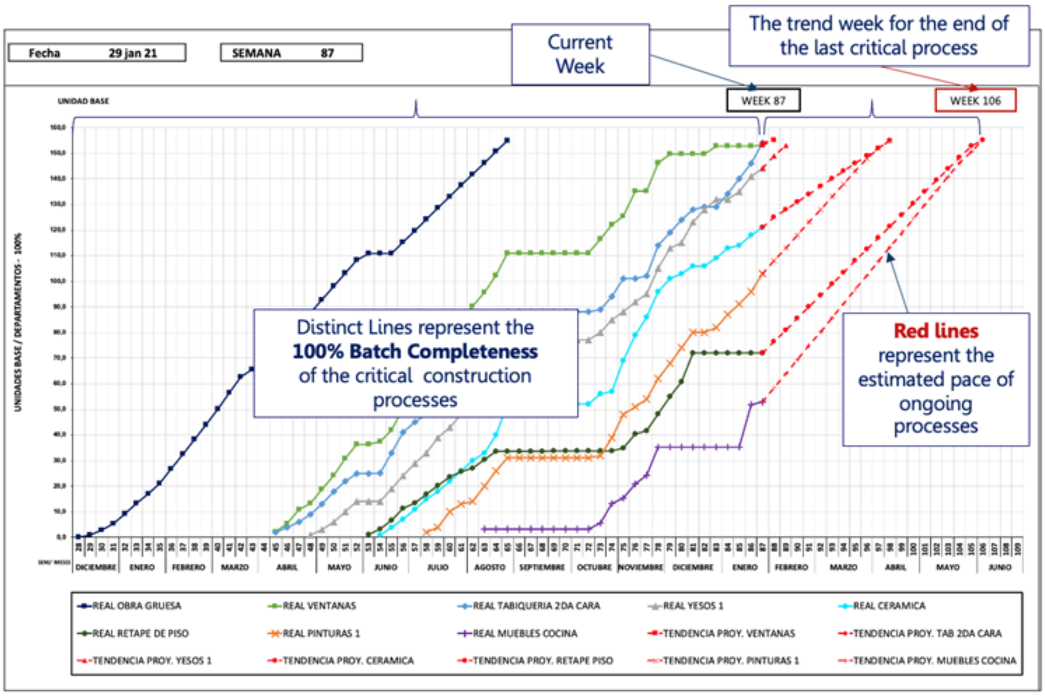

Figure 3: Example of an integrated chart to monitor the rhythm of different critical construction processes.

DEADLINE DEVIATION INDEX AND PROJECTION CHARTS

The data generated by the rhythm deviation provided the necessary information to generate the Deadline Deviation Index. In this context, data can be collected weekly by the construction site manager or by someone experienced in planning and control, simultaneously with the weekly plan data, to optimize data collection and processing. Both individual and integrated rhythm deviation charts facilitate data visualization for calculating the Deadline Deviation Index.

Deadline Deviation Index is calculated by the ratio of the sum of weighted delays and advances in critical processes (measured in weeks) to the total duration of critical activities on site, according to the formula outlined in Equation 1.

$$DD = \frac{\left[\sum \text{Number Weeks late X processes duration} - \sum \text{Number Weeks in advance X processes duration}\right]}{\sum \text{processes duration}}$$

Equation 1: Deadline Deviation Index Formula.

Lower and upper limit charts were employed to depict and monitor the Deadline Deviation index over the course of the project. These charts enable the establishment of delay or advancement thresholds tailored to each delivery stage. In the case of the company under study, upper and lower limits of 4 weeks were set as triggers to prompt the formulation of an action plan or adjustment of strategy within the lookahead planning process. This proactive approach aims to primarily address project delays identified through this indicator. Figure 4 illustrates an example of a Deadline Deviation Index Chart utilized during performance management meetings.

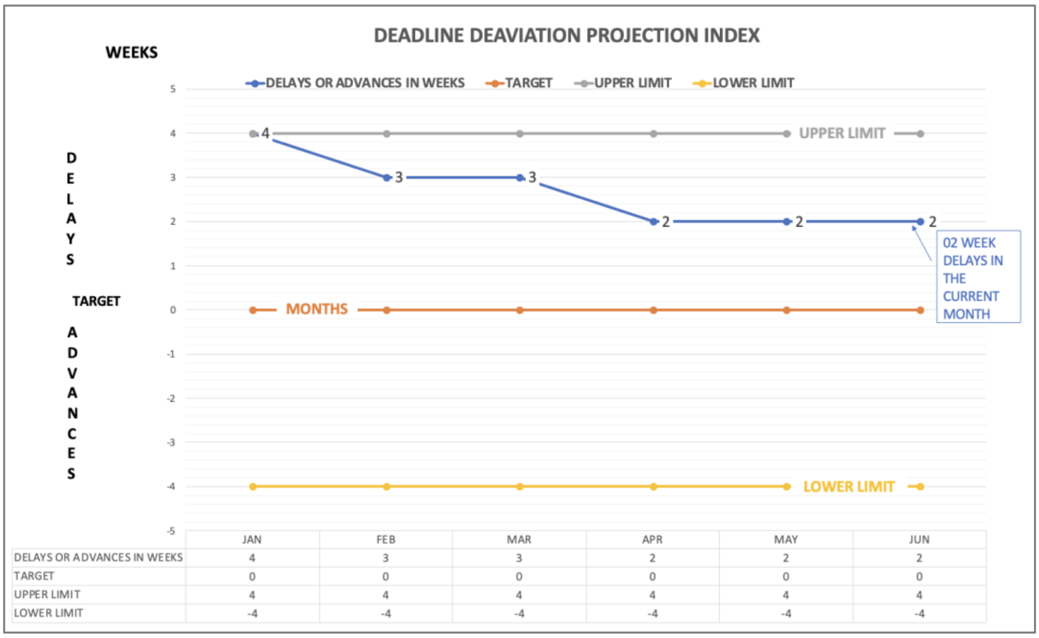

Figure 4: Deadline Deviation Index Chart applied in performance management meetings (example)

INDEX APPLICATION PROCESS

Throughout this study, data regarding the Deadline Deviation Index was examined across 12 construction projects. This indicator was precisely captured at the time of each delivery stages to visualize its progression throughout each project. This facilitated a flow of information supporting decision-making for both the project managers and the group of researchers, aiming to address identified delays and redirect the project's trajectory.

The implementation of the Deadline Deviation Index necessitates prior adoption of the LOB Technique and rhythm deviation charts. Initiating this tool involves training relevant personnel, emphasizing the advantages of maintaining accurate data and ensuring complete batch execution. The application process encompasses data collection, processing, and analysis.

Data Collection: Completion data should be gathered weekly by a qualified professional to assess task fulfillment and quality. This assessment can be synchronized with weekly task monitoring to minimize additional time for data processing. Recorded data should feed into a control table to generate rhythm deviation charts.

Data Processing: Processing involves data storage, visualization, and dissemination. Processed data yields actionable insights for decision-making across various analysis scenarios. Information should be presented in an accessible format for all stakeholders. Indicators and charts derived from rhythm deviations support analytical processes.

Analysis of Data and Information: Analysis of rhythm deviations primarily aligns with medium-term planning, although time projection analyses occur during specific meetings to assess project performance. For residential projects exceeding 12 months (typical in this study's sample), performance review meetings are held monthly. Thus, it's advisable to conduct time projection analyses more frequently to ensure timely intervention and course correction.

INFORMATION AND DATA ANALYSIS

An initial evaluation of the implementation of the Deadline Deviation Index was conducted across the 12 projects under study. This assessment utilized four distinct classifications based on the stage of Lean implementation within each project: Prior Lean implementation (PL), Early Lean implementation (EL), Basic Lean (BL) practices implementation, and Initial Stability (IS) achieved with Lean. Figure 5 illustrates the outcomes for each project categorized under one of these four implementation stages.

Furthermore, for this analysis, Deadline Deviation data was collected at the four distinct stages of project delivery. Since the projects did not occur simultaneously, it was necessary to establish a comparable timeframe for this evaluation. Projects 1 and 2 were analysed prior to the introduction of Lean practices within the company. Projects 3 and 4 were in the initial stages of implementing lean practices. In contrast, projects 5, 6, 7, 8, and 9 fully engaged in the implementation of fundamental Lean practices. Projects 10, 11, and 12 can be considered the most advanced in terms of Lean implementation compared to the others, having achieved an initial level of stability. Figure 5 displays the outcomes of the Deadline Deviation Index across four distinct delivery stages for 12 projects.

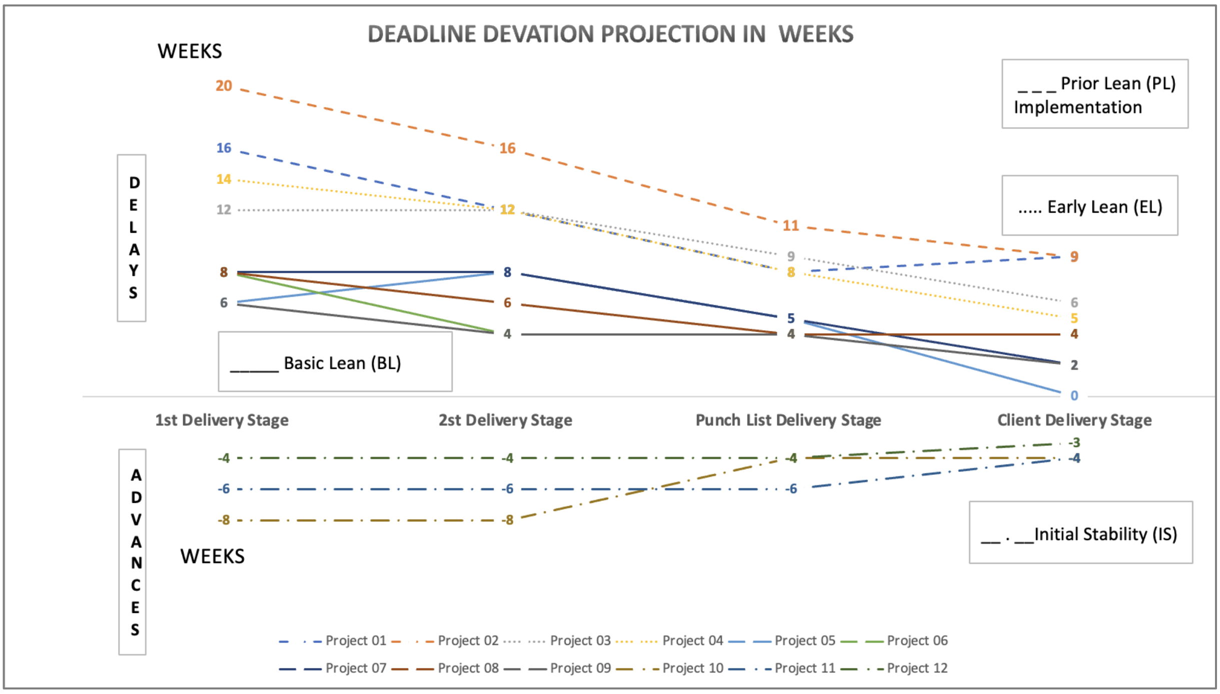

Figure 5: Results of Deadline Deviation Index during 4 different deliveries stages, for 12 projects.

From the analysis of the chart presented in Figure 5, it is noticed that the Deadline Deviation data exhibit greater variability across different delivery stages for projects executed before the implementation of Lean practices in the company and for projects in the early stages of Lean implementation, such as Projects 1, 2, 3, and 4.

As the Lean implementation stage progresses, there is a decrease in variability in the Deadline Deviation data across different delivery stages. For Projects 5, 6, 7, 8, and 9, which were fully engaged in implementing Lean practices, the variation in the Deadline Deviation index is lower than for Projects 1, 2, 3, and 4.

Finally, the Deadline Deviation data remains more stable across different delivery stages for Projects 10, 11, and 12, i.e., for projects in a more advanced stage of Lean implementation.

In this context, it is observed that for projects further advanced in Lean implementation practices, the Deadline Deviation index obtained from LOB data and rhythm deviation data provides a fairly accurate projection of the real project completion, regardless of the project stage. The indicator, therefore, proves effective in monitoring delays and advancements in construction projects, reflecting the Deadline Deviation based on Lean principles.

CONCLUSIONS

The research methodology employs an Action-Research approach within a Case Study framework, demonstrating the practical application of the proposed Index in real-world construction projects. This research has proposed and tested an index that may be used to monitoring and projecting delays and advancements of construction projects that integrates the Line of Balance technique with rhythm deviation analysis. This index represents an approach and, like other indexes, should not be analysed in isolation. Combining it with other information such as cycle time, batch adherence, batch completeness index, and percentage of plans completed (PPC) provides a more accurate project status.

LBPC is a critical aspect of Lean construction, allowing for the explicit management of workflows on-site and supporting decision-making at different planning levels. By integrating LBPC with the proposed Deadline Deviation Index, the paper contributes to advancing knowledge in the field of Lean construction management.

The findings of this study expose on the effective utilization of 12 residential building projects management tools, notably the Line of Balance technique, Rhythm Deviation control, and the Deadline Deviation Index, within construction projects. The Line of Balance technique, when coupled with the identification of delivery stages, serves as a valuable predictive tool for managing project timelines and mitigating delays. Likewise, Rhythm Deviation control, integrating lean principles, emphasizes the completion of tasks within specified timeframes, fostering a culture of efficiency and quality across project teams.

The findings of this study expose on the effective utilization of various project management tools, notably the Line of Balance technique, Rhythm Deviation control, and the Deadline Deviation Index, within construction projects. The Line of Balance technique, when coupled with the identification of delivery stages, serves as a valuable predictive tool for managing project timelines and mitigating delays. Likewise, Rhythm Deviation control, integrating lean principles, emphasizes the completion of tasks within specified timeframes, fostering a culture of efficiency and quality across project teams.

The implementation of the Deadline Deviation Index, alongside these techniques, offers a comprehensive approach to performance monitoring and decision-making. By systematically gathering and analysing data at different project delivery stages, stakeholders can identify trends, anticipate challenges, and proactively address deviations from planned timelines. The paper introduces practical tools such as lower and upper limit charts, coupled with the Index, provide actionable insights for timely intervention, strategy adjustments, performance monitoring and decision-making thereby enhancing overall project management effectiveness.

The analysis of research results further highlights the importance of Lean implementation stages in influencing project performance. Projects exhibiting Initial Stability with Lean practices demonstrate improved resilience to timeline deviations compared to those at earlier stages of implementation. This underscores the significance of continuous improvement efforts and organizational learning in optimizing project outcomes.

Future studies could explore the application of the proposed tool in non-repetitive projects, to further expand knowledge and understanding in the field of Lean construction management. This aspect contributes to the ongoing discourse on continuous improvement and innovation in construction practices.

COLLABORATIVE PLANNING OF SUBCONTRACTORS USING THE LAST PLANNER SYSTEM AND BIM: A CASE STUDY ON A GAS SUBCONTRACTOR IN REPETITIVE HOUSING PROJECTS

Xaver Brioso[1], Karla Delgado[2], Rodrigo F. Herrera[3], Miguel Lozano[4] and Luis Bravo[5]

ABSTRACT

The objective of this study is to adapt the Last Planner System (LPS) for managing subcontractors in natural gas installations within repetitive housing projects, using BIM technology for enhanced modeling and efficiency. Our methodology was applied to a large-scale, multi-family, low-cost housing project in Lima, Peru. Through this application, we achieved high Percent Plan Complete (PPC) values and improved collaborative planning practices. This paper makes distinct contributions to the subcontractor management literature: (1) it demonstrates the practical integration of LPS with BIM to streamline subcontractor activities in a real-world setting; (2) it offers a novel approach for determining optimal Takt Time Planning for daily and weekly schedules, enhancing the predictability and reliability of subcontractor work; and (3) lessons learned from the implementation provide a roadmap that can be adapted to other subcontractor management scenarios.

KEYWORDS

Last Planner System, subcontractor management, gas facilities management, continuous improvement, BIM.

INTRODUCTION

The efficient management of subcontractors turns into a challenge in contracts with fixed prices and very short terms. Non-conformances due to poor deliverables are common, generating delays and cost overruns for all parties involved, especially for the main contractor (Akintan and Morledge, 2013). It is a very common practice in construction projects that the main contractor contracts subcontractors to transfer cost and deadline risks to it with the aim of not losing money. However, it is still necessary to analyze the relationship of subcontractors and contractors to improve their performance (Ribeiro et al., 2017). The Last Planner System (LPS)

is a production system that shows multiple workflows, identify deficiencies or wastes and promote continuous improvement (Aslam et al, 2020). In addition, LPS is a control system with the principal goal to reduce variation and uncertainty in construction activities (Hamzeh et. al, 2012). In addition, LPS is a collaborative tool that promotes continuous flow, teamwork and reliability (McConaughy and Shirkey, 2013). LPS encourages people to coordinate multiple activities and resolve problems with team agreements (Pavez and Gonzalez, 2012). However, there is still little information about successful results in the management of subcontractors. (Akintan and Morledge, 2013). The most frequently used system to implement the Lean philosophy in project works is the LPS (Smith and Ngo, 2017) and there is much evidence that projects with a Lean approach allow contractors to have better productivity, deadlines, and prices, among other indicators (McGraw Hill, 2013; Hasle et al., 2012). Nevertheless, with no adequate education and training, there could be resistance to change in subcontracting companies, and they would refuse to use Lean systems (Emuze et al., 2021).

With the implementation of Building Information Modeling (BIM) and Lean Construction, the AEC industry is making an important transformation. These are different initiatives, but both are making a great impact on the industry (Heigermoser et al 2019). According to recent studies the LPS is used in combination with 4D models in order to improve the project progress, and to prepare and show a better visualization during the planning meetings (Sacks et al., 2011; Toledo et al., 2014). The use of LPS becomes a potent tool when practitioners incorporate automated BIM workflows. With this incorporation, decisions and feedback are based on optimized information from the BIM models for the constrain analysis, identification of tasks, sizing, and sequencing (Gerber et al., 2010). Although Building Information Modeling (BIM) is utilized in this project for enhanced visualization and planning, the main focus of our research is on the application of LPS. We explore how LPS can be adapted to the unique demands of subcontracting within the construction sector, particularly in projects involving repetitive tasks like those seen in housing developments.

The Last Planner System (LPS) has been increasingly recognized for its potential to enhance subcontractor management in construction projects. LPS, a lean construction tool, focuses on reducing the variability in production planning and increasing the reliability of scheduling, which are critical for the efficient management of subcontractors. By involving subcontractors in the planning process, LPS facilitates improved communication and coordination, which helps in aligning their work with the project's main schedule and objectives. This collaborative approach not only mitigates the risk of delays but also enhances the overall project execution by integrating subcontractor inputs early in the planning phase. Despite its advantages, the literature reveals several gaps in the application of LPS in subcontractor management. Firstly, there is limited empirical evidence on the quantitative benefits of using LPS specifically for subcontractor management as opposed to general project management. Secondly, the strategies for effectively integrating technology, such as Building Information Modeling (BIM), with LPS to optimize subcontractor performance are not well-documented. These gaps underscore the need for more targeted research to explore and validate the use of LPS in enhancing subcontractor management across different types of construction projects. Therefore, the main objective of this research is to propose a method that adapts the LPS to the subcontract management, as well as to apply it for subcontracting natural gas installations in a highly repetitive housing project, which was modelled by using BIM technology.

LAST PLANNER SYSTEM (LPS)

LPS is a collaborative stakeholder system that combines tools, techniques, and practices to manage projects by reducing variability (Ballard, 2000); LPS proposes that planning and programming be considered as a system, performance be measured, and programming errors be analyzed, identifying the root causes of non-compliance, and adopting corrective measures, evaluating their impact (Ballard, 2000; Daniel et al., 2017). During the planning phase, LPS recommends that the level of detail for every activity should be increased as the execution date approaches; collaborative meetings, called Pull Planning, include subcontractors and contractor support areas (Verán and Brioso, 2021).

The LPS elements are the following: Master Planning: the general schedule is developed, deadlines and milestones are agreed, and construction processes are defined (Ballard, 2000). Pull Planning Phase Session: a meeting where all the support areas and subcontractors have to identify the "handoffs" and agree on the Takt Time Planning (TTP) and sectorization; TTP consists of defining the production units to be executed on a daily basis and their sequence; Sectorization consists of dividing the work areas or volumes into several sectors to create a balanced production line and define the limits between sectors. Agreements must be fulfilled as part of the subcontractor's contract (Elfving, 2021; Murguia and Brioso, 2016); Lookahead Planning: it is planned by time windows that usually have some weeks according to their variability (Ballard, 2000). Constraint Analysis: every week of the Look-ahead is analysed. A constraint can be defined as a previous requirement of an activity that can stop the production flow if it is not considered (Ballard, 2000; Brioso, 2011). Weekly Work Planning: compliance with the first week of the Lookahead is optimized and buffers are used according to variability and complexity (Ballard, 2000). Daily Programming: the maximum scheduling level is reached, and the use of common equipment is agreed with subcontractors (Ballard, 2000; Brioso, 2011). Learning (Reliability Analysis): performance measurements are made for every task and subcontractor, the root cause of a non-compliance is analysed, and corrective measures are adopted as soon as possible. LPS measures the weekly and daily plan performance through the percent plan complete (PPC), which is the number of completed tasks divided by the number of scheduled tasks (Ballard, 2000).

SUBCONTRACTORS MANAGEMENT AND LAST PLANNER SYSTEM

There is little information about subcontractors' management in projects that implement the LPS. A study shows that the perception of subcontractors about phase collaborative planning is positive, and that teamwork and a sense of collaboration are developed (Ribeiro et al., 2017). Other research shows that there are still barriers in the implementation of LPS in finishing subcontracts in the USA (Smith and Ngo, 2017). LPS cannot be implemented until changes are made through education and training (Emuze et al., 2021). Regarding the application of LPS and Lean concepts in the gas industry, there is very little information. A study proposes the use of the collaborative tool First Run Studies to Develop Standard Work in the ongoing remodeling of a Liquefied Natural Gas Plant (Hackett et al., 2015). On the other hand, another study explains that the use of Lean tools could be useful in Offshore Oil and Gas Construction (Lerche et al. 2019). In addition, other research indicates that the application of Lean concepts and tools in the oil and gas industry is still undeveloped and lacks details; however, it proposes that digital transformation and Lean concepts could complement each other to improve the collaborative engineering review process at Oil and Gas EPC Projects (Matta et al. 2022). Nevertheless, no results have yet been presented on the application of LPS in the execution of gas subcontracts in urban areas. Additionally, in recent years, various studies have been published showing that LPS has been implemented by different general contractors in Peru with successful results, showing performance indicators of the structure and finishing phases (Brioso et al., 2016; Brioso and Calderon-Hernandez, 2019). However, no information on subcontracts for gas installations in building projects in urban areas has been published.

BUILDING INFORMATION MODELING (BIM)

BIM is a work methodology based on 3D modelling that offers the necessary information and tools to stakeholders to plan, design, build and manage buildings and infrastructures (Cortijo et al., 2021). By the year 2003, the General Services Administration (GSA) of United States with the support of the Public Buildings Service (PBS), created the National 3D-4D-BIM Program. Then, in 2007, the GSA established, for all the major projects, that spatial program BIMs be the minimum requirements for submission to the Office of Chief Architect (OCA) (Edirisinghe and London, 2015). In addition, in the year 2007, the National Building Information Modelling Standards of United States (NBIMS-US) published the first BIM standards. After this publication, BIM protocols were used as addendum for construction contracts with the support of the American Institute of Architects (AIA) (Sarı and Pekeriçli, 2020). By the year 2007 appeared similar initiatives in the United Kingdom AEC industry. The UK government published Publicly Available Standards (PAS) to describe BIM services (Sarı and Pekeriçli, 2020). A few years later, in 2016, the government established that level 2 BIM is obligatory for all public projects. Also, the UK government developed a BIM committee to support contractors during the transformation process to BIM. Besides that, in order to accomplish embrace BIM in the projects, the British Standards Institute (BSI) defined information sharing standards called PAS 2292:2 and the UK government created a roadmap for public projects. (Edirisinghe and London, 2015).

BIM integrates the 3D model of a project with geometric and/or parametric information and is described as the digital representation of the physical and functional characteristics of any object (Sacks et al., 2018). BIM improves the projects design, encourages an efficient workflow and reduces errors during the process (Lévy 2011). The 3D model for a construction project has to be linked with data building elements or components. The information of elements or components are obtained from the level of development (LOD) specification (Lévy 2011). The BIM approach is based on collaborative planning, reasoning, discussion of ideas, decision-making, transparency, improvement of understanding, among other factors, which help employees develop soft skills (Brioso et al., 2022).

The use of Lean Construction and BIM is not restrictive between each other. The interaction of Lean and BIM permits different opportunities to make an efficient workforce and an effective process in the construction projects (Oskouie et al. 2012, Hamdi and Leite 2012, and Dave et al. 2013). An important contribution of the interaction between Lean and BIM is the LC-BIM matrix, which includes 56 positive interactions that support waste elimination and adding value concepts (Sacks et al. 2010). Literature describes some steps for the interaction between LPS and BIM. These studies presents a framework that integrates BIM with LPS at Master planning Level, Lookahead Planning and Weekly Work Planning in order to seek the reduction of waste and to increase collaboration with the project stakeholders (Bhatla and Leite 2004). Also, these studies describe the interactions between LPS and BIM functions, for example: Master Plan with 4D models; Lookahead Planning with Request for Information, Weekly Work Planning with Systematic registration of demands for information, among others (Garrido et al. 2015). Another study presented the advantages of the interaction between LPS and BIM for mechanical, electrical, plumbing and fire protection functions (Tillmann and Sargent, 2016). In this study, significant interaction between LPS and BIM were identified, which are presented in this case study.

METHODOLOGY

Figure 1 shows the research methodology. It is proposed to adapt the LPS processes to manage a natural gas subcontractor in a highly repetitive housing project located in the city of Lima, Peru.

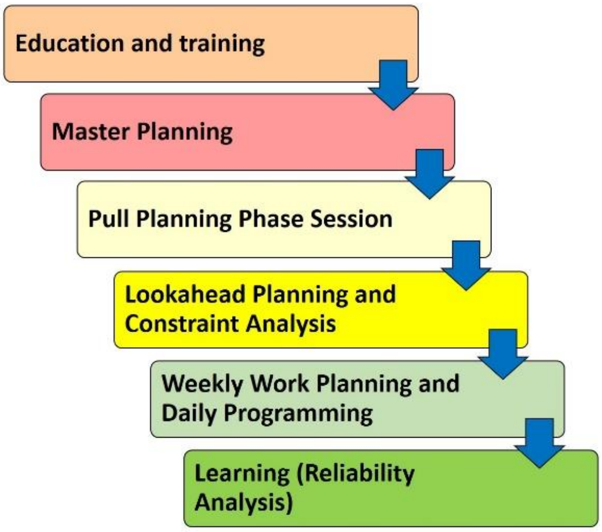

Figure 1: Research methodology

The steps are the following:

1. Education and training: subcontractor personnel, including foremen and site managers, were provided with a series of training sessions on the principles of the Last Planner System (LPS). These sessions included interactive workshops and simulations to demonstrate the practical application of LPS tools such as Pull Planning and Lookahead Planning. The aim was to ensure that all team members understood how to implement these methods in daily construction activities to improve scheduling accuracy and reduce waste.
2. Master Planning: The project's master schedule was developed using collaborative input from all key stakeholders, including subcontractors. This stage involved the use of BIM software to visualize project timelines and critical milestones. By integrating subcontractor schedules into the master plan, we aimed to align all activities and minimize conflicts in the workflow.
3. Pull Planning Phase Session: During these sessions, subcontractors and the main contractor's management team met to discuss and agree on the workflow and sequence of operations. The use of BIM models helped to identify potential logistical issues and sequence tasks effectively. These meetings were essential for establishing a clear and shared understanding of the project's operational demands and for enhancing the temporal and spatial coordination of tasks.
4. Lookahead Planning and Constraint Analysis: Subcontractors were required to submit detailed four-week lookahead plans, which were reviewed weekly to identify and address potential constraints such as resource limitations or scheduling conflicts. This proactive approach allowed for timely interventions, ensuring that project milestones were met without delays.
5. Weekly Work Planning and Daily Programming: Detailed daily work plans were created, specifying the tasks to be completed, the resources required, and the expected outcomes. These plans were adjusted based on real-time feedback and project developments. The daily updates provided a mechanism for continuous improvement and allowed for flexibility in response to on-site challenges..
6. Learning (Reliability Analysis): At the end of each week, a review session was conducted to assess the accuracy of the work planning and the reasons for any deviations from the plan. This analysis helped in identifying consistent patterns of issues that could

be addressed in future cycles. This stage was crucial for learning from experiences and for making systematic improvements to the planning and execution processes.

Regarding the case study, the main construction company has over 20 years of experience constructing buildings of all kinds in Peru, including massive affordable housing projects. In addition, the company has over 15 years of experience implementing LPS concepts and tools. On the other hand, the natural gas subcontractor has 20 years of experience and is the main gas supplier in Peru. It has also participated in projects where LPS has been implemented; however, it is usually informed about the general contractor's schedule at short notice which consequently leads to inefficiency and very low PPC values, with 70% on average.

The methodology was applied to a massive multi-family affordable housing project, which was modeled with BIM technology, Revit 2021 software. The project is located in the city of Lima, Peru, with a built area of 7,372 92 m2. It consists of 4 housing buildings with 16 floors, 512 apartments of 49.50m2 and 50.40m2 of covered area. The structure of every building is made of reinforced concrete and has low-cost finishes and installations. Figure 2 shows the typical floor plan of a building.

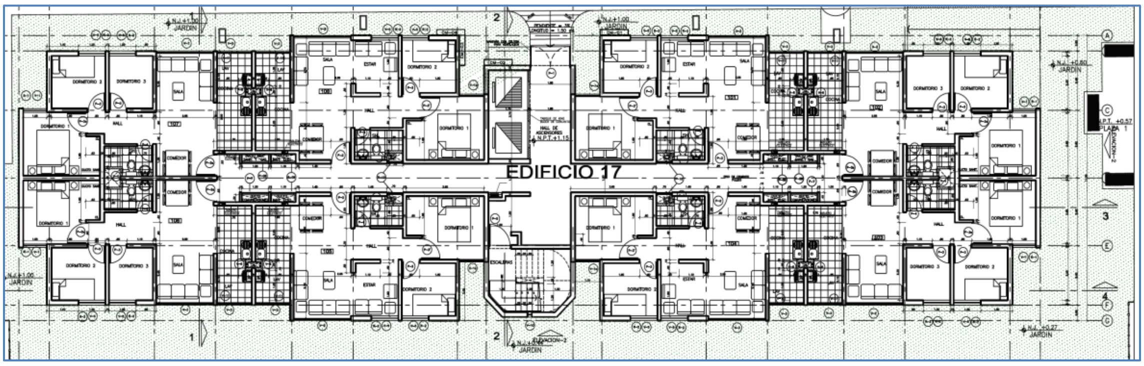

Figure 2: Typical floor plan of a building

The project natural gas installations will be divided by the stud, from the primary regulators that will be located on the first floor. The secondary regulators that will feed the individual lines in every apartment will be connected from the studs.

RESULTS AND DISCUSSION

The Lean Construction philosophy will be applied in the project of gas installations. Consequently, the project will be classified first to present the measurements of the project, the master planning, and develop a constraint analysis that will result in the released programming.

1. Education and training: the subcontractor's stakeholders, such as the coordinator and foremen, were educated and trained in LPS concepts, tools, and techniques. They were instructed in the dynamics of collaborative meetings that would be implemented from the start of the work. Its objective is to reduce waste in the construction processes.
2. Master Planning: the general contractor has extensive experience in this type of projects, so phase milestones and deadlines are precisely defined. The construction of every building lasts 7 months. The subcontractor became aware of this information and planned the following activities to complete them within the defined deadlines:

- Foundation slab: (a) Layout for ground gas network; (b) Excavation of trenches for network; (c) Placement of gas installations on the slab.
- Structure: (a) Layout of gas network; (b) Placement of valves and gas installations in walls and slabs.

- Finishes: (a) Placement of valves and accessories in the finishes; (b) Placement of protection against impacts and dirt.
- Common Areas: (a) Placement of risers, pipelines, regulatory cabinets and gas meters; (b) Execution of quality tests.

3. Pull Planning Phase Session: the subcontractor participated in the collaborative meetings where they agreed on the Takt Time Planning and the general sectorization of the phase shown in figure 3. The BIM model was used on every level of the gas installations, improving the understanding and analysis of the resources to be used.

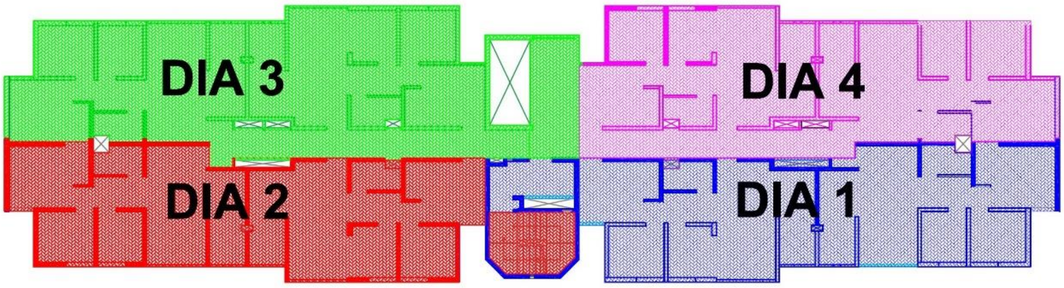

Figure 3: General sectorization of the phase

4. Lookahead Planning and Constraint Analysis: every week, the subcontractor schedules the activities for the next four weeks. The BIM model of every sector is analyzed on a daily basis (see figure 4) and the resources and quality tests of the activities to be conducted are determined. Figure 5 shows the pressure test. For every task, it is determined the constraints of materials, equipment, labor, safety and health, information, previous activities, design, environment, suppliers, subcontractors, among others.

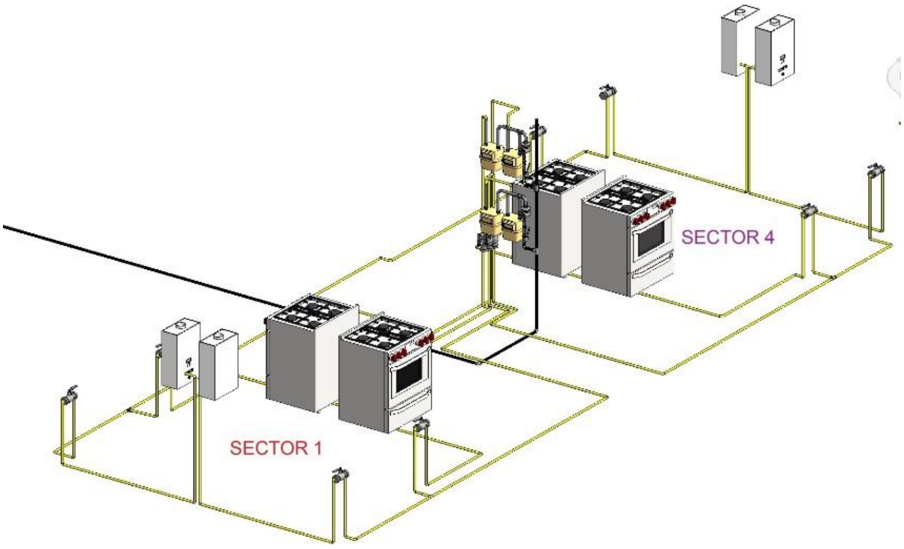

Figure 4: BIM model of every sector

Figure 5: Pressure test

5. Weekly Work Planning and Daily Programming: the subcontractor defined all the tasks that are ready to be executed in the week. Figure 6 shows the takt-time schedule (four sectors, S1 = Sector 1). BIM models are used, daily classifications are approved, and the resources corresponding to every day of the week are analysed.

Vertical and Horizontal Concrete Pouring		S1	S2	S3	S4

Figure 6: Takt-time schedule of structural work

Throughout all the processes, collaboration was received from the following stakeholders: construction supervisor, subcontractor coordinator, two foremen, and several operators. Among the most remarkable contributions, we can say: (1) The supervisor observes the drawings since the distances to the electrical points and hot water pipelines cause rework, and this situation originates gas installations shutdown; (2) Previous activities cause delays in several stages since drawings are not updated; (3) The natural gas subcontractor assures that the best system is updating the information on the drawings regarding the changes that could occur on site. This facilitates the work on the required items of gas installations. However, there are several companies that do not meet these updates; (4) The poor communication between the parties involves causes many losses, damages, and defects in the items; (5) Operator 1 observes that, in the structure and finishing stages, there are delays due to rework. This situation is due to the lack of knowledge of the regulations of gas installations; (6) Operator 2 indicates that, in the finishing phase, accessories must be secured with masking tape for better protection; (7) Operator 3 observes that for the best operation of installations network, pressure tests must be conducted: (a) during the structures phase, and (b) at the end of the finishing phase during the installation of valves and risers. After that, the root causes of non-compliances are analysed, corrective measures are adopted, and their effectiveness is monitored. For example, all gas installations must have their respective identification from the manufacturer, to avoid the misuse of other brands of accessories and the incompatibility of materials.

Finally, the weekly and accumulated PPC are measured, and their positive performance is verified. Table 1 shows the results of the following 9 weeks. It is observed that in week 2 there were 2 non-compliances, due to lack of materials and lack of quality tests. Corrective measures were immediately adopted, and a person was assigned for every measure to implement it. The routine was then repeated every week, promoting continuous improvement. This methodology leads to efficiency and very high accumulated PPC values, with 96% on average.

Table 1: Weekly and accumulated PPC

WEEK	SCHEDULED TASKS	COMPLETED TASKS	WEEKLY PPC	ACCUMULATED PPC	GOAL
1	10	10	100.00%	100.00%	85.00%
2	10	10	100.00%	100.00%	85.00%
3	10	8	80.00%	93.33%	85.00%
4	17	16	94.12%	93.62%	85.00%
5	24	24	100.00%	95.77%	85.00%
6	26	26	100.00%	96.91%	85.00%
7	27	27	100.00%	97.58%	85.00%
8	33	32	96.97%	97.45%	85.00%
9	34	31	91.18%	96.34%	85.00%

The integration of the Last Planner System (LPS) with Building Information Modeling (BIM) has significantly advanced subcontractor management in our case study project. Key improvements include:

- Enhanced Planning Accuracy: The use of BIM in conjunction with LPS allowed for more accurate and detailed planning schedules. For instance, the visualization capabilities of BIM helped in identifying potential scheduling conflicts early, which LPS methods then addressed through proactive adjustments. This integration led to a marked increase in Percent Plan Complete (PPC) values, from an average of 70% before implementation to 96% post-implementation.
- Improved Resource Allocation: By leveraging detailed BIM models at various planning stages, subcontractors could better predict and allocate resources. This was particularly evident in the weekly and daily planning phases where BIM’s detailed visualizations complemented LPS's structured scheduling approach.
- Increased Subcontractor Collaboration: LPS’s emphasis on regular and structured communications among all project stakeholders was enhanced by shared BIM models. This facilitated a more collaborative environment and improved the subcontractors' commitment to the project timelines and quality standards.
- Feedback and Continuous Improvement: The integration provided a feedback loop where BIM visualizations helped identify non-conformances quickly, and LPS protocols were used to implement corrective actions swiftly. This continuous improvement cycle significantly reduced rework and increased operational efficiency on site.

CONCLUSIONS

The integration of LPS and BIM allows more detailed processes and a better understanding of the natural gas project. BIM and LPS are synergetic, when they interact understanding is improved, decision-making is automated, and transparency is increased. Gas installation subcontractors could generate lower losses using LPS, since it allows better planning and scheduling of the different items identified. It is important that all parties involved are educated and trained in LPS and know the scope of the project. When the implementation of the planning is conducted from the master plan, it is necessary that all collaborators participate in the agreement from the beginning. It is essential to take the respective safety measures to create an environment of confidence to work safely. The most frequent root causes of non-conformances were determined, and this information was fed back into the collaborative planning of the following, determining the optimal classification, Takt Time Planning, subcontractor restrictions, weekly and daily schedules, and finally, the lessons learned from the implementation of the LPS for future projects, which can be adapted to other types of subcontracts.

A SYSTEMATIC APPROACH TO MAKING PEOPLE, PROCESSES & PROJECTS READY FOR MAKE-READY

Paul Ebbs[1], Steven Ward[2], Nour Al Hour[3], Emmanuel Manu[4] and Ehsan Asnaashari[5]

ABSTRACT

Project management methods like risk management (RM), production planning (including make-ready) and continuous improvement (CI), are often considered in isolation of each other. The literature recognises how teams struggle with implementing these methods according to known current best practices and standards. The purpose of this paper is to report the on-going development of a research artefact called IRMA 360^0 (Integrated Risk Management Approach) through a Longitudinal Action Case Study over four cases between 2016 and 2024. There is a particular focus on Case 4 – an ISO 18404 Certified Alliance.

In summary, this research has identified links between RM, make-ready planning and CI, and proposes IRMA 360^0 as a model to advance the Last Planner® System (LPS) by feeding what 'might' happen or might be possible through 'should, can, will, did, learn' functions. We conclude that both effective RM and make-ready are required to create and protect value which includes reliable workflow. However, to embed RM and make-ready planning a safe and collaborative environment is desired. In theory, RM is complex as it deals with uncertainty. On the other hand, make-ready is a relatively straightforward activity to 'just' screen tasks for constraints. However, in practice both are extremely difficult to implement.

KEYWORDS

Risk Management, Make-Ready, Last Planner® System, IRMA 360^0, Alliancing.

INTRODUCTION & BACKGROUND

Much has been written about the benefits of the LPS (e.g., Fauchier & Alves, 2013) but less about practical implementation challenges (Ebbs et al., 2018) or underpinning theories that support the LPS. During IGLC30, Ballard delivered a keynote speech titled 'The Last Planner System and the Waste of Making-Do (Koskela, 2004): a Research Proposal'. This was a broad call for research into three areas 1) Improve input flows; 2) Reduce incentives for making do; and 3) Improve the process for deciding what to do when timely delivery of standard input fails.

Eighteen years of research bookends Koskela's original paper on Making-Do and Ballard's call to focus on these research areas at IGLC30. Many scholars, practitioners and standards have made contributions to the LPS (incl. make-ready), RM and flow. The 8 Pre-requisite Flows

of Lean Project Production have largely emerged from Koskela's (2000) Transformation, Flow, Value (TFV) Theory, Ballard's (2000) Directives, Bertelsen et al., (2007) Preconditions, and Pasquire's (2012; 2017; 2018) work on Shared Understanding. The 8 Flows appear in slightly different guises but for this paper they are: 1) Information; 2) Equipment; 3) Materials; 4) People/Workers; 5) Prior Activity; 6) External Conditions; 7) Safe Space (Physical Space & Wellbeing); and 8) Shared Understanding.

The aim of this paper is to investigate the links between the 8 Flows, RM, make-ready planning and CI. The objectives of this paper are to:

1. Evaluate the practical challenges associated with embedding RM and make-ready planning on projects and programmes.
2. Assess the relationships between collaborative RM, make-ready planning, CI and project/programme reliability.

The remainder of this paper is structured as follows. Firstly, the literature of relevant concepts is reviewed. Secondly, the research methodology used to develop, test, and implement IRMA 360^0 is outlined. Thirdly, the key outputs from four cases are discussed which includes how IRMA 360^0 emerged from Ebbs and Pasquire's (2018) Flow Walk; an overview of IRMA 360^0 with a specific focus on RM and advancing make-ready; a summary of IRMA 360^0 participant feedback; and, how the rich data generated was used for both CI and to develop the DR.PAMPPSS (Design, Resources, Procurement, Access, Materials, Plant, Permits, Shared Understanding, Safety) make-ready codes and process aligned to the 8 Flows in Figure 3. DR.PAMPPSS built upon O'Connor's (2020) DRAMPPS constraint management technique by adding another 'P for Procurement' and 'S for Shared Understanding' during Cases 3 & 4.

LITERATURE REVIEW – RM & LPS

The RM literature is extensive, and much is beyond the scope of this research. The role of culture, organisational change (Mu et al., 2014; Olechowski et al., 2016), the need to collaborate at the 'fuzzy' front end (Pinto & Winch, 2016; Akerman et al., 2014), understand linguistics (Aven, 2012; Flores, 2013), avoid ignoring risks (Kutsch & Hall, 2010), and improve opportunity management within a holistic and iterative process is recognized (ISO 31000:2018). However, it is clear more case studies on collaborative approaches to RM are required.

There is a plethora of LPS (Hamzeh et al., 2007; Ballard & Tommelein, 2016, 2021; Ebbs & Pasquire, 2019; Mossman, 2020) and Collaborative Planning (CP) guidance (Highways England, 2020) freely available. However, while the LPS Guides provide some detail on how to screen tasks, the CP Guides generally focus more on constraint management than make-ready for every task. Many scholars have reported incomplete LPS implementations (e.g. Daniel, 2017; Hamzeh, 2011; Fireman & Formoso, 2013; Dave et al., 2015; Ebbs & Pasquire, 2018). They observed that whilst project teams may be enthusiastic about the LPS they seem to be unable to grasp the full depth of the system. Furthermore, Daniel (2017) identified that the technique entitled CP is frequently mistaken for the LPS in the UK and that its implementation often stalls at the level of make-ready. Differing epistemological and ontological views of the LPS may be contributing factors to the inconsistency in deployment.

The case study reported by Kamal et al. (2023) represents a recent example of misinterpreting the LPS as they included LPS within 'Collaborative Target Programming' alongside 'pull planning' and 'make-ready' rather than referring to LPS as the overarching system of interconnected parts (Ballard & Tommelein, 2016). Whilst they noted the use of DRAMPPSS make ready planning, they did not credit the sources (O'Connor 2020; Pasquire & Ebbs, 2017; Ebbs & Pasquire, 2018) related to its development.

The research and reporting of make-ready deployment (Ballard & Howell, 1998; Ballard, 2000) is not always explicit and appears limited to a few areas namely lookahead planning (e.g., Alves and Britt, 2011), constraint analysis and management (e.g., Lindhard & Wandahl, 2012), Tasks Made Ready (TMR) and Tasks Anticipated (TA) (e.g., Hamzeh et al., 2016), and the operating environment (Britt et al., 2014). Other IGLC literature from Emdanat and Azambuja (2016) and Samad et al., (2017) questioned the impact of many LPS metrics but propose even more LPS metrics that are beyond this paper's scope. Examples of 'making do' are reported by Koskela (2004), Fireman and Formoso (2013), and others. The cost of rework is also widely discussed but outside the boundary of this paper. Whilst both are not explicitly make-ready related, one could argue that making do and rework are symptoms of not making ready.

Regarding integrating RM and LPS, Ballard and Tommelein (2021) recommend conducting project RM in the Project Definition Function with risk mitigation strategies contained on the Project Execution Plan. Additionally, they maintain that the purpose of the LPS is for the Last Planners to create and maintain reliable workflow in pursuit of project objectives. To support this from a RM perspective, ISO 31000:2018 states that effective RM protects the effect of uncertainty on objectives and its purpose is to create and protect value (through opportunity and threat management) by leveraging the input of experts who have knowledge of risks. The eight RM principles listed in ISO 31000:2018 emphasize how critical collaboration is for effective RM and this may also explain why other RM scholars (such as Aven, 2012; Pinto & Winch, 2016) recognise implementation challenges.

In summary, when comparing both RM and LPS there appears to be significant relatedness from both a systems approach and implementation challenges. Both may benefit from closer alignment and learning from some common denominators such as people and available time.

RESEARCH METHODOLOGY

The struggle with make-ready was found in practice (Ebbs & Pasquire, 2018; Ebbs et. al., 2018) and from anecdotal conversations with experienced LPS practitioners at IGLC conferences. As a result, the original singular Case Study methodology was extended to a Longitudinal Case Study (Yin, 2018) using Participatory Action Research (Mackenzie et al., 2012) alongside some Design Science (van Aken, 2004), and post-rationalisation including a literature review of Collaborative RM, Make-Ready, and other RM domains such as Supply Chain RM.

Between 2016 and 2024 data was collected from many workshop participants (n=c.1000) across 15 infrastructure projects. The extensive primary data was analysed using Braun and Clarke's (2006) thematic analysis framework alongside Ebbs and Pasquire's (2018) approach to measure the Level of Conversation (LOC) of each risk and the risk categories that emerged. The LOC was established by totalling the number of survey responses, workshop scribbles, and dots used to prioritise and summarise risks captured through Steps 1-4 of the Flow Walk in Figure 1. Using excel, risks were then mapped to their relative risk categories that were developed through the Flow Walk's Step 5 to define the LOC of each IRMA 360^0 category.

THE CASE STUDIES – OVERVIEW, RESULTS & DISCUSSION

The Longitudinal Case Study ran between 2016 and 2024. It involved 21 action-research cycles within four case studies to develop the IRMA 360^0 artefact. Cases 1-3 are detailed briefly to articulate the key findings used as the foundation for nine action-research cycles in Case 4.

Researchers Background, Experience and Roles

The authors are divided into several groups. Author 'A' is a PhD Researcher and ISO 18404 Lean Expert. 'B' is also an 18404 Lean Expert who collaborated with 'A' on make-ready deployment since 2019. 'C' is an ISO 18404 Lean Leader who worked with 'A' on the 3rd and 4th Case Studies. 'D' and 'E' academic supervisors since 2019 and 2021 respectively and Pasquire (2012; 2017; 2018) was 'A's' academic supervisor from 2016-2021. Whilst developing the artefacts the ontological viewpoint shifted from positivist in 2016 to relativist in 2021 which reflects the complexity and difficulty of deploying RM and the LPS in full and the ontological and epistemological dimensions that emerged as the artefact was developed.

Case Study 1: UK Organisation X (n=150)

The research began in 2016 whilst ‘A’ (supported by Pasquire) was embedded in a UK Client Organisation (X) for 30 months to design, develop and test a Lean Project Delivery System that addressed the root cause of delays and disruption. Organisation X operated in a highly regulated and confidential environment. Some of the main findings were in relation to the need for clarity of purpose, shared understanding, and the challenges sustaining all aspects of LPS deployment - particularly the make-ready process. Ebbs and Pasquire’s (2019) ‘Facilitators’ Guide to the LPS’ was one of the outputs and Ebbs and Pasquire’s (2018) ‘Flow Walk’ emerged as an artefact to help formalise make-ready but also integrate RM into the LPS using the 8 Flows.

Case Study 2: UK Transport & Infrastructure Division (n=145)

With ‘A’ acting as a Lean Coach for a Global Engineering Firm, the Flow Walks went through another four action-research cycles (projects) which formalised as IRMA 360^0 in 2019. In hindsight, the Flow Walks were a macro-RM approach to make-ready rather than a specific task screening approach (micro). The data collected during all 5 Steps of the Flow Walk in each of the projects proved to be very rich. Whilst the participants noted how overwhelming the data was, this also highlighted the complexity of projects, the need for the right people to be involved early, and the value of the collaborative conversations and shared understanding triggered by the Flow Walk. The Covid Pandemic began shortly before the 4th action-research cycle in Case 2. This required the physical ‘Flow Walk’ to move online which resulted in significantly more data input from the participants during Step 1. Subsequent data analysis identified 272 ‘risks’ within 15 bespoke risk categories. This was circa 3x more ‘risks’ than previously identified.

‘Risks’ in the context of this research include opportunities, threats, assumptions, and pre-requisite make-ready items (typically known as constraints in LPS literature). This categorisation clarified there was more to the Flow Walk and RM than threat management.

IRMA 360^0

IRMA 360^0 emerged from iterations of the Flow Walk in 2019 and primarily supports Ballard’s first IGLC30 call “to improve input flows” by using the 8 Flows to trigger conversations about flow. IRMA 360^0 is proposed as an advancement of Ballard and Howell’s (1998) LPS (not a replacement) to further integrate RM with production planning and control and help structure CI initiatives with RM. Ebbs and Pasquire (2018) report how the development of IRMA 360^0 started in practice by recognising how teams struggle with make-ready and the concept of flow.

Figure 1 shows how the 8 Flows trigger conversations about what ‘might’ happen or be possible during the Steps 1-5 of the Flow Walk using divergent thinking during Step 1 & 2 to identify ‘risks’, and convergent thinking during Steps 3 - 5 to prioritise ‘risks’ and develop IRMA 360^0 categories. Figure 1 also shows how the 8 Flows are important triggers for learning and action within the other LPS functions and how the outputs from the Flow Walk inform the development of collaborative milestone, phase, and make-ready plans. For example, whilst phase pull planning what ‘should’ happen, the 8 Flows are helpful triggers to identify predecessors and ‘risks’. To ensure tasks ‘can’ happen as planned, every task must be screened for ‘risks’ during make-ready planning - the 8 Flows or DR.PAMPPSS make excellent prompts. Commitments are made for what ‘will’ be done after tasks are made ready and shared understanding is established. After reviewing what ‘did’ happen, missed commitments (delay and disruption) data can be trended against the bespoke IRMA 360^0 categories developed during the Flow Walk’s Step 5 ‘Categorise’. When teams need to ‘learn’ from missed commitments for example using a fishbone problem solving template, the 8 Flows are very effective at drawing out causes and effects of a specific problem. In summary, the emergent data that makes up the IRMA 360[0] categories after the Flow Walk, supports many conversations during general problem-solving workshops and the deployment of LPS ‘should, can, will, did and learn’ functions. The use of IRMA 360[0] data is discussed more in Cases 3 & 4. See Pasquire and Ebbs (2017), Ebbs and Pasquire (2018; 2019) for more on the development of IRMA 360[0].

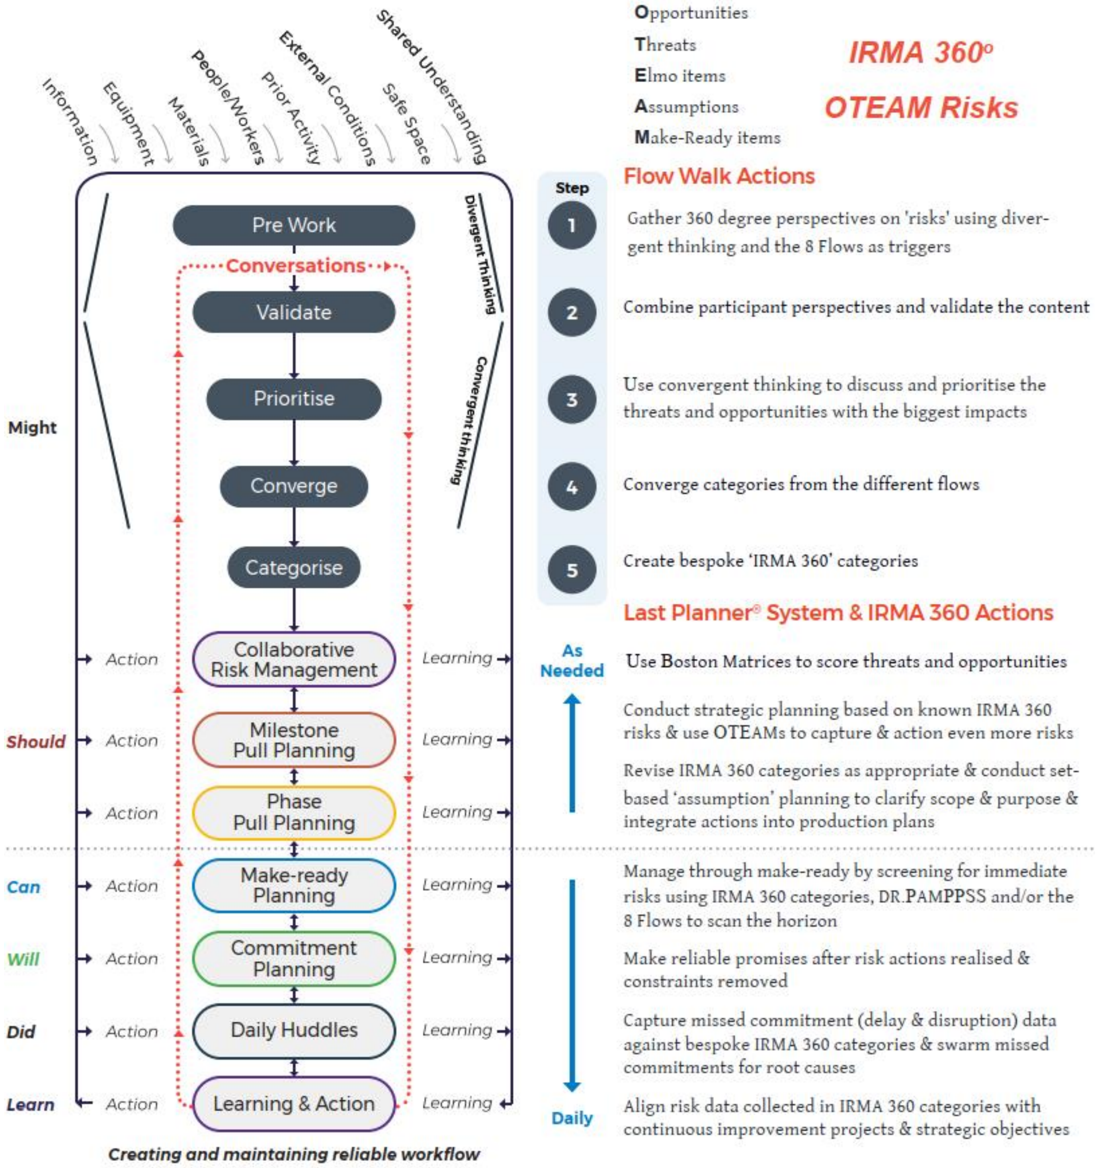

Figure 1: IRMA 360[0] Framework (after the Last Planner System)

CASE STUDY 3: MIDDLE EAST LOCAL INFRASTRUCTURE PROGRAMME (N=200)

After ‘A’ joined this programme with responsibility for lean deployment a clearer link between IRMA 360[0] and make-ready emerged. In practice O’Connor’s (2020) DRAMPPS process was less formal than the task-by-task screening approach documented in literature (Howell & Ballard, 1998; Hamzeh et al., 2007; Ballard, 2000; Ballard & Tommelein, 2016). Nonetheless, it was effective and another ‘S’ was added to include ‘Shared Understanding’ as a screening criterion for teams. Teams were also encouraged to map their DRAMPPSS to specific tasks to elevate their timely removal. Kamal et al. (2023) reported the use of DRAMPPSS in a micro tunnelling improvement project but did not acknowledge O’Connor (2020) or ‘A’ as the sources.

In parallel to continuing DRAMPPSS deployment, four IRMA 360[0] Flow Walks were conducted on four projects at various stages. During these, two more ‘stations’ were added to the 8 Flows to capture ‘Stakeholders’ and ‘Biggest Concerns’. The output was consolidated through a workshop (n=15) into 22 bespoke IRMA 360^0 programme categories. After a final round of thematic data analysis 410 specific 'risks' emerged within these 22 categories. This data was used on two more projects to develop risk registers from scratch, improve the quality of risk registers and align with programme delay and disruption data collection. Building on ISO 31000:2018's categorisation of RM, reflection upon the RM literature and practical observations of RM, it became clear that opportunity management was not given the same level of attention that threats were – in practice 'risks' are typically only viewed as threats. Furthermore, following Case 2, IRMA 360^0 'risks' were defined as opportunities, threats, assumptions, and make-ready (OTAM) items. Elmo (enough let's move on) was introduced in Case 4 and OTEAMs emerged as a useful framework for capturing 'risk' conversations requiring action during milestone and phase pull planning workshops. OTEAMs are discussed more in Case 4. The following findings were noted after post-rationalising Case 3. These fed into the action-research cycles of Case 4:

- The Last Planners are also the Last Risk Managers
- Nobody knows more about risks than everybody and everyone is a Last Risk Manager
- Thoughtful early stakeholder selection and team engagement helps avoid threats
- Leveraging multiple perspectives on risks creates rich 'current state' data
- Teamwork and diversity are critical to RM
- The IRMA 360^0 database is a checklist for projects when planning collaboratively
- Major risks are common across similar projects on an infrastructure programme
- The IRMA 360^0 categories and specific risks are sources for focused CI
- IRMA 360^0 supports requirements of ISO 31000:2018, 44001:2018 and 18404:2015
- Integrate Risk Managers into IRMA 360^0 workshops to leverage inputs/outputs and encourage the effective use of the rich data generated

CASE STUDY 4: UK HIGHWAYS ALLIANCE (N=220)

Figure 2 is a team identifying 'risks' during the 3rd Flow Walk action-research cycle of Case 4.

Figure 2: IRMA 360^0 Last Risk Managers during a Flow Walk in Case 4

Ebbs and Ward (2024) share more about Case 4 but in short, the Alliance is an enterprise of 7 partners and a diverse supply network delivering UK highway infrastructure upgrades. Building on feedback from the RM Lead after the 2nd action-research cycle, opportunity management was also incorporated into Step 3 of the Flow Walk illustrated in Figure 2, and into a subsequent mini workshop that used a simple Ease/Benefit Boston Matrix to evaluate opportunities. This was the first time the Flow Walk was used pre-contract award and the feedback noted "good team alignment on threats and opportunities and re-focusing Step 3 to prioritise threats and also opportunities helped shift the mood in the room". The output was used to create the initial programme risk register and improve collaboration within the Alliance. The RM Lead noted "by bringing risk, planning, and learning into one workshop where all stakeholders are present has reaped endless rewards. Not just from an engagement perspective but from a lean perspective by pulling all strands together and providing that golden thread between them in one forum. It has enabled all parties to look at the bigger picture and the required interfaces between different work disciplines and third parties and has helped to break down silos. As all parties are involved, this has really set the scene to ensure they are all bought into the same vision and mission. It also helps the understanding of key constraints held by all."

Like Case 3, the Alliance projects were all at various lifecycle stages. This supported building from Case 3's approach to rationalise the data under 'Alliance' Categories but without the need for a workshop. The categories developed by each project was consolidated by 'A' into Alliance IRMA 360^0 Categories using the LOC technique. The categories in Table 1 summarise the data analysis from across the Alliance. Note that Category #1 is not more important than #16, it only articulates how much conversation took place in relation to the 'risks' in each category. Ultimately, the LOC is dependent on who is present to have the conversations.

Table 1: Case 4 Alliance IRMA 360^0 Categories (n=200)

Rank	Category	Level of Conversation
1	Traffic Management & Roadspace	577
2	Labour & Skills Availability	555
3	Procurement, Logistics & Plant Management	509
4	Collaborative Planning & Programme Management	417
5	Design Information Management	383
6	Expectations, Leadership, Culture & Communication	348
7	Approvals & Governance	299
8	Material Management	299
9	Surveys & Existing Conditions	299
10	Stakeholder Management	269
11	External Conditions	246
12	Safety, Health, Wellbeing & Environment	223
13	Information & Quality Management	137
14	End User/Customer	114
15	Technology	70
16	Commercial Management	68

A similar IRMA 360^0 Category Framework in Table 1 was developed for Case 3 but 22 categories emerged. The top four categories in Case 3 were 1) Material Management; 2) Labour Availability and Skills; 3) Planning & Coordination and 4) Residents' Concerns. Case 3 categories provide an interesting correlation between category #2 in Table 1, but also with category #4 which indicates production planning 'risks' ranked highly in both Case 3 & 4, albeit the Cases are from different geographical regions and slightly different contexts.

Using IRMA 360^0 Data for CI & RM

The combined data from four action-research cycles underpins the categories in Table 1. The data was used for various purposes. For example, the first action-research cycle was a highway technology retrofit programme where Traffic Management and Roadspace booking constraints meant several shifts were lost per month. The team used Step 1 of the Flow Walk to collate appropriate data in relation to the 8 Flows. However, due to geographic and Pandemic constraints and rather than attempting a Flow Walk online, 'A' sorted the data into themes. A 2hr online structured problem-solving workshop followed with 20 key stakeholders using the themes created in Step 1. This resulted in no lost shifts and over £500k cost avoidance.

Like Case 3, the other action-research cycles were either during conceptualisation, mid-way through or during the construction (assembly) mobilisation period. The 9th action-research cycle in March 2024 used the 16 IRMA 360^0 Categories in Table 1 and the 8 Flows to trigger immediate 'risks' in each category. Three teams (n=19) from the same programme used this approach during a 1.5 hrs facilitated workshop. Each team worked independently but reported back to the collective group with the Risk Manager recording 49 'risks'. During the subsequent pull planning session (n=31) another 59 OTEAM 'risks' were identified. Whilst there was some cross-over on risks during both workshops, an additional 9 threats and 12 opportunities were added to the risk register. These workshops also helped to identify 37 mitigations to the 21 new risks, whilst also identifying a further 18 mitigations to 12 threats already on the risk register.

Make-Ready Action-Research Cycles

The roll out of a structured make-ready process shown in Figure 3 was part of a larger 18404 Lean Strategy and involved five action-research cycles. In Dec 2022, 29 OTEAM risks and 39 DRAMPPSS were identified during and after a pull planning workshop. In Feb 2023, 'A' facilitated a workshop with cross-functional site staff (n=12) using the question "what are the typical reasons why tasks are stopped or disrupted in relation to each of the 8 Flows?". 34 'reasons' emerged which ranged from not conducting a 24hr weather check to requiring an RFI.

Assembly Make Ready Codes (N=68)

	D	R.	P	A	M	P	P	S	S
	Design	Resources	Procure-ment	Access	Materials	Plant	Permits	Shared Understanding	Safety
Monthly	1 TQs	5 Personnel TBC	62 Req's	6 Traffic Mgmt	8 Acquisition Requests	10 Deliveries	13 Enviro & Ecology	16 Site Visit	14 RAMS
	2 RFIs	64 Inductions		7 Roadspace	9 Available	11 CCTV Req's	63 Dig	17 Handover & Maintenance	15 Temp Work Req's
	3 Inspection Test Plans					12 Preventative Maintenance Schedule	65 Quality Plan	18 Stakeholder Engagement	60 Working Area Width
	4 Survey Info						66 Load	59 Contracts	
	68 Inspections						67 O'head	61 Prior Lessons Learned	

Figure 3: Sample Alliance Assembly DR.PAMPPSS Make Ready Codes (February 2024)

The 34 codes were piloted, but feedback suggested "there were too many, DRAMPPSS is enough". In March 2023, a version of Figure 4 emerged with another team. The 34 reasons were mapped under DRAMPPSS but aligned to the colours/flows used in Ebbs and Pasquire's (2018) Flow Walk. By April 2023, the 'codes' increased to 55 and DR.PAMPPSS subsequently emerged after the team identified 'Procurement' as a critical make-ready prompt. By February 2024, through workshops to mobilise teams safely, effectively, and efficiently 68 make-ready codes emerged. The DR.PAMPPSS codes were used as prompts to screen 60 tasks in 1.5hrs. Figure 3 is a snapshot of the Assembly make-ready screening codes but without the weekly and daily codes (not shown for brevity). Figure 4 illustrates the make-ready screening process using both OTEAMs (captured during and following pull planning) and the DR.PAMPPSS make-ready processes. The numbers in the dashed red box on the pull planning post-it on the left of Figure 4 reflect the codes from Figure 3. The different coloured dots with numbers inside reflect the OTEAMs that were captured on a flip chart during a pull planning workshop and then mapped to specific tasks to identify when the risk actions needed to be completed by.

Figure 4: Examples of OTEAMs & DR.PAMPPSS mapping to phase pull plans

In parallel to the 'Assembly' roll out of make-ready, another retrofit programme had to identify and design 138 highway emergency areas within a constrained period. Four of the leadership team were on their I8404 Lean Practitioner journeys which collectively exposed them to various lean principles, theories, and techniques such as flow, change curve thinking, batch size reduction, LPS (incl. make-ready), visual management, and de Bono's Six Thinking Hats (Ebbs & Ward, 2024). As a result, there was significant coordinated 'pull' for lean. The Practitioners (supported by 'A') facilitated a series of workshops over 6 days in June and July 2023 to leverage perspectives and help projects mobilise safely and faster (n=80) whilst standardising approaches to design where possible. Following these workshops, the Design Lead asked "ok, so what's next for lean?", one of the answers was make-ready. Recognising that 'not every nail requires a hammer' a bottom-up approach to 'Pre-Assembly' make-ready was implemented. However, rather than conduct a workshop, an 8 Flow survey was conducted (n=24). This resulted in 28 initial codes that increased to 35. These were also structured under DR.PAMPPSS to maintain some consistency with the 'Assembly' codes. Some interesting observations emerged. Whilst the leadership were fully supportive and engaged with make-ready and the individual leading make-ready deployment was too, in hindsight, the pre-assembly teams' understanding of make-ready and the LPS in general was insufficient. 'Code #31' was added to capture and trend tasks 'not screened'. By Nov 2023 #31 equated to 60% of 4,500 tasks. Additionally, there was also reluctance to share the initial 'poor' TMR scores because it was assumed the 'wrong' reaction might be provoked. This knowledge provided more focus on the screening process and transparent reporting of TMR data.

In Nov 2023, the 'make-ready' lead then undertook the 18404 course reported by Ebbs and Ward (2024). During their Sponsor session in Dec 2023, they noted "I now know why you were asking me to do all these things including collecting and sharing the data, had I known what I know now I would have been even more disciplined with the roll out of make-ready, huddles and visual management. To be honest, I was only doing it because you asked me to [and I trusted what you were doing]". Furthermore, during the Stage 1 ISO 18404 External Audit in Feb 2024, the Auditor asked to see TMR Pre-Assembly data, but it transpired the make-ready lead had left the Alliance and the data trail was not updated for 3 weeks, which suggested some people relaxed their approach to make-ready without leadership. Overall, from September 2023 to Jan 2024 initial Pre-Assembly make-ready deployment data analysis showed TMR increased from 15% to 62%, and LEI (Lookahead Execution Index) went from 54% to 72%. LEI is a client measure of programme certainty. It takes the planned starts and finishes within a reporting period and records if those planned starts and finishes were achieved. The practical output of this and general lean deployment in the Alliance, which was heavily focused on RM, make-ready, and CI, reduced some project initiation to mobilisation periods by approximately 50%.

Elevating the Importance of Make-Ready: Moving the focus from Did to Can

The background to elevating the importance of ‘make-ready planning’ was in part related to deploying ISO 18404 to embed a lean culture and make lean normal practice. However, it was also vicariously related to IRMA 360^0 deployment as the rich data generated included many make-ready items within the ‘risks’ which highlighted the need for a more structured make-ready approach. The Alliance created a Single Page Lean Strategy with more detailed plans to support and structure deployment of critical elements such as training and coaching, visual management, the LPS, and specifically make-ready. The Alliance also created a ‘rich picture’ to show a programmatic and outcome-based intent. This evolved as the Alliance and lean competencies matured. For example, ‘Progress Tracking’ was replaced with ‘Make-Ready Planning’. Whilst the focus on make-ready formed part of a wider lean deployment through an 18404 framework to develop the lean competency of key mid-senior leadership, the make-ready pilots also influenced more strategic updates to the Alliance strategy (Ebbs & Ward, 2024).

CONCLUSION

The primary contribution of this research demonstrates how to improve input flows through the IRMA 360^0 framework based on the collective input from the ‘Last Risk Managers’. Within a complex project delivery or organisational improvement paradigms, significant thought and collaboration is required. Projects, strategic objectives, and improvement activities are realised from many conversations which constantly occur between the Last Risk Managers. Outcomes are ultimately the result of establishing shared understanding between people, however, the process of realising outcomes inherently involves RM, production commitments, rework, making do, and learning. Whilst the theory of make-ready ‘to screen every task for constraints prior to committing to production’ is relatively simple, this research highlights that embedding make-ready planning (and the ‘full’ LPS) is much more complex. Many contributing factors require consideration such as the operating environment, contract model, and knowledge and understanding of the LPS which includes make-ready and linguistics.

Aven (2012) emphasized the need to understand linguistics in RM and Flores (2013) articulated how we invent the future through conversations. IRMA 360^0 is a system that helps facilitate conversations to understand risks and concerns before making commitments. The common denominator in conversations is people, however, their ontology naturally differs based on their socio-technical constructs. Therefore, the more of the ‘right’ people in the room, to have the right conversations at the right time, the richer the conversations. You don’t know, what you don’t know until you know it, and knowledge of risks alone does not equate to understanding and in some cases as Kutsch and Hall (2010) posit, leads to ignoring them.

In conclusion, we propose that an integrated approach to collaborative RM and make-ready within a LPS framework to trigger and capture the conversations that emerge with the required commitments for CI is useful. Furthermore, for effective production planning and control RM, make-ready planning, and CI cannot be considered in isolation of each other. Whilst IRMA 360^0 appears to support this integration, a collaborative systems thinking environment is also desired (such as the Alliance model reported in Case 4) to help people feel safe to become ready for make-ready and integrate RM with the LPS. Whilst the generalisation of the case study findings of this research may be harder without further independent testing of IRMA 360^0, the implementation challenges of RM, make-ready and the full LPS are well recognised. There is a plethora of guidance and research on RM, LPS and CI but the empirical evidence provided here suggests IRMA 360^0 may help integrate these approaches and provide the framework to not only formalise make-ready planning at the heart of project conversations but also integrate RM with the LPS as a standalone [risk] management system that ISO 31000:2018 calls for.

PROMOTING HEALTH AND SAFETY ON UK CONSTRUCTION SITES USING LEAN CONSTRUCTION STRATEGIES

Himesh Chaudhari[1], Saad Sarhan[2], Mohammed Abdelmegid[3], Ali Saad[4] and Mani Poshdar[5]

ABSTRACT

Poor health and safety (H&S) conditions in the construction industry are linked to ill-defined social and economic factors. To mitigate poor construction H&S performance, it has been widely recommended that Lean Construction (LC) strategies be adopted. Existing literature shows a strong correlation between implementing LC and improving construction H&S performance. However, limited research utilises qualitative research based on primary data to understand the perspectives of experts with real-world experience on the LC/H&S relationship. To address this gap, we conducted a novel study interviewing eight highly experienced LC experts to gain insights into how LC can enhance H&S in construction projects. Going beyond theory, we conceptualised a model linking key LC methods to root causes of H&S accidents to enable tangible improvements. This model intends to guide construction professionals in adopting and implementing LC strategies to foster safer construction workplaces. Our findings affirm and extend prior research by emphasising the efficacy of LC methods in improving H&S performance in construction projects.

INTRODUCTION

Construction is one of the most dangerous industries, with a higher death rate among its workers (National Safety Council, 2023). This does not include fatalities from suicide – of which this industry also has one of the most. Accidents in this industry often result in death or serious injuries. Every year, a significant percentage of employees are temporarily or chronically disabled due to injuries sustained on construction sites (Health and Safety Executive, 2023). According to the United States Bureau of Labor Statistics (2021), the annual number of deaths in the construction sector in 2020 was 1,008, which accounted for 21% of all deaths among US workers. In Great Britain, Construction-related fatal injuries jumped

by 55% from 29 to 45 in the 2022/23 reporting year and it remains the sector with the highest number of deaths, according to the Health and Safety Executive (HSE, 2023). The most common types of fatal accidents in the United Kingdom (UK) in 2022/23, as reported by the HSE, are as follows:

- Falls from a height.
- Struck by moving object.
- Struck by moving vehicle.
- Trapped by something collapsing/overturning.
- Contact with moving machinery.

Construction-related accidents lead to productivity losses and increased construction expenses due to project delays, employee absences, healthcare procedures, employee health coverage, legal costs, reimbursement costs, and recovery sessions. These social and economic losses have an overall effect on human well-being (Schaefer et al., 2008).For these reasons, several research studies have suggested various techniques and approaches to improve the Health and Safety (H&S) performance of the construction industry. Lean Construction (LC) has been among the key research themes to enhance the H&S aspects of construction. According to LC principles, accidents are causes of process waste in terms of duration, budget, and workforce productivity, which obstruct workflow and impact product quality. Therefore, from a productivity perspective, injuries must be avoided (Mitropoulos et al., 2007) As a rule of thumb in LC, it is essential to ‘stop production whenever it feels unsafe’. In addition, ‘Respect for People’ is a core principle in LC. Several studies suggested that implementing LC principles across worksites can offer an opportunity for construction professionals to improve the H&S of construction work environments (Salem et al., 2007; Antillon et al. 2019, Melo and Costa, 2023). At the same, it has been argued that a focus on H&S from an early stage in projects, using LC, can also help companies achieve their sustainability targets and objectives (Emuze and Smallwood, 2013; Sarhan et al., 2021) and improve project value delivery (Gomez et al., 2020). This paper investigates the value of LC in tackling H&S concerns, specifically the root causes of construction project worksite accidents.

During the past two decades, the efficacy of LC practices towards enhancing H&S has been a source of considerable discussion. However, the topic has been primarily investigated for individual LC methods with limited investigations on the conceptual relationship between LC and H&S. There is little known about how LC tools and techniques could actually help to improve H&S performance on construction sites. The novelty of this study is through its distinctive methodological approach, which aims to inductively explore professionals' knowledge, opinions, and observations to unfold a phenomenon and pinpoint the link between LC and H&S. The paper contributes to knowledge and practice by providing a better understanding of the value of LC in reducing common construction site accidents. The paper is structured to start with a background section, followed by the methodology and the rationale behind the choice, the results, and closing with the overall discussions and conclusions.

BACKGROUND AND RESEARCH OBJECTIVES

An occupational accident is an unexpected event that leads to personal harm or illness, damage to assets, resources, equipment, the environment, or any impact on business opportunities (Hughes & Ferrett, 2012). The nature of construction activities, fluctuations in workplace conditions, climate impact, construction materials, and the constant need for mobility are among the challenges linked with construction worksites (Perttula et al., 2003).

As a result of such circumstances, employees are more likely to be engaged in various types of injuries.

Numerous studies have been conducted to identify the various causes of workplace accidents in the construction industry. Defects and engineering issues can introduce potential hazards, which can stem from inaccurate design or execution flaws (Bellamy et al., 2008;). Weak planning and supervising, poorly maintained worksites, and lack of expertise within the workforce are among the project management-related causes of accidents (Bellamy et al., 2008). Moreover, human-related issues such as the psychological state, training, physical and emotional abilities, and motivational factors, are among the key causes of accidents (Bellamy et al., 2008; Kletz, 1993; Sawacha et al., 1999). Administrative failures and the lack of implementation of H&S standards are also contributing factors (Toole, 2002). Overall, these findings highlight the multifaceted nature of construction-related accidents and the need for a holistic strategy that encompasses management, training, compliance, and a safety culture.

One of the fundamental concepts of LC is to constantly optimise operations to reduce waste, such as non-value-adding activities and other interruptions within the flow of operations. It is well established that reliable workflow in construction operations cannot be achieved without safe work practices. Hence, every event that can impact employees' well-being and obstruct the flow of value-adding activities can be viewed as a 'source of waste' that should be eliminated (Sarhan et al., 2018). Accidents often lead to a variety of consequential wastes, lower efficiency, economic losses, and project delays. Therefore, workplace H&S management can minimise the adverse impacts of accidents such as loss of work time and compensatory payments (Jang & Kim, 2007). Aside from the productivity perspective, a key aspect of LC is promoting 'respect for people' (Emiliani, 2008; Liker, 2011; Korb, 2016) and incorporating ethical responsibility towards maintaining employees' physical and mental health (Rother, 2010; Akers, 2011; Gomez et al., 2020). Therefore, from a theoretical standpoint, LC and H&S are well-aligned and interrelated. It is already well-established that the effective application of LC can promote H&S in the workplace and minimise accidents. However, this study contributes to knowledge by addressing the following research objectives:

- Identifying the most common causes of accidents on UK construction sites and investigating their root causes,
- Exploring the relationship between LC and H&S performance,
- Providing practical insights from industry experts on the barriers and enablers of adopting LC for improving H&S performance on construction sites, and
- Developing recommendation for construction firms and professionals on how LC can be used to tackle these identified issues.

Several LC methods have the potential to improve H&S performance in construction projects. For example, the Last Planner System (LPS) can enhance workplace safety by empowering employees, aligning tasks with individual abilities, and promoting collaboration. Through pre-construction hazard assessments and regular monitoring, it proactively addresses potential causes of accidents, including ineffective practices, anxiety, and poor cooperation (Saurin et al., 2001; Sacks et al., 2005; Leino and Elfving; 2011; McHugh et al., 2021). Another example is the 5S method, which emerges as a potent safety tool by fostering a clean and organised workspace, enhancing comfort, and effectively managing resources. It directly addresses potential causes of accidents such as bottlenecks, inadequate work conditions, and workplace risks like slips, falls, and operating in narrow spaces (Ng et al., 2012). Visual management has been shown to be instrumental in advancing workplace safety through improved visibility, risk management, and clear warning signals. It directly addresses potential causes of accidents by enhancing communication, strengthening monitoring and scheduling, fostering site expertise and shared understanding, and promoting compliance with legislation. This proactive approach minimises the risk of accidents arising from weak communication channels, inadequate monitoring, lack of expertise, misunderstandings, and faulty decision-making (Melo and Costa, 2023). Other lean approaches for reducing onsite accidents include the use of standardised work (Mollo et al., 2019), Five Whys (Leino and Helfenstein, 2012), leading performance measurement indicators (Ng et al., 2012), Kanban (Jang and Kim, 2007), prefabrication and supply-chain management (Arbulu et al., 2005; Adekunle et al., 2023), BIM (Etges, 2020) and unmanned aerial systems (Melo and Costa, 2023).

METHODOLOGY

As indicated earlier, the main purpose of this study is to investigate how the application of LC can enhance H&S performance on construction sites. An inductive approach for qualitative data analysis was adopted in this study to gain a better and more practical understanding of the relationship between LC methods and H&S performance. Semi-structured interviews were conducted with eight UK industry experts in the field of LC. These experts were selected based on their extensive experience and expertise in implementing lean practices in construction projects. A snowballing technique was adopted, where each expert was asked at the end of every interview to recommend the next interviewee with relevant expertise and knowledge. Snowball sampling is an effective research method that is commonly used in social science research when the population under investigation is either hidden or difficult to reach (Browne, 2005; Waters, 2015). Table 1 provides details about the selected experts in terms of their profiles, years of relevant experience, and current work location. Interviews were conducted online and recorded for data analysis purposes after taking consent from the participants. Each interview lasted for about 30-45 minutes. The qualitative data collected through these interviews were analysed using thematic analysis (Braun and Clarke, 2006), aiming to identify patterns, themes, and key factors that contribute to the intersection of LC and H&S performance. A qualitative data analysis software (i.e. NVivo) was used to support with data coding and analysis, following the guidelines provided by Sarhan and Manu (2021).

Table 1: Interviewee Details

Expert no.	Professional's profile	Work experience	Work location
E1	Lean Construction Consultant	20 Years	Global
E2	Head of Project Planning	11 Years	UK
E3	Lean Construction Leader	19 Years	UK
E4	Lean Practitioner	8 Years	UK
E5	Productivity and Performance Manager	32 Years	Europe
E6	Senior Project Manager	28 Years	UK
E7	Chief Executive	46 Years	UK
E8	Director of Lean Consultancy	18 Years	Global

The choice of semi-structured interviews allowed for a flexible and systematic exploration of the experts' insights, experiences, and observations. The interview questions were designed to elicit detailed responses regarding specific lean tools, methodologies, and practices believed to influence H&S performance in construction. Four main open-ended questions were used for this purpose, as follows:

- **Q1.** What are the most common H&S problems / issues on construction sites?
- **Q2**. What are the main causes of these accidents or related H&S problems?
- **Q3**. How can lean construction help to improve H&S performance in construction?
- **Q4**. Which Lean construction (LC) tools or strategies could be used to address H&S issues in construction projects, and how?

RESULTS

In this section, the outcome of the thematic analysis of the collected data is provided. Four themes were identified based on the responses of the interviews. Two were related to H&S in construction and two were focused on their views on the interrelationship between LC and H&S. The following sub-sections present the results of the four identified themes.

COMMON H&S ISSUES ON CONSTRUCTION SITES

In order to set the context for the interview, the experts were asked about their experience with H&S and what they perceive as the most common H&S issues within the industry. Different types of H&S issues were highlighted. E1 and E7 found that falls from height are the most common, indicating that improper Personal Protective Equipment (PPE) compound this safety hazard. E2, E4, E5, E7 and E8 consider slips, trips and falls the most common issue. E2 also mentioned tiredness and fatigue, especially towards the end of the shift when workers may be making decisions that lead to injury. This aligns with findings of research by Turner and Lingard (2020) that investigated the impact of the physical demands of the construction work and (experienced and anticipated) bodily pain on the mental health and productivity of construction workers. E3 considered chemical hazards, obstructions on the site of vehicles, and the motion of people as major issues. While E4 mentioned that in the last 6-7 months of their work, utility strikes came up as a safety issue on construction sites. E6 stated that they are currently working on a highway project, and their team identified people-plant interference as the biggest hazardous factor.

CAUSES OF CONSTRUCTION SITE ACCIDENTS

The next question was intended to support the focus of the research on addressing the root causes of accidents. Therefore, the experts were asked about their views on the causes of site accidents. E1 indicated that poor planning is among the key causes of accidents. They stated that *"when the work methods are not agreed, the operational definitions are not established, and the first run studies are not done, these will cause on-site accidents".* E3 made a similar notion by suggesting that "*the most common cause of accidents is a lack of site planning because a lot of the hazards are identified within planning before workers go to the site…and to be honest, many people don't see these hazards individually*". E2 considered fatigue and lack of experience as causes of accidents, highlighting the role of human error in worksite accidents. This may also suggest the need for considering the implications of occupational stress and job-burnout on workers' safety performance (Sarhan *et al*., 2023). A similar finding was mentioned by E4, who indicated that personal behaviour is a major cause of accidents. They also explained that *"Employees know that what they're doing is wrong. They're taking the shortcut there, trying to do things quicker whether that is driven by targets or whether that's driven by intentionally, but it causes accidents*". E6 asserted that human behaviour is a main cause of accidents by saying that *"H&S starts at home, it starts with the individual. People forget having things in their minds and being under pressure to go out and do their day-to-day work, and they end up with safety issues. And this is where behaviour change is* *required”.* It is important, though, to consider how project and organisational systems (e.g. contracts, payment methods and performance measurement systems) influence behaviours. E5 pointed out that lack of awareness and communication gaps play a major role in accidents. They added that untidy workplaces, unsafe working environments, and misunderstanding of information cause a large number of onsite accidents. E8 also identified poor communication as a key cause of accidents. E7 mentioned several general causes including employees behaviours, resources, activity management, planning and scheduling. They also indicated that among the causes is that *“people are reluctant to develop a plan at work, and when developed, they are reluctant to stick to that plan”.*

THE ROLE OF LC IN IMPROVING THE H&S PERFORMANCE IN CONSTRUCTION

When it comes to the participants’ views on the role of LC in improving H&S, E3 considered that a key concept in LC is about dissecting the activities into small activities and ensuring that each activity feeds into and adds to pre-identified value with the project stakeholders. The concept of flow is also essential and the interdependency between activities should not be overlooked. They asserted that the correct application of the Transformation-Flow-Value generation (TFV) concept can enhance H&S performance in construction. In addition, they indicated that the use of digital tools along with the Last Planner System (LPS) provides good results in terms of identifying the H&S hazards. They also highlighted that collaborative planning addresses H&S, as employees can know which machines/equipment are going to be used, the number of people working, and the motion of the machine and workers. E2 explained that a lean strategy ensures that the risk assessments and methods statements are delivered in time, so that employees can assess them for accuracy and workability. E4 and E5 see that visual management plays a big part in advancing H&S in construction, as it enables transparency and information sharing. As per E6, LC has a major effect on H&S risks. Based on their experience, proper planning can reduce unnecessary machinery movement by 50% and reduce carbon emissions, which are considered a hazard to the employees, surrounding people, and the environment. E1 described that *“there is a lot more to lean construction than the last planner, but that’s how firms choose to write it up. The last planner has lots of planning conversations. The first conversation is about risk analysis and safety at construction sites. Also, 5S is very important as it will reduce trip hazards and so on, and another thing which I think would make an enormous difference going it would improve productivity along with reducing hazards”.* E7 and E8 affirmed that collaborative meetings, daily briefings, and safety checks as part of a LC strategy can help to minimise H&S hazards. E7 provided an example by indicating that *“to identify potential areas for risk as part of activities, we ask a series of questions for each planned activity like: have you got the detailed design? have you got the resource or access? Safety considerations about materials, plant permits, and are they all identified?”.* These are the necessary pre-conditions for starting any construction activity on site, which are conceptualised in LC literature as the seven flows needed to avoid the ‘Making-Do’ kind of waste (Koskela, 2004; Kraemer et al., 2007).

BENEFITS AND BARRIERS OF IMPLEMENTING LC TO IMPROVE H&S

A key objective of the interviews was to understand the correlation between LC and H&S performance to establish practical solutions for H&S improvement through LC. Therefore, the final group of questions focused on identifying the benefits and barriers of LC implementation to enhance H&S performance in construction projects. E1 mentioned that the focus of LC on value generation is a key benefit to H&S as LC will enable a systemic process for holistic improvement considering the complexity of construction systems. E2 indicated that *“the way you plan your work better through LC means that you're eventually improving H&S in a proactive way”.* However, they shared their concerns that although the benefits of

LC have been evident over more than two decades, the market is not yet mature enough to understand the correlation between LC and H&S, due to the general perception that lean is about time and cost savings. E3 confirmed a similar notion that a key barrier is related to industry culture. They asserted that there is a lot to do in terms of embedding LC into current industrial practices and challenging the traditional perception of lean as a mere productivity enhancement tool. They also highlighted the importance of change management to influence current practices and provide evidence of the overlap between LC and H&S. E7 supplemented this view by stressing the problem of aging workforce that are usually resistant to changes. They emphasised the role of project leadership in promoting LC practices and demonstrating their benefits to the H&S of construction workers.

E4 highlighted transparency as a key strength of LC to help construction teams in minimising H&S hazards. They also indicated that the availability of data through LC tools can play a key role in establishing Key Performance Indicators (KPIs) for H&S monitoring and control. E5 considered the behaviour change as both a benefit and a barrier in terms of H&S improvement. They clarified that the ability of LC to influence behaviour towards a safer work environment can highly improve H&S performance of construction projects. However, they highlighted the risk of disruptions and confusion caused by new initiatives, especially in traditional industries such as construction, which might create safety hazards that impact the overall H&S performance. E6 provided an interesting view of the role of LC in using modern production methods in construction, such as modular construction and Just-In-Time, which are generally safer methods of construction compared to traditional hazardous heavy site activities.

In summary, the key benefits identified from the interviews were related to transparency, look-ahead collaborative planning, communication improvement, risk reduction, enhanced efficiency, modern methods of construction, and prioritisation of workers' wellbeing. On the other hand, the main barriers were related to the industry culture, behavioural aspects, time and cost of implementation, and standards and guidelines.

DISCUSSION

In exploring the complex relationship between LC and H&S performance in construction projects, our findings align with the acknowledgement that the causes of poor construction H&S are multifaceted. The expert interviews emphasised that LC practices directly counter several root causes of H&S accidents. LC can provide practical solutions to enhance H&S in construction projects. For example, collaborative planning emerged as a powerful mechanism fostering a shared understanding of construction activities (Pasquire and Court, 2013) and identifying hazards proactively. Daily huddles were identified as reinforcing safe procedures and enabling transparent discussions of risks. Visual management was recognised for its effectiveness in risk management by monitoring and eliminating hazardous actions on construction sites. These mechanisms collectively address human errors, oversight, miscommunication, and noncompliance – prevalent causes of H&S accidents on construction sites.

Importantly, LC practices were perceived not only as a group of tools and methods but as a catalyst for deeper cultural and systemic changes within the construction industry. They instil a sense of order, efficiency, and collective responsibility while flagging hidden risks. Participant experts highlighted the connection between LC and modern building techniques by emphasising their inherently safer nature. Utilising LC to create ecosystems centred on worker well-being was identified as an effective means to elevate the priority placed on accident prevention. As opposed to the traditional view of the workforce, which visualises individual employees conducting work along their linear career paths to create value for their organization, a workforce ecosystem is considered a more inclusive and integrated approach for strategically managing a diverse group of internal and external workers. The concept of a workforce ecosystem can be defined as "*a structure focused on value creation for an organization that consists of complementarities and interdependencies. This structure encompasses actors, from within the organization and beyond, working to pursue both individual and collective goals*" (Altman et al., 2021, p. 1).

Despite the evident benefits of adopting LC for improving H&S performance in construction projects, a key emerging barrier is the ingrained industry mindset that safety, profit, and efficiency represent competing aims. LC is often viewed as a set of solutions for waste reduction and productivity augmentation rather than an ethos enabling both safer and more productive job sites concurrently. Overcoming this scepticism requires leadership commitment, active worker engagement, and measurable H&S gains linked to LC adoption. The participants stressed that meaningful change management relies on demonstrating the compatibility of safety, profit, and efficiency within a LC strategy.

Based on the findings from the literature review and semi-structured interviews, we formulated a conceptual model that links the root causes of accidents, as reported in Haslam et al. (2005), with LC methods (see Figure 1). This developed conceptual model provides general guidelines to support H&S improvement in construction projects but is not intended to be a comprehensive approach. It serves as a steppingstone for further research and practical implementation by providing a framework for construction professionals, project leaders, and policymakers to enhance safety protocols by adopting LC principles.

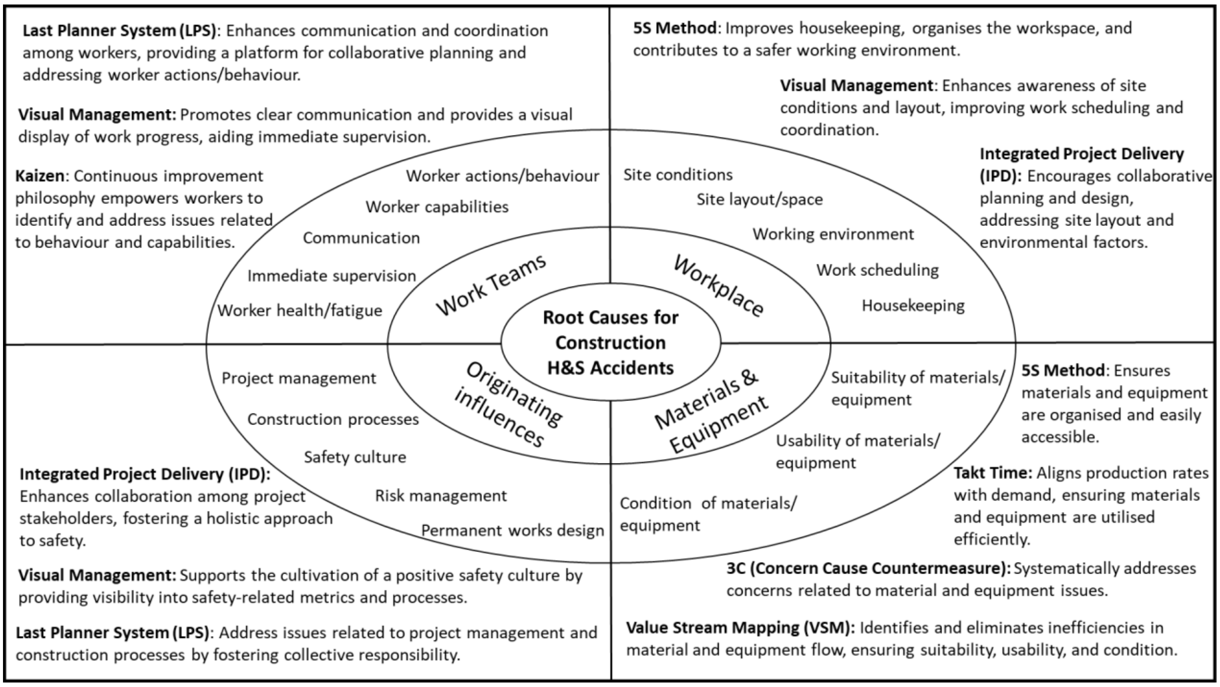

Figure 1: Conceptual model linking LC methods with root causes of construction accidents.

CONCLUSION

Poor health and safety performance remains a critical issue in the construction industry leading to injuries, fatalities, social and economic impacts. Prior research has connected LC principles of waste reduction and continuous improvement to enhanced safety outcomes. This study sought to elucidate the practical mechanisms underpinning this relationship based on insights from eight LC experts sharing their knowledge and suggestions from decades of first-hand industry experience.

Key findings reveal tangible methods by which the LPS, Visual Management, 5S among other LC methods proactively identify hazards while fostering orderly, transparent work ecosystems centred on worker wellbeing. Beyond isolated techniques, a lean culture and holistic systems approach was perceived to drive safer practices across different project dimensions. However, barriers related to industry culture and the prevailing views of cost, schedule, and safety as competing priorities persist. It is recommended that leadership commitment to worker-centric ecosystems is critical for successful implementation of LC to improve H&S performance.

The study concluded with a conceptual model that connects the root causes of onsite accidents with tailored LC countermeasures to provide actionable guidance for health and safety enhancement. The findings of this provide guidance to construction project managers and professionals on how to effectively use LC concepts, tools, and techniques to avoid or minimise the occurrence of accidents and related H&S problems on construction sites.

As an exploratory qualitative study based on interviews with a small purposive sample of industry experts, the findings are not meant to be generalisable without further validation. Quantitative examination is suggested to statistically correlate LC adoption maturity levels to H&S metrics such as incident rates and safety culture index. Comparative case studies of projects using varying degrees of LC methods would shed further empirical evidence on direct and indirect impacts on H&S outcomes. Future research avenues may also explore the longitudinal impact of LC adoption on the industry H&S performance and investigate the dynamics of such implementation within construction companies. Finally, further research is also needed to investigate how LC can help to tackle and minimise mental health issues in construction.

AN EXPLORATORY STUDY ON VISUAL MANAGEMENT AND PROCESS TRANSPARENCY IN CONSTRUCTION

Mauricio Neyra[1], Michelle Diaz[2] and Sulyn Gomez[3]

ABSTRACT

Several managerial approaches have emerged to address current construction challenges. Among them, information management addresses construction hurdles through process transparency, a core function of Visual Management (VM). Research on VM in construction has focused on its theoretical development and practical implementation. Conversely, research on process transparency has focused on highlighting its significance for construction through transparency strategies. This study aims to extend the research on process transparency and VM by identifying their current applications, measuring their degree of implementation, and highlighting their impact on team performance in two case studies based on observational protocols in Peru.

The main findings are: (1) Process transparency implementation was mainly driven by internal team efforts for job facilitation, while VM primarily served job facilitation, site signage and transparency functions, (2) One site had a higher degree of process transparency while the other had a slightly higher degree of VM, and (3) team performance improvement was associated with visual practices serving the functions of transparency and job facilitation. Some recommendations for the implementation of VM systems on construction sites and for future research were also presented.

KEYWORDS

Lean Construction, information management, process transparency, Visual Management, team performance.

INTRODUCTION

Construction is a project-based industry with relatively high complexity and low efficiency (Vrijhoef & Koskela, 2008). Construction projects often face problems such as misunderstanding of tasks, lack of process integration, delays, and unfulfillment of quality requirements (Galsworth, 2017). Researchers have studied different managerial approaches to mitigate the current challenges of the construction industry, e.g., safety management (Levitt & Samelson, 1987), production management (Koskela, 2000), risk management (Mills, 2001). Among them, information management (Adekunle et al., 2022) is of high relevance given that:

1. Construction projects involve a vast and dynamic amount of information often limitedly displayed or inefficiently updated (Valente & Costa, 2014; Saldias, 2010).

[3] Quality Leader, DPR Construction, Redwood City, USA, sulyng@dpr.com, orcid.org/0000-0003-2367-9880

2. Every task within a construction project should be fully understood to ensure that the overall production system operates as a continuous stream of activities (Brady, 2014).
3. Reassignment of personnel between work sectors, changes in product specifications, and adjustments to construction site settings make the immediate and accurate dissemination of information necessary (Formoso et al., 2002).
4. Information deficit in the workplace is highly associated with production waste (waiting, defects, over-processing, etc.) in construction processes (Formoso et al., 2002).

Information management aims to provide all project stakeholders with up-to-date, accurate, accessible, understandable, and relevant information (Reinbold, 2020). Enhancing process transparency increases information availability by making the attributes of construction processes visible to everyone. It is defined as "the ability of a production process (or its parts) to communicate with people" (Dos Santos et al., 1998). Process transparency seeks to deal with poor process orientation, ineffective decision-making, and prominent levels of waste and variability in construction processes (Formoso et al., 2002).

Tezel et al. (2016b) presents the improvement of process transparency as one of the main functions of a sensory strategy for information management called Visual Management (VM), which aims to "improve organizational performance through connecting and aligning organization vision, core values, goals, and culture with other management systems, work processes, workplace elements, and stakeholders, by means of stimuli" (Tezel et al., 2009a). The improvement of process transparency through VM is expected to have an influence on waste reduction (Koskela, 1992; Formoso et al., 2002), which enhances team performance for quality during process execution. This paper presents the first findings of an extensive research project that aims to assess the impact of implementing a visual management system on process transparency and team performance for quality in construction. The scope of the paper is limited to presenting the findings of analyzing the current applications, degree of implementation, and impacts on team performance of process transparency and VM in 2 construction sites from a railroad project in Peru.

LITERATURE REVIEW

VISUAL MANAGEMENT

VM is a managerial strategy that emphasizes short-range sensory communication (Tezel et al., 2016b). Communication is not limited to visual messages, but involves all 5 senses: taste, touch, smell, hearing, and sight (Liff & Posey, 2004). VM is achieved in visual workplaces (Galsworth, 1997). A visual workplace presents an information field integrated with the work setting, where the actual information need might occur, thus extending access to information to a larger number of people (Tezel et al., 2011). VM supports managerial practices (Tezel et al., 2009a) such as Health, Safety, Security & Environment (HSSE), production, quality, inventory, and knowledge management. VM also provides specific functions at an operational level: (1) transparency, (2) discipline, (3) continuous improvement, (4) job facilitation, (5) on-the-job training, (6) shared ownership, (7) management by facts, (8) simplification, and (9) unification (Tezel et al., 2009b).

Taxonomies and typology

Numerous VM taxonomies have been proposed based on its purpose, such as regulating human behavior (Galsworth, 1997) or presenting information to users (Bititci et al., 2016). For instance, Tezel et al. (2015) proposed a taxonomy of visual practices, which are visual elements implemented in the field to improve a specific aspect of construction operations (see Table 1).

Table 1: Taxonomy of Visual Practices (Adapted from Tezel et al., 2015).

Purpose	Examples
Removing visual barriers	Site layout organization, using chain-link fences, etc.
Standardize identification and location	Marked pathways, site maps, ID cards, etc.
Systematic site order	5S implementation.
Production control	Material tag control, scaffolding control, Kanban, etc.
Production leveling	Heijunka boards, simple colored beats, etc.
Prototyping and sampling	Product prototypes, material samples, etc.
In-station quality	Colored boards, Andon boards, etc.
Site signage	Safety signs, safety information, desired practices, etc.
Performance management	Overall progress boards, productivity metrics, etc.
Improvising Visual Management	Aids for on-site quality control and assurance.
Work facilitation	Visual work instructions, project drawings display, etc.
Mistakeproofing	Poka-yoke devices.
On-site prefabrication	Prefabricated construction elements.
Distributing system-wide information	Visual information for the workforce.

By integrating VM taxonomies, Brandalise et al. (2022) proposed a typology that classifies visual elements by complexity and context dependence in 3 levels and 7 attributes (Figure 1).

Level 1: Device	A visual display designed to achieve a certain degree of control by its visual appeal only for a certain period (e.g. permanent safety signals).
(1) Degree of control	*Visual indicator,* which shares information with voluntary compliance. *Visual signal,* which catches attention and generates a reaction. *Visual control,* which impacts behaviors by limiting physical quantities. *Visual guarantee,* which ensures desired outcomes by mistake-proofing.
(2) Visual expression	Static (immutable) or dynamic (updated over time).
Level 2: Practice	A visual device designed to fulfill a specific function with a communication, collaboration, or managerial integration role (e.g. Kanban, Andon, 5S).
(3) Main function	Control artifact, execution procedure, target specification, material delivery, prototype, or others (specified in Tezel et al. (2015)).
(4) Communication role	One-to-one, one-to-many, many-to-one, or many-to-many.
(5) Collaboration role	Collaborative (stimulating interactions) or non-collaborative.
(6) Integration role to management routines	Integrated or not integrated.
Level 3: System	Two or more integrated visual practices with greater impact on the project.
(7) Integration of practices forming a system	Integrated or not integrated.

Figure 1: Typology of Visual Elements (Adapted from Brandalise et al., 2022).

Visual Management Implementation

Some VM practices adapted for construction projects are well described in the literature, such as 5S (Tezel & Aziz, 2016), Kanban (Costa & de Burgos, 2015), and Andon (Kattman et al., 2012). At the beginning of its adoption in construction, VM was mostly applied in site offices to support managerial decisions, and only health and safety warning boards, focused on information giving, were usually found in construction site working areas (Tezel et al., 2016a). However, recent studies have shown the application of many other visual practices in construction sites (Moser & dos Santos, 2003; Tezel & Aziz, 2016; Tezel et al., 2015).

PROCESS TRANSPARENCY AND LEAN

Lean Construction, guided by Lean Thinking, aims for continuous improvement and value flow (Womack & Jones, 1996). To achieve this, construction processes should be easily understood by everyone involved (Dos Santos et al., 1998). Process transparency involves making the main process flows visible and comprehensible from start to finish (Koskela, 1992), allowing for easy problem identification within the production system (Moser & dos Santos, 2003).

Koskela (1992) outlines six strategies for enhancing transparency: (1) reducing interdependence between production units, (2) using visual artifacts that allow immediate recognition of process status, (3) making the process directly observable, (4) incorporating information into the process, (5) maintaining a clean and orderly work site, and (6) representing invisible attributes through measurements. Formoso et al. (2002) suggested 10 performance indicators to evaluate process transparency (see Table 2).

Table 2: Process Transparency Indicators (Adapted from Formoso et al., 2002).

Transparency indicator	Definition / Criteria
(1) % of workstations presenting no interference from another process	Sharing space, equipment, or materials with other crews.
(2) Number of visual indicators	They only provide information.
(3) Number of visual signals	They aim to generate a response.
(4) Number of visual controls	They limit physical quantities.
(5) Number of visual guarantees	They ensure outcomes through mistake-proofing.
(6) % of process stages observed from the most favorable viewpoint	Stages clearly observed throughout the whole process.
(7) % of process stages clean and tidy	Minimum material waste and visually organized.
(8) Number of process performance indicators collected regularly	Adress the ease to collect indicators from the process.
(9) Number of workstations analyzed	Required for the 1st indicator.
(10) Number of process stages	Required for the 2nd indicator.

METHODOLOGY

This paper presents an exploratory research based on two case studies of construction sites in Peru using 3 sources of evidence: participant observation, document analysis, and unstructured discussions (Yin, 1994). Participant observation was selected due to the role of the first author as field supervisor, with data primarily collected during quality inspections. Unstructured interviews, characterized by undetermined questions and answers (Minichiello et al., 1990), complemented participant observation and involved conversations with site managers to enhance data collection. Documentation consulted included field notes, photos, daily reports, and weekly reports.

The first author collected data from the Site A from January 3rd to January 13th, 2024, and from the Site B from January 15th to January 28th, 2024. The scope of study for VM analysis was the construction field and its execution procedures. For transparency analysis, two main construction processes were sampled from each site, taking time constraints into consideration.

Data on VM and process transparency was compiled in observation protocols. The VM protocol (Figure 2) classified visual elements through a checklist (Tezel et al., 2009a; Brandalise et al., 2022; Galsworth, 1997; Bititci et al., 2016; Tezel et al., 2015), and analyzed them through guided questions (Valente et al., 2019). The process transparency protocol (Figure

3) identified transparency indicators (Formoso et al., 2002) along with transparency strategies (Koskela, 1992). Team performance for quality was assessed through field notes on defects and rework activities. A grading system is provided to ease the comparativeness of the units studied. Inferences were drawn from the relationships between the indicators, potential causes of significant results, and the primary VM functions observed in the field.

VISUAL ELEMENT			
Name:		**Location:**	
Affects processes? Which ones?	◉	◉	◉
CLASSIFICATION			
Function (Tezel et al., 2009a): Select all that apply.	☐ Transparency ☐ Discipline ☐ Continuous improvement ☐ Job facilitation ☐ Unification ☐ On-the-job training ☐ Shared ownership ☐ Management by facts ☐ Simplification		
Level (Brandalise et al., 2022):	☐ Visual device	☐ Visual practice	☐ Visual system
Degree of control (Galsworth, 1997)	☐ Visual indicator ☐ Visual signal ☐ Visual control ☐ Visual guarantee		
Visual expression (Bititci et al., 2016)	☐ Static ☐ Dynamic		
Purpose (Tezel et al., 2015)	☐ Removing visual barriers ☐ Standardize identification and location ☐ Production leveling ☐ Systematic site order ☐ Performance management ☐ Work facilitation ☐ Mistakeproofing ☐ Prototyping and sampling ☐ Distributing system-wide information ☐ On-site prefabrication ☐ Improvising Visual Management ☐ Site signage ☐ In-station quality ☐ Production control		
Role of communication	☐ One-to-one ☐ One-to-many ☐ Many-to-one ☐ Many-to-many		
Role of collaboration	☐ Collaborative ☐ Non-collaborative		
Role in managerial routines integration (If so, in which ones?)	☐ Integrated with management routine ☐ Not integrated with management routine ☐ HSSE ☐ Production ☐ Quality ☐ Inventory ☐ Knowledge ☐ Other: ____________		
Other practices of the system	◉	◉	◉
ANALYSIS (Valente et al., 2019)			
1) Visual attributes	- What is the content to make available?	- Which kind of coding is used?	
2) Visual implementation	- What is the frequency of use?	- Who is responsible?	
3) Visual information	- Which type of data is used?	- Where is information placed?	
4) Problem solving	- Which type of problems are avoided?	- Is there a standard procedure?

Making the process directly observable. *(If identified, how is it applied?)*					
Incorporating information into the process. *(If identified, how is it applied?)*					
Maintaining a clean and orderly work site. *(If identified, how is it applied?)*					
Representing invisible attributes through measurements. *(If identified, how is it applied?)*					
Transparency indicators (Indicators #1 to #5 - Formoso et al. (2002))					
1) Is there an interference with other processes? Which ones?			2) Is process information displayed? How? (Visual indicators)		
3) Are there any visual signals? Which ones?			4) Are there any visual controls? Which ones?		
5) Are there any visual guarantees? Which ones?					

Figure 3: Process Transparency Protocol (Summarized).

RESEARCH FINDINGS

Two construction processes were analyzed at each construction site and a total of 19 different visual elements were identified, 8 of them being observed in both sites.

PROCESS TRANSPARENCY

In both sites, the execution of masonry walls of concrete blocks was studied. Site A was re-starting activities after a pause period, so only the first stages of its processes could be studied. The denomination for each process is shown below:

- (A1) Execution of off-site prefabricated slabs and on-site compression slabs in Site A.
- (A2) Execution of masonry walls of concrete blocks in Site A.

- (B1) Waterproofing and backfilling of street-level slab in Site B.
- (B2) Execution of masonry walls of concrete blocks in Site B.

Figure 4 and Figure 5 illustrate some stages of the construction processes mentioned above.

Figure 4: Main Stages of the Construction Processes A1 and A2.

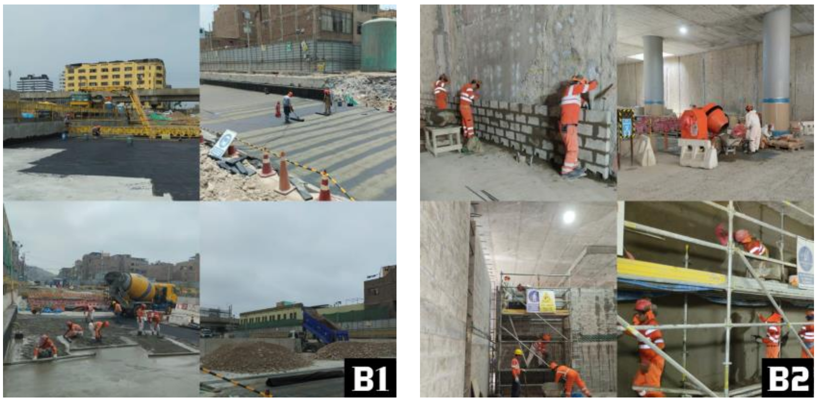

Figure 5: Main Stages of the Construction Processes B1 and B2.

The application of the six transparency strategies is verified through a check/cross marking and their specific ways of implementation are explained if the strategy is applied (see Figure 6).

TRANSPARENCY APPROACHES OF PROCESSES A1, A2, B1, B2					
1) Reducing interdependence between production units.			4) Incorporating information into the process.		
A1	✓	Use of safety barriers in the surroundings of the process.	A1	✓	Labeling of precast slabs.
A2	✓	Use of safety barriers in the surroundings of the process.	A2	✓	Markings for block positioning.
B1	✓	Use of safety barriers / Labeling of materials.	B1	✗	
B2	✓	Use of safety barriers in the surroundings of the process.	B2	✓	Markings for block positioning, wall height, concrete pouring level, span dimensions, and inspection status.
2) Using visual artif. that allow immediate recognition of p. status.			5) Maintaining a clean and orderly work site.		
A1	✓	Sound alarms during lifting.	A1	✓	Identification of a waste disposal area.
A2	✗		A2	✓	Identification of material collection area.
B1	✓	Lateral markings to identify layers of backfilling.	B1	✓	Material waste constantly disposed.
B2	✓	Markings for inspection status.	B2	✗	
3) Making the process directly observable.			6) Representing invisible attributes through measurements.		
A1	✓	Illumination improvement / Rebar markings for anchorage.	A1	✗	
A2	✓	Rebar markings for anchorage.	A2	✗	
B1	✗		B1	✗	
B2	✗		B2	✓	Metrics for placed blocks (not too clear).

Figure 6: Transparency Strategies of Processes.

Figure 7 shows the identification of transparency indicators #6, #7 and #10. Each one of the process stages studied is verified according to its compliance with the observability and cleanliness indicators through a green check (complies) or red cross (does not comply).

	Stages (Indicators #6, #7 and #10):	O	K		O	K
A1	1) Arrival of prefabricated slabs	✗	✓	5) Hook release	✓	✓
	2) Preparation for lifting	✗	✓	6) Concrete chipping of the main slab	✓	✓
	3) Lifting of slabs	✗	✓	7) Perforation of holes for steel anchorage	✓	✓
	4) Positioning of slabs	✓	✓	8) Steel anchorage in main slab	✓	✓
A2	1) Scarification of concrete at the base of the walls	✓	✓	4) Preparation of mortar mixture	✓	✓
	2) Perforation of holes for steel anchorage	✓	✓	5) Application of mixture and placement of blocks	✓	✓
	3) Vertical rebar anchorage in slab	✓	✓	6) Horizontal reinforcement between block rows	✓	✓
B1	1) Repair of cracks and imperfections on concrete surface	✓	✓	5) Waterproofing test	✓	✓
	2) Priming of bituminous material	✓	✓	6) Placing of geotextile	✓	✓
	3) Placing of 1st waterproofing layer	✓	✓	7) Mortar pouring	✓	✓
	4)Placing of 2nd waterproofing layer	✓	✓	8) Backfilling and compacting	✓	✓
B2	1) Scarification of concrete at the base of the walls	✓	✓	9) Steel reinforcement in pilasters and beams	✓	✓
	2) Perforation of holes for steel anchorage	✓	✓	10) Formwork for pilasters and beams	✓	✓
	3) Vertical rebar anchorage in slab	✓	✓	11) Concrete pouring in pilasters and beams	✗	✓
	4) Preparation of mortar mixture	✗	✗	12) Formwork stripping of pilasters and beams	✓	✓
	5) Application of mixture and placement of blocks	✓	✗	13) Scarification of concrete on pilasters and beams	✓	✓
	6) Horizontal reinforcement between block rows	✓	✓	14) Preparation of mortar mixture	✓	✗
	7) Preparation of liquid concrete	✗	✗	15) Wall plastering	✓	✓
	8) Concrete pouring in wall cavities	✗	✗			

O: Observable from the most favorable viewpoint | K: Kept clean and tidy

Figure 7: Transparency Indicators of Process Stages.

Table 3 enumerates the transparency indicators #1 to #5 of each process and presents an interference rating (IP, 0 = With interference, 1 = No interference), and a visual display rating (VD, 0 = not implemented, 0.5 = partially implemented, 1 = well implemented). To quantify the degree of process transparency, Table 4 presents a general 5-scale rating.

Table 3: Transparency Indicators of Construction Processes.

Process	Process interf.	Visual indicators	Visual signals	Visual controls	Visual guarant.
A1	No (1)	Slab labels (1)	Safety signs (1) Sound alarm (1)	Steel marks (0.5)	No (0)
A2	No (1)	Slab marks (1)	Safety signs (0.5)	Steel marks (0.5)	Prototype (0.5)
B1	No (1)	No (0)	Hot work sign (1)	Layer marks (0.5)	No (0)
B2	No (1)	Wall marks (0.5) Span marks (1) Status marks (0.5)	Safety signs (1)	Pouring level (0.5)	No (0)

Table 4: Process Transparency Observation Results.

Process	Fraction of observable stages (OS)	Frac. of stages clean/tidy (SK)	Fraction of implemented strategies (IS)	Interference rating (IP)	Sum of average VDs (SVD)	Total process transparency degree (TD)
A1	5 / 8	8 / 8	5 / 6	1	2.5 / 4	4.08
A2	6 / 6	6 / 6	4 / 6	1	1.5 / 4	4.04
B1	8 / 8	8 / 8	3 / 6	1	1.5 / 4	3.88
B2	11 / 15	10 / 15	4 / 6	1	2.2 / 4	3.62

According to the grading system, process A1 is the most transparent (TD = 4.08), while process B2 is the least transparent (TD = 3.62).

VISUAL MANAGEMENT STATUS

Out of the 19 different visual elements identified, Site A presented 4 unique elements, Site B presented 7, and both sites presented 8 repeated elements. Both construction sites had implemented visual systems for HSSE management, and some visual practices for quality and performance management. A single visual device without managerial role was also identified in site B. Figure 8 presents the elements classified according to their level and location.

Level	Site A	Site B
System	(1) Color coded safety signs, (2) Labelling of enclosed areas, (3) Safety cone retractable barriers for enclosed areas, (4) Plastic jersey barriers, (5) Solid waste storage signs, and (6) Inspection elements of scaffoldings.	
	(7) Labeling of liquid materials, and (8) Visual reminders for safety meetings.	(9) Safety plan board on-site.
Practice	(10) Markings for block positioning, and (11) Construction element labeling.	
	(12) Markings on steel rebars for anchoring, and (13) Temporal prototype of concrete block reinforcement.	(14) Lateral markings for backfilling layers, (15) Markings for masonry wall height, (16) Concrete pouring level, (17) Markings of span dimensions on masonry wall, and (18) Markings for metrics of placed blocks.
Device	-	(19) Markings of inspection status.

Figure 8: Visual Elements Identified.

Figure 9 presents the functions (Tezel et al., 2009b) and purpose (Tezel et al., 2015) of each element identified.

Level	Element	Site	Functions	Purpose
System	(1)	A and B	Discipline	Site signage
	(2)		Transparency / Job facilitation / Shared ownership	Standardize identification and location
	(3)		Discipline	Removing visual barriers
	(4)		Discipline	Standardize identification and location
	(5)		Transparency / Discipline	Site signage
	(6)		Transparency / Discipline	Production control
	(7)	A	Transparency / Job facilitation	Standardize identification and location
	(8)		Transparency / Discipline / Simplification / Unification	Distributing system wide information
	(9)	B	Transparency / Discipline / Simplification	Distributing system wide information
Practice	(10)	A and B	Transparency / Job facilitation	Work facilitation
	(11)		Transparency	Standardize identification and location
	(12)	A	Transparency / Job facilitation	Work facilitation
	(13)		Transparency / Job facilitation / On-the-job training	Work facilitation
	(14)	B	Transparency / Job facilitation	Work facilitation
	(15)		Transparency / Job facilitation	Work facilitation
	(16)		Transparency / Job facilitation	Work facilitation
	(17)		Transparency / Job facilitation	Work facilitation
	(18)		Transparency / Continuous improvement / Management by facts	Performance management
Device	(19)	B	Transparency	-

Figure 9: Functions and Purpose of Each Visual Element.

A 20-scale rating was developed to assess the degree of VM of each element:

- *Level:* Visual device = 2, visual practice = 4, and visual practice of a system = 8.
- *Degree of control:* Visual indicator = 1, visual signal = 2, visual control = 3, and visual guarantee = 4.
- *Visual expression:* Static = 0, and dynamic = 1.
- *Role of communication:* One-to-one = 1, many-to-one = 2, one-to-many = 2, many-to-many = 3.
- *Role of collaboration:* Non-collaborative = 0, and collaborative = 2.
- *Role in managerial routines integration:* Not integrated = 0, and integrated = 2.

Figure 10 presents the remaining classification and VM score of each element identified.

Level	Site	Element	Degree of control	Visual expression	Role of communication	Role of collaboration	Role in managerial routines integration	VM Score
System	A and B	(1)	Visual signal	Static	One-to-many	Non-collaborative	Integrated	14
		(2)	Visual signal	Static	One-to-many	Non-collaborative	Integrated	14
		(3)	Visual control	Dynamic	One-to-many	Non-collaborative	Integrated	16
		(4)	Visual control	Dynamic	One-to-many	Non-collaborative	Integrated	16
		(5)	Visual signal	Static	One-to-many	Non-collaborative	Integrated	14
		(6)	Visual signal	Dynamic	One-to-many	Non-collaborative	Integrated	15
	A	(7)	Visual signal	Static	One-to-many	Non-collaborative	Integrated	14

Figure 10: Classification and VM score of visual elements.

According to the rating system, elements (3), (4) and (8) have the highest VM score in the study.

TEAM PERFORMANCE FOR QUALITY

The team performance study was addressed by observing the incidence of defects or rework during the execution of construction processes and the quality inspection of process stages.

- *Process A1*: One defect in the alignment of pipe holes on the precast slabs and one rework activity due to vertical displacements in 5 anchorage perforations were observed.
- *Process A2:* No defects or rework were identified. However, we observed overprocessing and overproduction wastes on the scarification of concrete at the base of the walls by covering larger areas and exceeding roughness requirements.
- *Process B1:* Four defects of lack of adherence of waterproofing layers were identified.
- *Process B2:* There were 4 defects pertaining to the depth of holes for rebar anchorage, 2 exposed horizontal reinforcement of masonry walls, excess height on 2 walls, excess thickness on 1 beam, and excess scarification in 2 pilasters.

DISCUSSION

Regarding the applicability of process transparency, the following inferences are drawn:

1. No interferences were observed among the studied processes during the period of observation, facilitating smoother operations and improved cleanliness, as noted by Formoso et al. (2002). However, process B2 exhibited significant untidiness (SK = 10/15), which was attributed to simultaneous work in sectors of the same process, highlighting the relevance of minimizing interferences within the process itself.
2. Stages not observable from an optimal viewpoint, indicated the existence of visual barriers (Formoso et al., 2002), observed in processes A1 (OS = 5/8) and B2 (OS = 11/15). In A1, distant lifting equipment was an unremovable barrier, while in B2, drum mixer location was a removable barrier and built masonry walls were unremovable.
3. We observed some systematic applications of the 1st and 5th transparency strategies within the visual systems in HSSE management, promoting continuity, standardization, and overall improvement. However, the 2nd strategy, seen in processes A1 and B2, lacked consistency to be considered systematic. Meanwhile, subcontractor initiatives drove the implementation of the 3rd and 4th strategies, aimed at facilitating construction

processes. Solely process B2 adopted the 6th strategy, employing simple markings to indicate daily block placements, but their clarity and comprehensibility were limited.

4. Processes studied at Site A exhibited higher process transparency (4.06) than Site B (3.75). This difference may stem from Site A having fewer processes, facilitating better management. Adjusting results for the total number of processes may be necessary.

The main VM functions applied where transparency, discipline, and job facilitation. Meanwhile, both sites presented standardized identification and location, work facilitation, and site signage as main purposes. The total VM score of site B (159) was slightly higher than site A (152).

The study identified visual systems associated with the HSSE managerial practice, highlighting the advantages of integrating visual systems with managerial routines. The quality of the system design was driven by external safety and environmental regulations. However, the implementation followed a rigid top-down approach, as found in Tezel et al. (2015).

Addressing performance deficiencies observed during the study involved implementing visual practices and transparency strategies. While process B2 (TD = 3.62) presented 4 defects pertaining to the depth of holes for rebar anchorage, A2 (TD = 4.04) prevented them by a transparent control through marks in the rebars (VM score = 9). Similarly, exposed horizontal reinforcement in masonry was detected twice in process B2, while A2 clarified it through a displayed prototype (VM score = 9). Within process B2, exceeding wall height was prevented with reference markings (VM score = 8), and excess beam thickness was controlled by marking pouring levels (VM score = 8). Further structured analyses are needed to validate these findings.

Finally, we highlight that implementing VM implies structuring the site as a visual workplace aligned with management agreements, while process transparency requires a particular focus on construction processes and their relationships. Therefore, studying each independently clarifies their distinct features, enabling more efficient analysis and application.

CONCLUSIONS

Past research on process transparency and VM provides a solid basis for methodically studying transparency strategies and visual practices on construction sites. Their applications are process-oriented and site-oriented, respectively. Process transparency strategies were identified as an indirect consequence of internal team efforts for job facilitation, considered a basic level of implementation lacking systematization and visual communication. On the other hand, VM implementation mainly addressed the functions of transparency, discipline, and job facilitation.

The ratings developed to measure the degree of process transparency and VM allowed the comparison between the sites studied. Processes studied at Site A presented a higher degree of process transparency than Site B. However, the global VM score of Site B was slightly higher than Site A. Therefore, we conclude that implementing process transparency and VM do not imply a single effort, but different methods of development.

Improvements on team performance were observed in the prevention and control of defects and rework wastes associated with the implementation of visual practices serving the functions of transparency and job facilitation, and with the implementation of the transparency strategies of incorporate information into the process and make it directly observable.

The exploratory study provided a basis for further research on the influence of VM and process transparency on team performance. Its main contributions are the individual parallel analyses of process transparency and VM to address their differences, the development of observation protocols based on existing indicators and parameters from the literature review, and the introduction of a grading system to measure the degree of process transparency and VM for both study inquiries and implementation efforts. Furthermore, it highlighted the importance of visual systems integrated into management practices that lack visual representation in the field such as production management, knowledge management, and quality management.

LEAN REFLECTION PRACTICES AND ORGANIZATIONAL KNOWLEDGE MANAGEMENT: A GENERAL CONTRACTOR CASE STUDY

Elizabeth Gordon[1], Keila Rawlinson[2], Neha Dabhade[3] and Dean Reed[4]

ABSTRACT

This paper is the sixth in a series discussing the transition of a self-performing general contractor (GC) towards early systems of measurable collaboration to achieve more reliable outcomes. This approach, known as a Systems Approach to Quality (SAQ), enhanced project performance and team culture. This paper investigates the impact of the Monday Quality Calls (MQC) initiated by the Quality Leadership Team (QLT) in 2015 as a forum for reflection, learning, and collaborative tacit knowledge sharing to build SAQ competencies and support organizational change efforts. The research aims to understand the characteristics of the MQC portfolio, evaluate the influence of the QLT, and assess trends in content development over seven years. Findings reveal the MQC's representation of the GC's work and highlight opportunities to enhance geographic and role diversity in participation to support further organizational efforts. Moreover, the paper underscores the value of the MQC as a multi-modal knowledge-sharing platform, facilitating team coaching, onboarding, and refining organizational strategies and processes. The study proposes future research and advocates for similar metrics tracking and knowledge-sharing initiatives in the industry. Ultimately, this paper contributes to refining organizational approaches to quality management and fostering collaborative learning in the Architecture Engineering Construction industry.

INTRODUCTION

KNOWLEDGE MANAGEMENT TO INFORM THE REWORK PROBLEM IN THE CONSTRUCTION INDUSTRY

This paper marks the sixth installment in a series of works authored by the current authors and others, aiming to document, analyze, and learn from the journey of organizational change undertaken by a prominent "self-performing General Contractor (GC) focused on highly

complex and technical projects” (DPR homepage 2024). Central to this contractor's ethos is the commitment to "Exist to Build Great Things" (DPR homepage 2024), not solely in project deliverables but also in fostering excellence in individuals, teams, and relationships. Nonetheless, as Spencley et al. 2018 outlined, this GC faced recurring rework issues common within the construction industry. These issues manifested as unpredictable variations in project outcomes, with instances where work was completed per plans and specifications but did not meet client expectations, thus necessitating rework. Furthermore, warranty issues occasionally demanded post-completion rework, and there were other cases where substantial resources were expended to address punch list items before project closeout (Spencley et al., 2018).

The crux of the problem lies in the entrenched operational practices within the industry, characterized by significant silos among key stakeholders—owners, architects, designers, general contractors, and subcontractors—and challenges with knowledge sharing resulting in knowledge fragmentation and loss during transmission (Spencley et al., 2018; Gil, 2002). As Gil (2002) describes, knowledge and information are distinct; while information has been collected, documented, and referenced, knowledge expresses understanding from experience or education and can be explicit or tacit. Explicit knowledge is documented where tacit knowledge exists in the minds of individuals (Gil, 2002). Gil describes tacit knowledge as having “operational and logistic dimensions” and how knowledge transference amongst stakeholder firms is problematic, leading to assumptions and uninformed decisions (Gil, 2002). These challenges contribute to deliverables not meeting stakeholder expectations (Spencley et al., 2018). Therefore, the challenge is establishing a way to “signal know-how between architects and builders” (Gil, 2002) and the seamless flow of knowledge and information from those with technical, logistical, and operational expertise to designers and owners while minimizing the loss of translation of expectations to those executing the work (Spencley et al., 2018).

To address these challenges, the GC’s approach centered on promoting measurable collaboration early in project lifecycles (Spencley et al., 2018) to “signal know-how” (Gil, 2002). Subsequently, Gordon et al., 2021a recognized this approach as a systematic application of principles encompassing leveraging existing knowledge and information, understanding expectations through identifying Distinguishing Features of Work (DFOW) from each stakeholder’s perspective and aligning them to measurable acceptance criteria at key Points of Release (PoR) across project phases. This approach to sharing tacit knowledge aimed “to develop means and methods for enhancing high-competence contractors and supplies to signal- and designers to retrieve-know how along AEC product development” (Gil, 2002) with the customer. Collaboration facilitates bridging information and knowledge sharing, mitigates risks, supports adaptability to late design changes, improves supply chain efficiency, and fosters product design innovations (Gil, 2002).

Termed a Systems Approach to Quality (SAQ), this methodology yielded promising results, as evidenced by a 2021 case study comparing SAQ-implemented projects with a control group that implemented a prescriptive compliance-based quality approach. The SAQ intervention group demonstrated superior performance across critical success factors for cost, schedule, change management, and quality and fostered more collaborative work cultures (Gordon et al., 2021a). Further studies by Gordon et al., 2022 and 2023 unearthed additional insights. The GMP sign date as a percentage of the overall project timeline, staffing and resourcing patterns, and communication variances in RFIs and PCIs are performance predictors desired by this GC.

Gordon et al. (2021b) describes the organizational change implementation efforts to integrate SAQ into the GC’s approach to work between 2013 and 2020. This paper focuses on how building from tacit knowledge was foundational to their organizational change strategy. Gil 2002 highlights how knowledge transference within companies is also complex. Thus, to address this struggle, the QLT initiated the Monday Quality Calls (MQC) in 2015. The MQC forum aimed to understand, articulate, and disseminate project strategy and SAQ execution principles from different types of projects, including scale, geographies, customers, and core markets, from perspectives of diverse roles at standard phases in the project lifecycle to further support, and develop organizational change endeavors. Through the MQC, the QLT organizational change strategy sought to make tacit knowledge of project team implementation strategies explicit. Within the standard project lifecycle timeline, project teams reflected and shared successes, challenges, and opportunities for improvement on their overall project approach and specific deliverables.

After seven years of MCQ production, the main research question the authors wanted to explore is: What can be learned from the MCQ information and knowledge gathered to inform our organizational change journey moving forward, and what insights can be provided to others embarking on this journey? Specifically, this work sought to answer the following questions: 1) What are the characteristics of the portfolio of work captured in the MQC, and does it represent the GC's body of work? 2) What insights do the characteristics of calls offer regarding the influence of Quality Leadership? 3) Are there observable trends in the development and maturity of the content of the calls?

The remainder of this practice-oriented paper will describe the theoretical framework for the MQC, the IGLC literature review related to this topic, the methodology for investigating the research question, the data collection process, analytical findings, data limitations, discussion of findings, and formative conclusions.

THEORETICAL FRAMEWORK

SYSTEMS APPROACH TO QUALITY (SAQ)

The MQC described the project and organizational strategy and the creation and execution of SAQ. SAQ focuses on understanding and identifying key Points of Release when work will be released to the subsequent phases, as well as building from knowledge and information to inform stakeholder expectation discussions. After identifying project stakeholders and accountable decision-makers, SAQ involves conversations to understand DFOW, which are areas of the work that require increased attention to ensure the work is built right the first time from each stakeholder's perspective. Through conversations, the stakeholders document DFOW alignment to Measurable Acceptance Criteria (MAC) before releasing work for production. When production work is completed, it is evaluated to ensure it meets the agreed MAC before release to the next phase. If deliverable outcomes do not meet documented MAC, causal analysis is performed to understand the breakdown in the process and develop solutions to prevent the issue's reoccurrence (Spencley et al., 2018; Gordon et al., 2021a).

THEORY INFLUENCING MONDAY QUALITY CALLS (MQC) STRATEGY

A few key concepts influenced the MQC strategy. In mid-2019, the Lean and Integrated Delivery Leader, the fourth author of the paper, challenged the first author to consider the QLT and Quality Leadership Network's (QLN) strategy to build the organization's competencies to implement SAQ. The Lean and Integrated Delivery Leader provided the first author with the Competency Development Model (Ortiz & Reed, 2015). Ortiz and Reed delineated competence levels ranging from unawareness to awareness, from awareness to understanding, from understanding to capable, and from capable to mastery. They proposed a developmental approach aimed at elevating competency across these levels, commencing with informing, followed by educating, training, coaching, and ultimately, mentoring, to achieve mastery. Additionally, their model described the message content and focus for fostering competency through each developmental pathway (Ortiz & Reed, 2015).

To build the organization's competencies, from unaware to aware, the first and fourth authors decided to build a "You are Here Map" for project teams based on a standard project workflow. In each phase of the project lifecycle, pursuit, preconstruction and design development, design development and coordination, fabrication, installation, and construction, the strategy was to provide teams with basic information. This included project strategy to implement SAQ, considering if they had started this approach from the beginning of the project or were starting at that phase in the project lifecycle. Examples of process workflows, tools, and scripts for how to have the conversation and examples of DFOW and MAC that other teams had produced for that phase and work would also be provided. The MQC would be a pivotal tool to provide examples of what operationalizing SAQ at different stages in the project life cycle looked like. While no two projects are identical, and each has unique challenges, the MQC aimed to provide enough examples of emerging operational and strategic trends.

The MQC relied on understanding and capturing the knowledge of those who understood and mastered SAQ principles in their work and were leading others. The purpose was to learn from these leaders and teams and assist others in competency states of unawareness, awareness, or understanding but not yet capable of integrating SAQ in their approach to work. In McKinsey's 2015 article on the "Four Building Blocks of Change," the importance of seeing leaders behave differently encouraged the authors to include storytelling and modelling as critical components of the MQC. The vision and strategy for moving the organization through competencies included focusing on knowledge capture, project team competency building, integration of SAQ principles into organizational processes, and communication of successes and learning. The QLT worked toward supporting business unit quality strategies and developing more quality coaches who could assess and work with project teams through coaching, modelling, flipped classroom activities, and other tools (Gordon, 2019).

IGLC LITERATURE REVIEW

Our review of the IGLC database identified 21 papers pertinent to the query "knowledge management." While numerous papers outlined theoretical frameworks for capturing project knowledge, and some offered case studies, none specifically addressed the longitudinal process of documenting and disseminating project team knowledge within an organization. Consequently, our paper fills this gap in the literature, offering valuable insights for scholars and practitioners initiating similar endeavours.

METHODOLOGY

The research methodology can be described through Saunders, Lewis, and Thornhill's Onion Model; the research philosophy's outer layer is realism, a scientific inquiry approach (Saunders & Tosey, 2013). The authors examined the MQC series by drawing from the design and systems thinking innovation lab hosted by the Center of Innovation in Design & Construction Industry (CIDCI 2022). The web of abstraction tool was utilized to frame and re-frame the question: How might we learn from what we did to understand, capture, and share project team successes, challenges, and opportunities for improvement to support the quality organizational change initiative? Questions from the web abstraction exercise and discussions with industry colleagues were categorized to understand the problem better. Three distinct categories of investigation emerged.

The first category of questions sought to ascertain whether the calls represented the GC's body of work by geography, core market, and contract value and whether the series adequately represented the diverse roles within project teams.

The second category of questions aimed to assess how the MQC documented the Quality Leadership Team's (QLT) corporate change journey, how the calls reflected their influence, and what could be learned to inform future strategy. Questions grouped into this category included: Did the geography of the teams delivering on the calls align with QLT's presence and their coaching with project teams, or were other organizational mechanisms influencing SAQ implementation? Would there be an observable increase in the number of team members participating in sharing their project team implementation story as SAQ became more ingrained in the operational framework? Also, of interest was exploring the patterns of project DFOW production, an output of SAQ project implementation (Gordon et al., 2021b), compared with previous organizational data findings. Furthermore, what could be derived from understanding the demographics of attendees in these calls?

Finally, the third category of questions sought to learn whether the knowledge and content reflected organizational goals and if it matured over time. The call content could be mapped to cost, schedule, safety, quality, team culture, and strategic goals, reflecting standard areas for project metrics as documented in Gordon et al. (2021a, 2022, and 2023). The authors sought to understand if there had been a noticeable change in the topics or presenter characteristics.

The following research layer used a multimethod qualitative and quantitative design (Saunders & Tosey, 2013). The qualitative data, including MQC recordings, presentations, and internally published narratives, assessed content characteristics. The quantitative data of presenter characteristics, attendance records, project characteristics, and project DFOW files were also evaluated.

The third layer of research is described by action research, as the authors worked with practitioners to gather and document their explicit and tacit knowledge to “bring about organizational change” (Saunders & Tosey, 2013). The fourth layer of this research is longitudinal, as the work studied spanned from 2018-2023. Finally, the inner layer of research, the data collection, is described in more detail in the following section. The data analysis entailed mapping the data about each call to the respective categories of questions. Visualizations were subsequently generated to analyze the data for each category of questions. Finally, the data analysis was compared with previous research based on the company’s implementation of SAQ and juxtaposed against the development of the QLT and QLN.

DATA COLLECTION

The QLT started the MCQ in 2015. The content included discussions about developing a quality objective, a standard quality implementation plan reflective of SAQ, processes, and systems to support SAQ, practitioners' experiences, project implementation stories, and coaching from leaders. In September 2019, the first author led the series' relaunching, focusing mainly on project implementation stories. A standard set of questions related to how the project team implemented SAQ was developed with the QLN to help the teams reflect on their journey and prepare for sharing on the MQC. The QLT, QLN, Operations/Business Units, and Corporate Services selected projects and presenters for the MQC that had implemented SAQ principles. The first and second author interviewed teams to understand their project's story, and the project teams presented their stories in a virtual forum. Questions and discussion were encouraged. The calls were open to everyone, and the QLN distributed call invites to their networks.

Also, the MQC shifted to a platform with advanced collaboration features like call recording, transcriptions, chat messaging, file sharing, and news article publishing. Recordings and summaries were shared via email and stored in an online searchable notebook. In 2021, the authors reviewed the process with organizational leaders. They decided to improve dissemination by publishing summaries as news articles and developed a standard PowerPoint to aid call production.

DATA FINDINGS

PREVIOUS RESEARCH

In previous research, Gordon et al. 2021b assessed the implementation of SAQ by counting the projects with DFOW files in the project folder enterprise system. The results presented by year the project mobilized and DFOW project revenues as a percent of annual sales for the year:

- 2016: 3 projects, DFOW project revenues as percent of annual sales is 5%
- 2017: 17 projects, DFOW project revenues as percent of annual sales is 29%
- 2018: 37 projects, DFOW project revenues as percent of annual sales is 31%
- 2019: 66 projects, DFOW project revenues as percent of annual sales is 42%
- 2020: 67 projects, DFOW project revenues as percent of annual sales is 55%

The results presented by region:

- Central: 17 projects with DFOW files, 24% of revenue as a percent of regional sales
- Northeast: 31 projects with DFOW files, 44% of revenue as a percent of regional sales
- Northwest: 60 projects with DFOW files, 39% of revenue as a percent of regional sales
- Southeast: 49 projects with DFOW files, 36% of revenue as a percent of regional sales
- Southwest: 34 projects with DFOW files, 28% of revenue as a percent of regional sales

Additionally, the results were presented by the core market, which refers to the market of the GC's customers:

- Advanced Technology: 34 projects with DFOW files, 33% of core market sales revenue
- Commercial: 42 projects with DFOW files, 41% of core market sales revenue
- Healthcare: 37 projects with DFOW files, 23% of core market sales revenue
- Higher Education: 13 projects with DFOW files, 42% of core market sales revenue
- Life Sciences: 44 projects with DFOW files, 42% of core market sales revenue
- Other: 20 projects with DFOW files, 24% of core market sales revenue

DATA FINDINGS FOR MONDAY QUALITY CALLS (MQC)

Between 2017 and 2023, 76 MQC focused on a project implementation story. In each year, a few project teams presented more than once. Only distinct project numbers were used to assess the work portfolio by contract value. Of the distinct project numbers that were shared, 19% had contracts greater than $250 million, 17% had contracts between $100 - $250 million, 19% had contract values from $50 - $100 million, and 33% had contracts between $10 - $50 million and 12% had contracts less than $10 million. The graph on the left shows the percentage of calls from each region for each year. The graph on the right shows the percentage of calls from each core market presented each year.

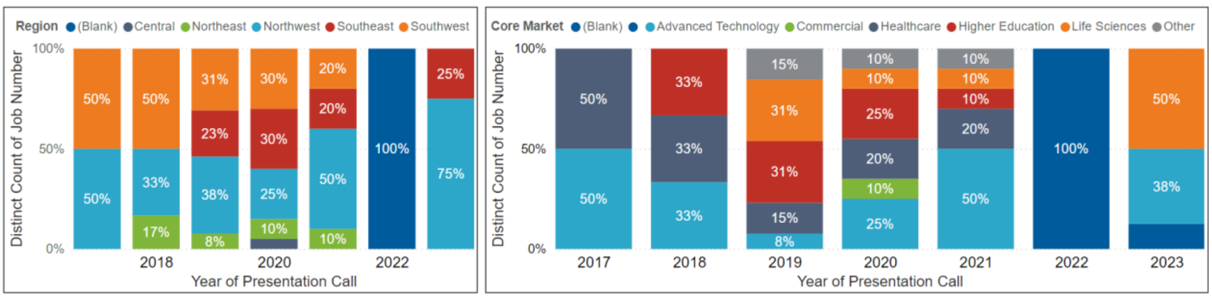

Figure 1: Percentage of MCQ from each region and core market by year.

In Figure 1, the chart to the left shows that all regions contributed a story to the calls during the seven years. Aggregate analysis reveals that Central had the lowest percentage of participation in the MCQ series, with two calls, and the Northwest had the largest percentage of participation, with 38%. Southeast contributed 22% of all calls, Southwest 24%, Northeast 12%, Central 3%, and Blank 1%. The chart to the right shows that all core markets are represented in the MQC. Advanced Technology core market comprised 33% of all calls, Higher Education 20%, Life Sciences 17%, Healthcare 16%, other 9%, Commercial 3%, and 1% blank.

Furthermore, for each year, the count of MCQ Project Implementation story and attributes of the call, including the median contract value, whether the project had DFOW files, the median value of the count of DFOW files in the project repository, and the median and count of presenters for all calls that year were tallied. The information was also compiled for seven years.

Table 1: Attributes of MQC Project Implementation Stories presented each year.

Year	Count of Project Stories	Median Value for Contract Value	% of calls with DFOW files	Median value for Count of DFOW files	Median number of presenters	Count of presenters
2017	2	$292.4M	50%	111	1.0	2
2018	7	$260.4M	43%	111	1.0	7
2019	17	$61.1M	76%	62	1.0	17
2020	25	$74.7M	64%	13	1.0	37
2021	16	$159.4M	38%	7	1.5	34
2022	1	$100.0M	0%	0	1.0	1
2023	8	$84.6M	75%	4	2.0	24
Total	*76*	*$110.0M*	*59%*	*14*	*1.0*	*122*

The median value for the project contract ranges varies over the years, and the larger contract values reflect the GC's large project portfolio being showcased more frequently. Most of the projects presented had DFOW files readily accessible in the enterprise repository. The data also shows that the median value of projects with DFOW files fell drastically over the years while the median number of presenters increased slightly.

In Figure 2, the graph on the left visualizes the percentage of MQC presenters from each workgroup each year. The resources are as follows: DM = Design Integration Management, VDC = Virtual Design and Construction, SPW = Self-Perform Work, RISQ = Risk, Insurance, Safety Quality, Precon = Preconstruction Services, PM = Project Management, MEP = Mechanical Electrical and Plumbing, Field = Superintendent and foreman. The graph on the right shows the percentage of standard work topics covered, including team culture, cost, planning and scheduling, quality, safety, and the company's strategic focus areas.

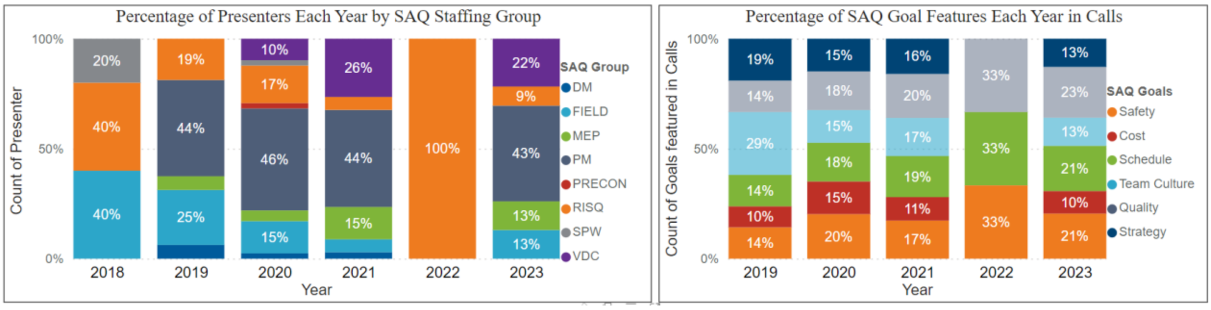

Figure 2: Presenters by SAQ Staffing Groups and SAQ Goals featured by Percentage.

Figure 2 shows that all roles had the opportunity to present their perspective over the years. The distribution of roles presented on the calls was highly uneven. The project management group had the most visibility on the calls to share their experiences with 36% representation, and the preconstruction dedicated resources had the least time with only one presenter. The calls' content was analyzed yearly, and all workgroup topics were discussed, except for 2022. In 2022, there was one call with a Quality Manager, and only three topics were discussed. Of the 117 presenters, 21% were repeat presenters, and 17% had graduated from an online 4-week quality training course, which began at the end of 2020.

Figure 3 shows the number of participants in the MQC Project Implementation Stories by region each year. The superimposed line graphs also show the number of unique attendees compared to the total attendees each year. Overall, 3137 participant hours were logged for 895 unique participants, an average of 3.5 hours per participant.

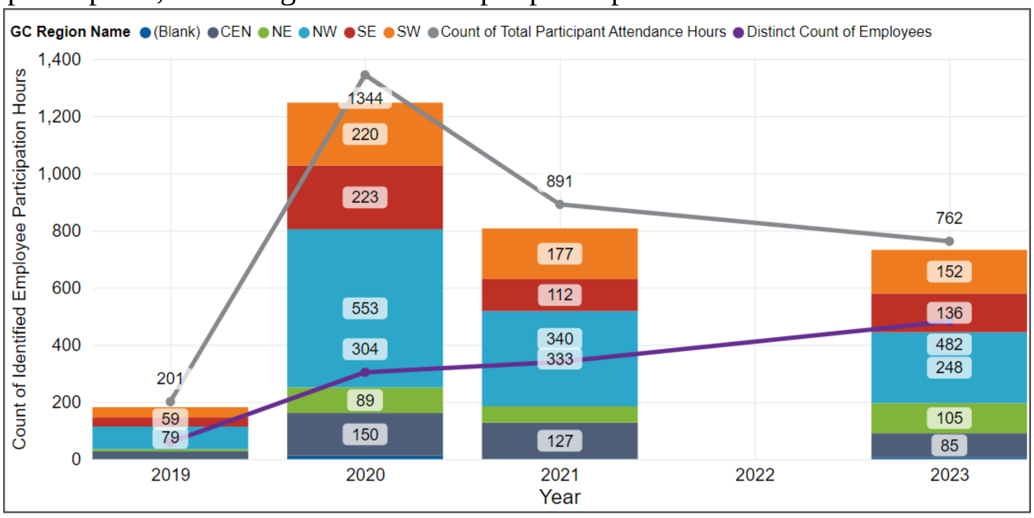

Figure 3: Shows the count of attendees by region and the difference between unique attendees and total counts.

Each year, attendees on the calls represent all regions. The data shows more attendees but fewer unique attendees each year. This gap starts to close in 2023, with a more even distribution of attendees in 2023 across all regions.

LIMITATIONS OF THE DATA

Limitations of the data include 1) The Study sample reflects 131 Monday Quality Calls (MQC) documented from 2017 to 2023. 2) Only MQCs focused on a single Project Implementation Story with job numbers in the Excel MQC tracker were analyzed. 3) Other MQCs demonstrating SAQ principles across multiple projects describing process implementation and other trainings and discussions were excluded from the analysis. 4) DFOW file counts were tallied if accessible in the enterprise project document control repository. Some projects had

DFOW files maintained in customer systems, and these were not counted. 5) Presenter roles were counted if they existed and were categorized based on previously defined classifications from Gordon et al., 2022. 6) Attendee tracking commenced in the fall of 2019 with the transition to a new collaboration platform. 7) Attendee roles represent current positions and include all 131 MQCs, not solely Project Implementation Stories. 8) Not all attendees of the MQCs were able to be related to employee records, which is why the participation hours exceeded the employee records in each instance. This analysis also highlights gaps created when the organization relies on manual records processes. For example, the primary recorder could not attend the 2022 call. Thus, the participation records were not recorded.

DISCUSSION

The data shows that the MQC Project Implementation stories represented the GC's work by core market and size of the project contract. The calls did not adequately represent the geography of the regions. The Central region accounted for 3% of MCQ; however, the previously collected data on DFOW file production shows that Central had 24% of all project revenue from 2016-2020 implementing SAQ. The Northwest region accounted for 38% of calls and was documented as having a similar distribution of projects with DFOW files through 2020. This finding aligns with the geographical region of most of the QLT from 2013-2020. The percentage of participation in the MCQ from each region represents how strongly the individual members of the QLT and QLN value capturing and sharing this knowledge across the company. Geographical participation in knowledge capturing and sharing is essential for evaluating strategic implementation.

Gordon et al. (2021b) show DFOW file findings distributed across all core markets. Similarly, the MCQ has project examples distributed across all markets. Also, the percentage of MQC with DFOW files reflected similar results observed during the organizational results documented by Gordon et al. (2021b). Organizationally, 2019 and 2020 had the highest percentage of projects with DFOW files. Similarly, there were more MCQ projects with DFOW files in those years. These observations suggest that the MQC reflected the GC's portfolio of work. While 2023 shows that 75% of MQC had DFOW files, 60% of calls that year were nominated by a leader the first author had worked with on several projects, highlighting the importance of tracking who nominated the calls.

When looking at presenter characteristics, the MCQ does not adequately reflect all the roles in the company. There was one preconstruction workgroup presenter during the seven years. While all roles, DIM, PM, VDC, MEP, RISQ, and Field, participated in the preconstruction phase, the data shows that the dedicated preconstruction role was absent. This highlights an opportunity to describe further how these dedicated resources can support and lead SAQ implementation through their daily work streams. Furthermore, in this study of presenter characteristics, participating in the 4-week online quality training was not a determining factor for those teams who implemented and presented.

The data also shows a wide range of attendees and that key influencers attended every call. The audience attending the calls is vital to show who is participating in these calls and to reflect on why. The first three years of data, 2019, 2020, and 2021, show a higher number count of attendees but fewer new attendees due to the frequency of the calls. In 2019 and 2020, calls were weekly; in 2021, they shifted to twice monthly; in 2023, there were calls approximately 4-6 weeks. Specifically, 2020 demonstrates a solid base of extended QLN regularly attending the calls and supporting the company in implementing the DFOW process in the early years, as documented in Gordon et al. (2021b). In 2023, 60% of the calls originated from the Northwest; however, that year shows that the attendees of the calls were evenly distributed across all regions. These changes can be attributed to the change in communication and frequency of the information. Last year, instead of relying solely on the QLN to distribute the calls, the first author marketed the MQC in company-wide communication channels. Thus, it is also essential to track and understand how changes in communication and frequency of calls affect attendance.

All the company goals and strategic focus areas were addressed each year, except for 2022, when there was only one call by a quality manager. This demonstrates that describing a project's results and process to achieve those results must consider all workstreams: safety, quality, cost, schedule, and team culture. While the number of presenters increased each year, reflecting a maturity of the call content to share more project role perspectives, reviewing the information by overall implementation or deliverable implementation, assessing the type of workflow process discussed, and the phase in the project lifecycle would aid in assessing patterns in content and maturity of content.

CONCLUSION

The present study highlights the benefits of documenting organizational change management efforts and project team implementations in a multi-year and multi-modal process to refine the understanding, language, and presentation of SAQ. The MQC process and coaching platforms have helped teams describe their interdisciplinary and multi-factored approach to achieve improved and more reliable performance outcomes. Repeat presenters matured in their project team implementations and demonstrated their growth and development. Providing a coaching platform facilitated reflection on the continuous improvement and learning process. This has enabled the authors to refine and standardize their approach to helping project teams describe the complex and dynamic situations (Bertelsen 2003a, 2003b) they face from different standard project team roles. This forum was essential for the diffusion of ideas across the organization and promoted innovation, as teams could build off the work and knowledge of others. Additionally, this foundation of knowledge has proved immensely helpful in mapping the content to maturing language in the organization to articulate company goals better.

The value for other practitioners is understanding that this work formed an information network that weaves and cascades through the organization. These modes allow for storytelling and modeling through video recordings, slide deck presentations, and SharePoint summary news items that "signal know-how" (Gil, 2002) of project teams. This foundation facilitates team coaching, connects peers to peers for relatable knowledge building, onboard new team members, and prepares external marketing and communication materials. MCQ content has been shared at conferences such as Lean Construction Institute and Advancing Construction Quality to advance the knowledge and practices of the industry. The QLT saw this knowledge capture as a foundation to support learning and development frameworks while raising the competency of individuals who developed project and organizational systems reflective of SAQ. However, it has been difficult for the organization to incorporate this new knowledge into existing learning and development materials.

The authors recommend expanding the work to ensure the discussed MCQ processes are captured and reflected in organizational standards. Additionally, the authors recommend further developing learning and development experiences to build the competency of measurable collaboration alongside technical training as the organization matures in SAQ adoption. To support organizational competency growth, skill-building is essential. The authors suggest that others embarking on this journey track similar metrics, including project attributes, presenter roles, attendees, and topics, as metrics to gauge their influence and inform their strategy. Furthermore, the authors recommend tracking the motivation or driving factors of the teams that implemented and shared in this forum. Understanding what assisted them in creating the strategy and routines for implementation and who nominated them could help the QLT gain insight into the channels for spreading ideas and the influencers of organizational change, which can aid in refining strategy. Additionally, analyzing the data collected on the MCQ enabled the authors to understand the portfolio of work captured through the calls, presented gaps in the content, revealed where geographically more focus was needed, and began to track the maturity of the content. A deeper understanding of the captured processes is needed to quantify the maturity of the content.

For further research, the authors suggest conducting a similar investigation to quantify project performance outcomes and contributing factors described by Gordon et al. (2021b, 2022, and 2023) to the MQC projects. Additionally, the authors suggest broadening the MCQ analysis to consider the processes discussed on the calls to assess content maturity. Finally, the authors believe there are opportunities to leverage emerging Artificial Intelligence capabilities to capture knowledge and provide knowledge transference to assist teams in understanding the strategy and actions necessary to achieve predictable outcomes.

ABSTRACT

This empirical archival study investigates the distribution of alliance contracts (ACs) between small and medium-sized enterprises (SMEs) and large enterprises (LEs). Previous research has identified concerns about ACs in relation to the participation of SMEs in public procurement markets in the construction sector. The aim of this study was to understand how these contracts are distributed in the construction sector and to provide additional information for industry players on ACs. The study analyzed 80 investment alliance projects from 2011 to 2023, demonstrating a decreasing trend in SME participation against an increase in LE involvement. The findings revealed a concentration of ACs among a few LEs, with a significant portion of SMEs not participating in these alliances. While 81 SMEs have engaged in Finnish ACs, this number is small compared to the total number of SMEs in the industry, pointing to an imbalanced contract distribution favoring LEs. The study also noted a steady rise in the relative share of alliances in the overall construction market. This research sheds light on the challenges of asymmetric AC distribution and offers valuable insights for public works procurement bodies, industry consultants, and AC participants and researchers, highlighting the need for balanced contract allocation.

KEYWORDS

Lean construction, alliance contract, archival study, enterprise

INTRODUCTION

In many countries, the alliance contracting format, which originated in Australia, and integrated project delivery (IPD) developed in the United States, have become widespread in construction projects, often combining lean construction methods and elements into these collaborative contracts (Lahdenperä, 2012; Young et al., 2016). IPD is a contractual and operational approach that unifies the various parties involved in a construction project, including their contracts, procedures, and operating principles. IPD incorporates numerous aspects of lean construction (Lahdenperä, 2012). An alliance contract (AC) is employed for collaborative contracting in

various construction scenarios, where the emphasis may not be solely on lean construction principles. Instead, these contracts prioritize shared risk sharing, joint decision-making, and enhanced collaboration between the parties involved (Davis & Love, 2011). However, there are some indications that large enterprises (LEs) are engaging in ACs, while small and medium-sized enterprises (SMEs) are not as prominently involved (Dainty et al., 2001; Davies, 2008; Tezel et al., 2018). SMEs are expected to generate a relatively high number of jobs and minimize changes in income distribution (Ayyagari et al., 2007). Therefore, the European Union (EU) includes the participation of SMEs in public procurement markets among the objectives of its public procurement legislation (The European Parliament and the Council of the European Union, 2014). In Australia, similar legislation aims to promote the public procurement of SMEs, indigenous communities, and local industry (Hoekman, 2018). According to Kidalov (2011), in the United States, at the federal level, the Small Business Administration seeks to encourage the participation of small minority and women-owned businesses in federally funded road projects. As the aim is to involve a wider range of firms in growth while ensuring the most efficient use of public funds, the involvement of SMEs in the construction sector is socially and economically significant (Thai, 2017). This rationale is grounded in economic theories, whereby the public entity benefits from a combination of the lowest price, preventive corruption, and a fair playing field for all construction actors (Anechiarico & Jacobs, 1995; Thai, 2017).

The project alliance model originated in the 1980s when the oil and gas industry decided to develop a collaborative contractual model for investment projects (Olsen et al., 2005). Oil and gas companies adopted this approach in the 1990s, and with the success of these projects, the alliance model began to spread to infrastructure maintenance and construction (Rahmani et al., 2016). Alliances establish an integrated project organization between the contractual parties, usually the client, contractors, architects, and other designers. The aim of establishing a joint organizational structure is open communication, information sharing, and joint problem-solving (Lahdenperä, 2012). The main objectives of the alliance are to create an open culture of agreement and cooperation between the contracting parties, which will allow for a more holistic perception of the risks and benefits of the project and enable joint decision-making and risk and benefit sharing (Rahmani et al., 2016).

In the EU, public procurement contracts significantly impact the economies of its member states, representing over 16% of the EU's gross domestic product (GDP) (The European Parliament and the Council of the European Union, 2023). Similarly, in the United Kingdom, the construction industry is a major economic contributor with an annual turnover exceeding £100 billion, nearly 10% of the UK's GDP; approximately 40% of this turnover is attributed to the public sector (Menteth et al., 2014). Public entities are therefore seeking more value for money in their construction projects, and in this respect, alliance contracting has set high expectations (Love et al., 2010).

Recognizing the challenges and complexity of traditional procurement methods, particularly in managing significant risks, public procurement has played an important role in seeking alternative contracting models (Lahdenperä, 2015; Walker & Jacobsson, 2014). Experiments with public procurement entities began in Australia, where the model was adapted to different types of projects and local markets (Rankohi et al., 2023; Sanderson et al., 2018; Valkama et al., 2019). In countries where alliances have been promoted, public procurement authorities have been the drivers of change and have adopted alliance model practices in their procurement policies and procedures (Walker & Jacobsson, 2014). The role of the public sector has been a key factor in the development of the alliance model and its increasing use in the construction industry. Therefore, the rationale behind selecting ACs has primarily been based on the characteristics of the project and the type of client.

Many studies identify the benefits of alliances for the contracting parties and for the public entity in terms of improved liaison, adherence to budgets and schedules, and the achievement of objectives important to the client, reducing the disputes and litigation typical of the sector (Davis & Love, 2011; El-adaway et al., 2017; Young et al., 2016). Despite the importance of public procurement and the role of ACs in public construction projects in countries where the model has been adopted, there is limited research on how ACs are distributed in the market between SMEs and LEs. Understanding the distribution of contracts can reveal market conditions and barriers that may have an impact on reducing competition, such as oligopolies and monopolies. This study presents a comprehensive sample of the Finnish construction market and the parties to ACs and contributes to answering the question of how ACs are distributed in the construction business landscape. The aim of this study is to shed light on the current situation through a geographically limited but comprehensive sample of the Finnish dataset and to encourage similar research in other countries. The findings of the study could be used by policymakers to target the use of public funds in the construction sector more precisely to relevant groups of companies. For the lean community, the study contributes to mirroring the economic and social impacts of lean construction.

This research endeavor will also provide a modest contribution to the relationship between lean construction and ACs. It presents novel insights into the implementation of lean methods within Finnish ACs, including the utilization of the "last planner system," the "big room" approach, and other lean methods. This is intriguing because ACs have not originally been seen as a distinct characteristic of lean construction. For example, Miles and Ballard (1997) contended that alliance-like partnerships were not established with the intention of enhancing efficiency, productivity, speed, or the smooth flow of production in a construction project; therefore, they have a logical link to the productivity ethos of lean construction. They reasoned that the applicability of an alliance-type collaboration to lean construction is therefore uncertain (Miles & Ballard, 1997). In subsequent years, the relationship between alliances, namely IPD initiatives, and lean construction has been further reinforced, indicating that these two advancements in the construction industry are useful concepts together (Lahdenperä, 2012; Young et al., 2016).

METHOD

Archival research was chosen as the research method (Das et al., 2018) and was encouraged by the researchers' sufficient access to the research data, which was possible in the Finnish context. The research relies mostly on quantitative data. The research study data were collected from all ACs implemented in Finland from 2011 to 2023. The data were first collected using a publicly available catalog from a consultancy specializing in alliances (Vison Ltd., 2023), which provided basic information on alliances. This basic information included the name of the project, the name of the client, and the budget. The names of the projects and companies investigated were anonymized. Numerical codes 1–80 were used for projects, and the letter-number combination C-1 to C-112 was used for companies.

Based on these data, the researchers sought the following additional information on these projects from public and available sources (news, Internet search, Finnish research databases): 1) which companies were contractors in the alliance, 2) the turnover category of these companies (i.e., which companies are SMEs and which are LEs), 3) the time schedule of the ACs, and 4) any indication of the lean methods used in the project. In this study, in line with the EU convention, SMEs are defined as enterprises with fewer than 250 employees and an annual turnover not exceeding EUR 50 million, which are independent of enterprises that do not qualify for the definition of an SME (The Commission of the European Communities, 2003). Tezel et al. (2018) also used this method of dividing firms in their study of SMEs.

The researchers inserted the data into an Excel spreadsheet. Projects related to maintenance or other service ACs were excluded from the data. The number of excluded projects was 14. After screening the data, 80 construction investment alliance projects remained to be analyzed. The total budget value of the selected projects is €9.049 million. Details of the analyzed projects are presented in Table 1.

Table 1. Details of the projects

Project No.	Project type	Timeline	Client	No of SMEs	No of LEs	Budget [M€]	Lean methods used
1	Railway renovation	2011–2015	Public entity	0	1	80	BR, LPS
2	Housing renovation and expansion project	2011–2013	Public entity	1	1	18	BR
3	Road construction project	2012–2016	Public entity	2	1	192	BR, LPS
4	Office and laboratory building project	2019–2021	Public entity	3	1	18	NA
5	Health care building project	2014–2016	Public entity	5	1	51	BR
6	Travel center project	2014–2016	Public entity	2	1	19.2	NA
7	Power plant project	2015–2017	Public entity	1	2	50	NA
8	Courthouse and police headquarters building project	2014–2017	Public entity	0	1	31	NA
9	Office and laboratory building project	2014–2016	Public entity	0	1	30	NA
10	Housing façade renovation project	2014–2018	Private company	2	1	23.3	BR, LPS
11	Housing project	2014–2016	Private company	5	2	13	NA
12	Expansion project of the health care building	2015–2017	Public entity	3	3	14	NA
13	Airport paving works project	2015–2016	Public entity	1	3	20	LPS
14	Tramway construction project	2017–2021	Public entity	0	4	266	BR, LPS, TVD, VM
15	Hospital building project	2018–2021	Public entity	3	5	265	BR
16	Hospital building project	2015–2021	Public entity	0	3	153	BR, LPS
17	Airport expansion project	2015–2020	Public entity	0	1	100	BR, LPS
18	Renovation project of the cultural center	2015–2017	Public entity	0	1	30	NA
19	School building project	2015–2017	Public entity	1	4	20	BR, LPS
20	Police headquarters building project	2015–2016	Public entity	0	1	20	NA

The data were analyzed as follows: 1) the alliance contractor companies were divided into SME and LE categories, 2) the groups were divided into two subgroups: contractors and designers, 3) the alliance contractor companies were summed by subgroup in step 2. The analysis allows for an estimation of the number of SME partners in alliance projects and the distribution of ACs in Finland. By linking the timeline of ACs signed, it is also possible to assess how the involvement of SMEs in alliances has evolved over time in Finland.

In the last part of the analysis, the relative share of ACs in the total construction market was analyzed using public statistical data from Statistics Finland (SF) and the database of the Finnish Association for Quality in Construction (Finnish Association for Quality in Construction (FAQC), 2023). The aim of the analysis is to link the data to the research questions and provide explanations both quantitatively and over time. SF's data were used to estimate the size of the construction market, and FAQC's data were used to compile SME and LE data for analysis. The FAQC's data on certified construction companies in different turnover categories are reliable and, as required by the Finnish public procurement function, comprehensively cover the entire SME sector and LEs operating in the market.

FINDINGS

The mean budget value of the ACs in these projects was €113.1 million, and the median was €50.5 million. In terms of project value, Figure 1 shows the distribution of contract values of ACs in euros.

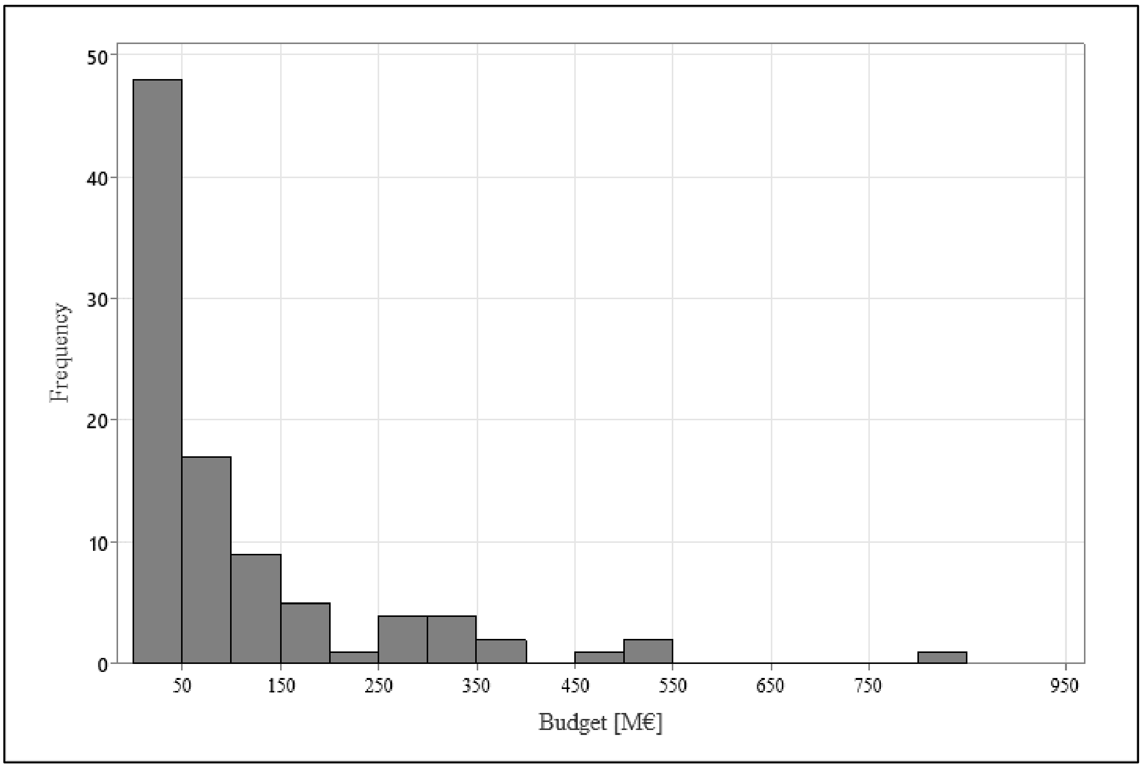

Figure 1. Distribution of the value of alliance contracts

Of the total, 40% of the parties to the ACs were SMEs, and 60% were LEs. There was a downward trend in the number of parties in the SME group, while there was a clear upward trend in the number of parties in the LE group. At the peak, the share of SME parties was 67% in 2012 and 2014, but the mean of the last four years of observation was 33% for the number of SME parties. The trends and relative proportions of AC parties by year are shown in Figure 2.

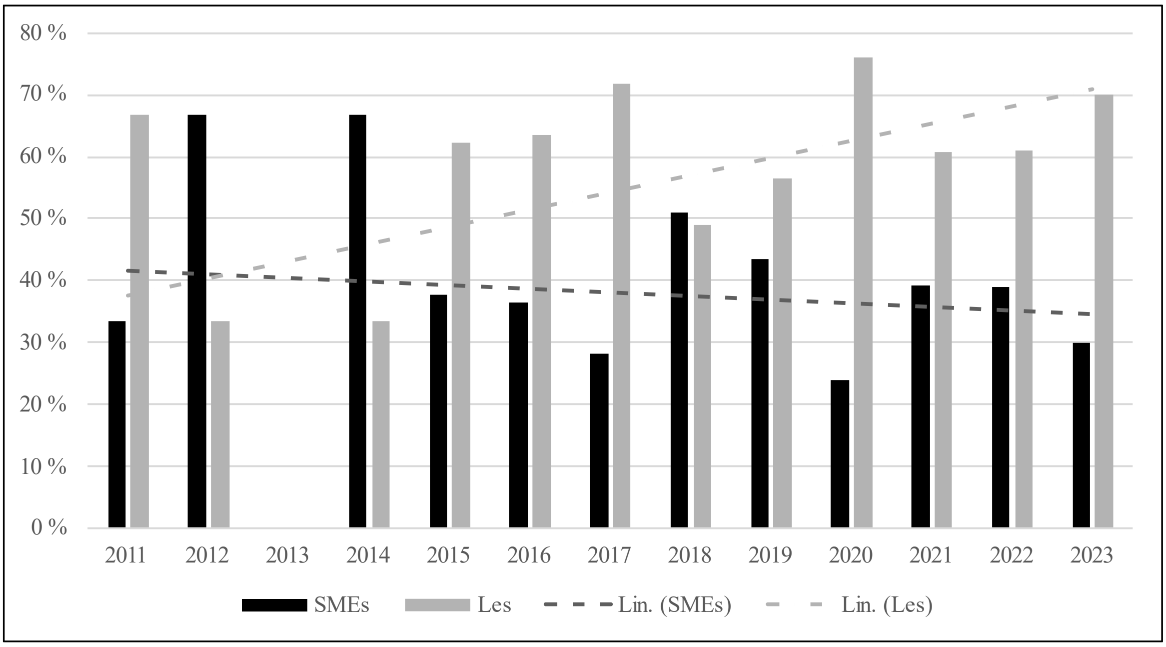

Figure 2. Distribution of ACs between SMEs and LEs

In the analysis phase, the same companies were identified as recurring alliance partners. Table 2 summarizes the 15 companies with the highest number of ACs.

Table 2. Distribution of ACs among companies

C-15	5	X			X
C-31	5		X	X	
Sum	148				

As demonstrated in Table 2, 15 companies, of which only 2 were SMEs, were selected 148 times out of 292 as contract partners. This means that 51% of the ACs have been signed with only 15 companies. Of these 15 companies, only 2 were SMEs, and both were architecture firms. In addition to this group of firms, ACs have been signed with 97 other firms, of which

79 are SMEs and 18 are LEs. In total, 292 AC parties were involved, with 115 individual firms in the surveyed data. This indicates that just 11% of the companies (all LEs) have signed more than half of the ACs. When considering contracts with a maximum budget value of €50 million, there were 67 SMEs and 65 LEs as contractors in these contracts, so the contracts were evenly split between the groups.

For the analysis period, the relative share of the budget value of ACs in the revenue value of the overall construction market was also assessed. In 12 years, the annual budget value of ACs has risen from €15 million to €1 billion. The revenue value of the construction market varied over the period from EUR 11.6 billion to EUR 12.9 billion (Statistics Finland, 2023). The relative share of ACs in the Finnish construction market has steadily increased, as illustrated in Figure 3.

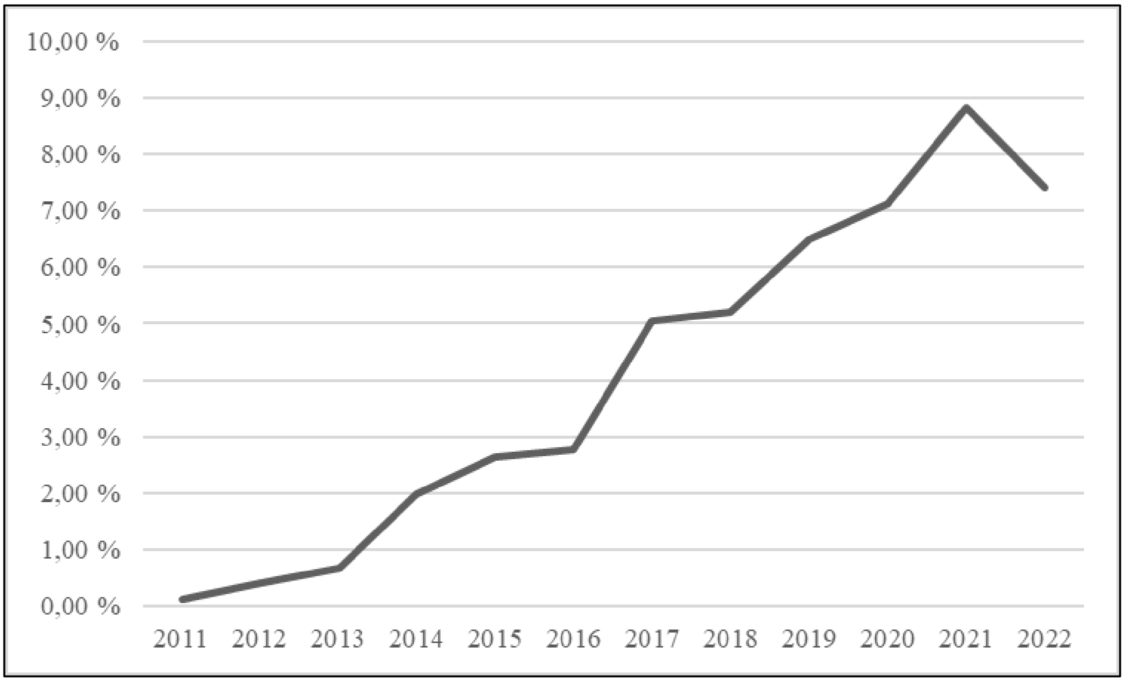

Figure 3. Relative share of ACs in Finland's total annual construction market

While the findings of this study suggest that ACs are mainly distributed among LEs already present in the market, only 81 SME companies have participated in ACs. However, this number represents about 9% of the total number of these SMEs in the construction sector, which was 857 in Finland in 2022 (FAQC, June 2023). For LEs, 31 out of 77 companies (about 40%) have participated in ACs in the period under review. According to the FAQC (June 2023), there were 77 LEs in Finland in 2022. The evidence indicates that a significantly higher number of LEs than SMEs have been awarded ACs. For 2022, the downturn in the construction sector in Europe caused by the pandemic and Russia's invasion of Ukraine is likely to be reflected in the downward trend in Figure 2.

The most often employed lean methods in AC projects were the "big room" and "last planner system." The latest lean construction innovation, "takt planning," was implemented in three projects, whereas "target value design" was utilized in two projects. "Visual management" and "choosing by advantages" were each utilized in a single project. Out of the 80 projects, 38 did not have any reference to the utilization of lean methods in public sources.

DISCUSSION

Alliance projects have been shown to bring many benefits to contracting parties, but there are limited studies available on how ACs are distributed among firms in the market. The three main findings of this study from the projects studied are as follows: 1) the distribution of ACs in the group studied is skewed toward LEs, 2) a significant proportion of ACs is distributed among a few LEs, and 3) the relative share of ACs has increased relative to the size of the construction market throughout the follow-up period. Each of the three findings and their significance are discussed separately below.

One explanatory factor for the distribution of ACs to LEs may relate to the fact that the alliance model was mainly developed for large and complex construction projects (Hietajärvi et al., 2017). Large, risky, and complex construction projects inherently exclude smaller companies with a limited capacity to bear the risks of the project, regardless of the contract model. On the other hand, although large projects require large firms as contracting partners, the construction sector globally depends on SMEs, which, in practice, also do most of the work of these large firms, including work in alliance projects (Akintan & Morledge, 2013; Kale & Arditi, 2001). This has generated debate in the sector and in research on how trade contractors should be considered in the alliance model (Aslesen et al., 2018; Dainty et al., 2001). One issue raised by the data is that actors in the SME sector, such as smaller architectural and engineering firms, participate in alliances using traditional contracts with alliance partners, thus distributing the value of the alliances to the SME sector. More research is needed on these issues.

However, the findings indicate that the mean size of ACs was just over €100 million and the median was about half of that. The ACs studied included many smaller school and housing projects as well as renovations. Nevertheless, these contracts were also disproportionally awarded to LEs. These findings suggest that the objectives of public procurement in terms of enhancing SME opportunities may not be achieved as intended in the alliance model. Based on the data, SMEs seem to be mainly smaller design firms. The share of design costs in construction rarely rises above 10–20% of the contract value, so the question arises: Are alliances in practice large construction contracts for one large construction company? These observations open an interesting question for further research: Are these phenomena observed only country- or market-dependent, and what other factors are behind this observation?

The distribution of a significant proportion of ACs to just a few LEs also raises interesting questions. Are these actors pioneers and forerunners of the industry and, therefore, overrepresented in the survey (Holt, 2015)? Has the alliance model been a strategic choice for these companies, and their success in doing so is reflected prominently in the study (Kim & Park, 2006)? Is the alliance model a form of Schumpeterian hypothesis-like innovation to which only large companies can typically afford to dedicate their resources, and would this also explain the findings of this study (Nam & Tatum, 1989)? Does this finding suggest that relations between individuals in the sector (including decision makers in procurement entities) and large companies were already strong before the alliance model emerged and that cooperation has been further strengthened by the collaborative nature of ACs (Blayse & Manley, 2004)? Is it a game-theoretic setting where, as cooperation flourishes, an oligopolistic mechanism prevents the entry of the SME sector (De Valence, 2010)? Oligopolistic competition focuses on competition based on specialization in certain types of projects or forms of procurement in the construction sector or on alliances or partnerships with customers (Contractor & Lorange, 2002; De Valence, 2010). Instead of looking at these individual factors, further research, such as multivariate analysis, is recommended to seek these answers (Rencher, 2005).

The contribution of this empirical study is relevant since it also shows that the relative budget value of alliances is increasing in one local construction market, but on the opposite side of this trend, the share of SME companies in alliances is decreasing. Hence, more and more budget value is being transferred from ACs to LEs. However, this study cannot answer the question of why these differences have emerged and are growing between SMEs and LEs. Nevertheless, our research indicates that as a few major companies secure a larger portion of ACs, including those smaller ACs, there is potential for dominant industry leaders to exploit their market power in a highly competitive setting. The market may thus progressively form toward oligopolies, leaving small and medium-sized businesses with diminishing opportunities to form partnerships with companies of similar scale. Therefore, we consider it important to investigate and record this issue, especially because many advocates and practitioners of alliances have emphasized the significant benefits of alliance agreements in public discussions and among researchers and practitioners (Davis & Love, 2011). These advantages include transparency, collaboration, and, among other benefits, the implementation of lean construction principles and practices (Schöttle et al., 2014).

The discovery that lean methods were not publicly emphasized or mentioned in nearly half of the projects suggests that the Finnish realization of alliance and lean may not always involve a combination of the two. Instead, it appears that certain ACs are executed without incorporating lean methods. However, the discovery that the "big room" and "last planner system" were the most frequently employed lean methods indicates that lean construction has indeed had an influence on Finnish alliance projects. It is also possible that ACs are perceived by contracting parties primarily as simply cooperation agreements, with no prerequisite for a lean component, and that the primary goals of alliances, which are frequently improved collaboration, joint decision-making, and joint risk sharing, are sufficient for many of the projects studied (Rahman & Kumaraswamy, 2002). Nevertheless, the data we gathered are not entirely comprehensive and conclusive. Specifically, in cases where there are no publicly available references for a project, conducting interviews or surveys might offer supplementary insights into the methodologies used. Further qualitative research is necessary to gain more clarity regarding the impact of lean in Finnish ACs.

LIMITATIONS

This study is not a statistical analysis of the randomness of the observed phenomena; therefore, a more detailed and statistically rigorous further study on a larger sample of projects is recommended. However, in many studies, it can be difficult to randomly allocate companies to experimental conditions, although this study has managed to obtain a complete sample of all ACs in one country over a 13-year period. Despite the geographical limitations, the complete sample size enhanced the reliability of the conclusions.

The main limitation of the study is its interpretation based solely on numbers without qualitative background data. However, there are intentions to gather qualitative data on the entire dataset in a later phase of the research project. Unfortunately, this qualitative data cannot be and is not included in this short conference paper. Another obvious limitation relates to the geographically limited market and language area. The reliability of the study is enhanced by the open data availability of the study to other researchers. Researchers are also willing to share data on request. The researchers also stressed the internal validity of the study by underlining the possibility of competing explanations. The study would benefit significantly from combining qualitative research with the numerical data currently being collected.

Another limitation is the comparison of the budget value with the revenue value of the construction sector. In reality, the budget value is spread over several years after the contract year; therefore, comparing the budget value to the annual turnover value as a relative figure is not absolutely correct. However, the approach used to present the time series contributes to minimizing this error.

One limitation of the reliability of the study is that the research sample was obtained from a company involved in the alliance facilitation business. It is therefore possible that the list is not exhaustive or that there are contracts on the list that are not ACs. The researchers have tried to mitigate this limitation by identifying the details of each contract from public sources, and some of the contracts on the list were other types of contracts (e.g., project management contracts) and have been excluded from the data. On the other hand, a company that has collected information on its ACs has also included ACs in which it was not involved, which suggests neutrality in maintaining the list.

CONCLUSION

This study is motivated by a research gap on the role of SMEs and LEs in ACs. The study was carried out as an archival study covering all alliance construction projects in Finland over a period of 13 years. In addition, the relative change in the budget value of Acs in this market was assessed. The aim of this study is to stimulate debate among researchers and practitioners on the distribution of ACs in the construction sector and to encourage further quantitative and qualitative research.

The survey indicates that the number of ACs awarded to a group of LEs is clearly higher than to SMEs. The study's findings, with an even split between SMEs and LEs and a median contract size of just over €50 million, also raise a question about the effectiveness of the alliance model in promoting SME opportunities in public procurement. This difference suggests that further research is needed to understand the market-specific factors influencing this phenomenon and to assess whether the alliance model disproportionately benefits larger firms.

From the projects examined, it was found that a significant proportion of ACs are distributed among a few LEs. These LEs may be pioneers in their field, strategically choosing an alliance model of lean construction to succeed, or their dominance may be the result of innovation dynamics in which only large companies can afford to invest significant resources. Whatever the speculated reasons, in order to clarify these aspects, we encourage other researchers to explore the phenomenon in more depth than this short paper, which focuses on numbers and a limited geographical area, is able to accomplish.

The third central finding revealed that the relative budget value share of ACs has been increasing relative to the size of the construction market for 13 years and is approaching one-tenth of the total market. However, the share of SMEs in these alliances is decreasing. This trend suggests that the budget value of ACs is increasingly being transferred to LEs, which raises serious questions about the differences and opportunities between SMEs and LEs in the sector. The limited sample and data available in this study are not sufficient to assess the reasons; therefore, this study serves as an inspiration for further investigation into the dynamics of ACs, especially from the perspective of SMEs in the construction sector.

ACKNOWLEDGMENTS

We express our sincere gratitude to Vison Ltd. for their assistance and significant preparatory efforts that enabled the publication of this paper.

RECONCEPTUALIZING A MODEL FOR LEAN CONSTRUCTION SUPPLY CHAIN

Didas S. Lello[1] and Fidelis A. Emuze[2]

ABSTRACT

The inefficiency of construction projects in Tanzania made popular cost overruns, extensive delays, reworks, defects and accidents, including resource waste within the construction supply chain. Although scholars have proposed diverse ways to combat supply chain problems, these efforts lack an integrated lean construction supply chain (LCSC) model. Given the persistent resource constraints characterizing the construction industry, this study reconceptualizes an LCSC model for deployment to drive out waste. A critical review of relevant literature was conducted to identify which lean supply chain model predominates in construction in order to develop an LCSC model that integrates lean construction tools and supply chain strategies that were found to proffer better solutions. The paper offers novel theoretical insights that lay a foundation for subsequent empirical and practical implications for LCSC efficiency.

Construction, Lean, Supply Chain, Model, Project

INTRODUCTION

Research on the application of supply chain management started first to be investigated in manufacturing industries (McSharry et al., 2023). Given its usefulness, studies on the framework have now taken its course on construction projects. Substantial studies have been carried out on the applicability of supply chain management for construction projects (Chauhan et al., 2022; Cigolini et al., 2022). Further, lean construction practices and principles are widely researched and reported in construction (Koskela et al., 2020; McSharry et al., 2023). Construction supply chain research has also integrated lean project delivery approaches (Le & Nguyen, 2023; Sarhan et al., 2018). Vigorous integration of lean and supply chain strategies can address construction project productivity and resource efficiency problems (Koskela et al., 2020; Le & Nguyen, 2023). However, most of these studies have only focused on applying lean principles, with little emphasis on integrated lean supply chain approaches (Sarhan et al., 2018). These two phenomenological approaches (i.e. construction supply chain and lean construction) have been constantly and distinctly deployed on their own merits.

While lean construction aims at meeting customer needs, continuous improvement, and resource waste minimization (Demirkesen & Bayhan, 2020; Meng, 2019), construction supply chain integration helps with commitment and communication to enhance synergy and co-value creation (Koskela et al., 2020; Le & Nguyen, 2023). Supply chain integration increases

collaboration and networking of key actors (contractors, consultants, developers) aligned in project delivery (Ballard & Elfving, 2020; Le & Nguyen, 2023). This dyadic synergy is key for lean construction supply chain (LCSC) efficiency at both inter- and intra-organisational levels, which will benefit these LCSC actors. Various studies have been expedited to provide solutions to the current construction supply chain problems in various regions, both in traditional and other project delivery paths. For instance, prior studies were carried out to test the use of traditional construction supply chain to reduce delays because of pre-construction deficiencies in construction projects (Koskela et al., 2020; Meng, 2019).

Although the Architecture, Engineering and Construction (AEC) industry contributes an average of 11% to the GDP of Tanzania's economy (Kikwasi & Escalante, 2020), studies suggest that the development of the industry in Tanzania is hindered by various factors including time/cost overruns, inadequate productivity, insufficient professional knowledge capital, competencies, skills, innovation, building codes, and the industry's supply chain fragmentation (Kikwasi & Escalante, 2020; Kikwasi & Sospeter, 2023; Lello et al., 2023; Bajjou & Chafi, 2020). To address these deficiencies, a robust study is required. At the same time, an LCSC model is lacking in Tanzania. Such a model will also curb challenges related to defects, rework, waste, lack of a common base for project information, lack of standard work, lack of collaboration, and lack of teamwork (Kikwasi & Escalante, 2020; Kikwasi & Sospeter, 2023; Lello et al., 2023). This will contribute to improvements in the construction industry compared to traditional management methods (Koskela et al., 2020; Meng, 2019). Therefore, drawing on the lean and supply chain integration theories, this paper addresses the following research question: *What model will promote lean construction supply chains in Tanzania?*

AN OVERVIEW OF RELATED LITERATURE

Given the construction challenges stated above, this study contends that robust lean tools integration, supply chain integration, lean innovative capability, and stakeholder support (conducive industrial policies, building codes, standards and IT systems embedded within LCSC) can significantly address resource limitations, thus offering positive practical consequences and innovations (i.e. LCSC efficiency) in construction projects. Prior research also indicates that construction projects constitute only 62% of value-adding activities and 12% of support activities (Demirkesen & Bayhan, 2020). This suggests that non-value-adding activities still dominate most of the current project works. Although policy recommendations by experts (e.g. Kikwasi & Escalante, 2020; Kikwasi & Sospeter, 2023; Lello et al., 2023) have been issued recently, comprehensive research efforts to eliminate waste in construction (given the persistent resource limitation) have not been thoroughly carried out. In addition, studies that have empirically investigated the supply chain of projects delivered through lean tools (i.e. using an integrated LCSC model) are scanty (Le & Nguyen, 2023). As an integral part of a major PhD research project, this study reconceptualises an initial integrated LCSC model, which will be tested and validated for deployment basing on sample data from Tanzania's construction industry.

THEORETICAL CONSTRUCTS OF THE MODEL

Considering the nature of construction problems and their proximal effects, this subsection proposes the following study constructs based on lean and supply chain integration (SCI) theories to guide the proposed LCSC model (see Figure 1):

Resource limitation. Resource constraints (e.g. finance, human capital and other tangible assets, such as equipment and supplies) will continue to shape organisational dynamics and routines as resources continue to be scarce. Drawing insights from lean theory, the primary driver of efficient production in the construction industry is its efforts to synthesize and deploy variables for novel project undertakings (Johnson et al., 2023; Zimina & Pasquire, 2011). As stated earlier, "lean" refers to generating value for clients while using less resources (Drevland & Lohne, 2023; Mossman, 2018). It involves a set of principles, axioms, techniques, tools and ways of thinking (sub-theories) that, when combined and applied, can assist individuals and teams in enhancing the processes and systems in which they operate (Koskela et al., 2020; Mossman, 2018).

Supply chain integration. Based on the *SCI theory*, the study opines that robust internal and external supplier and customer integration (Li et al., 2022; Perdana et al., 2019) has potential to leverage supply chain problems inherent in the construction industry. It aims at eliminating traditional functional silos and integrating the functional departments of a company into a single entity in order to meet the requirements of customers at the lowest system-wide cost (Li et al., 2022; Perdana et al., 2019). SCI scholars (e.g. Lello et al., 2023; Li et al., 2022; Perdana et al., 2019) advocate that all the nodes in the network and innovation ecosystems, whether inside or outside the firm, should focus on communicating, exchanging and sharing key information at various sub-systems, activities, relationships and operations.

Lean tools integration**.** Lean tools in construction are viewed as techniques, methods and principles that when strategically deployed have the potential to address resource waste and efficiency challenges. These include: the Last Planner System (LPS), Building Information Models (BIM), Integrated Project Delivery (IPD), Target Value Design (TVD), Lean Project Delivery System (LPDS) model, Choosing by Advantages (CBA), Just in Time (JIT), and the like. Drawing insights from lean theory and the dynamic capability literature, this study contends that construction organisations which can develop dynamic capabilities in effectively and efficiently deploying lean tools, enhances them to integrate, construct, and reconstruct internal and external resources to cope with the fast-changing environment (Johnson et al., 2023; Li et al., 2022).

Lean innovative capability**.** Johnson et al. (2023) define Lean Innovation Capability (LIC) as “an organization’s ability to achieve sustainable innovation performance that meets core customer needs while constantly iterating offerings to validate and learn by continuous market feedback-all via the effective leveraging and mindful embracing of resource limitations” (p. 3). In this context, firms must innovate by developing new processes, organizational forms and business models to achieve differentiation (Li et al., 2022; Manda et al., 2023).

Stakeholder ecosystem support. Based on the supply chain integration and stakeholder resource-based view literature, firms can acquire sustainable competitive advantages by establishing sustainable relationships with key stakeholders (Li et al., 2022; Manda et al., 2023). This enables them not only to capitalize on supply chain resources, but also sail through multiple stakeholder limitations and needs. For instance, while strategic IT vendors can offer supporting technologies (such as BIM, AI, business-to-business (B2B) platforms, blockchain, machine learning, etc.), the government/regulatory institutions can provide valuable policies, professional fee tax incentives and building codes that aim at achieving LCSC efficiency.

Lean construction supply chain efficiency**.** Performance (of organisation or project) is a multi-faceted phenomenon which in general depicts the level of effectiveness and efficiency of previous acts (Lello et al., 2023). The traditional view of project or organisational performance, has been expanded to include the modern dimensions of environmental and societal performance pillars. Therefore, according to Lello et al. (2023), a company’s performance is assessed not only by its capacity to satisfy and keep customers, but also by demonstrating its level of profitability and sustainability. This study focuses on efficiency outcomes that entail making best use of available resources such as project capital/life cycle cost limits, equipment and time saving in project execution. Effectiveness (e.g. visually appealing facilities, etc.) and commercial aspects (the “absolute values” of business performance such as profitability, cash flow and market share, patent counts, etc.) are not the scope of this work.

METHODOLOGY

The conceptual paper is based on the preliminary literature review of lean and supply chain integration (SCI) theories. The conceptual framework developed is the preliminary stage of a major research project (doctoral study) expected to solve the challenges impeding LCSC efficiency experienced in construction operations. The keywords for the search included "lean" AND ("construct*" OR "construction" OR "building" OR "built environment" OR "civil engineering" OR "engineering") AND ("supply chain" or “supply chain integration” or “supply chain network*” or “supply chain collaboration” or “supply chain allianc*” or “supply chain coordination”) AND (“model*” or “framework”)”. The search was dominated by, but not limited to, Web of Science (WoS) and publications in the International Group of Lean Construction (IGLC) repository. The WoS is considered the most reputable peer-reviewed database, with science citation indexed journals. The IGLC database was selected due to its lean-focused research direction. While there were articles addressing global LCSC concerns, preference was made for articles relating to developing countries (emerging economies) as the study context is characterized more by them. Although an attempt was made to consider the latest articles, the retrieved articles ranged between 2000 and May 2023 based on the PRISMA[3] exclusion/inclusion criteria. Initial search resulted in 381 articles. After limiting to subject area and relevance (i.e. engineering & construction building technology), 49 articles were finally obtained from WoS. These were supplemented with additional relevant articles from the IGLC repository. Content analysis was employed to extract relevant information on which lean supply chain model predominates in construction that feeds into developing the conceptual LCSC model that addresses supply chain problems as shown in Figure 1.

RESULTS

This section presents the literature review results on various supply chain models that have been explored in LCSC research in order to identify a model that predominates in construction. This synthesis has broadened and deepened our understanding of how these lean efforts have contributed to the theoretical and empirical examination of the phenomenon. Further, unpacking the extent of exploration in this discourse will aid the development of an integrated LCSC model and increase our awareness of proposed solutions to Tanzanian supply chain problems that alleviate their effects and proffer guidelines on policy recommendations.

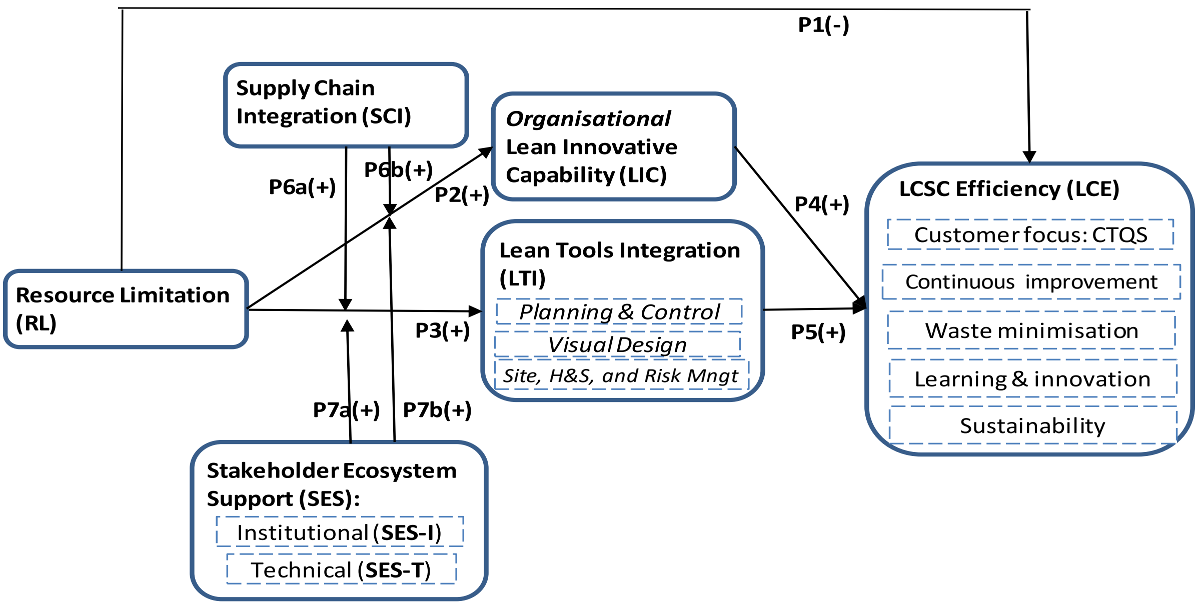
Prior studies have presented various model relationships (see Table 1). For example, a hypothetical LCSC model that employed the study between the applicability of lean principles, construction supply chain collaboration and project performance, centred on key elements (customer focus, continuous improvement, learning and innovation, waste minimization) for lean construction success was established by Meng (2019). However, the impact of the relationship on each construct was not tested and lacked validation. Demirkesen and Bayhan (2020) explored lean construction success factors and clustered them into; financial, managerial, technical, workforce, culture, government and communication. Their results revealed that lean training, availability of lean tools and techniques and market share were lean implementation's most important success factors. Although their findings demonstrated potential to improve efficiency, their study offered little understanding on how resource limitation among project actors could be addressed by vibrant supply chain integration, stakeholder ecosystem support and lean innovative capability of AEC organisations. Table 1 summarizes other models and their contributions adopted by various researchers in construction. LCSC models related to other industries (such as manufacturing) were excluded in this study.

[3] Preferred Reporting Items for Systematic Reviews and Meta-Analyses

Table 1. Summary of previous LCSC models

Author(s)	Model Main Constructs	Methods/Theory	Contribution
Meng (2019)	Applicability of lean principles, lean CSC collaboration, and project performance.	Interviews and descriptive statistics	Lean principles are found to apply to various types of construction projects. Lean management has an impact on project performance.
Demirkesen & Bayhan (2020)	Success factors are clustered as financial, managerial, technical, workforce, culture, government, and communication.	Analytical Network Process (ANP) model based on Importance Weights	These constructs are considered key lean implementation success factors.
Le & Nguyen (2023)	Virtual design construction (design integration), project planning and control, onsite construction and safety management, and sustainable CSC performance.	Integrated Delphi – Fuzzy AHP Process	Proposed a strategic and operational framework for Lean Construction (LC) practices' contributions to sustainable CSCM trends in the forthcoming years.
Asadian & Leicht (2022)	Construction teams, LPS procedure, social interactions, team dynamics, and planning performance.	"Interaction Process Analysis" (IPA)	Proposed an untested hypothesized model.
Zhang & Wu (2011)	Implementation ability, process management, lean degree of employee, lean improvement culture, and adaption ability.	Analytical Network Process (ANP)	Offered an appraisal model to improve Lean implementation ability in China's construction industry.
This study	Resource limitation (RL), Lean tools integration (LTI), Supply chain integration (SCI), Stakeholder ecosystem support (SES), Lean innovative capability (LIC), LCSC efficiency (LCE)	Theory of constraints, lean and supply chain integration theories; structural equation/regression modelling	Proposes a strategic and pragmatic (operational) model for an integrated LCSC in construction. Its successful deployment is instrumental in achieving LCSC efficiency (LCE).

The synthesis summarized in Table 1 suggests that models that integrate lean approaches and construction supply chain constructs are lacking. In addition, a considerable chunk of studies on the phenomenon was conducted adopting mainly; integrated Delphi – Fuzzy AHP process and related Multi-criteria Decision-making (MCDM) methodologies. However, despite substantial attempts to utilize MCDM models, these studies were dominated by conceptual and relatively few empirical studies. They lacked other logics that may further expand and enrich our understanding on theoretical and empirical implications. Moreover, models that employed structural equation modelling and multivariate regression analysis techniques were lacking in these studies. Therefore, this study proposes an initial LCSC remodeling that is more comprehensive and pragmatic for value addition, which will be tested and validated by employing these techniques. To achieve an integrated LCSC model and to limit the envisaged empirical investigations and discussions, we select six (6) constructs (see Figure 1) as key predictors influencing LCSC efficiency. Referring to the research question and drawing on the proposed theoretical framework, the selected theoretical constructs include: (1) resource limitation, (2) lean tools integration, (3) supply chain integration, (4) lean innovative capability, (5) stakeholder ecosystem support and (6) LCSC efficiency. Although there could be diverse ways of remodeling LCSC, the basis for selecting these constructs is anchored on two basics: (1) the model aims at addressing the identified supply chain problems in Tanzania, and (2) the theoretical underpinning is backed by conceptual model building literature which underscores that, models (conceptual, numerical, statistical) are simplifications (reductions) of complicated real-life scenarios (Bernard & Ryan, 2010; Imenda, 2014). The combined effects of these two basics support pragmatists' view in which the behavior of one construct impacts another construct (Imenda, 2014; Greene et al., 1989), thus concretizing LCSC efficiency. For example, it can be noted that; the identified problems and effects (i.e. inappropriate delivery practices, delays, rework, waste etc.) can be addressed by integrating sufficient lean tools pegged on the lean theory. Resource limitations (such as finance, knowledge, technologies etc.) could be swiftly leveraged by the aura of lean innovative capabilities (Johnson et al., 2023; Meng et al., 2019). Further, inefficient procurement systems can be improved through effective integration of supply chain strategy that involves key resourceful supply chain actors/partners grounded on supply chain integration theory. Moreover, inadequate capital and a lack of industrial policies, building codes, and incentives can be intervened through stakeholder support systems (institutional/technical) based on stakeholder resource-based view (RBV) theory. The model will benefit contractors, consultants, and developers. The subsections that follow expound these constructs along with propositions.



Note: H&S – Health & Safety; Mngt. – Management; CTQS – Cost, Time, Quality, Safety; P – Proposition.

Figure 1. Proposed conceptual model

DISCUSSION

PROPOSITION ONE

Johnson et al. (2023) indicate that innovation requires human capital and other assets, such as equipment and supplies as resources (Johnson et al., 2023). While some firms do better than others, it stands out that with no strategic resources, there will be no innovation (Johnson et al., 2023; Li et al., 2022). Empirical studies have employed different theoretical frameworks and have developed various conceptual models to probe the effect of resource limitation on LCSC efficiency (Johnson et al., 2023; Koskela et al., 2020). This study contends that the problems related to defective design, poor quality, inferior working conditions and low safety arrangements, coupled with resource constraints, have a detrimental impact on LCSC efficiency. As stated earlier, empirical studies on slack and its effects on innovation suggest that performance increases as resources increase up to a point where incremental costs exceed benefits, resulting in an inverted-U shape metric (Johnson et al., 2023). In contrast, an opposite trend occurs as resources get diminished. Prior research substantiates that innovation decreases relative to cases where resources are plentiful, in which firms with low levels of slack had the lowest innovation levels (Johnson et al., 2023; Troilo et al., 2014). This will in turn negatively impact LCSC efficiency. Thus, it can be postulated:

P1: Resource limitation has a negative impact on LCSC efficiency.

PROPOSITION TWO AND THREE

As discussed, the lean concept is centred on creating value for customers with fewer resources (Drevland & Lohne, 2023; Mossman, 2018). It optimizes resource efficiency and time/schedule constraints and ensures the budget is not exceeded, thus satisfying the customer (client/employer) (Mossman, 2018). According to Meng (2019), "wasteful processes and activities consume resources but do not add value to the final deliverables" (p. 3787). Therefore, lean, innovative efforts to remove all non-value-adding processes and activities are vital for lean construction (Koskela et al., 2020; McSharry et al., 2023; Meng, 2019). Prior empirical studies on slack (plentiful resources) and its effects on innovation suggest that performance increases as resources increase to a point where incremental costs exceed benefits, resulting in an inverted U shape (Johnson et al., 2023). However, circumstances in which resources are constrained (similar to having lower slack/munificent resources "relative" to other industry players) but where organizations continue to innovate successfully reflect conditions of lean innovation (Johnson et al., 2023; Troilo et al., 2014). This lean innovative capability enhances organisations achieve innovation performance with limited resources. At the same time, to achieve this aim in the AEC project context, the integration of lean tools comes into effect. For example, planning and controlling tools such as LPS are confirmed to have far superior project results (Liu et al., 2022; Warid & Hamani, 2022). Their main strength is their ability to handle uncertainties by increasing planning reliability and predictability, thus decreasing workflow variability (Liu et al., 2022; Warid & Hamani, 2022). Hence, it is propositioned:

P2: The negative impact of resource limitations/constraints is positive when lean innovation capability is high.

P3: The negative effects of resource limitations/constraints turn positive when lean tools integration is high and robust.

PROPOSITION FOUR

As stated earlier lean innovation capability (LIC) of an organization is its ability to achieve sustainable innovation performance that meets core customer needs while constantly and effectively leveraging resource limitations (Johnson et al., 2023). Drawing insights from this perspective, we argue that AEC firms (especially start-ups), usually characterized by a financial, human, and material resource shortage, fail to achieve LCSC efficiency. These effects constrain construction production, exchange, and consumption (Johnson et al., 2023; Koskela et al., 2020**;** Troilo et al., 2014). LICs (such as product-market fit, experimentation culture, mission-oriented leadership, and network learning capability) can significantly improve LCSC efficiency (Hong et al., 2019; Johnson et al., 2023). For instance, visionary leadership provides clear and decisive directions for an organisation, symbolizing strategy and culture on what to do and why (Johnson et al., 2023; Lello et al., 2023). Prior research showed that innovative companies under resource constraints had managers who focused on translating innovation strategies into strategic goals, objectives and performance (Hong et al., 2019; Johnson et al., 2023; Meng, 2019). We also argue that we can use the LIC construct to set a baseline effect to test for positive mediation in leveraging the negative effects of resource limitation, thus improving LCSC efficiency. Therefore, we opine:

P4: LIC has a significant and positive impact on LCSC efficiency.

P4a: LIC positively mediates the relationship between resource limitation and LCSC efficiency, such that the negative impact of resource limitation turns positive when LIC is high.

PROPOSITION FIVE

To achieve LCSC efficiency (i.e., value creation for end customers, waste minimization, etc.), lean tools integration (LTI) plays a vital role. It includes key tools that a main contractor can use to improve predictability, eliminate variability in production (Liu et al., 2022; Warid & Hamani, 2022) through standardization, and reduce lead time (Broft, 2019). As previously described, these key lean tools include the last planner system, building information modelling, target value design, choosing by advantages, just in time, to mention a few. Studies indicate that effectively using these tools has significantly improved lean construction performance (Broft, 2020; Koskela et al., 2020; Le & Nguyen, 2023). Scholars (e.g. Le & Nguyen, 2023; Liu et al., 2022) grouped these lean tools into four categories: design and engineering, planning and control, construction and site management, and health and safety management. This study also suggests that the negative impact of resource limitation on LCSC efficiency is leveraged by LTI mediation. Studies that have examined this relationship are limited. Remodelling resource limitation and LCSC efficiency without factoring LTI cannot yield the envisaged LCSC efficiency. Thus, it can be opined:

P5: LTI has a significant and positive impact on LCSC efficiency.

P5a: LTI positively mediates the relationship between resource limitation and LCSC efficiency, such that the negative impact of resource limitation turns positive when LTI is high.

PROPOSITION SIX

The lean approach challenges scholars to fundamentally rethink value from the customer's needs (Broft, 2020; Koskela et al., 2020). According to Broft (2020), this includes the identification of the 'entire' value stream. The value stream is "the set of all the specific actions (including key project stakeholders) required to bring a specific product or service through the critical management tasks of any business" (Broft, 2020, p. 280). In supply chain integration (SCI), all key supply chain actors need to be able to make a full contribution to ensure that the client's needs are fulfilled and that value creation is maximised (Broft, 2019; Li et al., 2022; Malaeb & Hamzeh, 2018). Drawing on the flow model of production perspective, where production is conceived as a flow of materials and semi-products leading to an integrated final product (Koskela et al., 2020), the analysis of these construct relationships argues that both internal and external SCI can positively moderate the relationship between resource limitation and lean tools integration as well as between resource limitation and lean innovative capability. According to Koskela et al. (2020), any form of waste, i.e., non-value-adding activities existing in the production system of the organisations within the supply chain, will need to be reduced or removed. Vibrant organisation and governance of key supply chain actors (suppliers,

specialized subcontractors, etc.), processes and activities can lead to high productivity and fast delivery (Ballard & Elfving, 2020; Broft, 2019; Le & Nguyen, 2023). To achieve this effect, robust lean tools integration is inevitable. However, to effectively plan, design and control (by employing lean tools) the works (material handling, site logistics and productivity, etc.), strategic engagement with key supply chain actors should be considered (Dakhli & Lafhaj, 2022; Le & Nguyen, 2023). This can positively leverage any negative impact of resource limitation on both lean tools integration and lean innovative capability. Prior research demonstrated that a 7% to 8% improvement is attributed to construction site logistics and supply chain management (Dakhli & Lafhaj, 2022). Thus, SCI has the potential to act as a critical vector and catalyst between resource limitation and lean tools integration as well as between resource limitation and LIC, where innovative lean tools coupled with lean innovative capability must be orchestrated. Therefore, it can be suggested:
P6: SCI moderates the relationship between resource limitation and lean tools integration (**6a**) and between resource limitation and lean innovative capability (**6b**).

PROPOSITION SEVEN

Stakeholder research in AEC focuses mainly on key inbound (direct/core) supply chain actors such as customers, suppliers, and subcontractors (Koskela et al., 2020; Lello et al., 2023; Li et al., 2022). Outbound (indirect/peripheral) supply chain actors, such as government institutions, have been overlooked in LCSC contexts. Given the resource constraints that characterize the AEC industry, construction organisations are always under pressure to deliver projects successfully. This is attainable when these organisations employ innovative lean tools (Koskela et al., 2020; Le & Nguyen, 2023) and lean innovative capability (Johnson et al., 2023). However, strategic integration with peripheral partners (such as institutional stakeholders and IT vendors) can greatly foster corporate flexibility and quick responsiveness (Johnson et al., 2023; Malaeb & Hamzeh, 2018). The delivery of AEC projects involves knowledge- and service-intensive undertakings usually regulated by third-party stakeholders (government/regulatory organs) (Lello et al., 2023; Yip et al., 2019). These stakeholders provide strategic policy frameworks, such as building codes, environmental certifications, and safety guidelines (Lello et al., 2023; Yip et al., 2019), influencing lean tools integration and lean innovative capability. To attain this, AEC designers must seek ways to incorporate all stakeholder interests and then transform the interests into clear design specifications for the new product/service development process (Lello et al., 2023; Yip et al., 2019).

Data science innovations are widely considered as unequivocal vectors for supporting not only SCI but also information sharing, knowledge/skills and innovation networks. For instance, IT vendors, which are also key stakeholders, play a pivotal role in providing the necessary supporting IT infrastructure (e.g. BIM, AI, blockchain, big data analytics, etc.) (Adekunle et al., 2023; Dakhli & Lafhaj, 2022; Liu et al., 2022). In the current digital era (industry 4.0 & 5.0), this technical support employing big data and Internet of Things provides innovative methods that aid organizations in developing high-performing teams and a culture that is performance-focused (Adekunle et al., 2023; AlBalkhy et al., 2023). Nascent studies are now shedding light on the application of technical supports to deal with the problem of lack of synchronization, which has constantly hindered creation of a stable flow in the production system, thus degrading performance and value creation (Lello et al., 2023; AlBalkhy et al., 2023). This will thus leverage the negative impacts of resource limitation on both lean tools integration and lean innovative capability. It can be postulated:
P7: Stakeholder ecosystem support (both institutional and technical) positively moderates the relationship between resource limitation and lean tools integration (**7a**) as well as between resource limitation and lean innovative capability (**7b**).

No prior research has proposed such an integrated model (see Figure 1). In this context, its realization will unfold a novel contribution to theory and practical implications. Moreover, to measure/test and validate the theoretical constructs, the proposed LCSC remodeling will use indicators well-established in previous studies in the literature. For instance, scholars will identify these variable indicators mainly based on the Integrated Delphi – Fuzzy AHP Process (e.g. Le & Nguyen, 2023; Demirkesen & Bayhan, 2020). One of the advantages of this approach is the ease of comparison among alternatives and easy adjustment (Demirkesen & Bayhan, 2020).

CONCLUSIONS

Achieving LCSC efficiency of the AEC projects has been hindered by the lack of an integrated and pragmatic LCSC model that can aid in the alleviation of cost overruns, time overruns, supply chain quality concerns, environmental and safety challenges. Based on a critical literature review approach, this study was conceptualized to solve the mentioned problems to eliminate resource waste (non-value adding activities) through LCSC. Drawing on insights from the lean theory and SCI view, six (6) theoretical constructs were identified as key variables in developing a novel LCSC model for deployment by the AEC actors (e.g. contractors, consultants, developers etc.). Future studies will examine the seven (7) propositions closely to gauge if hypotheses that can be measured can then be developed and tested. In this study, a proposition tries to suggest a link between two or more concepts that may not be tested scientifically while a hypothesis can be tested to estimate the impact of these relationships on LCSC efficiency. Undertaking this endeavor is instrumental in identifying, understanding and removing constraints in operations thus aiding work progress. Therefore, this study presents not only a preliminary step of a doctoral study but also lays a potential foundation on how the theory informs future empirical investigation in eradicating LCSC problems using sample data from Tanzania, thus contributing to and advancing the LCSC literature. The research will further elicit responses from industry participants to answer the research questions and draw up recommendations for the main study. It will further aid theoretical, empirical, practical and policy implications in achieving LCSC efficiency in the construction industry.

DIGITAL TWIN BASED INTEGRATED DECISION SUPPORT SYSTEM FOR ENHANCED DECISION-MAKING IN THE LAST PLANNER SYSTEM

Zhong Wang[1], Mohamed Sabek[2], Yulun Wu[3], Qipei Mei[4], Gaang Lee[5] and Vicente A. González[6]

ABSTRACT

This paper discusses the enhancement of decision-making within the Last Planner System (LPS) through digitalization, emphasizing the role of a Digital Twin-based Integrated Decision Support System (DT-IDSS) aligned with Lean Construction 4.0 principles. The proposed conceptual framework DT-IDSS aims to address the challenges in LPS decision-making in terms of autonomation, data integrity, user-centricity, and decision-making rapidness, by integrating user-centric design with advanced technologies such as Digital Twins, Internet of Things, Blockchain, and Artificial Intelligence. It features a decentralized reality capture flow for data processing and storage, and an information loop fostering collaborative stakeholder engagement. The system's user-centric development loop adopts an agile, iterative approach, meeting the dynamic needs of construction projects. The integrations of workflows and technologies in the proposed framework has a huge potential in addressing challenges in the deficiency in system integration, which are essential to effectively support information, computation, visualization, and services, thereby enabling stakeholders to make informed decisions. Future research will focus on assessing decision-making effectiveness, enhancing system scalability, improving data management security, and achieving interoperability with existing management systems. This research contributes to the digital transformation of decision-making process, aiming to provide guidance for future developments in this rapidly evolving field.

INTRODUCTION

In the field of Lean Construction, the significance of efficient and accurate decision-making cannot be overstated. The Last Planner System (LPS) is a Lean-based production planning and control system that aims to reduce variability in workflow, improve the predictability of planning, and decrease the waste of production; while acting in tandem on the social and technical aspects of planning and control in projects (Ballard, 2000). This system highlights the importance of "last planners," the individuals responsible for planning the tasks of those executing the work, such as builders and subcontractors, which empowers these planners to have a greater impact on planning and decision-making processes (Babalola et al., 2019). Hamzeh (2009) identifies key decision-making activities in the LPS are:

- **Master scheduling:** Value proposition translation, milestone setting, schedule development, and integration of master scheduling.
- **Phase scheduling:** Milestone planning, collaborative planning, reverse phase scheduling, and schedule adjustment.
- **Lookahead planning:** Lookahead filtering, constraint identification, constraint removal, and operation design.
- **Weekly work planning**: Task selection and assignment, quality criteria application, and learning from failures.

For over three decades, the LPS has become one of the most popular tools within Lean Construction, contributing a multitude of benefits to the construction industry (Sbiti et al., 2021). However, similar to various other construction project management approaches, LPS can be considered to fall under the category of the gambling paradigm. In this paradigm, decisions are made under conditions of uncertainty, where the outcomes are not certain, but the probabilities are known (Blackwell, n.d., Chapter 1). This type of decision-making often indicates that not all available information is being used effectively or in a timely manner. As a result, decision-makers may oversimplify their process, failing to gather and integrate all the relevant information (Fox et al., 2015).

This lack of comprehensive information utilization is a significant factor contributing to some of challenges that the LPS implementation faces in construction projects such as partial implementation issues (Babalola et al., 2019; Lindhard & Wandahl, 2015), the failure to involve key people in decision-making (G. Ballard et al., 2020), the inherent projects’ complexity (Altan & Işık, 2023), underestimation of the social processes impact on technological adoption (Ballard, 2000; Noueihed & Hamzeh, 2022), and the limitations of applying deterministic planning in uncertain project environments (Ballard, 2000; Singh et al., 2024).

To address these challenges, digitizing the decision-making process has become one of the primary areas of focus in construction and engineering project management. Although there has been extensive research on developing digital decision support systems, challenges persist in implementing automated solutions that maintain data integrity and prioritize user-centered design (Boje et al., 2020; Rane & Narvel, 2022; Sacks et al., 2020). Previous studies have concentrated on integrating technologies such as Digital Twins (DTs) (Huang et al., 2021), Internet of Things (IoT) combined with Blockchain (Rane & Narvel, 2022), and computer vision (Mavrovounioti et al., 2015; Reja et al., 2022) to enhance decision-making in project management. However, the practical integration of these complex systems remains a major challenge (Boje et al., 2020). Therefore, a decision support system framework that facilitates the practical application of these technologies in the field is necessary.

Liu et al. (2010) investigated the effectiveness of Integrated Decision Support Systems (IDSS) in improving decision-making within the project management domain. IDSS are defined as interactive computer-based systems that aid in decision-related tasks and are essential in harmonizing data, processes, and technology to facilitate timely and accurate decisions (Liu et al., 2008; Shim et al., 2002). Their research delves into various integration aspects, including data, processes, and technology, culminating in a summarized framework depicted in Figure 1. This framework promotes a unified, interconnected, and user-friendly approach to decision-making (Ren et al., 2023).

For instance, when planning weekly tasks in the Last Planner System (LPS), decision-makers require various supports: information (e.g., progress updates, resource availability, task details), visualization (e.g., aerial site views, task flowcharts), computation (e.g., feasibility studies, cost estimation, risk management), and services (e.g., planning boards, documentation software). In an IDSS, these supports are enhanced: information support through service integration (e.g., shared drives, data management platforms) ensures data accessibility; visualization support through process integration links logical relationships; computational support through data integration converts computational data into decision-making data; and service support through presentation integration reduces cognitive load. These integrations are vital in facilitating an effective decision-making process and can be effective in addressing challenges for the decision-making process associated with the LPS. However, choosing a suitable theoretical framework to guide the IDSS development and pinpoint effective technologies and methodologies for decision-making support in the LPS, continue to be a matter that requires further investigation.

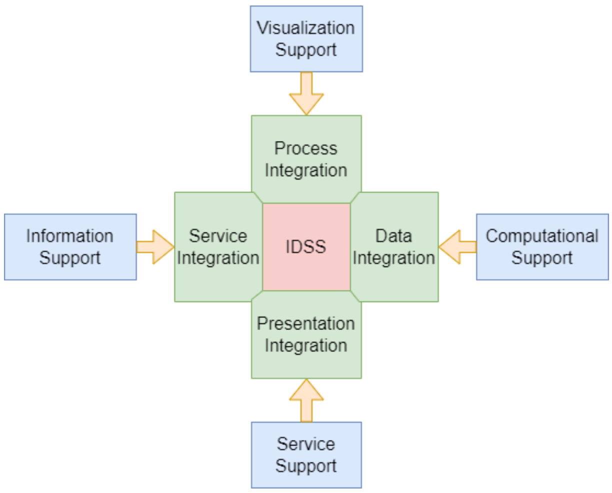

Figure 1 Integrated Decision Support Systems (IDSS) Framework, adapted from Liu et al. (2010)

Lean Construction 4.0 (González et al., 2022) presents a promising theoretical framework that reflects on some of the fundamental technology, production and people/culture shifts in the Architecture, Engineering, and Construction (AEC) sector. This framework combines the production principles of Lean Construction with Industry 4.0-inspired smart and digital technologies (SDTs), underpinned by human-centered design. This synergy aims to enhance and expedite the AEC industry's digital transformation not only by applying Lean Construction principles in tandem with SDTs, but boosting the effectiveness of decision-making processes within AEC organizations. Lean Construction 4.0 also cultivates a project management style that is both more efficient and sustainable, centered on human requirements, which leads to an effective manner to deal with the unique challenges of large-scale infrastructure projects. Through this integrated approach, Lean Construction 4.0 opens new avenues for optimizing resource utilization, mitigating risks, and accomplishing project objectives with an unparalleled level of precision and efficiency.

Building on the foundation of Lean Construction 4.0 (González et al., 2022), this paper presents a novel approach: a Digital Twin-based Integrated Decision Support System (DT-IDSS) to support the LPS implementation. The aim is to weave Lean Construction 4.0's SDTs into LPS's decision-making processes. This involves enhancing key decision-making activities in the LPS by utilizing an IDSS in crucial areas such as data collection, data analysis, decision-making application development, and information flow. The objective is to not only tackle current challenges in digital decision support systems but also to pave the way for future advancements in the development of digital IDSS in Lean Construction domain.

A BRIEF REVIEW OF DECISION SUPPORT SDTS AND INTEGRATIONS

The concept of Digital Twin (DT) has become a fundamental element in revolutionizing decision support systems among various industries. Essentially a DT serves as a digital reflection of physical entities, systems, or processes, facilitated by ongoing and timely information exchange (Sacks et al., 2020). In construction, DT goes beyond the simple digital representation of project products and processes to offer a dynamic and real-time link between the physical and digital realms. This connection enables continuous monitoring and analysis, providing deep insights and control over infrastructure projects. Creating a DT involves developing a virtual model of a physical asset, integrating real-time data from sensors and IoT devices to accurately replicate the asset's behaviour and performance (VanDerHorn & Mahadevan, 2021). Populating the DT requires continuously updating the model with live data, enabling real-time monitoring, analysis, and optimization of the asset's operation and maintenance (Boje et al., 2020). This offers a dynamic and holistic view of construction projects, integrating real-time data and predictive analytics to enhance decision-making processes (Boje et al., 2020). DT technology, known for its deep impact on data integration and visualization, has established itself as a fundamental aspect of decision support systems in diverse sectors (VanDerHorn & Mahadevan, 2021).

Based on Lean Construction 4.0, the collection of detailed data from the construction production environment is critical to generate DTs for decision-making (Bou Hatoum & Nassereddine, 2022). This ties in with the advancements in lean project management efficiency through the integration of IoT and Blockchain technologies, signaling a shift towards more secure, transparent, and instantaneous data management in construction projects (Martínez et al., 2022; Rane & Narvel, 2022; Wu et al., 2023). In this realm, IoT sensors act as crucial links between the physical and cyber worlds, capturing real-time data for subsequent modeling and analysis (Bou Hatoum & Nassereddine, 2022). Concurrently, Blockchain technology, known for its decentralized structure, immutability, and strong authentication processes, is vital for ensuring secure and reliable data distribution (Li et al., 2019). From the reality capture and data distribution perspectives, the integration of IoT and blockchain can address the dynamic challenges faced during infrastructure project management that often lead to delays, rework, and increased overhead costs (Amade & Nwakanma, 2021; Fobiri et al., 2022). By leveraging blockchain and IoT, the project management process can be transformed, offering real-time data insights, improved asset management, and enhanced security and transparency (Ghimire et al., 2016). This technologically advanced approach not only aligns with the principles of adaptive and intelligent IDSS, but also extends these principles by providing practical, real-time solutions for managing resources efficiently in large-scale infrastructure projects. The adoption of this Blockchain-IoT integrated architecture represents a significant leap in data collection and information distribution for digitalized, decentralized decision support systems.

Following the collection of data from construction sites through reality capture and IoT sensing, the timely generation of semantically enriched DTs remains a challenge (Boje et al., 2020). The integration of Artificial Intelligence (AI), via computer vision technology, into the real-time generation of DTs in construction and infrastructure projects is fundamental. It offers transformative possibilities in production management practices by providing real-time data modelling and analytics, which enables a dynamic and highly accurate representation of physical assets and revolutionize how projects are planned, monitored, and executed (Sami Ur Rehman et al., 2022; Shamsollahi et al., 2022; Soman & Molina-Solana, 2022; Xu et al., 2021). This integration is also one of the practical applications of SDTs within the Lean Construction 4.0 framework, enhancing production management practices(Stowe et al., 2020). Recent studies in this domain have underscored the value of computer vision and deep learning technologies in enhancing real-time monitoring and decision-making. For example, the application of Computer Vision-based Construction Progress Monitoring (CV-CPM) has demonstrated how real-time, accurate monitoring of project progress can be achieved (Bozorgzadeh & Umar, 2023). Also, reinforced learning with linked-data based constraint checking shows the potential of applying AI-based models to provide computational support for the decision-making in the LPS (Soman & Molina-Solana, 2022). Further, the development of regression-based deep neural networks for equipment monitoring and advanced 3D pose estimation techniques illustrates the capability of these technologies to provide detailed, real-time insights into construction operations (Cheng et al., 2023; Golparvar-Fard et al., 2013; T. H. Wang et al., 2023). These advancements in AI not only facilitate a more dynamic and holistic view of project environments but also align with the core principles of adaptive and intelligent IDSS. By enabling the continuous synchronization of physical and digital worlds, AI technologies contribute significantly to the creation of real-time, accurate DTs, which are crucial for the proactive management of safety, resource allocation, and overall operational efficiency.

Despite these technological advances, a gap remains in the form of an IDSS that cohesively combines these technologies within the decision-making workflow. This paper seeks to bridge this gap through the introduction of a User-Centric Digital Twin-Based Integrated Decision Support System conceptual framework, as illustrated in Figure 2. The proposed framework provides a vision to integrate the strengths of IoT and robotics for reality capture, blockchain for secure data distribution, and advanced AI-based data processing, all within a DT framework for IDSS. This user-centric approach aims to harness the full potential of these technologies, providing an innovative and robust solution for efficient and effective decision-making within the LPS.

THE DT-IDSS FRAMEWORK

This section offers a comprehensive overview of the proposed DT-IDSS Framework. The discussion is proceeded in the following order: system overview, decentralized reality capture flow, decision-making information loop, and user-centric development loop. Additionally, this section also presents the current research progress in applying the proposed framework.

USER-CENTRIC DIGITAL TWIN-BASED INTEGRATED DECISION SUPPORT SYSTEM OVERVIEW

The LPS decision-making process, as mentioned in the introduction section, can be considered to fall under the category of the gambling paradigm, characterized by decisions made under uncertainty. To mitigate this uncertainty, the decision support is anchored by four key pillars: information, visualization, computation, and service (Galjanić et al., 2022; Liu et al., 2010; Shim et al., 2002), which is shown in Figure 2. At the core of the system lies information support, providing essential data crucial to make informed decisions. This includes updates on project progress, availability of resources, and specific details about tasks. Key to this component is the integration of services, ensuring seamless access to important information for decision-makers. Service integration focuses on combining functions and services within the DT-IDSS, ensuring that different components of the system are compatible and accessible. This integration encompasses not just the harmonization of internal components but also the optimization of the user interface and external interactions, thus enhancing the overall utility of the system.

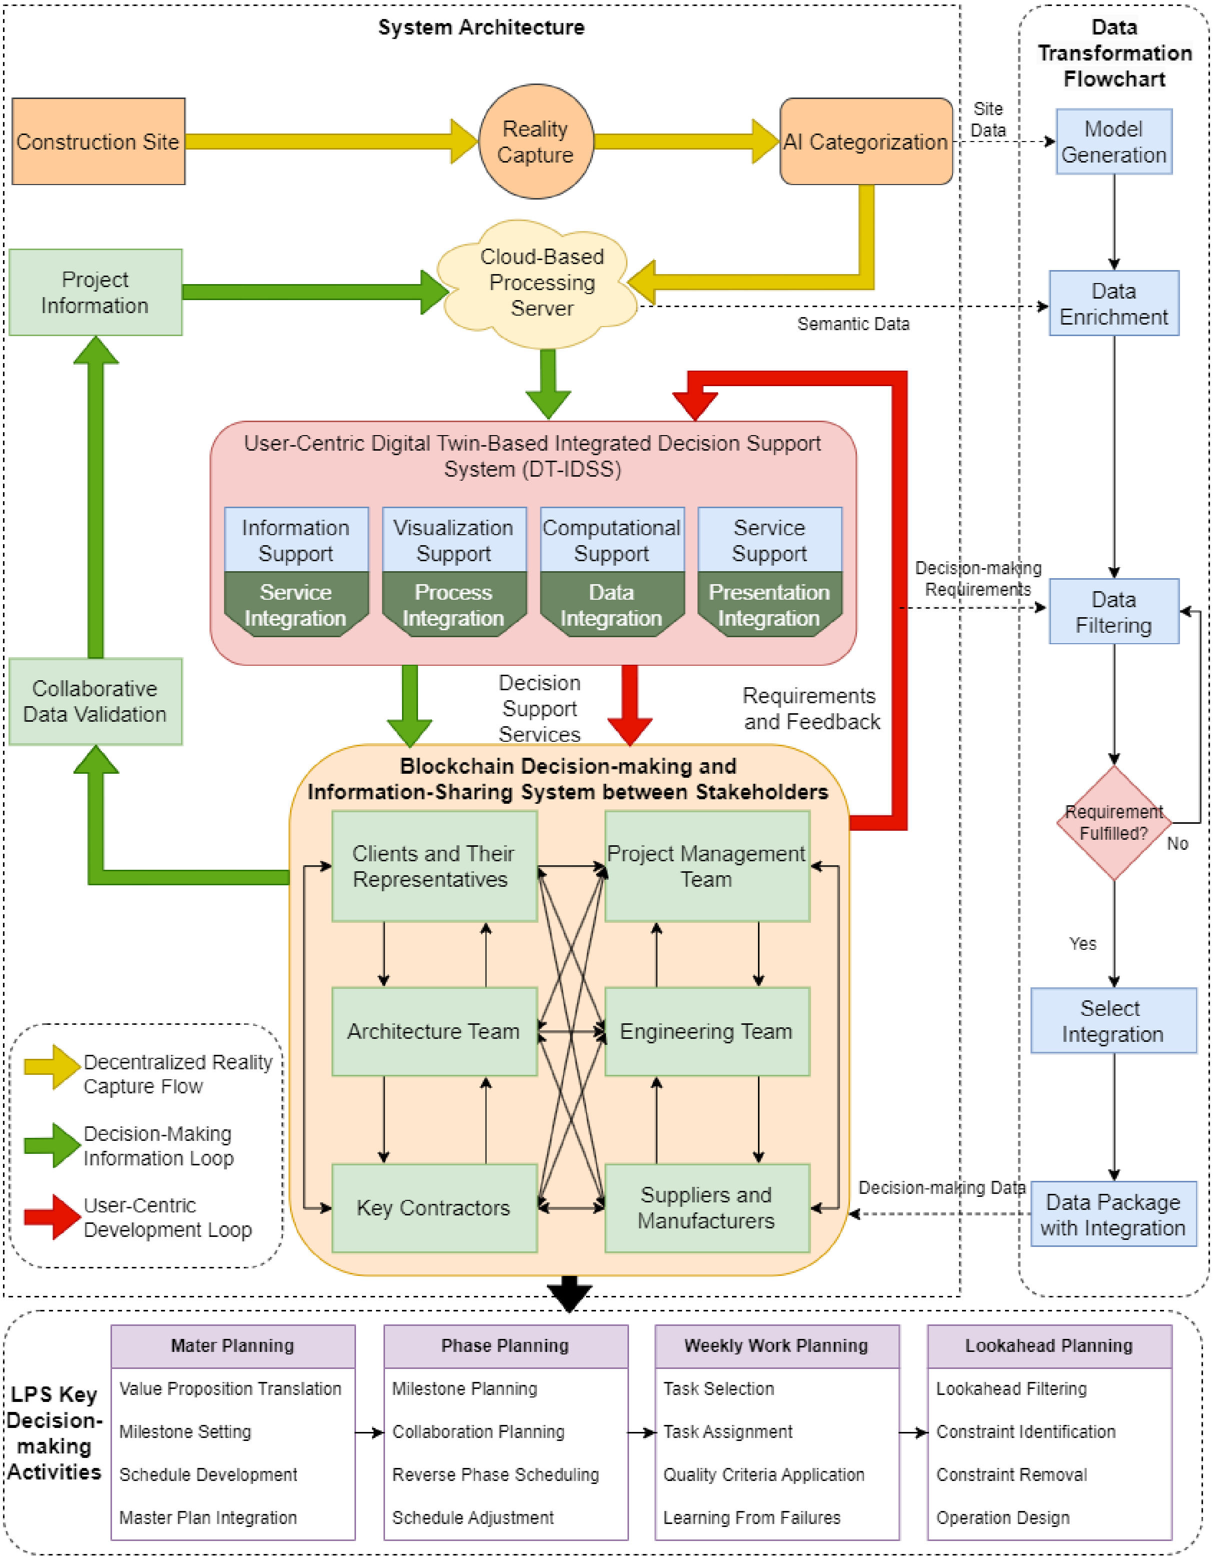

Figure 2 User-Centric Digital Twin-Based Integrated Decision Support System (DT-IDSS)

Visualization support enhances the data experience by presenting information in formats such as charts, images, videos, 2D/3D models, and Building Information Modeling (BIM) constructs. This is done in a manner that is easy to understand and user-friendly, necessitating the integration of processes to create cohesive and intuitive visual representations of data. On the other hand, computation support leverages computer systems and algorithms to streamline complex data interpretation, assisting in key areas such as planning, cost estimation, and risk analysis. This support depends on the effective integration of data, converting extensive computational outputs into practical, actionable insights.

Service support consolidates various essential tools and applications for efficient decision-making, aligned with the project's overarching objectives. This includes a range of digital planning tools, document management systems, and BIM technologies, all optimized through presentation integration for a user-centric approach. The aim here is to reduce the cognitive burden on decision-makers and make the decision-making process more efficient. Presentation integration focuses on creating a consistent user interface across the DT-IDSS, standardizing visual design and interactive elements to ease user interaction. It also involves using consistent metaphors and mental models across various components to simplify learning and minimize interference in usage.

The service support of the system offers a variety of user-focused services, like customizable interfaces for different user roles, dashboards for stakeholders. Services in presentation integration are designed to deliver a consistent and intuitive user experience across various devices and platforms, boosting stakeholder engagement and facilitating decision-making. This comprehensive approach to decision support within the DT-IDSS framework not only streamlines the management of infrastructure projects but also markedly improves the efficiency and effectiveness of the decision-making process.

DECENTRALIZED REALITY CAPTURE FLOW

As illustrated in Figure 2, the primary aim of the reality capture process is to guarantee the prompt and precise transmission of data to a cloud-based processing server, ensuring the data's integrity throughout. This workflow is designed to gather the maximum amount of information feasible, tailored to meet decision-making requirements. Consequently, it is distinct from the decision-making process, a strategic separation that ensures the data remains pure and accurately represents the original information as captured and processed. In the user-centric integration development process, the data sourced from this flow undergoes only filtration without any alteration, maintaining its authenticity.

In this setup, reality capture sensors are classified into three types: photogrammetry sensors (e.g., CCTVs and stereo cameras), sensors for geometric information (e.g., location trackers and Geofencing), and Unique Identification (UID) sensors (including RFID and Bluetooth Low Energy-based beacons). The data captured by these sensors is transmitted via Narrowband Internet of Things (NB-IoT), a specialized communication technology designed for IoT sensors. Operating on cellular telecommunication bands, NB-IoT is optimized for extending wide-area connectivity to IoT devices. It offers several advantages, including low power consumption, extensive coverage, high connectivity density, and enhanced security, making it particularly suitable for infrastructure projects (Miao et al., 2018).

AI models are employed to categorize all collected data and transfer the categorized data for the model generation. For instance, computer vision models can be applied to categorize and preprocess photogrammetry data. An example using Yolov8 developed by the IHT lab in the University of Alberta (https://www.iht-lab.com/) is shown in Figure 3. Moreover, deep learning-based models with GIS data can be applied to the 3D reconstruction process, as shown in Figure 4. Depending on the computational requirements of these tasks, the AI models may be deployed either locally at the sensor level or integrated with the cloud-based processing server.

In the proposed framework, a cloud-based server is established as an independent central unit for storing, processing, and distributing IoT data within a decentralized reality capture system. This server stores both unprocessed and processed data, ensuring its availability for the

DT-IDSS as required. Importantly, it plays a vital role in creating 3D mesh models and adding semantic attributes derived from IoT sensors and project information, aiding in the creation of real-time, semantically enriched DTs. At this stage of research, the DTs are BIM models enriched with information from reality capture, sensors, and collaborative project meetings. These DTs serve as dynamic data reservoirs, aiming to improve the efficacy of real-time decision-making processes. The server is designed to manage intricate processing tasks such as action recognition, performance evaluation, quantity calculation, and the assessment of cognitive loads on workers. Its contribution to the decision-making information cycle is essential, bringing substantial value to this integrated system.

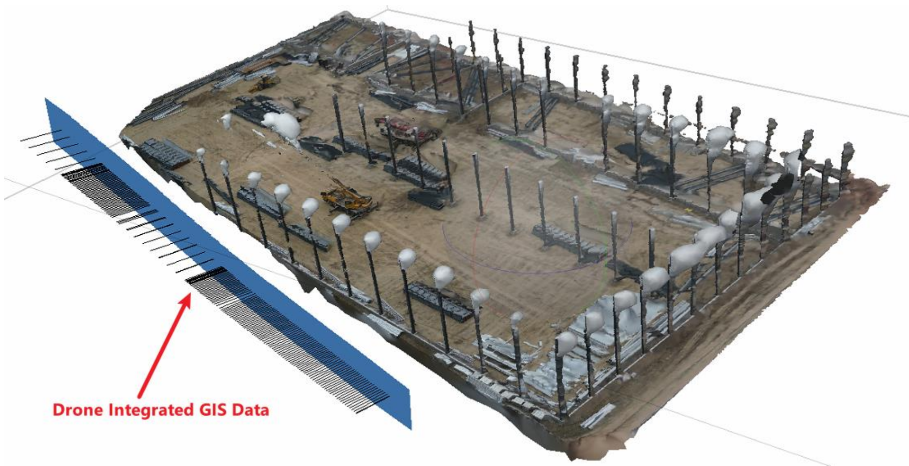

Figure 4 Example of Deep Learning Based 3D Reconstruction Using GIS Data

DECISION-MAKING INFORMATION LOOP

The decision-making information loop follows the Lean Construction 4.0 principle of *"development of human trust in the decision-making system"* (González et al., 2022). As illustrated in Figure 2, the design aims to support decentralized and collaborative interactions among stakeholders. This involves stakeholders actively participating in reviewing, validating, and updating data to ensure its accuracy and relevance to the project's needs. Stakeholders play a pivotal role in checking and refining the data within the system, while also maintaining the immutability of records, contributing their expertise, and fostering a shared understanding of project information. After the project information is validated, it is transmitted to the cloud processing server for the generation of semantically enriched DTs, which act as information conduits for the DT-IDSS. The blockchain technology here provides a decentralized approach of data management, which ensures that once data is entered, altering it requires consensus and must be transparent across all stakeholders (Wu et al., 2023). This cooperative model ensures that the system's data is current, reflective of the project status, and enriched by the varied insights and skills of all involved parties, thereby improving the quality and dependability of the decision-support framework.

Data integration within the DT-IDSS is crucial for reliable decision-making, as it ensures consistently updated and synchronized information across the system. This integration minimizes data redundancy and enables smooth data flow between system components, preserving data integrity. The establishment of clear integration standards and the maintenance of data completeness and synchronization are vital for effective decision-making. This strategy allows for quick dissemination of critical updates, such as design changes. The DT-IDSS enhances computational support by utilizing advanced techniques (e.g., data fusion, cloud computing, and blockchain) to combine and coordinate data from various sources, including architectural design software, project management tools used by the project management team, onsite reports from contractors, and inventory systems from suppliers. Leveraging decentralized blockchain technology, modifications in these data sources are instantaneously updated across all platforms accessible to stakeholders, which ensures that stakeholders receive timely, reliable, and highly integral data. As a result, they can quickly adapt their work schedules and tasks to align with evolving project requirements.

USER-CENTRIC DEVELOPMENT LOOP

The user-centric development loop in the DT-IDSS follows the Lean Construction 4.0 principle of *"consciousness about human-centered systems"* (González et al., 2022, p. 10). This method promotes an iterative and collaborative approach that is essential to agile UX design practices. It prioritizes user needs in the development of decision-making applications, ensuring that the system is not only technically proficient but also practically relevant (Wang et al., 2023). This approach is vital for successful integration of services, processes, data, and presentations, as illustrated in Figure 2, thereby improving the overall functionality and user experience within the DT-IDSS framework.

In this process, stakeholders (end-users) are actively engaged throughout the entire development cycle of DT-IDSS applications. Their crucial role involves reviewing, confirming, and enhancing system features to ensure the DT-IDSS effectively addresses practical requirements. The stakeholders' continuous involvement in validating functionalities, providing insights, and giving feedback is instrumental in the system's ongoing development. This constant loop of user engagement keeps the system in sync with the evolving needs of construction and infrastructure projects, allowing it to adapt to changes and foster a sense of ownership among all involved parties.

Agile software development principles are integrated into the design of the DT-IDSS, with a focus on sprints that address urgent needs of stakeholders. Regular meetings with interdisciplinary teams of stakeholders ensure clear communication and the swift resolution of immediate issues in the development of DT-IDSS applications. In this development cycle, backlog grooming is a continuous activity, involving regular updates to the backlog with new stakeholder requirements, feedback, and changes. At the end of each sprint, a review session is held where stakeholders can evaluate the latest version of the system and provide comprehensive feedback. Stakeholder requirements are meticulously gathered through interviews, surveys, observations, and workshops. The feasibility and impact of these requirements are analyzed, then prioritized based on the value they bring to stakeholders and the project. These consensus-based requirements are documented clearly and in detail, for instance, through user stories, to ensure they accurately reflect stakeholder needs and avoid any misunderstandings or ambiguities. An example of user-centric application designed for site surveying and progress monitoring is shown in Figure 5, applying the user-centric development framework for remote inspections adapted from Wang et al. (2023)

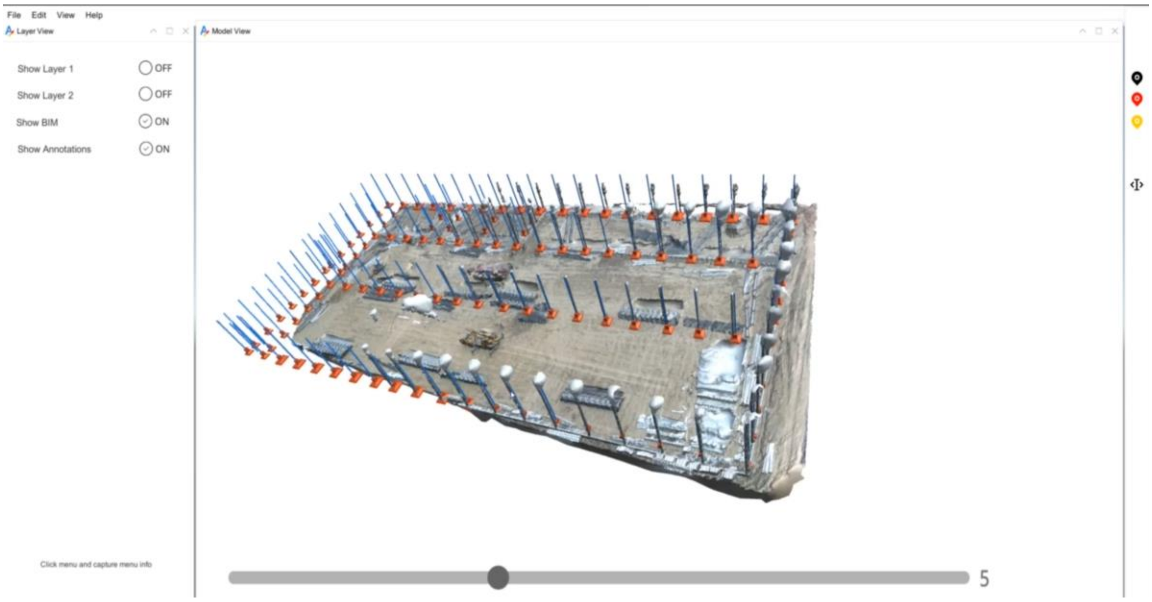

Figure 5 Application Developed for Site Surveying and Progress Monitoring

CONCLUSION AND FUTURE WORKS

This paper has highlighted the critical importance of timely and accurate decision-making in the LPS and how the digital transformation of these processes can significantly enhance project management efficacy. The proposed DT-IDSS, grounded in Lean Construction 4.0 principles, harnesses cutting-edge technologies like DT, IoT, Blockchain, and AI to tackle the complex challenges faced in LPS decision-making processes. The DT-IDSS is characterized by key elements such as a decentralized reality capture flow for accurate data processing and storage, and an information loop for decision-making that encourages collaborative involvement of stakeholders. Furthermore, the system's development loop places a strong emphasis on a user-centric, agile, and iterative approach, aligning with the dynamic needs of construction projects.

The DT-IDSS shows potential in facilitating various decision-making aspects. It assists in precise work sequencing and task allocation by utilizing real-time data on project progress and resource availability. This contributes to better forecasting, risk management, and adjustment of project schedules to accommodate changing conditions. Additionally, the DT-IDSS gives special consideration to human-centric factors, improving workforce management and safety. It offers customized work schedules to optimize team performance and well-being, while AI-driven predictive analytics help identify potential risks, creating a safer and more adaptive work environment. This comprehensive strategy is in line with Lean Construction principles, focusing on both efficiency and the human aspects of project management.

Though this framework represents an initial result of multiple ongoing research at IHT lab in the University of Alberta, it has not yet been fully developed and validated. Future research is proposed in several areas: 1) Assessing Decision-Making Effectiveness: Implement empirical studies to evaluate the impact of the DT-IDSS on decision-making and overall project results; 2) Enhancing System Scalability and Flexibility: Aim to refine the framework to cater to diverse project sizes and complexities; 3) Improving Data Management with a Focus on Security: Prioritize streamlined data management for efficient data sharing, while enhancing data security and privacy, especially regarding reality capture and data distribution in the DT-IDSS; 4) Achieving Interoperability with Existing Management Systems: Work on making the system compatible with existing project management and enterprise resource planning systems for seamless integration and data exchange.

LEAN-BIM SYNERGY IN THE CONSTRUCTION DESIGN PHASE: AUTO-GENERATION AND EVALUATION OF THERMAL ALTERNATIVES

Karim El Mounla[1,2], Djaoued Beladjine[3] and Karim Beddiar[4]

ABSTRACT

This study explores the integration of Lean principles with Building Information Modeling (BIM) to enhance decision-making in the relatively unexplored field of thermal design for construction projects. Recognizing the limitations of current design processes, characterized by insufficient alternatives and a lack of team collaboration, we introduce a new decision-making tool. This tool centers on a breakthrough framework and algorithm that bridge BIM with Lean techniques. It facilitates the automatic generation and evaluation of insulation material alternatives for residential buildings by integrating the Pleiades software database and Industry Foundation Classes (IFC) BIM data. Our study details an automated process for selecting insulation materials through an iterative, criteria-based approach that systematically identifies the three most viable solutions using Set-Based Design methods. It then selects the optimal one by examining and evaluating their criteria according to the project's needs based on energy efficiency, profitability, and sustainability through the Choosing By Advantages method. Additionally, by incorporating Big Room and BIM, our tool promotes enhanced communication and collaboration from the outset of the design phase, underscoring the significance of this integration in automating and optimizing thermal engineering projects.

KEYWORDS

Lean Construction, Set-based Design, Choosing By Advantages, Building Information Modeling, Big Room.

INTRODUCTION

In the construction industry, the design phase is the foundational stage where a project's trajectory toward efficiency and sustainability is determined (Bello et al. 2021). This phase is more than just the inception of architectural concepts, it is the period when the crucial elements of scope, cost, and time are precisely defined. Any discrepancies at this stage can have a significant effect, causing repercussions throughout the construction lifecycle (Yusof et al. 2015). Therefore, a meticulous focus on the design phase is not just prudent, it's imperative for the successful execution of any construction project (Herrera et al. 2021a; b).

In the last decade, several studies have highlighted the pivotal role of the synergy between Lean principles and BIM in enhancing the efficiency of construction projects, particularly during the design phase (Eldeep 2022; Herrera et al. 2021b; Sajedeh et al. 2016). Initially, it is crucial to understand the individual contributions of both Lean and BIM. Lean construction

focuses on eliminating waste and optimizing processes, while BIM provides a detailed digital representation of the project, enabling better planning and visualization (El Mounla et al. 2023; Sacks et al. 2010).

When these two methodologies converge, they create an efficient tool for improving decision-making. Decision-making is a critical aspect of the design phase, as it sets the foundation for the entire project. Decisions made during this phase have far-reaching implications on cost, duration, and overall project quality. By integrating Lean's efficiency-driven approach with BIM's comprehensive, visual, and data-rich models, stakeholders can make more informed, precise, and timely decisions (El Mounla et al. 2023; TUDublin and Sheramn 2019).

However, traditional design practices often encounter challenges due to their linear and segregated nature, leading to communication breakdowns, resistance to change, and costly design alterations down the line (Castañeda et al. 2023; El Mounla et al. 2023). These outdated methods inhibit flexibility and can be detrimental to the project's overall adaptability and success. Moreover, after conducting the literature, review we found that applying Lean/BIM synergy in the thermal field has not yet been explored. The significance of decision-making in the design phase cannot be overstated, as these early-stage decisions have lasting implications on all subsequent phases of construction. Informed, strategic choices are essential, shaping the project's aesthetics, functionality, economic feasibility, and regulatory compliance (Lee et al. 2012a; Rempling et al. 2019).

Set-Based Design (SBD) and Choosing By Advantages (CBA) are integral methodologies in construction and engineering that streamline decision-making and enhance project outcomes. SBD involves exploring a broad spectrum of design options and methodically narrowing them down to the most suitable solutions by eliminating less feasible alternatives (Castañeda et al. 2023; Sahadevan and Varghese 2018, 2019). This approach ensures comprehensive consideration of all relevant criteria from the project's inception, avoiding the premature exclusion of viable options. In addition, CBA complements SBD by offering a structured decision-making process that focuses on the comparative advantages of each option, ensuring decisions are both transparent and value-driven (Lee et al. 2012b; Mathern et al. 2018; Parrish et al. 2007). This integration is evident in complex construction projects, such as steel fabrication, where SBD's broad exploration of design alternatives including material properties and construction methods pairs with CBA's evaluative approach focusing on benefits like durability and ease of installation. This synergy optimizes decision-making, balancing feasibility with value, as exemplified in the work of (Parrish and Tommelein 2009).

In addition to these two methods, the Big Room is another Lean method that serves as a collaborative hub. It aims to bring together architects, engineers, contractors, and clients, to collectively plan, design, and manage the construction process (Fosse et al. 2017). Integrating BIM into this method significantly enhances interaction and understanding among these stakeholders. For example, a case study on a complex construction project shows how the Big Room served as the central coordination point. The project team used BIM to develop a comprehensive 3D model of the building. This model, accessible in the Big Room, allowed stakeholders to visualize the project in real-time, identify potential design conflicts early, and make informed decisions collaboratively (Fosse et al. 2017).

The research problem addressed in this study focuses on enhancing the decision-making processes for thermal engineers during the residential building design phase, particularly in selecting optimal insulation materials to achieve energy efficiency, sustainability, and high performance. The core challenges include the limited application of SBD in construction projects, which is constrained by the time and resources required for complex decision-making. This complexity arises from the need to evaluate various materials against numerous criteria and the necessity for improved collaboration among stakeholders, including architects and engineers. Additionally, integrating advanced technologies to streamline these processes is essential. To address these issues, our solution proposes a decision-making tool that integrates Lean methods with BIM. The process begins by integrating BIM within the Big Room to enhance collaboration and communication, thereby facilitating the identification of project goals and improving the flow of information for decision-making. Then this tool employs SBD to systematically explore insulation material alternatives from the Pleiades database and IFC files, facilitating the automatic generation of the top three insulation options. Subsequently, CBA is applied to evaluate these options and select the best insulation material, considering environmental standards like France's Environmental Regulations 2020 (RE2020). This innovative approach not only promotes sustainability by prioritizing materials that meet stringent environmental criteria but also broadens the thermal engineer's perspective by considering a wider range of high-performance materials. This improves the design phase's efficiency and effectiveness in construction projects, contributing to the broader goal of energy-efficient and sustainable building practices.

METHODOLOGY

In our study, we combined three distinct research methodologies to ensure a comprehensive and robust analysis: the Construction Research Approach (CRA), Systematic Literature Review (SLR), and Semi-Structured Interviews (SSI). Central to our methodology, CRA is an innovative approach aimed at creating new constructs or solutions specifically designed to address practical problems in the real world. It not only facilitates the development of tangible interventions but also enriches the theoretical framework within the field by bridging the gap between theory and practice (Piirainen and Gonzalez 2013). This approach is pivotal in guiding our research toward making significant practical and theoretical contributions. Complementing CRA, the SLR method allows us to thoroughly review and synthesize existing research, ensuring our study is deeply grounded in current academic discourse. Additionally, SSI provides nuanced insights by exploring diverse perspectives and experiences related to our research problem. Together, these integrated approaches enhance the reliability and relevance of our findings, promoting a balanced understanding that advances both practical applications and theoretical knowledge (Lukka et al. 2003).

To understand the methodology applied in our study, table 1 illustrates a structured process for integrating these methods together to construct our decision making tool. The journey begins with a SLR method where research is conducted to identify gaps and limitations in existing research (Monla et al. 2023). This step is essential for understanding the problem space and setting the foundation for application. Subsequently, SSI is conducted to provide depth and context to the research topic by gathering qualitative insights. This method helps in understanding user needs and collecting more specific requirements (Attouri et al. 2022).

Following this, the process involves discussions with experts to further understand and refine the requirements based on their expert knowledge and to validate the findings from the interviews (Attouri et al. 2022). This ensures that the frameworks created are grounded in practical realities and expert insights. With this information, the decision-making tool is developed based on the information gathered from the previous steps. Once developed, the tool is then validated by experts to ensure that it meets the intended requirements and standards before being released.

The last phase, which involves testing in real case study and then comparing the results obtained with the theoretical framework, is planned as a future step to evaluate the effectiveness of the decision-making tool in a practical and theoretical settings. This will provide an opportunity to observe how well the application performs in the real world and to identify any areas for improvement. The work completed thus far includes identifying research gaps, engaging with users and experts, as well as developing and validating the tool, setting a strong foundation for the final testing and implementation phase.

Table 1 Methodology applied in our research: A sequential process CRA to deployment of an efficient decision-making tool.

CRA Steps	Description	Action
1	Choose a practical problem with theoretical basis, focusing on under-analyzed or challenging topics.	SLR method was used to identify gaps and limitations.
2	Form a long-term collaboration with target organizations, establishing a team, funding, data access, and result dissemination agreements.	SSI was applied to provide depth and context to the research topic.
3	Gain thorough practical and theoretical understanding of the subject, analyzing the organization's current situation and theoretical research field background.	
4	Design and develop a theoretical and practical solution, emphasizing innovation and prototype development.	A framework was created, and a tool is being built based on the information gathered from the previous steps.
5	Implement and test the solution within the partner organization, typically through pilot sites.	The developed tool will be reviewed by experts to ensure it meets the intended requirements and standards. The tool is then tested in a real case study and compared with theory.
6	Reflect on the solution's scope and transferability by evaluating the success of test markets and considering broader applications. Then, identify and analyze the study's theoretical contributions and their impact on existing theories.	

To delve into details in applying SLR method, the operation starts by searching for articles related to SBD in the design phase of a construction project. A total of 31 papers between journals and conferences are obtained after filtering through the steps presented in Figure 1 (Schiavi et al. 2022; Xiao and Watson 2019). The process begins at the top with the identification of a collection of keywords, which are then used to conduct a search through Google Scholar and Scopus, resulting in the gathering of 416 papers, encompassing both articles and conference papers.

Following this initial collection, the inclusion and exclusion criteria are applied. This involves filtering the papers by reading their abstracts and titles, which helps to assess their relevance to the research topic. The process also includes eliminating duplicate papers to ensure uniqueness in the review. Additionally, the criteria specify retaining only those papers that are written in English.

After this filtration stage, a thorough reading of the full papers is conducted for the remaining ones to further evaluate their suitability for the review. This in-depth reading helps confirm that each paper contributes valuable information to the research topic. At the end of this process, 31 papers are retained for in-depth analysis and synthesis, indicating a significant reduction from the initial 416 papers, thereby focusing the review on the most relevant and high-quality research available. A deep knowledge in the domain was recognized that aids in identifying gaps and limitations within the SBD.

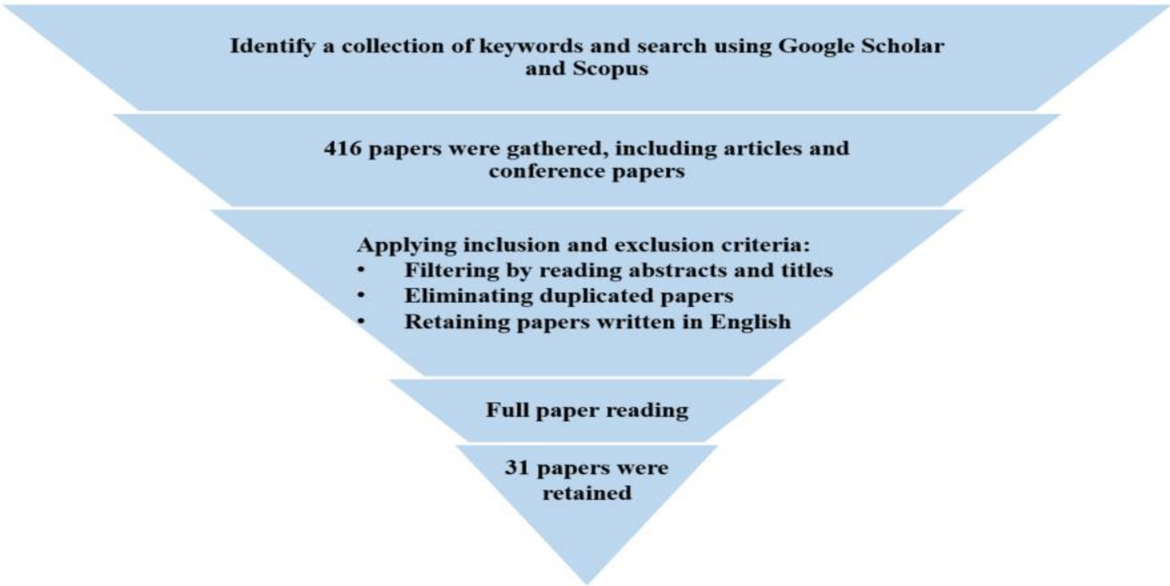

Figure 1 Systematic Literature Review procedure.

Critical limitations in applying SBD for thermal insulation selection in construction were identified: resource intensity, time-consuming analysis of all alternatives, decision complexity, information overload, integration challenges with tools like BIM, and difficulties aligning stakeholders. Therefore, our objective is to create a tool that simplifies the SBD process for thermal engineers by integrating Lean methods with BIM, thereby facilitating more efficient and effective decision-making in the design phase. Additionally, by automatically generating alternatives and selecting the best three solutions, we significantly decrease the time required for the procedure. Moreover, this approach aims to improve project outcomes by ensuring that the chosen insulation materials align with both project goals and environmental standards, such as France’s 2020 Environmental Regulations (RE2020).
