Recognized for its balance of qualitative and quantitative analysis, SSI involved detailed discussions with experts in construction design from both academic and professional backgrounds (Attouri et al. 2022). The selection of the 25 experts for our project focused on their expertise in the AEC field, specifically in Lean and BIM methodologies. This process began by engaging academic researchers to validate our framework, which incorporates Lean methods like SBD, CBA, and the Big Room with BIM, tailored for applications in the thermal field. These researchers, chosen for their contributions to Construction Blogs, International Group for Lean Construction (IGLC) conferences, and other scientific publications, brought a wealth of knowledge, with experience ranging from five to twenty years. Meetings with them were conducted via Teams and face-to-face during scientific events like the IGLC 2023 conference in France and symposiums in Brest. Following this validation phase, we expanded our inquiry to include professionals such as architects and thermal engineers, conducting surveys to delve into the practical challenges and requirements of applying our framework in real-world scenarios. Specifically targeting French thermal engineers ensured the relevance of our findings to the French work environment, with selected experts also well-versed in BIM to closely align with our framework's focus. The insights obtained from these experts are pivotal, not only for completing but also for testing our decision tool in actual case studies, thereby refining our framework's accuracy, ensuring it aligns with industry best practices, and enhancing its potential to improve the design phase of construction projects. Through this rigorous validation and feedback process, our framework has gained credibility and applicability, demonstrating its effectiveness in thermal field applications. The feedback from experts was very positive, indicating that our work is essential and significant.

Table 2 Survey questions assessing the effectiveness of SBD in thermal engineering decision-making.

Number of questions	Questions
1	How effectively do you think the SBD aids decision-making for thermal engineers?
2	How would you rate the framework's ability to tackle the challenges faced in applying SBD in thermal engineering projects?
3	Do you find that the integration of CBA and the Big Room concept significantly improves SBD's application in thermal engineering?
4	How feasible do you consider the application of this framework in practical thermal engineering scenarios?

RESULTS AND DISCUSSION

LEAN METHODS COMBINATION BENEFITS

Table 3 illustrates the integration and impact of SBD, CBA, the Big Room concept, and BIM on the design process. SBD, as introduced by (Lane and Woodman 2000), focuses on delayed decision-making and considers multiple design alternatives to minimize rework and suboptimal outcomes, a concept further refined by (Ballard 2000) through positive and negative iterations. Complementing SBD, CBA, as outlined by (Arroyo and Long 2018), systematically evaluates options based on their advantages, aiding in making more informed decisions. The Big Room concept further enhances this process by fostering collaborative decision-making among all stakeholders in a shared space, ensuring a comprehensive approach to design. Additionally, the synergy of these methods optimizes efficiency, with SBD aligning production to actual demand, CBA prioritizing initiatives for discussion, and the Big Room facilitating multidisciplinary collaboration. Furthermore, BIM's role, emphasized by (Lee et al. 2012b; Lee and Cho 2012), is crucial in supporting SBD through enhanced 3D visualization and data management, enabling rapid evaluation of alternatives and maintaining accuracy throughout the design process. This synthesis is the result of a detailed analysis of the literature conducted in the state-of-the-art phase. It combines insights from various articles we have studied. The table effectively demonstrates how these methodologies, when used together, enhance the design process, making it more targeted, and effective.

Table 3 Lean methods processes and their combination benefits with BIM.

Combining CBA with SBD	Enhancing Decision-Making: Adds structure to SBD's decision-making process. Focusing on Value: Highlights the value and benefits in SBD's design choices. Facilitating Stakeholder Agreement: Helps align stakeholders during the SBD process. Aiding Iterative Refinement: Can be used at various SBD stages for refining design solutions. Resolving Conflicts: Provides clear rationale for choosing solution over another in SBD.
Combining Big Room with SBD and CBA	Fostering Collaboration: Brings stakeholders together for collective decision-making. Providing Immediate Feedback: Speeds up the SBD and CBA processes through instant input. Offering Diverse Insights: Enriches decision-making with varied expertise. Ensuring Transparency: Makes the rationale behind decisions clear to all stakeholders. Facilitating Conflict Resolution: Allows for immediate discussion and resolution of disagreements.
BIM with Lean methods	Enhanced Decision-Making: The combination of BIM, SBD, and CBA facilitates data-driven decisions, optimizing project outcomes by allowing thorough evaluation and comparison of multiple design options. Improved Collaboration: Integrating BIM with the Big Room concept promotes real-time communication and teamwork among all stakeholders, leading to a unified understanding and alignment of project goals. Increased Efficiency: This approach streamlines the design and construction process, reducing rework and modifications by ensuring well-informed, efficient decisions from the start.

OUTCOMES OF SEMI-STRUCTURED INTERVIEWS AND THE DEVELOPMENT OF A DECISION-MAKING TOOL

On the other hand, our SSI, reinforce existing literature while also uncovering new insights specific to the thermal field. These interviews highlighted key motivators for adopting SBD and CBA in thermal projects. These motivators include reducing waste, boosting productivity, shortening project durations, and enhancing decision-making processes. Additionally, the concept of the Big Room, where project stakeholders collaborate closely, emerged as a significant factor in improving project outcomes. In light of these findings, our initial step was to create a framework, which we then refined into a decision-making tool improving the thermal field. This tool, incorporating principles of SBD and CBA, along with the collaborative approach of Big Room and BIM, aims to enhance decision-making in thermal design projects. It is designed to enable better decision-making at the beginning of the design process, resulting in a more efficient assessment of thermal solutions and strategies. By integrating these methodologies, the tool specifically addresses the distinct challenges and demands of thermal engineering. This enables professionals to make well-informed, effective decisions that are align with project objectives and sustainability criteria, while also featuring automated processes to further streamline its use.

Figure 2 demonstrates a comparison between the traditional thermal engineering process and our improved method, which applies our framework. Initially, thermal engineers would manually define parameters, select two solutions, simulate them using thermal software, and then choose the best option.

Our framework applies the Big Room concept, where, using BIM, the thermal engineer, architect, client, and other engineers can identify the project's goals and make suitable decisions. For example, they use the 3D visualization provided by BIM to identify solutions and solve problems. This approach improves communication and collaboration, enabling the team to make the right decisions necessary for advancing the design phase. Then, through coding, SBD is applied to explore all possible alternatives from the Pleiades database and information obtained from IFC files to automatically generating the top three insulation materials that meet the project's objectives and have the best performance. These three solutions are then integrated directly into three different IFC files and connected to Pleiades software for thermal simulation of the building. Subsequently, CBA is used to evaluate and select the best insulation material from these options after analyzing the results from Pleiades. This tool enhances sustainability by selecting insulation materials that meet environmental standards, such as RE2020. Additionally, by testing all possible alternatives, it provides a broader vision for the thermal engineer, aiding in the selection of better insulation materials that may offer superior performance. By applying Lean methods in conjunction with BIM, we create more innovative and efficient thermal design solutions, thus elevating the overall effectiveness of the design phase in construction projects, a key factor in achieving energy efficiency and sustainability in buildings.

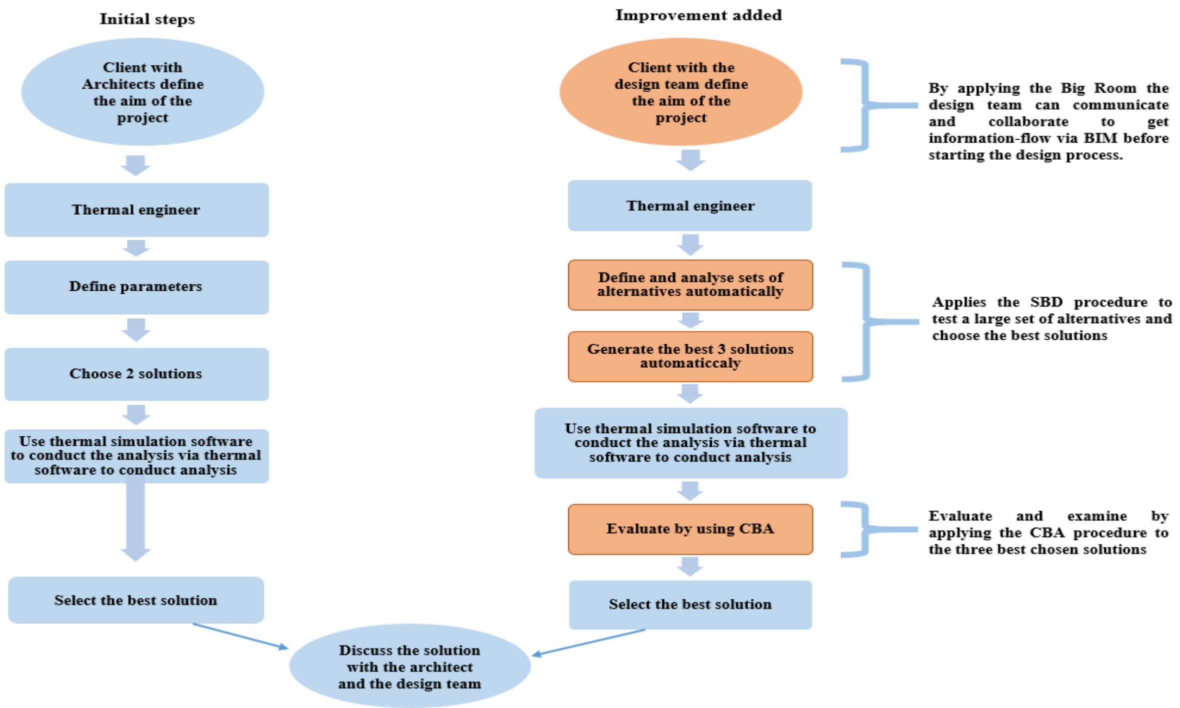

Figure 2 Traditional framework (left) versus Proposed framework (right) (with the orange rectangle indicating the additional value our framework provides).

AUTOMATING PROCESSES USING THE R STUDIO PROGRAM

To delve into the specifics of our work and the creation of the automation process, figure 3 illustrates a flowchart that outlines the procedural code for a thermal engineering application. The process initiates with the crucial step of "Identifying parameters", involving a strategic combination of data from both the Pleiades software and IFC BIM models. This integration of two distinct data sources is essential for accurately identifying relevant attributes and uncovering potential correlations. By leveraging the strengths of Pleiades and IFC BIM, we aim to develop a comprehensive understanding of the parameters that will guide the "Generation of sets of alternatives" for insulation materials. This approach ensures a thorough and nuanced analysis, setting a strong foundation for the subsequent stages of the process. Once these sets are created, the "Start the process" step initiates, where insulation material is selected based on the engineer's criteria.

If the chosen material "Complies with the requirements" such as thermic conductivity, CO2 emission, density… the process returns to generating alternatives, indicating an iterative approach to find the optimal solution. In case of non-compliance, the alternative is discarded, and the results are stored in a database. This phase includes a crucial decision point, "Last alternative?" If the answer is "Yes" the process progresses to "calculating scores for each alternative based on their criteria" followed by a generating of "top 3 solutions".

The flowchart also illustrates a client-server model through the App block, featuring a User Interface (UI) component that interacts with the server to process 'Input' and deliver 'Output'. This suggests that user inputs through the UI initiate server-side processes, which in turn provide outputs back to the client. The "request-response" mechanism between the client and server indicates that the decision-making tool, facilitating dynamic interaction as the server processes data and returns results for display or further analysis. Integrating a decision-making tool is a key part of automating the workflow, thus enhancing the decision-making process in thermal engineering projects.

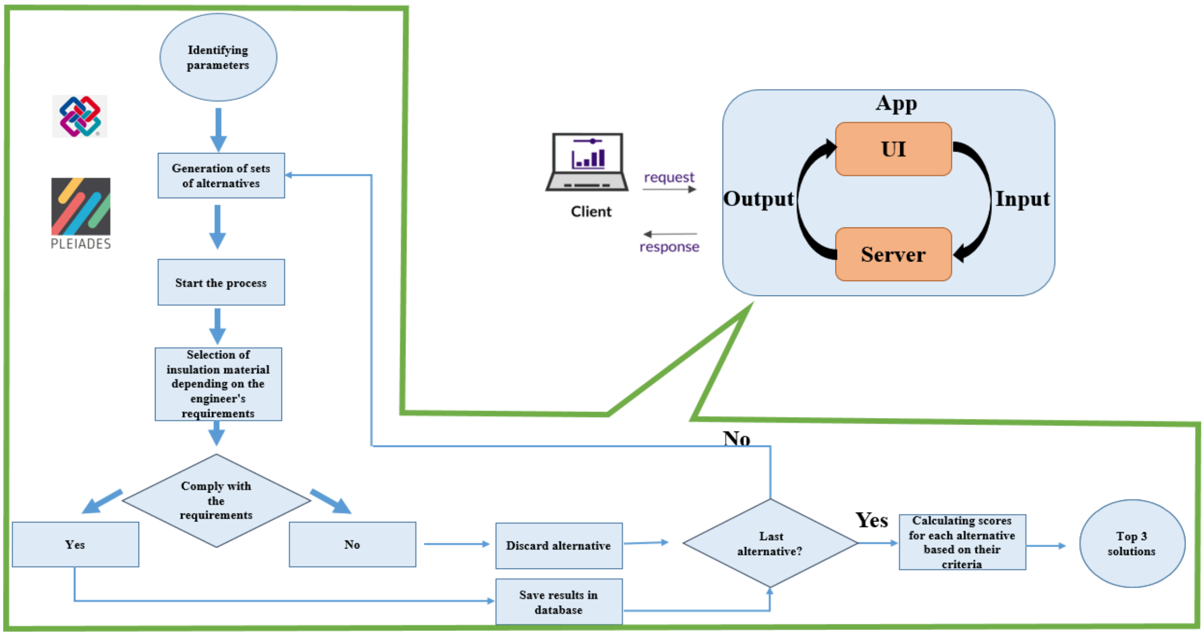

Figure 3 Architecture of decision-making tool for Lean-integrated thermal design process.

In our study, we have demonstrated the feasibility of enhancing the design phase by applying Lean principles with BIM, leading to significant improvements in the thermal engineering process for building design. The results, as illustrated in the figures above, show a clear distinction between the traditional approach and our research framework. Our method leverages automated parameter definition and a comprehensive evaluation of insulation material alternatives, leading to a more effective selection process. This approach, enhanced by the use of a decision-making tool, aligns with digital construction methodologies and provides a structured, streamlined method for thermal engineering. The key improvement is in the decision-making process, where thermal engineers can now evaluate a broader range of options using SBD and CBA techniques, ensuring the selection of the most optimal solution based on multi-criteria analysis. This not only improves the accuracy and consistency of the design process but also significantly reduces manual efforts and time spent on repetitive tasks. The integration of Lean principles with BIM technology in our framework represents a forward step in addressing the challenges of energy efficiency and sustainability in building design, show casing the potential for innovative solutions in the field of thermal engineering.

CONCLUSION AND FURTHER WORKS

In conclusion, this research has established a novel framework that synergizes Lean principles with BIM to optimize the design phase in construction, with a specific focus on thermal engineering. Grounded in comprehensive literature reviews and validated through surveys and semi-structured interviews with industry experts, the framework introduces automation in the generation and evaluation of design alternatives and then choosing the best 3 solutions automatically. This automation, facilitated through a decision-making tool, has demonstrated its effectiveness through its constituent elements in enhancing decision-making, reducing costs, and increasing the value of construction projects. Future work for this article involves completing the coding of the decision-making tool and then testing it in real-case studies. Additionally, applying this tool to other aspects of thermal design will add significant value, especially for HVAC systems, which present challenges in decision-making. This process will ultimately ensure the tool's effectiveness in practical applications.

ACKNOWLEDGEMENTS

The authors would like to thank Brest Métropole for co-funding this study, and Delphine DESGRES for her careful reading of the article.

BIM AND IOT INTEGRATION FOR CONSTRUCTION AND LOGISTICS MANAGEMENT: A STATE-OF-THE-ART REVIEW

Kamyar Fatemifar[1], Qinghao Zeng[2] and Pardis Pishdad[3]

ABSTRACT

Considered a promising avenue for achieving improvements in construction and logistics management, the integration of Building Information Modelling (BIM) and the Internet of Things (IoT) has proposed the ability to revolutionize the Architectural, Engineering, Construction, and Facility Management (AECFM) industry. Many studies have been examining different applications of BIM and IOT integration, specifically within the context of industry 4.0 through recent years. However, the existing literature appears to be fragmented due to the absence of review and categorization, leading to difficulties for practitioners and researchers in identifying trends and gaps. This paper delves into the convergence of BIM and IoT within the field of construction and logistics management by reviewing and categorizing the current cited literature derived from various journals using OpenAlex. On the one hand, the results suggest the utilization of RFID and LoRa for logistics, tracking, and inventory management with BIM and IoT as the most frequent topic. On the other hand, the implementation of BIM and IoT for simulating emergency evacuation scenarios is the least mentioned topic. The main foci within each topic-subcategory are also highlighted and described respectively.

KEYWORDS

Building Information Modeling, Internet of Things, Construction Management, Logistics Management

INTRODUCTION

Nowadays, we are witnessing a significant improvement in the productivity of several industrial sectors as the outcome of digitization. As a result of this promising outcome, the utilization of digital tools to design, build, and operate buildings and infrastructure assets is also becoming a common practice in the Architecture, Engineering, Construction, and Facility Management (AECFM) industry (Borrmann et al., 2018). To address the new challenges originated by the change of practice as an outcome of digitalization, Building information modeling (BIM) offers a model-centric information storage and distribution approach for construction projects, similar to other model-based product development approaches in many other industries (Kagermann, 2015). Additionally, the Internet of Things (IoT) is another industry 4.0 concept gaining more

attention from practitioners by the day, based on the Global Standards Initiative (GSI) recommendation for the Internet of Things, IoT has been defined as the global infrastructure for the information exchange network that can facilitate the interconnecting physical and virtual assets (things) based on communication protocols such as the Radio-Frequency Identification RFID, Wireless Sensor Network technologies, Low Energy Bluetooth, and other developing protocols (Bayani et al., 2017). In other words, IOT provides a standard platform and a unified language for IOT-enabled devices to exchange information and communicate with each other and with external networks. IoT contributes to a variety of aspects within the AEC industry with instances such as smart user-centric environmental quality adjustment or energy consumption optimization using IoT-enabled components for building systems. Utilization of IoT for tracking products, assets, and materials in various stages of procurement for construction projects would have considerable effects on efficient delivery and waste reduction through improved management and coordination of construction projects consequently, the use of IoT and BIM for tracking and logistics optimization is an instance of lean construction approach in practice (Dave et al., 2016). The utilization of BIM and IoT for procurement and progress tracking is an example of how integrating product-centric information models and IoT technology can address the challenges with supply chain automation and logistics optimization in lean construction (Araújo et al., 2021).

The convergence of BIM and the Internet of Things (IoT) holds a huge potential to revolutionize construction and logistics management (Dilakshan et al., 2021; Khurshid et al., 2023). Numerous studies have highlighted the significant achievements in the integration of IoT with BIM or other centralized information management approaches. For instance, Chow et al. (2006) introduced a resource management system for warehouse operations using RFID technology, emphasizing efficient resource allocation and real-time management. Adiono et al. (2017) introduced a rapid Warehouse Management System (WMS) utilizing Radio-Frequency Identification (RFID) as a means of information exchange for inventory reporting management, demonstrating the efficiency-enhancing capabilities of IoT in inventory management. Biswal et al. (2018) extended this concept to consumables supply chains in India, emphasizing the potential of IoT in enhancing distribution logistics. Given the diverse aspects by which BIM and IOT integration contribute to construction management and logistics optimization, a growing interest in research in this field can be observed (see Figure 3). Despite this trend, the existing literature related to BIM and IoT integration is fragmented leading to difficulties for practitioners and researchers in identifying research trends and potential gaps. Additionally, few papers have focused on providing specific focal categories towards BIM and IoT integration for construction and logistics management context. Therefore, in terms of research goals, this research aims to identify potential research gaps by systematic categorization and review of the state-of-the-art research foci on BIM and IoT integration in the context of construction and logistics management. The contribution for this research is providing a valuable resource for practitioners and researchers interested in this field.

RESEARCH METHODOLOGY

The methodology selected for this research is literature review, which involves systematic examination and synthesis of existing literature on a specific topic. The initial inspiration for the research methodology comes from the scoping review framework (Arksey & O'Malley, 2005). Unlike the expansive nature of scoping reviews, the state-of-the-art review in this study reflects a deliberate focus on providing the latest and comprehensive understanding of BIM and IoT in construction and logistics management. This research prioritizes a more detailed exploration of recent literature, aiming to capture the dynamic trends, challenges, and opportunities in this evolving field.

By applying the state-of-the-art review methodology, detailed procedures conducted in this study are displayed (see **Error! Reference source not found.**).

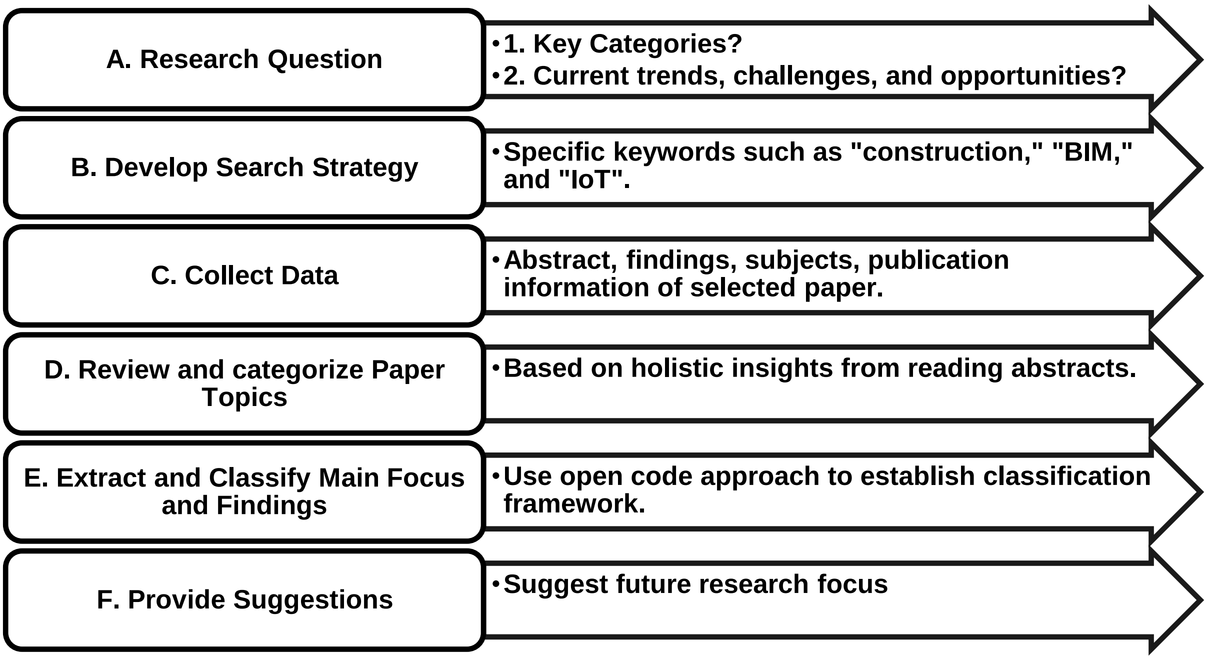

Figure 1: Process Flow Demonstrating Research Methodology

The research goals for this paper are (1) to systematically categorize and review the existing literature on the combined use of BIM and IoT in construction management logistics, (2) to identify research gaps and areas where further improvements and innovation are needed, and (3) to provide a valuable resource for practitioners and researchers interested in this field. Considering these goals, this paper is going to find answers to the following questions: What are the key categories of research for BIM and IoT implementations in construction and logistics management? What are the current trends, challenges, and opportunities for future research in this field?

After research goals and questions are determined, comes the selection of the reference database. Considered a user-friendly interface with various functions for researchers, OpenAlex is one of the free research databases that enable interactive filtering with organized and structured data, allowing researchers to identify and export query results for research.

As for the inclusion and exclusion criteria, all indexed papers in the Open Alex database are tagged with multiple concepts, based on the title, abstract, and available text. An automated classifier algorithm trained on the Microsoft Academic Graph (MAG) database serves as the tagging tool for the articles. The tags provided by Open Alex, which are named "concepts," in this paper are listed as "Building information modeling," "Internet of Things," "Scheduling (production processes)", "Engineering management", and "Operations management". (see Figure 2). Considering that the scope of research is limited by BIM, IOT, and Management adding the term "Logistics" to the inclusion criteria resulted in the removal of a sizable portion of citations from the literature. The research team decided not to include this term because adding it to the filters would have resulted in the omission of many studies with relation to construction logistics that didn't necessarily use the term logistics in their subjects and abstracts. Consequently, a wider range of subjects was evaluated, and the additional unrelated works were filtered out of the literature during the abstract review based on the qualitative judgment of the researchers.

Figure 2 Inclusion and Exclusion Criteria for OpenAlex

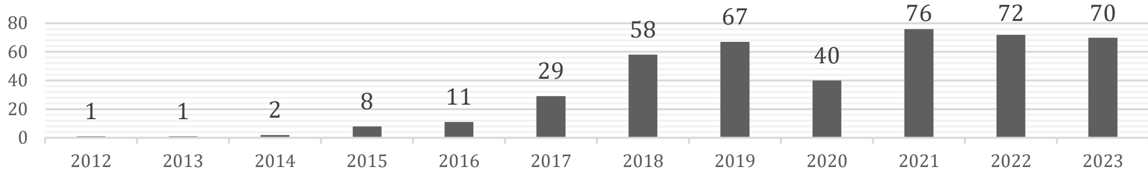

Figure 3: Publications by year including all English-published articles with BIM & IOT & Construction in the title, abstract, text, or concept (report from Open Alex)

Using the inclusion and exclusion criteria mentioned above, here are the search results demonstrating the number of publications (see Figure 3). As shown in the diagram, a significant increase in terms of the publication numbers occurred in 2015. Consequently, the publication time duration is limited from 2015 to 2023. Also, considering citation counts as a quality assessment of peer-reviewed publications, articles without citations were removed from the dataset.

While creating the categories for the articles, a rigorous method is employed to systematically organize and categorize the diverse information. The initial step involves assembling a spreadsheet dataset that encompasses articles associated with specific article IDs and corresponding bibliographical data including topics, summary of focus, and findings. After removing out-of-scope search results, reports, and duplicate items from the data, which consists of 404 papers, seventy-six articles with citations are chosen for full-text review. In the next stage, similarities among different topics and focus points of the articles are identified and the foundation for summarizing the common subject is established. Each article is assigned to only one category and subcategory.

Finally, an iterative categorization approach is implemented, where articles are initially grouped based on shared characteristics and subsequently refined to eliminate redundancies and ensure coherence. Using the open coding method (Cho & Lee, 2014), the categories are named thematically to encapsulate the subjects they represent, and the entire process is thoroughly documented for transparency and reproducibility. The results capture the diverse facets of the BIM and IoT implementations in construction and logistics management within the context of the Architectural, Engineering, Construction, and facility management (AECFM) industry.

LITERATURE REVIEW

As a result of the full-text review and open coding, this section discusses the categorization of literature based on areas of focus that emerge from the exploration of research papers with combined implementations of BIM and IoT in construction logistics and management (see **Error! Reference source not found.** and Figure 4). Categories and subcategories are proposed, based on specific applications and multifaceted ways in which BIM and IoT integration interact with various aspects of the construction and logistics management areas. In the following paragraphs, the logic behind categories and subcategories are explained respectively with additional examples provided from the literature. At this point, it is necessary to clarify that the categorization is merely the result of an open coding process and qualitative thematic analysis of studies by the authors. Furthermore, to provide future researchers with additional dimensions for potential gap spotting, The research topics were also categorized based on thematic connections with established classifications such as project management body of knowledge PMBOK (Project Management Institute, 2017) knowledge areas Each knowledge area represents a distinct domain of knowledge and practice within the broader discipline of project management. By breaking down project management into these specific areas, the PMBOK Guide facilitates a structured approach to understanding and managing projects. This approach allows project managers to focus on key aspects such as scope, time, cost, quality, human resources, communication, risk, procurement, and stakeholder engagement, ensuring comprehensive coverage and effective management throughout the project lifecycle. Additionally, the studies within each subcategory were also tagged based on topic relationships with common building lifecycle phases. The primary phases utilized for categorization purposes are Pre-construction (I), Construction (II), and Operation/Maintenance (III), Additionally, it is necessary to consider that in some cases the integrated implementation of BIM and IoT addresses the Entire building Lifecycle (IV) of buildings.

Table 1 Classification of Literature for BIM and IoT Implementations

Category	Sub-Category	Area of Focus	Phase	PMBOK Knowledge Area	References
Implementation and examination of New Technologies with the help of BIM and IoT	Cognitive Technologies	Operation and Maintenace Monitoring	III	Quality	(Santarelli et al., 2019; J. Xu, Lu, & Li, 2019; J. Xu, Lu, Xue, et al., 2019)
	Prefab and Manufacturing	Prefabrication, Supply Chain	I	Resource	(Wang, Altaf, et al., 2020; Wang, Wang, et al., 2020)
	Big Data	Estimation and Predictive maintenance	III	Cost	(Chu et al., 2021; Halmetoja, 2019)
	Distributed construction	Novel Offsite Construction Approaches	II	Time	(Dallasega et al., 2018; Pang et al., 2019)
	Digital Twin Applications in construction and maintenance	Procurement & Interactive Coordination of resources in Construction and Operation	III	Procurement	(Esmaeili & Simeone, 2023; Liu et al., 2023; Peladarinos et al., 2023; Rezaei et al., 2023; Rossi et al., 2019; Sepasgozar, 2021)
	Smart Building Systems	System Monitoring & Inspection	III	Integration	(Afzaal & Shoaib, 2021; Cantarero et al., 2018; Rahman et al., 2020; Vivi et al., 2019)
Integration/Optimization of information with the help of BIM and IoT	Blockchain & BIM Integration	Model-Based Traceability of Changes	IV	Scope	(Chung et al., 2022; De La Pena & Papadonikolaki, 2019; Fitriawijaya et al., 2019; Lu et al., 2021)
	Digital Twins & IoT Integration	Model-Based Real-Time Tracking and Procurement	IV	Procurement	(Chang et al., 2018; Esmaeili & Simeone, 2023; Nath, 2022; Tang et al., 2019)
	BIM Adoption Challenges Within Industry 4.0	Seamless Flow of Information	IV	Integration	(Al-Sinan et al., 2023; Begić et al., 2022; Mahajan, 2022; Yilmaz et al., 2023)
	BIM Adoption in Developing Countries	Process Implementation	IV	Integration	(Dosumu et al., 2023; Maqbool et al., 2023)
	BIM for Facility Management	Model-Based System Monitoring & Inspection	III	Integration	(Kameli et al., 2020; Lauria & Azzalin, 2023; Moreno et al., 2022)

Table 2 (continued) Classification of Literature for BIM and IoT Implementations

Category	Sub-Category	Area of Focus	Phase	PMBOK Knowledge Area	References
Construction Safety With BIM and IoT	Safety & Emergency Management	Safety For Workers and Equipment	II	Risk	(Park et al., 2018; Ribeiro et al., 2022; Sassi et al., 2022)
	Emergency Evacuation	Simulation Of Disaster Response	III	Risk	(Birajdar et al., 2020)
Construction Logistics and Transportation Optimization With BIM and IoT	IoT in Parts Transportation	Procurement Tracking	II	Resources	(Ben Neila et al., 2021; Sepasgozar et al., 2019; Tazikova & Struková, 2021; Treiblmaier et al., 2020; G. Xu et al., 2019)
	RFID and LoRa (long-range, low-power data transmission)	Procurement Tracking	II	Procurement	(Dervishaj et al., 2023; Gaba et al., 2018; Juraboev & Díaz, 2024; Kameli et al., 2020; Ragnoli et al., 2022; Teizer et al., 2018)
	Information and Communication Technologies (ICT)	Management Information System	IV	Communications	(Hammad et al., 2021; Li et al., 2022)
	AI & Supply Chain Innovations	Coordination In Distributed Construction	III	Resource	(Orooje & Latifi, 2021; Tien et al., 2022; Villa et al., 2022)
Facilitating User Comfort	Occupant Feedback & Digital Twins	Improve Occupants' Satisfaction	III	Stakeholder	(Dave et al., 2018; Donkers et al., 2022; Mao et al., 2018; Stojanovic et al., 2019; Su & Kensek, 2021)
Sustainability With BIM and IOT	Circular Economy in Construction	Sustainable Waste Management Solutions	III	Integration	(Batista et al., 2022; Sassanelli et al., 2021; Tao et al., 2018)
	Sustainable Construction Practices	Sustainable Construction Solutions	II	Integration	(Ben Neila et al., 2021; Klymenko et al., 2021; Mao et al., 2018; Petschen et al., 2023; You et al., 2020)

Within the category of "New Technologies", the sub-category of Cognitive Technologies (J. Xu, Lu, & Li, 2019; J. Xu, Lu, Xue, et al., 2019), is about the utilization of cognitive IoT and digital twins for efficient facilities management. Prefabrication and Manufacturing Technologies, (Wang, Altaf, et al., 2020; Wang, Wang, et al., 2020), is about BIM and IoT for real-time data synthesis, optimizing off-site construction processes. Other subcategories include the integration of Big Data with BIM and IoT for improved facility management (Chu et al., 2021; Halmetoja, 2019). Distributed Construction (Dallasega et al., 2018; Pang et al., 2019), which holds the studies on BIM and IoT for real-time logistics planning and monitoring, contributes to distributed construction. Digital Twin Applications (Esmaeili & Simeone, 2023; Peladarinos et al., 2023; Rossi et al., 2019), showcases reduced costs and improved efficiency of construction management through BIM and IoT integration. Finally, Smart Building Systems, presented in articles (Cantarero et al., 2018; Rahman et al., 2020), propose building system architectures with IoT, utilizing BIM.

The category of "Integration/Optimization," is about the utilization of BIM and IoT to facilitate collaboration and integration, especially within the context of construction management. Blockchain & BIM Integration sub-category (Chung et al., 2022; Fitriawijaya et al., 2019; Lu et al., 2021), contains references proposing transparency and traceability in supply chain management, ensuring accurate digital representation and enhancing trust with information exchange platforms. Digital Twins & IoT Integration (Chang et al., 2018; Esmaeili & Simeone, 2023; Tang et al., 2019), focuses on real-time data gathering, reducing costs and enhancing decision-making through the integration of BIM and IoT with digital twins.

The sub-category of BIM Adoption Challenges Within Industry 4.0, (Begić et al., 2022; Mahajan, 2022; Yilmaz et al., 2023), assesses digitalization and automation across construction project life-cycle phases, emphasizing the impact of technologies like BIM and IoT on the future of construction and the adoption challenges within the context industries already embracing initial BIM adoption stages. On the other hand, the subcategories of BIM Adoption in Developing Countries, (Dosumu et al., 2023; Maqbool et al., 2023), delves into challenges such as network infrastructure, standardization, and interoperability with implementing BIM in developing countries, recommending awareness and policy enactment. BIM for Facility Management sub-category, (Kameli et al., 2020; Lauria & Azzalin, 2023), contains various integrations of BIM and IOT specifically with RFID as a means of tracking and information exchange, for optimizing building maintenance.

Moreover, the category of safety is divided into two main sub-categories “Emergency management” and “Emergency evacuation,” where BIM and IoT are employed for simulation and management of user safety or critical circumstances. Safety & Emergency Management (Park et al., 2018; Ribeiro et al., 2022; Sassi et al., 2022), introduces BIM-based systems for disaster management, explores immersive visual technologies for safety training, and reviews emerging technologies for health and safety standards. Emergency Evacuation (Birajdar et al., 2020), reviews recent advancements in building fire detection and evacuation systems, emphasizing the role of BIM and IOT in enhancing safety protocols and simulation of immediate disaster response.

The category of “Logistics” explores the potential of BIM and IoT in Parts and Transportation management for construction. With parts transportation sub-category proposing cloud-based fleet management platforms and investigating the potentials of the Physical Internet for sustainable logistics networks (Ben Neila et al., 2021; G. Xu et al., 2019); RFID and LoRa technologies integrated with BIM models for efficient asset tracking, real-time monitoring, and location sensing in construction logistics (Gaba et al., 2018; Idrissi Gartoumi & Koumetio Tékouabou, 2023; Juraboev & Díaz, 2024; Kameli et al., 2020; Ragnoli et al., 2022); Information and Communication Technology (ICT), including studies defining BIM-based and IoT enabled information exchange platforms in the construction industry(Hammad et al., 2021; Li et al., 2022); And artificial intelligence Supply Chain Innovations category, (Orooje & Latifi, 2021), which reviews the integration of AI in BIM-IoT for healthcare facility maintenance management, emphasizing the transformative impact of technology on supply chain operations.

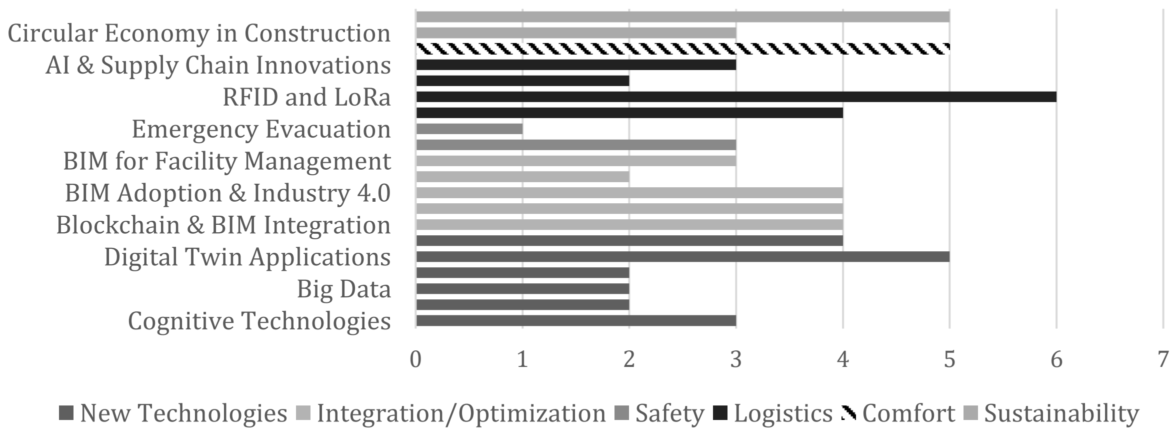

Figure 4: Categorization of Research Focus

The "Comfort" category is addressed through the interaction of IoT-enabled Occupant Feedback & Digital Twins, focusing on comprehensive building lifecycle management. Through the integration of real-world data, IoT sensors, and predictive models using BIM and BIM-Asset Management (BIM-AM) systems papers within this subcategory have implemented BIM and IOT to optimize air quality, enhance energy efficiency, improve building performance, and occupant comfort. (Dave et al., 2018; Donkers et al., 2022; Mao et al., 2018; Stojanovic et al., 2019; Su & Kensek, 2021)

"Sustainability" in construction is explored through two sub-categories of Circular Economy in Construction/Facility Management and Sustainable Construction Practices. Circular Economy in the built environment sub-category (Batista et al., 2022; Sassanelli et al., 2021; Tao et al., 2018), is more inclined toward the operation and maintenance phase, encompasses studies utilizing BIM-enabled simulation approaches for demolishing and disassembly processes, proposing real-time greenhouse gas emission monitoring systems using BIM and IOT, and integrating BIM-IoT-FM for sustainable water consumption. Sustainable Construction Practices, however, are about sustainability concerns in the earlier procurement and construction phases of buildings. This subcategory is also examined by studies investigating the potentials of the Physical Internet (PI) for sustainable logistics networks (Ben Neila et al., 2021); By proposing an informatization scheme for real-time monitoring of illegal behaviors in Construction and Demolition (C&D) waste disposal (You et al., 2020); and finally through the examination of the role of digitalization in manufacturing companies' sustainability-accounting framework, promoting sustainability in the corporate strategic decision making (Klymenko et al., 2021).

Figure 5 demonstrates the categorization of the article focus areas based on project management body of knowledge (PMBOK) knowledge areas, and their relationship with the provided themes of BIM and IoT applications in construction (see **Error! Reference source not found.**).

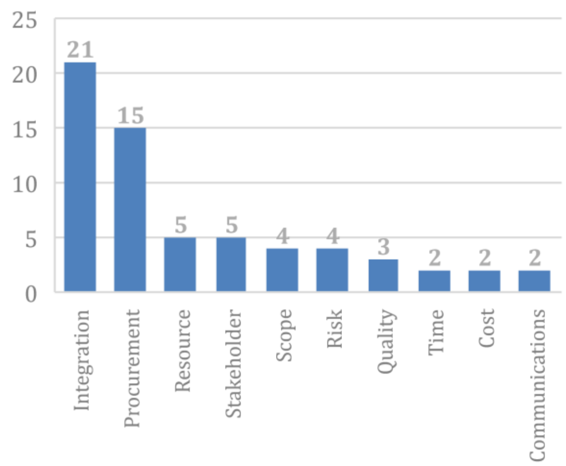

Figure 5: Number of references related to project management knowledge areas

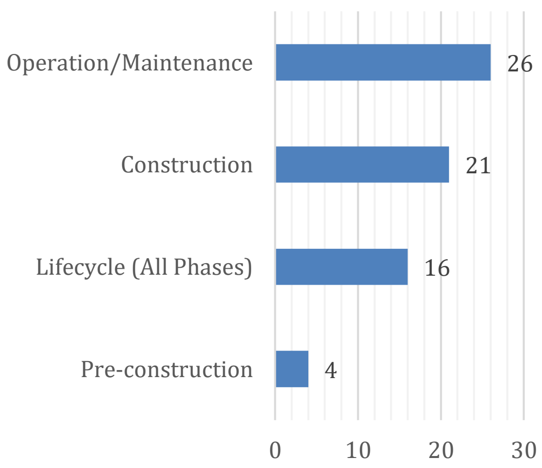

Figure 6: Analysing the number of references based on relation to construction phases

The distribution of articles across different phases of the project lifecycle (see Figure 6) reveals a comprehensive exploration of the synergies between Building Information Modeling (BIM) and the Internet of Things (IoT). The emphasis on the Operation/Maintenance phase, with the most articles, underscores a keen interest in leveraging BIM and IoT for sustained facility performance and efficiency. This phase represents a recognition of the long-term transformative impact of these technologies in ensuring optimal operational conditions and streamlined maintenance practices.

CONCLUSION

The examination of literature across various categories and subcategories within the scope of this research sheds light on key areas where the integration of BIM and IoT has been extensively explored. Notably, the utilization of “RFID and LoRa” for procurement tracking and construction logistics emerges as a well-explored area with a total of six references. These articles delve into the integration of BIM and IoT for real-time tracking and procurement, emphasizing its potential to enhance procurement and inventory tracking processes. Conversely, the “Emergency Evacuation” subcategory stands out as the least explored, with only one reference addressing the simulation of disaster response. This gap highlights a potential need for more research into innovative strategies leveraging BIM and IoT to improve emergency evacuation plans, ensuring the safety of users and equipment during unforeseen catastrophic events. Additionally, the “Distributed Construction” subcategory, within novel construction techniques, is also among the topics with few references highlighting the need for further exploration. Future researchers are encouraged to delve into these less-explored domains to contribute nuanced insights and innovative solutions, fostering a more comprehensive understanding of the challenges and opportunities in the integration of BIM and IoT in the construction and logistics industry.

The distribution of articles within project management knowledge areas suggests a substantial interest in understanding and enhancing project integration, with emphasis on Procurement, Stakeholder, and Resource aspects. The prevalence of articles in these subcategories indicates a recognition of their critical role in the successful implementation of BIM and IOT. Future research in this field could further explore innovative integration strategies, while paying more attention to less-represented areas such as Time, Cost, Communications, and Risk. Additionally, exploring the interplay between different knowledge areas while considering the effects of BIM and IoT integration would be valuable for advancing project management practices in the construction industry.

Additionally, the substantial focus on the Operation/Maintenance phase highlights the long-term benefits of BIM and IoT integration in the entire lifecycle efficiency of construction projects. While the Pre-construction phase features the least number of articles, its inclusion underscores the acknowledgment of early-stage planning and conceptualization as foundational to successful BIM and IoT integration. This holistic approach reinforces the transformative potential of BIM and IoT throughout every stage of construction, from project inception to ongoing facility management.

LIMITATIONS AND SUGGESTIONS FOR FUTURE RESEARCH

It is necessary to consider that the lack of research on BIM and IoT integration within any of the mentioned research areas in the conclusion section might be affected by other factors such as lack of potential for improvements or technical barriers however these factors are not examined and are excluded from the scope of this research.

Another limitation of this research originates from the limitations of scope. Although the provided categorization may be subject to updates and improvement in future studies, the intention here is to create a foundation for future reviews to build upon.

The aim of this study is merely to reflect and compare the literature within the context of proposed categories that are coming from open coding and exploration of the main focus for each reference to identify and suggest the potential gaps based on the provided results.

Considering the limitations of the number of articles included in this review, changing the initial search keywords and concepts might result in a more generalized categorization. Additionally, future researchers can include other factors such as research methodology and sample and demography information along with limitations suggestions, and implementations of each reference during the initial data collection phase to improve the generalizability of the results.

AN ONTOLOGY FOR REPRESENTING CRAWLER CRANE OPERATIONAL SPACE REQUIREMENT ON SEMANTIC WEB

Ajay Kumar Agrawal[1], Yang Zou[2], Long Chen[3], Hongyu Jin[4] and Mohammed Adel Abdelmegid[5]

ABSTRACT

Lookahead planning incorporates checking and removing operational constraints to develop achievable plans. The manual constraint-checking process is arduous because (1) Construction constraints are dynamic due to constantly changing project conditions, and (2) The information concerning constraints, e.g., attributes and status, are dispersed across heterogeneous databases. While semantic web technology has been used to automate constraint-checking and address these issues, space constraints, e.g., space needed for resource operation, have often been ignored. Cranes are crucial construction resources, necessitating checking of associated space constraints for developing constraint-free lookahead plans. Representing crane operational space requirements on the semantic web should be the first step for such checking. However, existing ontologies cannot do so.

This study aims to develop a Crane Space Representation Ontology (CSRO) to represent different components of the operational space of a crawler crane with a lattice boom. Built using Ontology Development 101 methodology, CSRO includes four classes, 19 subclasses, nine object properties, and seven datatype properties, representing crane operational space with diverse geometries like bounding box, cylinder, and cone. Automated consistency checking and task-based evaluation confirm the CSRO's consistency and effectiveness in addressing the competency questions regarding various aspects of space requirements for crane operation.

KEYWORDS

Last Planner® System, Lookahead Planning, Constraint Analysis, Semantic Web, Crawler Crane.

INTRODUCTION

Lookahead Planning (LAP) is a key stage in the Last Planner® System (LPS) (Ballard, 2000). It consists of three steps, i.e., task breakdown (breaking down the work processes into operations), constraint management (identification, checking, and removal of constraints associated with the operations), and design of operations (scheduling the operations according

to constraint status) (Hamzeh et al., 2012). Effective constraint management is crucial for continuous workflow, improved task preparation, and schedule adherence on construction projects (Lagos & Alarcón, 2021). However, constraint management lacks appropriate implementation (Dave et al., 2015) due to the complexity and dynamic nature of construction projects (Soman et al., 2020). To this end, attempts have been made to utilize automated data-driven approaches to support constraint management, such as semi-automated constraint identification (Zaeri et al., 2017), tracking the status of constraints (Xiao et al., 2021), and constraint checking in the schedules (Soman et al., 2020).

Constraint checking is the process of checking if the prerequisites for the scheduled activities are complete, which is critical to ensure that only achievable activities are committed (Soman et al., 2020). Most existing automated constraint-checking approaches related to schedules do not apply to the LAP process. These studies usually utilize Building Information Models (BIM) and construction schedules as the main sources of information for rule checking (Ji & Leite, 2018). However, the situations in construction projects are everchanging, and such dynamically changing constraint information is distributed in heterogeneous databases with different stakeholders (Soman et al., 2020), resulting in BIM being an insufficient source of information for constraint checking. To this end, Soman et al. (2020) developed a linked data based constraint checking system. Linked data offers an opportunity to connect cross-domain data in a machine-readable manner and make logical inferences from it (Pauwels, Zhang, et al., 2017). However, they fell short in checking space-related constraints, such as safety and site layout, which are essential in lean construction (Ballard, 2000).

Checking and removing space constraints in LAP is crucial for the seamless execution of construction projects to eliminate or minimize the waste of resources (Akinci et al., 2002). Different types of space-related constraints can be found on construction projects, including space requirements for working of resources, storing materials, and installing temporary facilities on site. Cranes are crucial for space constraint checking perspective in construction, as many activities rely on them for material lifting and transfer. Further, cranes have very high monetary implications on the overall project cost, necessitating their efficient use (Aghajamali et al., 2023). Thus, checking space constraints related to operations involving cranes is essential for generating reliable lookahead schedules. Similar to other constraints, the existing efforts towards checking such space constraints related to cranes mainly utilized 3D models and centralized databases as primary sources of information (Aghajamali et al., 2023). Further, such approaches failed to incorporate the dynamics of construction sites quickly (Hussein & Zayed, 2021), restricting their applicability in LAP.

Linked data facilitates addressing this gap by semantically interlinking heterogeneous datasets such as-built data collected using automated data collection technologies, BIM models, constraint information, and construction schedules to perform constraint checking. Performing such constraint checking requires all the information to be represented on the semantic web (Soman et al., 2020) with the help of ontologies. According to Gruber (1995), an ontology is *"an explicit specification of a conceptualization"*. It provides a way to formally describe the knowledge in a domain using concepts and their relationships. Several ontologies exist in the construction domain that can represent information, such as schedules (Farghaly et al., 2024), building topology (Rasmussen et al., 2021), and product-related information (Wagner et al., 2022). However, existing ontologies cannot represent the information related to the detailed operational space requirements of the cranes. This creates a bottleneck in performing linked data based space constraint-checking of crane-dependent operations in lookahead schedules.

To address this gap, this study aims to develop a Crane Space Representation Ontology (CSRO) to represent the space required by a crane to perform its lifting operation in a construction project. The scope of this study is limited to mobile crawler cranes with lattice booms, as they are commonly used in construction projects (Aghajamali et al., 2023).

LITERATURE REVIEW

SEMANTIC WEB AND LINKED DATA IN CONSTRUCTION

The semantic web is a transformation from the web of documents to the web of data, where the data is represented in a semantically interlinked and machine-readable manner (Berners-Lee et al., 2001). Linked data is a set of principles for representing the data on the semantic web in the form of subject-predicate-object triples.

Owing to the potential of semantic web technology to improve data interoperability, it has been extensively adopted in requirement checking from heterogeneous data. Pauwels, Van Deursen, et al. (2011) used the semantic web to check the acoustic performance regulations on building data. Fitkau & Hartmann (2024) checked safety regulations using the semantic web. However, limited attention has been given to checking the constraints that can prevent construction activities from being executed. Cao et al. (2022) developed an approach to check constraints related to the manufacturability of prefabricated components, such as resource availability, space availability, and lead time. However, they did not consider constraints related to space requirements for the operations of construction equipment. Soman et al. (2020) utilized linked data to check various constraints in lookahead schedules, such as cardinality, resource availability, and precedence. However, they used ifcOWL ontology (an ontology to represent Industry Foundation Class (IFC) data schema in Web Ontology Language (OWL)) to represent site and schedule data, which, is not well suited for performing reasoning on geometric data (Pauwels, Krijnen, et al., 2017).

ONTOLOGIES FOR REPRESENTING CONSTRUCTION SITE ELEMENTS

Ontologies act as the foundation over which the semantic web technology is built. They provide a common understanding of a domain, supporting interoperability between different applications (Farghaly et al., 2024). Ontologies are built using components such as classes, subclasses, and properties. Classes represent a collection of entities having common characteristics. Classes may contain subclasses, which represent more specific entities than classes and inherit the characteristics from classes. Properties provide additional information about the classes to furnish a complete description of intended knowledge (Noy & McGuinness, 2001). Several ontologies have been proposed to represent construction site-related data on the semantic web.

Being fundamentally based on IFC, ifcOWL is limited to the constructs defined in IFC. The Building Topology Ontology (BOT) is a domain ontology used to represent the topological relationships between building components (Rasmussen et al., 2021). The BIM Shared Ontology (BIMSO) represents BIM data related to buildings, which can be used for developing domain-specific ontologies such as design and scheduling (Niknam & Karshenas, 2017). The Building Product Ontology (BPO) focuses on describing singular instances of products that can be part of the building (Wagner et al., 2022). The Digital Construction Ontologies (DiCon) support formally representing and integrating the information related to construction workflow (Zheng et al., 2021). DiCon comprises an 'entity' module related to construction site elements such as equipment. Several ontologies facilitate safety regulation checking in construction, by representing site elements like equipment, materials, and personnel (Li et al., 2022).

The utility of the above-mentioned ontologies for performing space constraint checking related to cranes is limited for two reasons: (1) Only a few of the above-mentioned ontologies have classes, like construction equipment, that can be instantiated with construction cranes. (2) These studies addressed construction equipment at a general level, where the representation of the space occupied by construction equipment on a site was limited to a bounding box covering the entire equipment in a fixed orientation. However, the operations of crawler cranes on construction sites are complex. They involve changing boom length, rotation of boom, rotation of mast, rotation of the main body, rotation of counterweights, possible rotation of the lifted object, and space required for outriggers, among others (Aghajamali et al., 2023; Olearczyk et al., 2014). Therefore, a new ontology is needed to perform accurate linked data based space constraint checking of operations involving cranes, which should consider different components of the space required by cranes to operate. To this end, this study develops CSRO to represent the space requirement of mobile crawler crane operations.

ONTOLOGY DEVELOPMENT METHODOLOGY

Ontology Development 101 (Noy & McGuinness, 2001) was utilized to guide the development of CSRO ontology. This methodology was selected because of its simplicity and feasibility to be used by inexperienced ontology designers (Noy & McGuinness, 2001), and its widespread use in the construction sector (Wu et al., 2021). This study utilizes the Protégé system, a widely used open-source environment for developing, storing, and maintaining the CSRO ontology. The ontology development was done by following the below-mentioned seven steps as described in Ontology Development 101. These steps include determining the domain and scope of the ontology, exploring the reusing existing ontologies, identifying important terms in the ontology, determining classes and class hierarchy, defining the properties associated with the classes, defining the facets of the properties, and creating instances.

CRANE SPACE REPRESENTATION ONTOLOGY

This section discusses the development of CSRO through the seven steps of Ontology Development 101.

STEP 1: DETERMINE THE DOMAIN AND SCOPE OF THE ONTOLOGY

Firstly, the ontology's scope, intended uses, end-users, and domain were determined. It was performed by answering the following fundamental questions within the context of this research (Noy & McGuinness, 2001):

1. What is the domain that ontology will cover?
   In this research, the representation of a mobile crawler crane's operational space requirement on a construction site is the domain of the CSRO ontology.

2. What is the purpose of the ontology?
   The CSRO ontology will be used to represent a crawler crane's space requirements in the context of a semantic web representation of a construction site, thus supporting space constraint checking for operations involving cranes on construction sites.

3. Who are the intended users and maintainers of the ontology?
   The end users of the CSRO ontology are construction planners involved in the lookahead scheduling of operations on construction projects.

4. What are the competency questions for the ontology?
   The competency questions are a set of questions that the knowledge base based on the ontology should be able to answer (Noy & McGuinness, 2001). To develop the competency questions for CSRO ontology, literature related to mobile crawler crane planning was reviewed. The literature included academic publications, textbooks, and practitioners' guides related to mobile crawler cranes. The objective of the review was to identify the different components of the space requirement for the operation of the mobile crawler crane. The following competency questions were formulated for the development of CSRO ontology:

CQ1: What is the space required to place the crane at a particular location?
CQ2: What is the space required for the rotation of crane components such as the main body, boom, and counterweights of the crane?
CQ3: What is the space required for crane outriggers to be extended?
CQ4: What is the space required for the object to be lifted and its rotation while lifting?

STEP 2: CONSIDER REUSING EXISTING ONTOLOGIES

PURPOSE AND USE

Reusing existing ontologies can save time and effort in the ontology development process (Noy & McGuinness, 2001). To identify existing ontologies that can be reused to represent the knowledge related to crane space requirements, ontology libraries such as Ontobee, DARPA Agent Markup Language (DAML), and Linked Open Vocabularies (LOV) were searched. A literature search using Scopus was conducted to explore any research studies on crane ontology, as it is one of the most prominent literature databases (Hussein & Zayed, 2021). No specific ontology was found for the representation of the space requirement of the crawler cranes. However, some existing ontologies can generally represent construction equipment, which can be partially reused for crane representation. For instance, ifcOWL ontology has *IfcConstructionEquipmentResource* as a class, which can indicate construction equipment such as cranes. To represent spatial aspects of cranes, existing ontologies such as GeoSPARQL (*OGC GeoSPARQL – A Geographic Query Language for RDF Data*, 2011) and approaches such as Well Known Text (WKT) (Pauwels, Krijnen, et al., 2017) expressions were utilized in CSRO.

STEP 3: ENUMERATE IMPORTANT TERMS IN THE ONTOLOGY

Enumerating all the necessary terms is essential to ensure a complete representation of the intended knowledge. These terms make the foundation of class and class hierarchy development. To identify important terms for CSRO, this study utilized knowledge sources such as textbooks related to construction equipment (Peurifoy et al., 2018; Shapiro & Shapiro, 2010), literature concerned with crane space planning (Lei et al., 2013; Olearczyk et al., 2014) and web pages related to crawler crane components. The important terms identified for building CSRO consisted of two main aspects: (1) the terms related to crane components such as boom, boom mast, outriggers, and hoist rope, among others, and (2) the terms related to types of geometries used for representing crane space requirements, such as cylinder, cone, polyhedral surfaces, etc. Instead of considering each small component of the crane, only the prominent space-consuming components, whose bounding boxes incorporate the smaller crane components, were considered. For instance, elements like counterweights, the operator's cab, the winding drum (if present), the primary body of the crane, the engine unit (for crawler cranes), the access points, and walkways are considered together in a single component called 'Lower rotating body.' The meaning of each term was described in the ontology to ensure clarity during usage.

STEP 4: DEFINE CLASSES AND CLASS HIERARCHY

The classes and class hierarchy were defined from the identified key terms. A middle-out/combination development approach was used to this end. In this approach, a few of the most general and most specific concepts were defined first. They were then linked with some middle-level concepts. For instance, the ‘crane’ can be a general concept, and the specific geometry of space requirement for a crane operation can be a specific concept. They can be connected using intermediate classes, such as ‘geometry.’ This process is repeated multiple times till all the terms are designated in an adequate class hierarchy (Noy & McGuinness, 2001).

Figure 1 shows the class hierarchy of CSRO as shown in the Protégé interface. It consists of four classes, i.e., *Crane*, *CraneComponent*, *Geometry*, and *Solid*. The *Crane* class has *CrawlerCrane* as a subclass, which can be extended to other types of cranes. The *CraneComponent* class has different significant components of the crane as subclasses. The *Geometry* and *Solid* classes are not explicitly created in CSRO. The *Geometry* class is imported from Simple Features ontology (https://opengeospatial.github.io/ogc-geosparql/geosparql11/sf_geometries.ttl), and the *Solid* class is imported from Geometry (http://rdf.bg/geometry.ttl#) ontology for specific purposes.

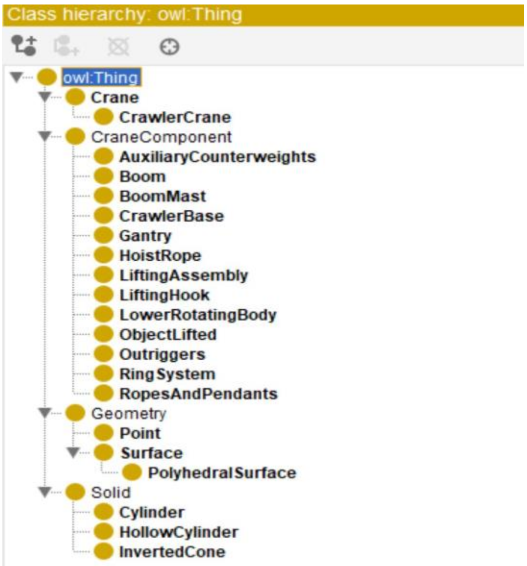

Figure 1:Class hierarchy of CSRO

The space occupied by the crane to be placed at a particular location was represented in CSRO using 3D bounding boxes covering its components. Despite not capturing accurate geometry, bounding boxes offer an approximate representation that can be used for space constraint checking (Chen et al., 2017). To represent such bounding boxes on the semantic web, the *PolyhedralSurface* sub-subclass, which is a subclass of the *Surface* class, was used.

The crane operation also involves the rotation of its components. For instance, The lower rotating body of the crane can rotate around the center of rotation while lifting the load (Lei et al., 2013). The Point subclass was imported from the simple features ontology to consider such a center of rotation. The space required for such rotation was represented in CSRO in the form of a cylinder with its radius and height depending upon the dimensions of the crane component. To consider this, the *Cylinder* subclass of the *Solid* class was imported from the Geometry ontology. Similarly, the crane boom also rotates while transferring the lifted object. The space required for such boom rotation is governed by the maximum and minimum possible radius of operation of the crane (Aghajamali et al., 2023; Lei et al., 2013). As the crane boom is inclined and rotates about a center point, the space required for such rotation can be roughly considered as a cone, as shown in Figure 2a. Therefore, the *InvertedCone* subclass was created as the subclass of the *Solid* class. As the boom rotates, the attached lifting assembly and the lifted load also rotate. The space required for such rotation takes the form of a hollow cylinder, as shown in Figure 2b. Therefore, the *HollowCylinder* subclass was introduced in the *Solid* class.

STEP 5: DEFINE THE PROPERTIES OF CLASSES – SLOTS

Object properties connect the classes, and datatype properties relate classes to specific values. (Noy & McGuinness, 2001). The object and datatype properties in this study were defined based on the different types of class-to-class and class-to-datatype relationships needed to represent the space requirement of the crane. A brief description of the object and datatype properties used in CSRO is given in Table 1 and Table 2.

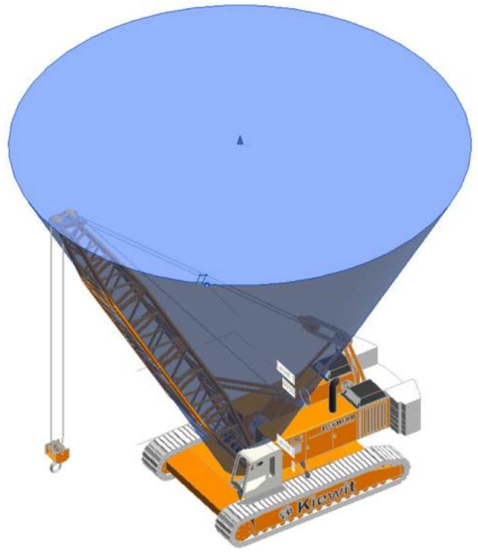

Figure 2a: Space requirement for the boom rotation

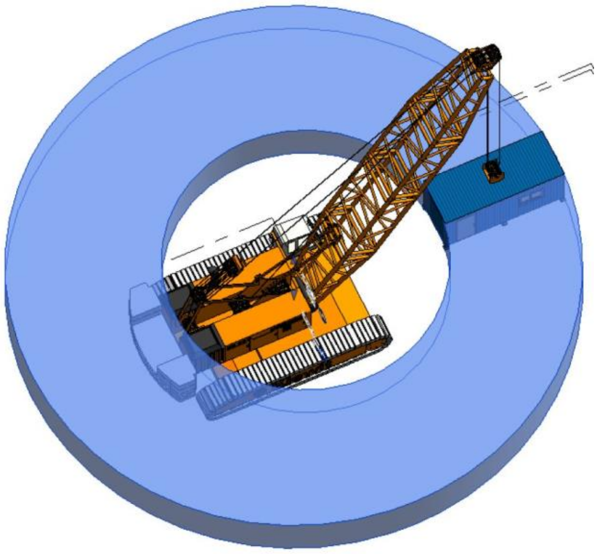

Figure 2b: Space requirement for rotation of the lifted object

Table 1: Object properties used in CSRO

Property names	**Purpose**	**Domain**	**Range**
hasComponent	Connecting a crawler crane class to its components	CrawlerCrane	Crane- -Component
hasBoundingBox	Connecting crane components to their bounding box representations in the form of polyhedral surfaces	Crane- -Component	Polyhedral- -Surface
hasCylindricalRotation- -Space	Connecting relevant crane components to the cylinder geometry representing their rotational space requirement	AuxiliaryCounter- -weights, LowerRotating- -Body	Cylinder
hasMaximumConical- -Space, hasMinimumConical- -Space	Connecting the crane boom to the inverted cone geometry representing its rotational space requirement at the maximum and minimum boom radius	Boom	Inverted- -Cone
hasMaximumHollow- -CylindricalSpace, hasMinimumHollow- -CylindricalSpace	Connecting relevant crane components to the hollow cylinder geometry representing their rotational space requirement at the maximum and minimum boom radius	LiftingAssembly, HoistRope, LiftingHook, ObjectLifted	Hollow- -Cylinder
hasVerticalMotion- -Space	Connecting relevant crane components to the cylinder geometry representing their vertical motion space requirement	LiftingAssembly, LiftingHook, ObjectLifted	Cylinder
hasCenterofRotation	Connecting geometries such as Cylinder and InvertedCone to their center of rotation.	Cylinder, HollowCylinder, InvertedCone	Point

Table 2: Datatype properties used in CSRO

Property names	Purpose	Domain	Range
hasModelNumber	Mentioning crane's model name and number using string datatype	CrawlerCrane	xsd:string
asWKT	Describing the geometries such as polyhedral surfaces and points using WKT literals	Geometry	WKT Literal
Innerradius, outerradius	Providing the float values of the inner and outer radius of the hollow cylinder	HollowCylinder	xsd:float
height	Providing the float values of the height of the hollow inverted cone	InvertedCone	xsd:float
length	Providing the float values of the length of the cylinder and hollow cylinder	Cylinder, HollowCylinder	xsd:float
radius	Providing the float values of the radius of the cylinder and inverted cone	Cylinder, InvertedCone	xsd:float

STEP 6: DEFINE THE FACETS OF THE SLOTS

The defined properties were connected to their domain and range. Domain and range are the classes/datatypes to which a property's subject and object belong in a linked data representation. Table 1 and Table 2 provide concise details about the domain and range of the properties in CSRO. Figure 3 depicts CSRO, including all its classes and properties.

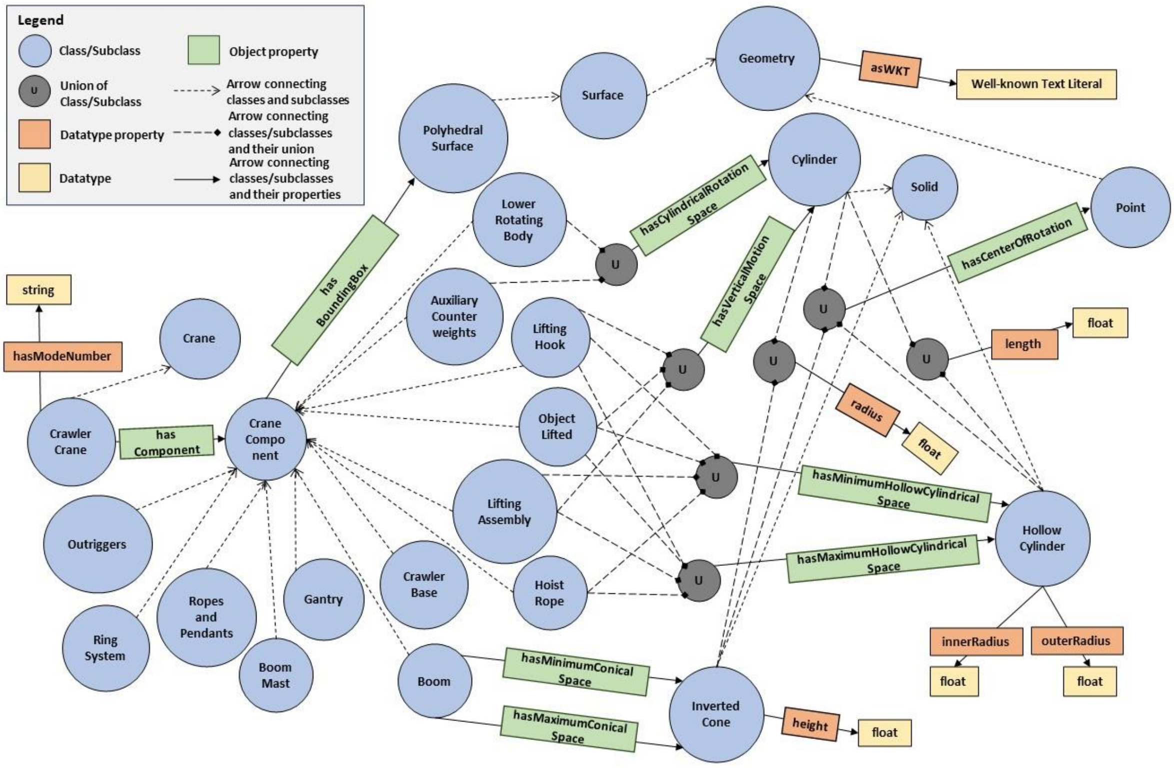

Figure 3: Crane Space Representation Ontology

STEP 7: CREATE INSTANCES

At this stage, individual instances corresponding to the classes and properties are defined, and the associated properties are assigned the values according to the instance. For demonstration, a Revit family of a crawler crane was imported into a Revit model, and the values of the properties were assigned accordingly. Figure 4a shows the crane with a bounding box around its boom. The coordinates of the corner of the bounding box are identified using the spot coordinates feature of Revit. The representation of this bounding box based on CSRO ontology is depicted in Figure 4b. Similarly, other space requirements can be instantiated.

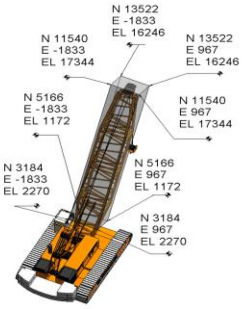

Figure 4a: Crane boom with bounding box

ONTOLOGY EVALUATION

The ontology evaluation ensures clarity, completeness, consistency, and fitness for the purpose of the developed ontology (Zheng et al., 2020). Several methods for ontology evaluation are available, including task-based evaluation, gold standard evaluation, and automated consistency checking, among others (Zheng et al., 2021). As CSRO was developed for the specific task of representing the space requirement of crane operation, automated consistency checking and task-based evaluation were used for its evaluation. These methods have also been used to evaluate other task-specific ontologies (Zheng et al., 2020). To check the consistency, this study utilizes Protégé's HermiT reasoner due to its faster speed and memory efficiency compared to other reasoners such as Pellet (Glimm et al., 2014). On running the reasoner, it showed no error, ensuring the consistency of the ontology. SPARQL queries were developed for task-based evaluation to check if the ontology-based knowledge base can answer the developed competency questions. The knowledge base was developed based on the crane family imported in Revit. An open-source tool named GraphDB was used to run the queries. The total space required to position a crane at a particular location can be expressed as the bounding boxes covering its components. Figure 5 shows the SPARQL query for extracting the bounding box of the crane boom. The query successfully fetched the bounding box in the form of the polyhedral surface, as shown in Figure 5. Similarly, the queries to address other competency questions were written. The queries could successfully extract the required information from the knowledge base and answer all the competency questions.

CONCLUSION AND FUTURE RESEARCH

In LAP, checking space constraints related to crane usage for crane-dependent operations is critical for developing quality assignments for trade crews and ensuring a reliable workflow. Given the complexity and dynamicity of construction projects, frequent constraint checks and adjustments to lookahead schedules are necessary. Further, the information required for constraint-checking remains in disparate, often non-interoperable databases. Therefore, conventionally used manual constraint-checking is tedious and error-prone, and most existing automated constraint-checking methods are not applicable in LAP. Consequently, LAP suffers from poor constraint-checking. Linked data based constraint-checking provides an opportunity to address these gaps. However, adequate space constraint-checking for crane-dependent operations using linked data is still lacking due to the unavailability of an ontology that can represent the space required for crane operation on the semantic web. Improper space constraint checking can result in time-space conflicts and unsafe conditions on the site, contributing to non-value-adding activities such as resource wastage. To address this gap, this paper developed Crane Space Representation Ontology (CSRO) for mobile crawler cranes with a lattice boom. CSRO considers the different elements of the space required for crane operation, such as the space needed to place the crane at a particular location and to rotate the crane's various components. The representation of such space requirements is done through different geometries such as cylinder, cone, and bounding box. The ontology is evaluated using automated consistency checking and a task-based evaluation approach. The evaluation results confirm the consistency of the ontology and its ability to answer intended competency questions.

This study contributes to research on leveraging technology for lean construction implementation by introducing a novel ontology to facilitate automated constraint checking in LAP. The CSRO can be semantically linked with the crane-dependent operations in lookahead schedules, as-built data, and other relevant information containers to perform automated linked data based checking of space constraints associated with operations involving crane usage. This provides two-fold benefits from a lean perspective. First, such space constraint checking can be used to develop constraint-free lookahead schedules based on the latest information from heterogeneous databases, improving workflow reliability and reducing non-value-adding activities on the site. Second, automation can reduce time, human effort, and error likelihood in the space constraint checking process, contributing toward minimizing rework and resource wastage in LAP and reducing potential non-value-adding activities on site due to errors in LAP.

In the future, CSRO should be extended to represent space required for other types of cranes as well, such as crawler cranes with luffing jib, cranes with telescopic boom, and tower cranes, among others. Future studies should extend CSRO to consider such additional operations such as walking, simultaneous slewing and lifting. Currently, significant manual effort is needed to process the heterogeneous information containers and ensure that the right information is expressed by the concepts of CSRO. Similar concepts might be represented by different terms in different databases, which might create ambiguities during representing data using CSRO. Future research should aim to develop automated tools for semantically annotating information containers to extract relevant data needed for crane space representation using CSRO. In addition, efforts should be made toward unification of semantic standards and development of equivalent relationships between the concepts. Finally, in the future, the authors will focus on utilizing CSRO to perform space constraint checking in lookahead schedules.

AUTOMATED DATA CAPTURE AND ANALYSIS TO DETECT PROCESS WASTE IN INTERIOR FINISHING WORK

Ashan Senel Asmone[1], Danny Murguia[2], Asitha Rathnayake[3] and Campbell Middleton[4]

ABSTRACT

Detecting process waste in complex production systems is still a challenge in construction projects. The integration of lean construction with automated data capturing technologies presents an opportunity to timely detect process waste and steer projects towards targets. By using vision-based technology for automated progress monitoring in a residential building, this study examines interior finishing work activities through the lenses of process/location flow and operations/trade flow. Location-based management tools (flowlines and line-of-balance) were used to visualise the data. Results showed that planned production deviated from actuals in all activities. Significant variability was observed within the completion of each activity at each location. The ratio between average production rate and exemplar performance indicated a missed opportunity to improve project performance. Resultantly, several waste types were identified including inefficient work, space not being worked in, unnecessary movement of people and unnecessary transportation of materials. The ability to actively pinpoint process waste provides managers with a granular understanding of inefficiencies, enabling targeted interventions to enhance productivity and reduce waste. The findings support that automated data capturing and analytics through the lenses of lean construction is a useful strategy to inform construction programmes to be more realistic, improving upon efficiency and waste reduction.

KEYWORDS

Flow, process, waste, location-based management (LBM), work in progress/process (WIP).

BACKGROUND

Waste is defined as the use of more resources than needed to generate an output, or the production of an unwanted output (Bølviken et al., 2014). According to Bølviken and Koskela (2016), the industry's significant waste is primarily attributed to the management approach in construction, which often prioritises contract management over production management. Additionally, this issue is exacerbated by the complexity of construction with multiple tiers of subcontractors and low-price procurement strategies. Bølviken et al., (2014) defined flow waste in construction as 1) unnecessary movement (of people); 2) unnecessary work; 3) inefficient

work; 4) workers waiting for work to be done; 5) space not being worked in; 6) materials not being processed; 7) unnecessary transportation (of materials).

Interior finishing work package is challenging due to the presence of multiple subcontractors, lack of detailed planning and control, and the complex linkages between tasks. Previous research has found high levels of work-in-progress (WIP), long cycle times, and significant process waste during this work package. Brodetskaia et al. (2011) found that subcontractor capacity unpredictability causes turbulent workflow, and re-entrant workflow patterns, in which crews return to the locations multiple times affecting performance. Murguia et al. (2016) applied the Value Stream Mapping (VSM) tool to detect process waste in interior finishing work and implemented a new work structuring, collaborative planning, and the flowline method to reduce cycle times. Due to the inherent complexity of this work package, it is difficult to determine which areas are performing optimally and which areas need improving.

To make visible and eliminate waste, a constant stream of production data generated in the field needs to be observed and analysed. However, project teams do not have the ability nor the bandwidth to collect this data whilst managing other aspects of construction. Therefore, a focus on production management along with automated data capture and analysis becomes a real need in order to identify areas where project teams should direct their efforts to avoid cascading delays. Technologies such as laser scanning (Wei et al., 2018), video data, computer vision, (Khosrowpour et al., 2014; Roberts et al., 2020; Görsch et al., 2022), and sensors (Akhavian & Behzadan, 2016; Barbosa & Costa, 2021) are used for this. Automated progress monitoring in construction involves capturing as-built data from sites and estimating progress by comparison with plans. One commonly used method for data collection is handheld 360-degree cameras (Ekanayake et al., 2021; Sami Ur Rehman et al., 2022).

By analysing internal processes and performance on the ground, it can be used to detect waste and see where efficiency optimisation is possible. To that end, the objectives of this paper are 1) to detect process waste in interior finishing work using vision-based automated data capture and 2) to describe the current challenges of vision-based data capture technology.

RESEARCH METHOD

A case study approach was used in this research to observe interior finishing work activities at a residential building development in London. Data collected included the construction programme and progress data. The construction programme was used to create the baseline to compare plans and actuals. The progress data were collected at weekly intervals using a 360^0 camera. A construction technology company provided services for this project to automatically analyse visual data using advanced computer vision techniques and record progress. The research team had access to the data via an online system including date of capture, 360^0 images, location (i.e., apartment), trade, activity, and percentage of cumulative progress.

However, our approach relied on investigating progress between two consecutive measurements (i.e., quantity of work carried out at a certain time interval) to better understand the flow of activities at each location. As such, flowline charts and line-of-balance (LoB) diagrams were used to visualise operation/trade flows and process/location flows. LoB diagrams have two visual representations, with some authors using dual parallel lines to represent activities, whereas others use boxes (Tzortzopoulos et al., 2020). In this paper, the second method was used. A data-to-dashboard approach (Murguia et al., 2022) was used to generate LoB visualisations automatically using Python codes purposively created for this research. With the data, the following metrics were calculated: 1) actual duration, 2) average cycle time, 3) average days worked, 4) number of visits to location, 5) production rate, and 6) observed exemplar and worst performance. These metrics have been proposed in previous studies (Rathnayake et al, 2023). We used these diagrams and metrics to visualise and quantify different types of waste at each unit location (i.e., apartment).

RESULTS

The case study was a residential building project constructed on a design and build contract. The internal fit-out activities were sub-contracted. Five fit-out activities in the critical path of the construction programme were observed, viz. erecting demising walls, internal wall closure, ceiling closure, painting, and flooring. For this study, observations and analysis were limited to a single level (level 4) which included ten apartments in total. A 360^0 camera was used to capture the weekly progress of interior finishing work. Cumulative progress was determined using a computer vision-based algorithm. The deployment of this technology was a pilot project within the business. Planners and site managers were unfamiliar with the potential to use the data to inform decisions. Traditional Gantt charts and activity counts were used as control metrics in measuring progress. Progress data were unused in production management.

PLAN AND ACTUALS

Data drawn from the online system were used to generate flowlines for the fit-out activities in level 4 (Figure 1). The horizontal axis shows calendar dates whilst the vertical axis shows the locations (apartments 401 through 410). An examination of the flowlines provides some understanding of actual performance. First, the flowlines indicated a clear mismatch between planned and actual progress. About 1/4th of the activities finished before their planned completion, while the rest of the activities were delayed, averaging a fourfold delay over their planned durations. Second, sequence deviations were observed between activities. For instance, flooring activities commenced in apartment 7 before painting even though the plan indicated a finish-to-start relationship between the two activities. This attests to the complexity of the interior finishing work package in managing several activities among several trades. Third, plans were made with the "level" (e.g., level 4) as the smallest unit as opposed to the "apartment". For instance, all the demising walls and internal wall closures were planned simultaneously across the ten apartments. However, granular data at the apartment level were available from the online system. Notwithstanding the above, the time lag between data collection made it impossible to differentiate the exact installation dates at each location. For instance, all demising walls for apartments 403 to 406 were installed between January 15th and January 29th. Therefore, the flowlines (in red) for these were identical across locations. Finally, the flowlines' slopes vary significantly between different locations suggesting different production rates. For instance, the production rates for internal wall closures (in blue) for apartments 401 to 404 were significantly different to those of apartments 405 to 410. Therefore, further analysis is needed to understand the differences and LoB diagrams were used to explore how much work was accomplished over time at each location (see Figure 2).

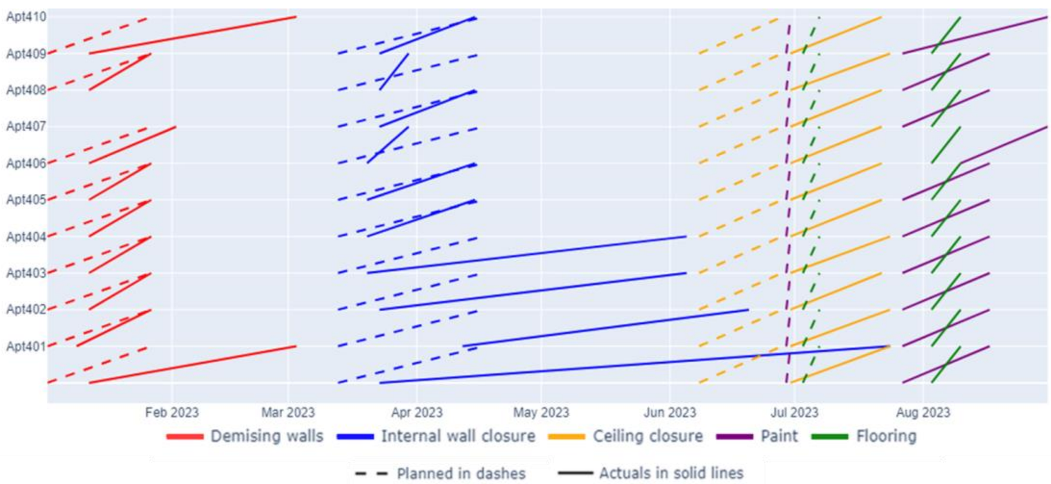

Figure 1: Flowlines – planned v actual

OPERATION/TRADE FLOW

In construction, products are stationary, and workers and equipment move across locations. Therefore, the two types of flow can be redefined as follows: 1) process/location flow, where different trades flow through a single location, and operations/trade flow, where a single trade flows through different locations (Sacks, 2016; Tommelein et al., 2022). Figure 2 shows the LoB diagrams for the five activities under examination across the ten locations. The horizontal axis indicates calendar dates, and the vertical axis indicates each location. The faint vertical bars in the background indicate weekends and public holidays. Each LoB illustrates one or more segments along the activity duration. Each segment is defined by two consecutive data capture events. The colour of each segment indicates the percentage of average daily work done during that period (i.e., % of progress/number of days, the corresponding colours can be found in the legend). Segments with no colour mean no work done.

Figure 2: Line-of-balance – operation/trade analysis

Each LoB diagram illustrates when work started, % of average daily progress between observations, revisits to the same location, and notably, when the locations were left idle with no area utilisation. However, a manual cross-check with site images showed that in many apartments the work was completed without any idle time as suggested by the data. In the case of painting, further investigations showed the separate work done earlier couldn't have been avoided due to the interdependencies of different activities. Managing this has to do not only the trade delivery monitoring but also with better planning the sub-activities. LoB diagrams are a handy way to visualise not only the progress of each activity over time but also the different types of process waste occurring at each location. As mentioned, area utilisation is clearly observed in the LoB diagrams, and so are sequence deviations from plans, as well as the distribution of a single trade over different areas of a level. An additional layer of information provided in these diagrams is the colour intensity indicating the rate of work done. This illustrates a variance between work done over different observed periods. For example, for apartment 1 ceiling closure, 47% of the work was done in 1 day and the rest over 16 days.

However, the LoB diagrams in Figure 2 only show one part of the story. As in the fit-out phase multiple trades are operating in close proximity to one another within a short period of time it is equally important to see how the different activities progress over time at a single location. Hence, LoB diagrams were drawn illustrating each apartment (see Figure 3).

PROCESS/LOCATION FLOW

Figure 3 shows a location analysis of a sample of three apartments. The LoB diagrams visually depict a number of process waste occurring at each location, viz. idle time, revisits, sequence deviations, and output inconsistencies (indicated by the varying colours of the boxes). Moreover, this visual prompt allows digging deeper into area utilisation at each apartment. The results show that apartment 401 took 156 net working days to complete the observed interior finishing work package activities from the first start to the last finish of an activity. However, it was only on 59 working days that an actual activity was carried out by at least one trade at this location, indicating an area utilization of 38%. This example indicates a common theme of wanton waste occurring during this construction phase, waste that can be easily identified using the right analytical tools to be dealt with by project teams to optimise their performance. However, it also is indicative of an underlying limitation of automated data capturing, where other uncaptured activities may be happening in these locations.

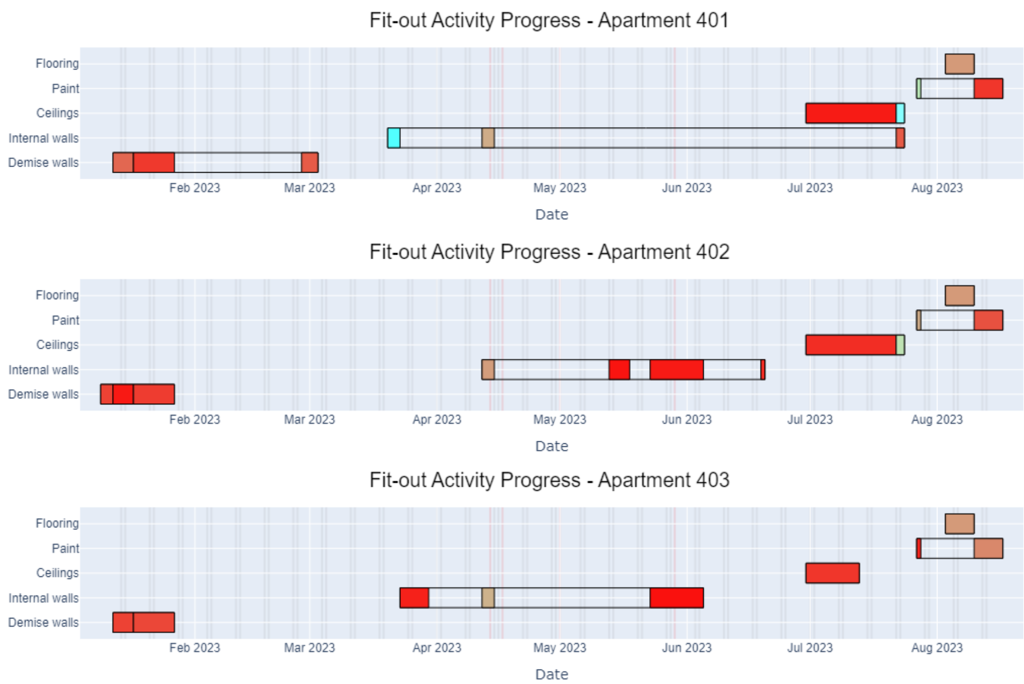

Figure 3: Line-of-balance – process/location analysis

To further explore process flow within locations, the research team analysed image data to obtain the actual start and end dates for all activities at a given location, as depicted in Figure 4. This figure introduces a novel flowline visualisation, showcasing activities on the Y-axis rather than locations, beginning from "demise walls" to "carpentry & joinery." The sequence of activities and their planned dates were extracted from the project Gantt charts and are depicted in blue. The actual data (in red) were derived from visual examination of the image data. Focusing on a specific location, level 4 – apartment 5, a notable gap between plans and actuals was observed in most activities. Notably, despite the first activity commencing earlier than planned, a substantial gap between the completion of demising walls and the initiation of MEP

1st fix was evident, indicating considerable work in progress (i.e. space not being worked in). Similarly, a gap exceeding one month was identified between the completion of internal walls and the start of MEP 2nd fix. Moreover, the production rate of MEP 2nd fix was significantly lower than the plan, as evidenced by the extended duration of the activity. The visual comparison between planned and actual start and end dates provide a clearer picture of progress. Whilst these analysis was conducted retrospectively, the tool and visualisation technique can be applied on future projects to monitor progress across locations (apartments, levels, buildings), enhance situational awareness, improve decision-making, and generate data for future projects.

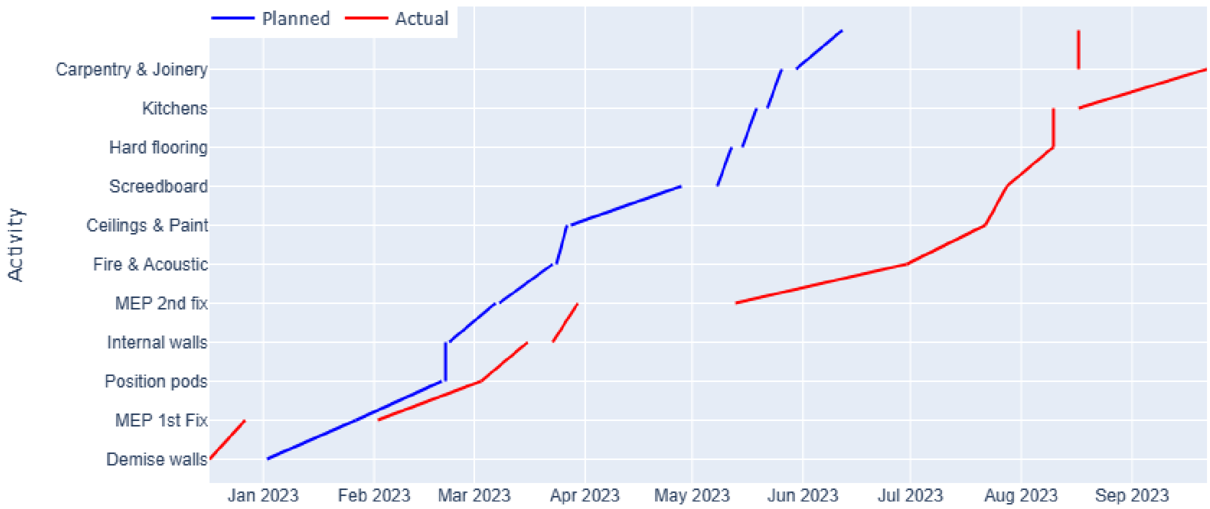

Figure 4: Process flow – example of level 4 apartment 5

METRICS

Table 1 provides some metrics on activity durations at the smallest location unit considered in this study, the apartments. As mentioned earlier, the Gantt Charts plans dictate fit-out activities at each apartment to be carried out simultaneously, yet evidence shows that there is significant variability between the time taken to complete activities in each apartment. For example, considering the activity of internal wall closure, that activity has a large variability in its overall completion times. However, looking closely at why that is the case it was observed that this activity has some sub-activities (e.g., drywall lining, single and double-sided partitioning) that were dependent on work completion by various other trades (e.g., demise wall, pipework, bathrooms, kitchen). Therefore, this trade could not complete their work at certain locations as per their schedule. The quantities of work conducted do vary between the different apartments, although that difference is not significant. These results are indicative of output inconsistencies.

The metrics of average cycle time and average days worked at an apartment are useful in terms of understanding process waste observed at the site. Both are measures of waste and are indicative of the mismatch between planned and actual realisation of plans, thus leading to waste. Apart from flooring activity, all other activities have varying average cycle times and days worked. With a variability of over 5 times with the planned duration in the case of painting. This type of metrics can be fed back to the planning process to make plans more realistic.

Table 1 further shows the number of visits from each trade to a single apartment to complete the activities during this duration. This was also observed in Figure 3. It is observed that while some activities are carried out from start to finish during one visit to the location, in many cases multiple visits are made to the same location over time to complete the same. Indicating idle time at these locations. Among the insights this shows, the distribution of a single trade over different areas of a level can be important information to the construction managers on site. Output inconsistencies at each location within level 4 are further collated in Table 2.

A summary of production rates for each activity is given for each location (i.e., apartment) and time interval (i.e., between two observations). In this study production rate is defined as the ratio of output to time. The output inconsistencies are observed to a greater degree when considering the varying production rates for both categories, location-wise and time interval-wise. In the example of ceiling works, the production rate ranges from 2.2 m/day to 16.4 m/day at different apartments. At the same time, in between the different observations made over the weeks when work is carried out an exemplar rate of production can be established at 6.43 m/day. On the other hand, the worst performance for this trade indicated a measly 0.01 m/day during a separate time. Interestingly, when analysing the complete results over time at each location, no inferences can be made from this data only to explain this behaviour of varying production rates. From the current observations, it is seen that high production rates are achieved at one location at the beginning of the work, and they fall off over time, yet the opposite happens at a different location. The only conclusion that can be made from the present data is that there is no consistency in the production rates. There may be several contributing factors explaining this variability. Further contextual data must be provided to determine these factors.

Table 1: Descriptions for observed fit-out activities (Level 4)

Activity (Trade)	**Planned duration (days)**	**Actual duration (days)**	**Duration per location (apartment) (days)**				**Visits to location (apartment)**	
			Minimum	**Maximum**	**Average cycle time**	**Average days worked**	**Minimum visits**	**Maximum visits**
Demise walls	20	53	17	34	21.3	16.4	1	3
Internal walls	26	126	8	30	17.3	13.1	1	2
Ceilings	15	24	23	24	24.2	16.4	1	1
Paint	2	35	10	35	12.8	10	1	1
Flooring	5	7	7	7	7	6	1	1

Table 2: Production rate metrics for observed fit-out activities (Level 4)

Activity	**Production rate (m2/day)**			**Per time interval**	
	Overall average per location	**Minimum per location**	**Maximum per location**	**Observed exemplar**	**Observed worst**
Demise walls	2.5	0.5	6.2	15.9	0.07
Internal walls	1.9	0.5	6.4	13.8	0.04
Ceilings	5.4	2.2	16.4	9.6	0.03
Paint	10.0	1.8	22.9	29.8	0.29
Flooring	21.9	21.9	21.9	5.52	5.52

The statistical inferences supplement the visual diagrams developed when informing the project teams of the interior finishing work packages. They are used to provide additional clarity, offering a comprehensive view of the sequence and interdependencies of various tasks within the interior finishing work packages. In tandem, these provide a more intuitive and accessible means for project teams to understand the temporal relationships between tasks, identify potential bottlenecks, and process waste to prompt optimised resource allocation.

DISCUSSION

This paper aimed to detect process waste in interior finishing work using automated data capture and analysis. The findings presented above show several inconsistencies between planned and actual work. This section discusses how the observed findings relate to the different types of process waste established in the lean construction literature.

According to Navon and Sacks (2007), project teams waste considerable time due to poor coordination, inaccurate and late information. If the work at a location is completed earlier than scheduled it results in early completion of activities, with waste of work efforts resulting in WIP at said location until the next trade moves following the schedule. This waste was observed in the data due to high variability in actual production duration in locations by many different trades. Relatedly, WIP (i.e., space not being worked in) as waste is noted throughout the observed period as locations are kept idle for long stretches of days in certain instances. For example, Table 1 shows the duration per location for each activity, indicating variations in the time taken to complete tasks in different apartments. Idle time in this case can be attributed to the coordination between trades in the critical path as well as the speed of their production during active installation. The varying production rates for each activity are presented in Table 2. The observed fluctuations in production rates suggest inefficient work at certain locations, which is yet another process waste. The delays and discrepancies between planned and actual durations may indicate potential issues with delivering the final specified results at each location. This is considered an indication of production defects. However, further contextual data such as quality reports must be used to substantiate this, which was not part of the scope of this paper. However, this work supports to overcome the manual observation of construction activities to measure performance, which has clear merits (Roberts et al., 2020).

Other types of waste identified are related to the unnecessary transportation of material and unnecessary movement of people arising from multiple visits to the same location to complete an activity. With multiple visits to a single location, further transportation-related issues can occur such as poor logistic conditions due to material and equipment left behind by different trades at locations where they intend to return. The waste types relating to inventories were not explicitly observed from the data. However, an additional waste discussed in lean management literature, underutilisation of talent, can be inferred by looking at the present data. This is suggested by the varying production rates for different trades. Some locations exhibit high productivity initially but experience a decline over time, indicating the potential underutilisation of talent. The trades could have potentially achieved more productive work in locations, given any contributing blockers to productivity were identified and managed within a timely manner. Therein lies an opportunity for improvement (Gondo & Miura, 2020).

In this research, several metrics were used to identify construction process waste, as discussed above. These metrics themselves provide a foundational framework for automated data capture and analysis for project teams. Thus, aiding them to identify and address shortcomings within their projects in a timelier manner. The results provide evidence to support the practical implications of such metrics, particularly in identifying and addressing sequence deviations to avoid cascading effects on project schedules. This in turn would help optimise area utilization for faster turnaround times and maintain trade output consistency for more accurate timeline predictions whilst reducing return visits to locations. When integrated into construction project planning and management, the study results help close the empirical data loop between planners and the site conditions during interior finishing works. This provides a comprehensive understanding of project performance when combined with existing benchmarks such as schedule performance and other similar frameworks (Marcy et al., 2021).

Due to the inherent complexity of the industry, it is difficult to determine which areas of the project are performing optimally and which areas are improving. Location-based management is useful in navigating through various project information and identifying where efforts should be concentrated. By analysing internal processes and performance on the ground during interior finishing work, this study provides the framework to address coordination issues, improve planning, and enhance the flow of activities.

Automated data capture and analysis, therefore, provides a very clear opportunity to improve site activity level performance and productivity by removing each of the identified waste streams incrementally. More realistically this sort of analysis can be used to identify and empirically explain the notion that actual performance happens not along the best case as assumed by the plan. The planning fallacy, a bias marked by the underestimation of time, costs, and risks in future actions despite historical evidence, is at times used to explain these challenges (Love et al., 2019). This work provides a basis on which dynamic assessment of progress against initial plans can be facilitated automatically, which can potentially provide insights to combat the planning fallacy. Visual tools enhance comprehension, aiding project teams in identifying bottlenecks and adjusting plans (Arditi et al., 2022). Moreover, instant issue recognition and agile decision-making enable prompt responses to challenges, mitigating the rigid adherence to optimistic planning assumptions. This study proposes a data capture and analysis framework for optimising project resource allocation (see Figure 5), offering a data-driven approach to address inefficiencies and process waste. Therefore, this study helps identify the intersection between the gathered data and useful insights to update planning practices in interior finishing work. Practices which can be expanded throughout the construction industry with further work.

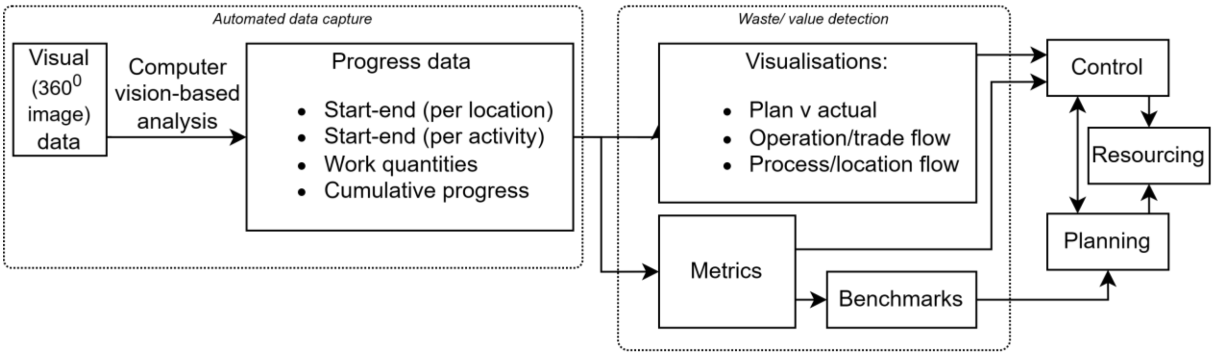

Figure 5: Automated data capture and analysis framework

CHALLENGES OF AUTOMATED DATA COLLECTION

Image data were captured on site at regular intervals and subsequently analysed using computer vision algorithms. However, upon analysing the resultant raw progress data, certain limitations were noted that need to be addressed to further advance the field. First, there were some discrepancies in the terminology and grouping of activities between the plans (Gantt Chart) and the actuals reported by the system. For instance, the plan had an activity named "Second drylining visit" whilst the system identified more granular activities such as "Frame", "Closure", and "Skim". Whilst having this granularity is a strength of the system, it was unclear how to match the planned activities and the corresponding actuals for flowline creation.

Second, the system does not support the analysis of re-entrant workflows (Brodetskaia et al., 2011). For instance, the activity "Plumbing" groups several elements that were installed at different times. However, they were all consolidated into a single activity within the system. From a workflow perspective, it is essential to disaggregate these elements to understand the interactions with other activities.

The third limitation was due to some instances of errors in the start-end dates and progress calculation presented by the system. A manual quality check was carried out when durations were too long, and we found some differences between the images and the progress data generated. During the data processing and verification stages, these were corrected for the analysis to the best of the authors' ability. Although this research cannot report the rate of detection error, further work is needed to ensure more quality in the data.

The fourth shortcoming was due to the data collection intervals. In many cases, most activities within several apartments were completed between two consecutive observations. Consequently, all the flowlines are the same, despite trades potentially moving daily between apartments. Thus, production rates at the apartment level are meaningless unless they are aggregated at the floor level. In other instances, some activities in the critical path are not properly reported due to activities happening within the time elapsed between two consecutive observations (e.g., the placement of prefabricated bathroom pods in each apartment). Therefore, the weekly data collection frequency does not cater for measuring production at the operational level. A trade-off is needed between more frequent data collection and the level of analysis required. However, presenting the available data with a flow point of view as opposed to cumulative progress is a valuable contribution of this study.

Automated data capture provides an opportunity for planners to quickly capture an approximate measure of work done. It is envisaged that further advances in this technology would make the accuracy and reliability of data improve over time. Even so, in its current form, this technology along with a construction flow point of view can help planners close the loop between actual site performance with their plans for interior finishing work. It can show where deficiencies of plans may occur, or where additional time, resources, and methods are needed.

CONCLUSIONS

Underpinned by operations and process flow, this research investigates process waste by leveraging progress data extracted from image data collected during the interior finishing work of a residential building. Flowlines and line-of-balance were produced to enable improved situational awareness. Awareness that leads to targeted interventions. A key contribution of this research is the data capture and analysis framework that supports the identification and visualisation of various types of process waste, such as inefficient work, space not being worked in, unnecessary movement of people and unnecessary transportation of materials. Overall, the study explores the intersection between process waste and advances in automated site data generation, integrating Lean Construction with advanced digital technologies. The current work is limited in its use of a single case study. Albeit the research methodology presented in this study can be utilised for other construction work packages with identifying relevant metrics for each work package. Another limitation is the lack of qualitative data to contextualise and draw the causes for the observations. This form of data capture in its current form should not be used in isolation. This data should be used in conjunction with other site data streams such as quality reports, site diary entries, and planners' reports. Data captured automatically need contextual information to allow for understanding variations. The data collection is also limited to the level of granularity the work package plans are made. With more granular plans, the data could further be delved into sub-activities. To that end, this work succeeds in detecting process waste in interior finishing work using vision-based automated data capture and identifies the current challenges of vision-based data capture technology.

EXPLORING USER EXPERIENCE AND EFFECTIVENESS OF AN INNOVATIVE LEANBUILD UK PROJECT MANAGEMENT SOFTWARE: USABILITY STUDY POST DEVELOPMENT STAGE

Muktari M. Musa[1], Emmanuel I. Daniel[2], Namadi S. Ahmed[3], Ifeatu C. Enedah[4], Momoh Job [5] and Samuel I. Haa [6]

ABSTRACT

This paper explores the usability and efficiency of the LeanBuild project management software; an innovative solution rooted in Lean Construction 4.0 principles. Through collaboration with the University of Wolverhampton UK, Kingston University UK, and London South Bank University UK, the LeanBuild Limited project presents a promising innovation in the construction industry.

The integration of usability evaluations and user recommendations in software development is limited, despite the importance of usability testing. Even with limited adoption of construction project management software, Target Value Delivery principles are often overlooked. The study employs a mixed-methods approach, incorporating focus groups, questionnaires, and interviews to assess the software's usability. Recommendations gathered from industry practitioners, academics, and IT professionals emphasize the need for improvements such as financial reporting, critical path display, resource assignment features, simultaneous file uploads, BIM integration, enhanced security, and E-Tendering and Marketplace integration.

The paper concludes that despite requiring further enhancements from its minimum viable product, LeanBuild is an effective solution, endorsed by users as a viable and scalable innovation with global applicability for efficient project delivery. This study highlights the importance of post-development usability checks and positions LeanBuild as a significant breakthrough in the construction software landscape.

INTRODUCTION

Lean construction (LC) researchers actively advocate the integration of both old and modern technologies within the framework of Lean Construction 4.0 (LC 4.0) (Musa et. al., 2023). In light of the revolutionary changes occurring in the construction sector due to creative digitalization, automation, and artificial intelligence, Lean Construction (LC) has embraced digitalization by utilising both conventional and innovative technology through the use of Lean Construction 4.0 principles.

Recognizing the potential for significant service and delivery benefits, Architecture, Engineering, and Construction (AEC) firms are increasingly embracing emerging construction technologies (McCoy & Yeganeh 2021a). This trend stands in contrast to the historical perception within the AEC sector that innovation disrupts established workflows and leads to inefficiencies (Love et al. 2014). Studies now show that strategic implementation of technologies can enhance collaboration, improve project predictability, and ultimately reduce costs (Azhar et al. 2017). However, challenges remain. McCoy and Yeganeh (2021b) highlight the need for upskilling the workforce and ensuring interoperability between different technologies for successful innovation uptake.. Therefore, there is a strong push for advocating the adoption of these technologies to maximise their potential in the construction industry (Momoh et. al., 2016, Musa et. al., 2023). The concept of LC 4.0 involves the seamless integration of digital technologies into the construction process (Hamzeh et al., 2021). As a result, the adoption of project management software becomes an essential tool to ensure the overall delivery of projects.

Currently, web app development has become a matter of paramount significance for firms as the global economy is experiencing an exponential rise in commercial digitalization. The increasing number of businesses choosing web applications as a means to address societal problems and facilitate service delivery further accentuates the significance of web applications (Agarwal & Venkatesh 2002). This has led to the development of LeanBuild project management innovation; a construction technology software in the UK that aims to optimise user experience and efficiency in the evolving demands of digitised project management. The software is efficient in managing diverse project types. It is leveraging on digitalizing an innovative framework called the Framework for Implementing Target Value Delivery (FFITVD) that aligns with the principles and values of TVD (Target Value Delivery) (Musa et. al., 2023). This is an approach for the automated management of large construction projects to secure cost savings and minimise waste. The digitalization of an innovative framework enhances technological fluidity, and user engagement, and fortifies the framework's intellectual property policies.

TVD is an innovative management approach that applies target cost, quality, and schedule to design to generate value for stakeholders by minimising waste and ensuring that every facet of the construction process aligns with the agreed-upon targets, encompassing cost, quality, standards, time, and stakeholder value (Musa, 2019, Orihuela et. al., 2015, Zimina et. al., 2012). The LeanBuild web app encompasses all essential software requirements for each phase of project management, starting from initiation to closure. It successfully integrates both TVD and the traditional construction approach into the user interface designs. The software is offered on a subscription basis to clients who will be able to manage their construction projects ‘end-to-end’ using an applied software package which, by its nature, is accessible on any enabled device. As a result, it becomes imperative to evaluate the effectiveness and acceptance of the software provision and properties (Musa et. al., 2023).

To develop a functional technological system for global utility, it is crucial to consider the influence of user experience (UX) within the context of technological innovation (Hassenzahl, 2001). Usability studies, a key component of UX design, aim to identify usability issues, improve the user interface (UI), and ultimately enhance the overall user experience, leading to increased user satisfaction, system adoption, and potentially, even greater innovation (Nielsen, 1993; Rogers, 2020, Desideria & Bandung 2020).

Conducting a usability check on the software has resulted in a significant enhancement by the implementation of the recommendations from participants. It underscores the importance for any developed software to undergo usability testing before launch and implement key recommendations to improve functionality and versatility. This approach ensures the software becomes a viable and scalable innovation for global utility.

RESEARCH GAPS

There is limited integration of usability evaluations of user recommendations before the official launch of the software (Shneiderman et al., 2009). Although there is widespread adoption of various construction innovations, most of the adoptions give little or no attention to the integration of Target Value Delivery (TVD) principles into the construction digitization process. Current literature indicates that the implementation of TVD remains inadequately realized in the construction space, with both organisations and project teams falling short of fully embracing its transformative potential (Musa, 2019, Musa et. al., 2023). While there is an innovative framework for implementing Target Value Delivery (FFITVD), the digitalization of the framework becomes a necessity to enhance the understanding of the framework, digital integration, user validation, and protection of the framework's intellectual property rights. The lack of digitalization of the framework is a shortfall, prompting further innovation to digitize the framework to system that facilitates seamless progression of construction activities, efficient resource allocation, timely production and delivery of project outcomes. Conclusively, there are numerous construction project management software in circulation; several of them lack full coverage of the entire lifecycle of a typical construction project.

AIM AND OBJECTIVES

This paper aims to evaluate and enhance the usability of the LeanBuild software for improved user experience.

a) To explore the overall user experience of the LeanBuild software, including ease of use, user-friendliness, and satisfaction.
b) To identify any usability issues that may hinder users from effectively utilising the software.
c) To gather feedback and suggestions from users for further improvements and enhancements.

LITERATURE REVIEW

EVOLUTION OF LEANBUILD FROM LEAN CONSTRUCTION TO LEAN CONSTRUCTION 4.0

Lean Construction (LC) takes its origin from the practice of the manufacturing industry that has gained adoption in the construction industry (Koskela, 2000; Musa, 2019, Demirkesen, 2021, Daniel, 2017). The target of LC is the full optimization of resources, adequate reduction of waste, and improvement of the entire performance of construction activities (Ahmed et. al., 2018, Nikakhtar et. al., 2015, Musa 2019; Daniel 2017, Francis & Thomas 2019). The procession in lean thinking forms the basis of LC, which harmonizes design and product delivery for both small and capital projects.

The construction industry's successful integration of Lean practices across a wide range of activities, from design and planning to execution and handover, has laid a strong foundation for further innovation (Babalola et al., 2019; Hamzeh et al., 2021). This evolution is driven by the emergence of modern digital solutions and the increasing utilization of the Internet of Things (IoT) dubbed Lean construction 4.0 (Hamzeh et al., 2021; Ramadan & Salah, 2019). LC 4.0 builds upon Lean principles by leveraging enhanced connectivity through digital technologies for improved construction management throughout the project lifecycle (Hamzeh et al., 2021; Oguntona et al., 2018; Al-Aomar, 2012). A key distinction between LC and LC 4.0 lies in its emphasis on data-driven decision-making and the utilization of advanced technological solutions. While the potential of LC 4.0 is significant, challenges such as a lack of industry-wide standards, workforce upskilling needs, and initial investment costs may hinder its widespread adoption.

PROJECT MANAGEMENT AND SOFTWARE SOLUTIONS IN CONSTRUCTION

Effective project management (PM) ensures construction projects are completed on time, within budget, and meet quality standards (Akintola & Goulding, 2006). It involves strategic planning, resource allocation, task management, and risk mitigation (Project Management Institute, 2017).

Traditional PM methods are giving way to Project Management Software (PMS) due to its advantages. PMS offers features for task & schedule tracking, resource allocation, team collaboration, project planning and progress reporting (Akintola & Goulding, 2006). However, choosing the right PMS can be challenging due to software complexity, limited scope, customization issues, integration problems, access restrictions, and security concerns (Musa et al., 2023; Goncalves, 2018)

Organizations should assess their needs before adopting new technology (Talukder, 2012). Tools like LeanBuild address challenges by offering comprehensive project management functionalities and user-friendly interfaces. Despite advancements in software development, the construction industry faces slow technology adoption (McKinsey & Company, 2020) as a result of the beliefs within the AEC sector and this have impeded the full realization of benefits offered by established and emerging technologies.

SOFTWARE USABILITY TESTING

The efficacy of any software depends on rigorous usability testing, a pivotal phase in software development. Usability evaluations assess user-friendly interactions and evaluate software's effectiveness before deployment (Sadowska & Piętak, 2015, Bandi & Heeler, 2013, Lárusdóttir, 2011, Dillon, 2015, Bruun & Stage, 2015). Thorough usability testing is an essential part of software development that determines how effective any software will be. Software usability assessments determine how user-friendly the interface is and how effective the programme is. Various methods exist for conducting usability tests, including:

a. Usability testing: In this approach, users are tasked with completing specific assignments using the software, their actions are observed, and the outcomes of their performances are systematically collected. This method identifies the challenge of a user trying the software and suggests an improvement scheme for the enhancement of the software's efficiency. (Moran, 2019, Hasan, 2014).
b. Heuristic evaluation: This approach involves gathering feedback from a group of experts on the software and identifying challenges through the practice of usability evaluation. The limitation of this approach lies in its inability to capture the comprehensive picture and overall user experience. (Ssemugabi & Villiers, 2010).

c. Expert review: This method entails obtaining feedback and insights from a single subject expert who reviews and identifies issues related to the software under evaluation. This method proves most beneficial when there is a need to pinpoint a specific issue; however, it falls short of providing a comprehensive overview of the user experience with the software (Privitera, 2019, Harley, 2018).
d. Evaluation of User Experience (UX): Among all the methods, the UX approach stands out for its holistic nature, encompassing fundamental aspects of user experience such as functionality, efficiency, effectiveness, and overall user satisfaction.(Musa et. al., 2023, Kaisa and Virpi, 2008).

Researchers have established that carrying out usability on time is a key factor in determining whether the software was developed in consideration of the intended users (Lárusdóttir 2011). User experience testing helps in revealing if the software would be adopted by the users based on their reviews, results, and recommendations. From the result of carrying out user experience testing, the user experience (UX) will undergo continuous improvement until the best of the software becomes globally utilizable.

METHODOLOGY

This section details the methodology employed to evaluate the usability of LeanBuild software, focusing on a user-centered design (UCD) approach (Morris et al., 1995). UCD prioritizes understanding user needs and incorporating their feedback throughout the design process to ensure the software aligns with established usability principles. These principles, as outlined by Krug (2000), encompass aspects like learnability (ease of initial use), efficiency (effectiveness in accomplishing tasks), memorability (recalling features after a period of non-use), error tolerance (forgiving user mistakes), and user satisfaction.

The researchers adopted a mixed-method approach, combining qualitative and quantitative data collection techniques to gain a comprehensive understanding of user experiences. This approach goes beyond surface-level data, capturing not only user behavior but also their perceptions, attitudes, and thought processes (Tashakkori & Teddlie, 2010). The study utilized a blend of established usability testing methods: focus groups, interviews, and questionnaires (Musa et al., 2023; Kontio, 2001; Lehtola et al., 2004; Sunikka, 2004).

Usability testing for this research involved participants from the UK (mainly from the University of Wolverhampton’s Construction Futures Research Centre UK, the School of Architecture and Built Environment at Kingston University UK, and the School of Engineering and Architecture of London South Bank University UK) and from Nigeria, (predominantly from Brains and Hammers Limited, IBTank Limited, Canon Projects, and Design and Shelters Limited).This research included participants from the UK and Nigeria to capture diverse user perspectives and potential market variations in construction practices. However, to mitigate bias, the study acknowledges potential limitations arising from sample size, cultural differences, and pre-development evaluation involvement of some participants. Focus group discussions: Five sets of focus groups discussions (including two face-to-face sessions and three online/virtual sessions) were held with a total of 25 participants to gather both qualitative and quantitative data on software usability. This group setting allows participants to bounce ideas off each other, potentially revealing learnability issues and areas for improvement in the software's initial user experience (Kontio et al., 2004; Beyea & Nicoll, 2000).

Questionnaire survey: The questionnaire survey was used to gather feedback aspects like ease of use, functionality, and overall satisfaction in a structured and standardized format. 21 out of the 25 focus group participants filled out the online questionnaire survey. The questionnaire survey was conducted using SurveyMonkey, a widely used online survey tool.

This method incorporated elements from frameworks like the User Experience Questionnaire (UEQ) (Sauro, 2011), ensured efficient data collection and facilitated comparison across participants, contributing to an understanding of user efficiency and overall satisfaction with LeanBuild.

Interviews: Interviews were conducted with about 14 out of the 25 participants in the focus groups to gather personalized insights into their experiences with the software application and specific areas of interest raised during focus groups. Prior consent was obtained from the interviewees, and the sessions were recorded to facilitate accurate transcription

The respondents in the study were industry practitioners, academics, and software/Information Technology (IT) professionals. With the combination of these different perspectives, the researchers hope to collect a holistic view of the usability of the LeanBuild software application and initiate paths for continuous improvement of the software. Given the relatively small number of participants (25 in focus groups, 14 in interviews), a descriptive analysis approach was deemed most appropriate. Descriptive analysis focuses on summarizing and describing the collected data, providing valuable insights into user experiences without relying on complex statistical inferences (Creswell & Creswell, 2018). This approach is particularly suitable for smaller sample sizes where statistical tests might lack power or generalizability (Maxwell & Reed, 2004).

RESULTS AND DISCUSSION

This section provides an analysis and discussion of the results derived from the study.

LEANBUILD SOFTWARE PRESENTED

The LeanBuild project management software is a construction technology software that aims to optimise user experience and efficiency in the evolving demands of digitised project management. The software is efficient in managing diverse project types. It is leveraging on digitalizing an innovative framework called the Framework for Implementing Target Value Delivery (FFITVD) that aligns with the principles and values of TVD (Musa et. al., 2023).

The LeanBuild web app encompasses all essential software requirements for each phase of project management, starting from project initiation, planning and design, execution, monitoring and evaluation and to closing. It successfully integrates both TVD and the traditional construction approach into the user interface designs. The software is offered on a subscription basis to clients who will be able to manage their construction projects ‘end-to-end’. Screenshots and demo of the LeanBuild application can be found on https://leanbuild.co.uk/

DEMOGRAPHY OF RESPONDENTS

Relevant information was gathered from the administered questionnaire regarding respondents' background, expertise, and familiarity with the use of the Internet and other software tools, particularly project management software.

The professional backgrounds and years of experience of the respondents are detailed in Table 1.

Table 1: Respondents' Professional backgrounds and years of experience

Professional background	% of Participants	Years of Experience	% of Respondent
Industry Practitioners	71%	Not more than 5 years	5%
Academics	14%	5 to 10 years	24%
Software/IT Professional	15%	10 to 15 years	38%
Others	10%	More than 15 years	33%

The analysis shows a varied distribution of experience levels among respondents, representing diverse professional backgrounds. Results indicate 96% possess internet familiarity, and 72% have used project management software, suggesting a majority are acquainted, potentially needing minimal training.

USABILITY CHALLENGES ENCOUNTERED IN PROJECT MANAGEMENT USAGE

The results of interviews and surveys highlighted key challenges in project management software utilisation. About 33% cited restrictions on file uploads, 22% mentioned software complexity and internet dependency. The development team addressed these concerns, streamlining the user interface for ease of use and allowing multiple file uploads, enhancing the overall efficiency of the software.

The study findings highlighted an essential suggestion that, the software's limitations are primarily geared towards the construction industry, leading to one-sided consideration. Addressing this feedback, the software's research and development team, equipped with substantial expertise, skills, and market awareness in the digital construction industry, is aligning lean principles and practices to shape the innovation for a more extensive range of sectors, encompassing construction, manufacturing, and other service-intensive industries.

EFFICIENCY AND INCLUSIVENESS OF LEANBUILD SOFTWARE

The software comprehensively covers the entire project lifecycle, with 100% of respondents attesting to this. While 76% found the project initiation clear, 24% expressed concerns about its focus on construction, limited financial reporting, and lack of quick signposts for estimates. For the planning phase, 90% found it adequate, but 10% raised unspecified potential issues. Additionally, 95% were satisfied with the execution stage, acknowledging it as a representative interface for project implementation. These results indicate the participants' recognition of the software's Minimum Viable Product (MVP) comprehensiveness, incorporating best practices at the execution phase.

The procurement interface received approval from 81% of respondents, while 14% were undecided, and 5% strongly disagreed. Concerns centred around the need for an easy search tool and a notification trigger for material requests. For the schedule interface, 90% agreed it encompassed all necessary elements, with 10% undecided. Suggestions included features on the Gantt chart for resource assignment and highlighting the critical path in red for better visibility. The development team valued these recommendations, enhancing the software to include resource assignment options and highlighting essential paths.

The cost interface received recognition from 95% of respondents for its adequacy, while 5% neither agreed nor disagreed. Suggestions included enabling direct uploads of BIM-enabled drawings and files for better transparency. For the closing interface, 90% acknowledged its efficiency, but 10% strongly disagreed, emphasising the need for a snag list and defective liability period. The development team carefully considered these suggestions, integrating them into the software before its official launch.

The project feed integration is a strategic innovation to enhance project team efficiency. 95% of respondents affirmed its benefits in interactive communication, collaboration, and coordination, while 5% did not disclose sentiments. Other suggestions for improvement included generating comprehensive downloadable reports, compatibility with files from other software, and a feature for efficient resource allocation management..

USABILITY AND EFFECTIVENESS ASSESSMENT OF LEANBUILD SOFTWARE

The questionnaire results indicate that most respondents find the project management software easy to use beginning from the signup interface. The software's label, instructions, and functionality were distinct with simple applicability as 100% of the respondents admitted to the clarity of the software's navigation and functionality.

Concerning the suitability of the software interface's visual appearance, 90% of respondents concurred that the visual representations employed for all project phases are visually appealing. Additionally, 100% acknowledged the clarity and lack of ambiguity in the tooltips and instructions for utilising the software. Extensive research contributed to the current visual presentation of the software, and the development team remains committed to making continuous improvements to enhance the visual aspects of the software.

The software's project dashboard serves as a comprehensive summary of any project, with 81% of respondents affirming that it encompasses all essential features of a typical project dashboard. However, 14% remained undecided, and 5% strongly disagreed with the suitability of the project dashboard interface. Some respondents suggested the addition of TVD and traditional methods to the software project dashboard. The dissatisfied respondents expressed reservations, noting that the dashboard seemed limited to construction activities and suggested adding features for accounting, procurement, and other reporting summaries.

INNOVATIVENESS OF LEANBUILD SOFTWARE

94% acknowledged LeanBuild's groundbreaking advancement compared to traditional project management software, with 6% not expressing their views. 78% find Target Value Delivery (TVD) Path the most innovative, 11% prefer project feeds, and another 11% highlight control procurement. Overall, 100% of the respondents agreed that the innovation covered the full cycle of a project from initiation to closing. These results align with the software's integration of lean construction practices, making TVD the most perceived innovative feature. What makes this software innovative is that the norm of large construction projects in the UK for 'packaged' management has primarily been a process known as the traditional method. The inclusion of TVD in the software has substantial advantages over traditional approaches and has identified no current directly competing offerings available in the UK.

The findings highlight the effectiveness of the UX in facilitating construction project execution, aligning with (Bruun and Stage 2015). Ongoing enhancements are necessary for comprehensive software development, including aspects like the financial interface, plugins, multiple security factors, and integration of BIM, E-Tendering, and Market Place Integration. As there is a need to meet the fast-growing market for improved management of ever more complex construction projects requiring sophisticated applications to support delivery, The software is unique in its ability to cover all stages of construction projects, ranging from initiation to planning, execution, monitoring & control, through to hand over and operation.

VIABILITY AND SCALABILITY OF LEANBUILD SOFTWARE

The research and development team of LeanBuild Limited UK, working alongside the University of Wolverhampton's Construction Futures Research Centre UK, the School of Architecture and Built Environment at Kingston University UK, and the School of Engineering and Architecture of London South Bank University UK, showcases a data-driven approach to construction software development. This collaboration allows LeanBuild to leverage the academic expertise of these institutions to conduct thorough market research and gain a profound understanding of current trends and demands within the construction software industry. The technical expertise and experience of the director of LeanBuild Limited, alongside the supporting team, have effectively validated the software's viability and strategically positioned it for continuous improvement. This iterative enhancement process ensures the software remains in alignment with lean principles. The team is dedicated to addressing user recommendations through collaboration with proficient and experienced professionals. This collective approach seeks further to augment the functionality and adaptability of the LeanBuild software, ensuring its continual evolution in consonance with industry requirements and user preferences.

The survey result shows that most participants (90%) score 7 or higher on the recommendation scale, indicating the software's readiness for widespread use. Although 10% provided a lower score, this positive majority highlights the software's scalability as an innovative tool. Additionally, the gradual adoption of Target Value Delivery (TVD) in the UK industry is acknowledged, recognizing that it takes time for new ideas to get fully integrated into any industry.

The software's structured planning is evident as a contemporary innovation that not only supports job creation but also stimulates growth in both national and international construction markets. Leveraging a broad construction client base in the UK, Nigeria, and worldwide, it advocates for the adoption of construction technology software to enhance business operations. This positions LeanBuild software solution as highly scalable.

INTERVIEWS FINDINGS AND RECOMMENDATIONS

The interview outcomes offer valuable insights and recommendations for enhancing the LeanBuild software. Figure 1 displays the diverse suggestions along with the corresponding number of interviewees who provided these recommendations.

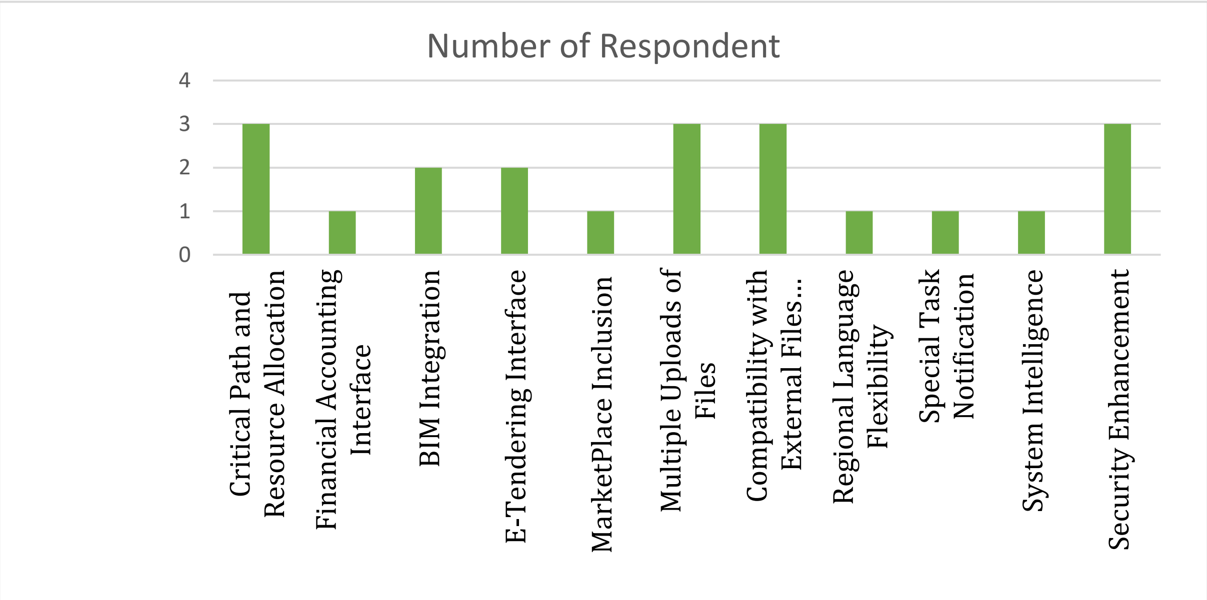

Figure 1: Suggestions and number of respondents that made the recommendation

Figure 1 outlines recommendations to enhance LeanBuild software, including a financial accounting interface and comprehensive critical path display on the Gantt chart for identifying delays. Respondents suggested features like simultaneous multiple file uploads, drag-and-drop functionality, critical paths integration for schedule monitoring, and direct resource assignment.

Stakeholders recommended an instructional guide for estimating activities or materials, BIM integration, compatibility with external files, and interfaces for snag lists and defective liability periods. Users emphasised simplicity, intelligence, multilingual support, and mobile accessibility. These suggestions align with ongoing efforts to refine LeanBuild's functionality and accessibility.

CONCLUSIONS

This study investigated the user experience and efficiency of the LeanBuild software post-development. Employing a mixed-methods approach involving focus groups, questionnaires, and interviews, the research gathered diverse perspectives from industry practitioners, academics, and IT professionals. The research and development team of LeanBuild UK collaborated with esteemed institutions in the UK.

The findings yielded key recommendations for software improvements, including financial reporting, critical path display, and resource assignment features. Stakeholder suggestions encompassed simultaneous file uploads, critical path integration, and direct resource assignment. Ongoing enhancements were proposed in financial interface, plugins, security, and integration of E-Tendering and Market Place. Users emphasised simplicity, intelligence, multilingual support, and mobile accessibility.

Despite limitations such as a small sample size and limited generalizability, the study's significance lies in highlighting the necessity of conducting usability checks after the development stage but before the software launch. The study introduces a digital innovation advocated by lean construction experts, addressing the entire project lifecycle by incorporating Target Value Delivery (TVD) and traditional construction approaches. Additionally, it underscores the benefits of conducting usability tests post-development and before the software launch, emphasizing the positive endorsement of LeanBuild as a scalable and globally applicable innovation for efficient project delivery.

This study recommends conducing user experience studies with construction professionals from other countries to understand cultural variations in software interaction and preferences.

A BIM-Lean Approach to Implement Lean Principles in Offsite Construction Projects: A Cable-Stayed Bridge Case Study. In D. B. Costa, F. Drevland & L. Florez-Perez (Eds.), *Proceedings of the 32nd Annual Conference of the International Group for Lean Construction* (IGLC32) (pp. 684–696). doi.org/10.24928/2024/0146

A BIM-LEAN APPROACH TO IMPLEMENT LEAN PRINCIPLES IN OFFSITE CONSTRUCTION PROJECTS: A CABLE-STAYED BRIDGE CASE STUDY

Mohamed Assaf[1], Otto Hedges[2], Zeyu Mao[3], Hamidreza Golabchi[4], Xinming Li[5], Vicente A. Gonzalez[6] and Farook Hamzeh[7]

ABSTRACT

Recently, the attention to offsite construction (OSC) has grown due to its potential for waste minimization, higher quality, and speedy construction. However, OSC projects are sometimes adopted at a slow pace due to inefficient workflow. Further, OSC adoption requires a high level of information sharing to integrate the manufacturing of components, onsite assembly, and logistics processes. Previous research on the integration of Lean principles with advanced technologies, i.e., BIM and blockchain, in OSC was limited to improving the onsite operations only. To this end, this research aims to bridge this gap by providing a BIM-blockchain system to apply lean principles in enhancing the workflow of the OSC projects considering offsite, onsite, and logistics operations. Lean principles, namely Kaizen, Heijunka, Just-in-Time, One-piece flow, and Poke a yoke, form the focus of this study. Further, the study presents a secure information-sharing system based on blockchain technology to update the status of the process, i.e., pulling material from the inventory. A case study is introduced to validate the developed system. The proposed system is expected to improve the efficiency of the OSC operations and enhance the integration of stakeholders.

KEYWORDS

Lean Construction, Offsite construction, BIM, Smart contract, Blockchain.

INTRODUCTION

Cable bridges are some of the most complex infrastructure projects that require careful planning, design, and construction (Souza et al. 2022). These bridges typically have long spans, high loads, and complex geometries, making them challenging to build. Additionally, these

bridges are usually constructed using offsite construction techniques, as they include several prefabricated components and volumetric modules (Yu & Chen 2020). Furthermore, cable bridges often must be constructed over water bodies, deep gorges, or other challenging terrains, which adds another layer of complexity to the project. As a result, cable bridge construction projects can be expensive, time-consuming, and prone to errors (Kim et al. 2011).

To solve this problem, a plausible solution would be adopting lean construction in the cable bridge projects. Lean construction has proven to be an effective methodology for reducing waste, improving productivity, and enhancing quality in construction projects. By adopting a lean approach, project teams can streamline their processes, eliminate non-value-added activities, and focus on delivering value to the customer (Bajjou et al. 2017). Similarly, advanced technologies such as Building Information Modeling (BIM), blockchain, and extended reality technologies can also be utilized to optimize cable bridge construction. For example, Using BIM enables project teams to simulate different scenarios, collaborate efficiently, and reduce rework. Extended reality technologies provide comprehensive visualization and a better understanding of the process, leading to improved project outcomes (Goh et al. 2014). Moreover, Although several scholars have recently proposed integrating lean principles and advanced technologies to solve complex project implementations, such as offsite construction projects (Hadi et al., 2023), this approach has yet to be fully explored in the literature. To this end, this study aims to improve the implementation of cable-stayed bridges by answering the following two research questions (RQs): RQ 1: What are the current drawbacks of bridge construction supply chain, and the role of lean principles in addressing them? RQ 2: How can lean principles be implemented in bridge construction using BIM and blockchain technologies?

Hence, the study objectives can be summarized as follows: 1) Discover the difficulties in the bridge construction supply chain, the role of lean principles in addressing them, and how advanced technologies can promote the use of lean principles; 2) Analyze the current state of cable-stayed bridge construction and identify the possible drawbacks using value stream mapping method; 3) Provide improvements to the discovered drawbacks and implement these improvements with the aid of BIM and blockchain technologies.

LITERATURE REVIEW

BIM AND LEAN CONSTRUCTION

There are challenges in implementing offsite construction (OSC) due to issues with design errors and level of completeness (Hussein et al, 2021). Site restrictions must be carefully considered during the design to limit redesign and other negative outcomes, including loss of productivity and a decrease in quality and onsite safety (Jung and Yu, 2022). To address the aforementioned problem, previous researchers have adopted BIM technology in offsite construction projects. For example, Park et al (2009) concluded that the use of 3D CAD (computer-aided drafting) in cable-stayed bridge construction greatly improved the constructability of the bridge. Nevertheless, BIM research for offsite construction has mainly focused on methods and tools on the practical level but not the organizational level (Santos et al., 2017). Al Hattab and Hamzeh (2018) pointed out that even though BIM is being utilized in many companies as a tool, it is mainly used to supplement traditional management strategies and achieve short-term goals, while comprehensive and detailed implementation procedures and guidance tend to be missing.

To systematically use BIM technology and make organizational-level improvements, it is suggested that the combination of BIM and lean construction can be a plausible solution (Rafael et al., 2010). Howell (1999) describes Lean Construction as “the application of a new form of production management to construction” in reference to the Toyota Production System developed by Taiichi Ohno beginning in the 1950s (Liker, 2021). Some key lean ideas have shown their efficiency in construction include (Hei et al., 2024; Kifokeris & Tezel, n.d.; Zeng et al., 2023): Value Stream Mapping (VSM), which assists practitioners in identifying the point of deficiencies in the process; Kanban, which is a visual scheduling system used to manage and control the material and task flows in a production system; Just-in-Time, which is an inventory control strategy aimed at producing goods or delivering services only as they are needed; Heijunka, which is a method used to reduce unevenness in production and minimizing overburden for different stations; One-Piece flow, which is a production method where items are processed one at a time without batches, and Poke a yoke, which refers to techniques implemented to prevent defects from occurring during the production process.

The combination of BIM and lean construction in offsite construction has also been reported in several studies. Moghadam (2014) proposed a systematic approach to offsite manufacturing management by integrating lean principles, BIM, and simulation. The proposed approach can identify the current building practice challenges and propose improvements through simulation. Gbadamosi et al. (2019) developed a design assessment and optimization system for offsite construction building assembly by combining lean construction and BIM technologies. The framework enhanced the constructability of offsite construction projects and can reduce the inefficiencies in resource use.

BLOCK CHAIN AND SMART CONTRACT

Even though the combination of BIM and lean shows a promising research trend in optimizing offsite construction processes, there are still major challenges that need to be addressed in cable-stayed bridge construction projects. Barkokebas et al. (2021) pointed out that digital strategies (like BIM) in offsite construction have not been fully implemented and have even been misused. For example, previous research was mainly focused on using lean and BIM to improve on-site operations only. To this end, a few studies tried to consider off-site operations in bridge construction projects. For example, Celik, Petri, & Rezgui, (2023) invesigated the collaboration between BIM and blockchain throughout life cycles and supply chains. They aimed to enhance the streamlined processes and improve resource traceability in projects. Elghaish et al., (2023) initiated the research effort to focus on addressing the disconnection nature of blockchain and smart contracts adoption across construction procedures. Celik et al., (2023) proposed a Blockchain-based BIM data provenance model to support information exchange in a real-world bridge construction project, where blockchain has been used to record metadata of BIM objects. These proposed approaches provide stakeholders with the availability of upstream information and enable construction practitioners to share their building components' information.

The theoretical implications of integrating lean construction and blockchain have been studied recently by scholars. For instance, Kifokeris et al., (2023) have shown the positive impact of integrating lean with blockchain and smart contracts in facilitating lean construction through building mutual trust and recording all of the data. Similar results were also discovered by Hadi et al., (2023). However, the need to implement these theoretical benefits still persists. Hence, this paper presents a BIM-Lean-supported smart contract system to comprehensively enhance the workflow of OSC projects and foster lean implementation in cable-stayed bridge construction projects by considering both offsite, onsite, and logistics operations.

RESEARCH METHOD

This section illustrates the research method that is adopted in this study. Figure 1 shows the proposed system and the overall methodological approach. Four main parts are included in this study: Literature review, process understanding and analysis, process improvement, and process implementation and validation. The literature review, as discussed in the previous section, seeks to demonstrate the association between lean construction and new technologies, i.e., building information modeling (BIM) and blockchain. In the second part, the main activities and processes in cable-stayed bridges are identified through reviewing past studies. Moreover, discovering the deficiencies and drawbacks is performed using the VSM. In order to do so, all the resources and stations (manufacturing stations) are identified. This information is used to develop the current state VSM. The current state of VSM assists practitioners in identifying the points of deficiencies in the process. These deficiencies can include the following: 1) waiting time for each process and 2) work-in-progress (WIP) items that can disrupt the workflow and create variations among stations.

To improve the process, the deficiencies identified in the previous part are studied, and ideas for improvements are proposed. To come up with improvement ideas, the authors of the current study carried out brainstorming sessions. After evaluating these improvements, they are visualized with the future state map of the VSM. A simulation model is developed to quantify the improvements achieved in the future state map. It is worth mentioning that this simulation model is detailed in another study carried out by Assaf et al., (2023). However, this study mainly focuses on the digital system that integrates lean construction with BIM and smart contracts.

In the process of implementation and validation of this study, the proposed improvements are implemented in virtual environments (BIM models). In this section, a 3D BIM model is developed to visualize the discussed improvements. This is also followed by developing a 4D BIM model to simulate the implementation of the bridge after employing the improvements. The study also goes beyond static visualization to actual digital implementation. The developed BIM models are then integrated with blockchain and smart contract technologies to serve as a digital system that keeps up-to-date tracking data and visualizes lean concepts, such as Kanban and just-in-time. The digital system will allow the user to submit a request for products (modules) when their inventory is low, without relying on fixed schedules.

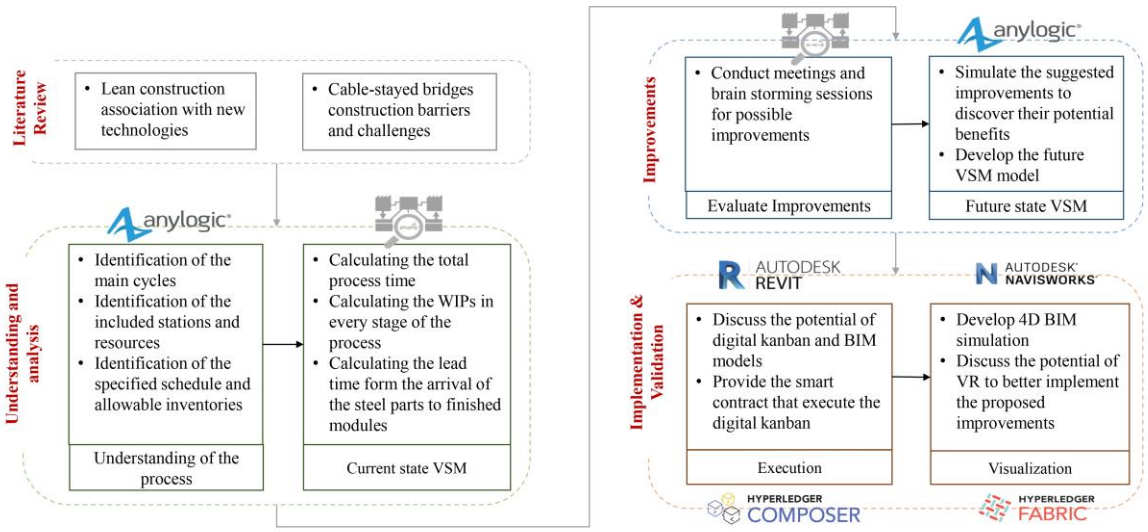

Figure 1: The proposed system in the current study

RESULTS AND IMPLEMENTATION

The proposed system is validated through a case study. The case study represents the construction of a cable-stayed bridge that was presented by Yu & Chen (2020). The bridge comprises both onsite and offsite construction techniques. The onsite technique includes the following tasks: footings construction works, columns construction works, pylons construction, tie beams construction, cables (strands) installation, and concrete works of the stitches (joints). In addition, the bridge also comprises a wide range of offsite processes, including the following:

1) the fabrication of the main and cross girders; 2) the assembly of steel modules on the yard; 3) the fabrication of precast slabs to be placed on top of the steel modules.

CURRENT STATE MAPPING

The production process of the cable-stayed bridge is hampered by several deficiencies. Hence, the lean transformation practice is discussed below. This paper uses VSM to reveal the value stream of the project and determine problem areas. The simulation results shed light on the inventory amount between each station. Based on the simulation, the current state mapping of this girder bridge project is drawn sequentially using VSM notation, as shown in Figure 2. By walking through the whole value mapping, the calculation shows that the actual value-added time for the current process is 34 days. However, the production lead time will be 110.7 working days. This indicates that the process efficiency ratio has just reached 31%, while 69% of the time will be wasted or non-value-adding.

The Takt time (5 days/module) has also been calculated by dividing the total operating time by the total daily customer demands. The analysis revealed that the cycle time of some workstations, such as cable tensioning, installing slabs, and reinforcing joints stations, is less than the takt time. However, the cycle time of the main girder station and build module station are higher than the takt time.

FUTURE STATE MAPPING

Future state mapping implements lean principles to reduce waste and improve flow. The ability to achieve a piece flow for this project is difficult due to the nature of the construction process. Each module must be fully installed, aligned, joined, and cured before the next module can be placed. This is due to the tight working space and connection requirements between modules. Each module connects to the previously installed module in the current state. As shown in Figure 3, using BIM, the construction manager can modify the installation process to install multiple modules at the same time to better achieve a one-piece flow. This is identified in the future state map as kaizen burst immediately below the construction manager to signify that the BIM Manager and construction manager work together with the information provided to and from the workstations to determine modules that can be installed independently of one another.

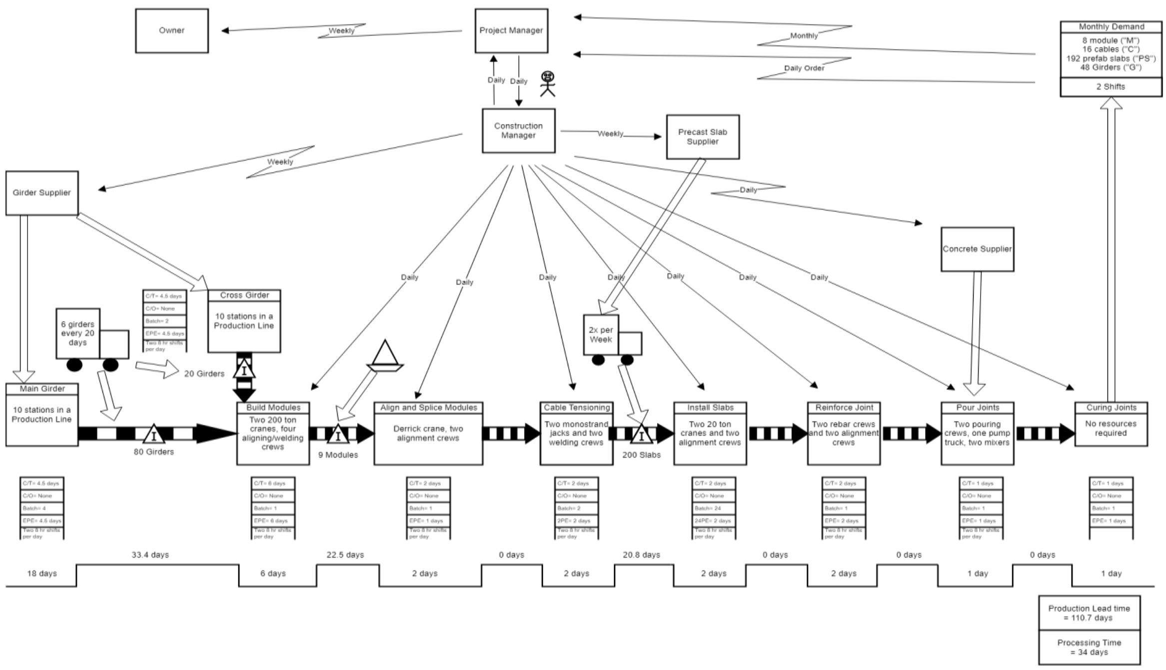

Figure 2: Current State Mapping

The inventory associated with the precast slabs can be eliminated by delivering slabs "just in time". A safety stock of 24 slabs is provided, which is enough to complete one module, and is available in the event there are supply issues with the slab provider.

The girder supplier can build a girder every 4.5 days. Their process allows them to create a cross girder and main girder at the same time, without changeover. Since we require four main girders and two cross girders per module, the total time for girders per module is 18 days. Due to the duration of the girder construction compared to the downstream module construction (6 days), the girders were pre-ordered and are required to be stored on-site, creating waste. The future state map indicates the need to go and see the girder production to better understand and reduce the timing of the girder supply. Options include introducing a changeover for the cross-girder assembly line to also create main girders or finding an additional girder supplier.

The girder inventory is waste in that it must be managed, moved, and takes up valuable working space on site, and in the event that there is an issue with the girders, the amount of inventory accumulated will exacerbate the level of waste. The upstream girder supplier requires significant lead time, so there is a need to create a supermarket, sized appropriately, with attention given to the kanban so that the girder supplier has ample time to create the necessary girders while limiting the amount of storage required. This is identified on the future state map with the supermarket pull system. Moreover, kanban helps ensure that inventory levels are optimized and that materials are available when needed. A kanban system is developed through BIM to signal when more materials are needed for the construction process. By doing so, it is expected to minimize waste by reducing excess inventory and preventing stockouts.

The align and splice module activities and the cable tensioning must be completed at a minimum before starting a new alignment and splicing of a module. This means that the duration of the activities, starting from aligning and splicing modules to the curing, could vary between 6 and 10 days. As such, a pull process between the Align and Splice Modules activity and the Build Modules Activity was appropriate, as the beginning of the construction of a new module was dependent on the availability of the downstream processes to accept it. This is identified on the future state map as a pull process.

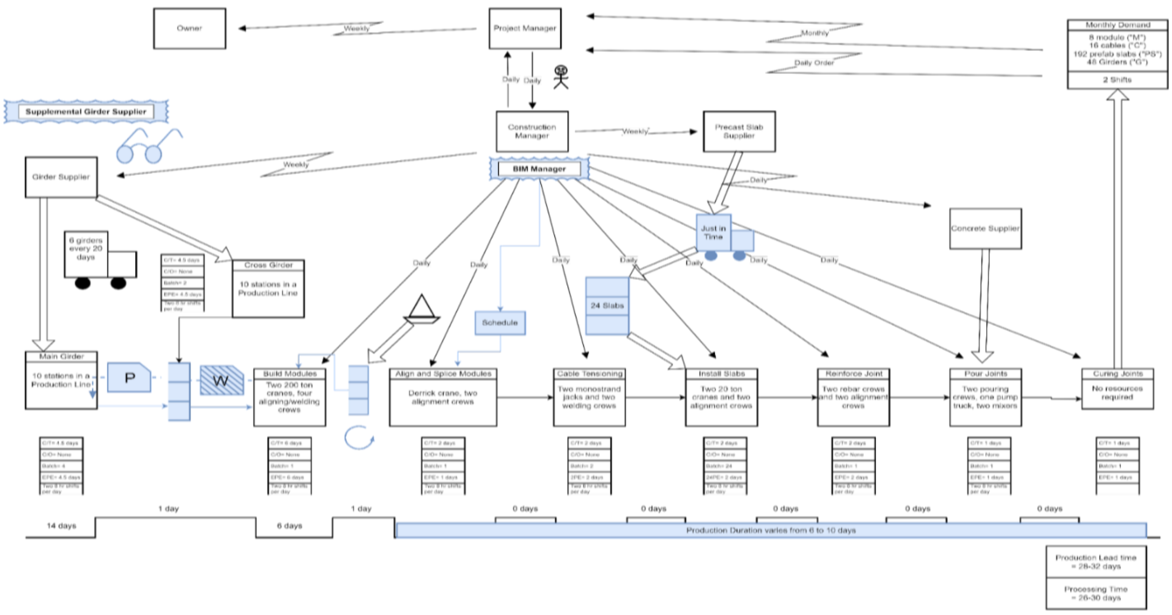

Figure 3: Future State Mapping

IMPROVEMENT IMPLEMENTATION

Knowing we can improve the process, we still lack a system that can implement these improvements. To address this, we applied a BIM-based smart contract approach to implement these improvements on a digital system that allows the user to perform the following tasks: 1) submit a request for specific elements when needed; 2) submit any document any defects at any point of the project; 3) inquiry of any past resolved issues.

BIM-Based Smart Contracts

This subsection discusses the development of the BIM-based smart contract model that helps implement lean improvements (González et al. 2022). Figure 4 shows the developed BIM model and details the included prefabricated components. The model comprises three main prefabricated components: precast slabs, manufactured steel modules, and steel girders. Every component in the model is marked with an ID that will be used in the smart contract system. The component ID specifies the component type and installation location. The processes of installing the prefabricated components, along with the onsite works, form the primary operations of this case study. The following section shows the development of a smart contract that facilitates the implementation of the discussed lean principles.

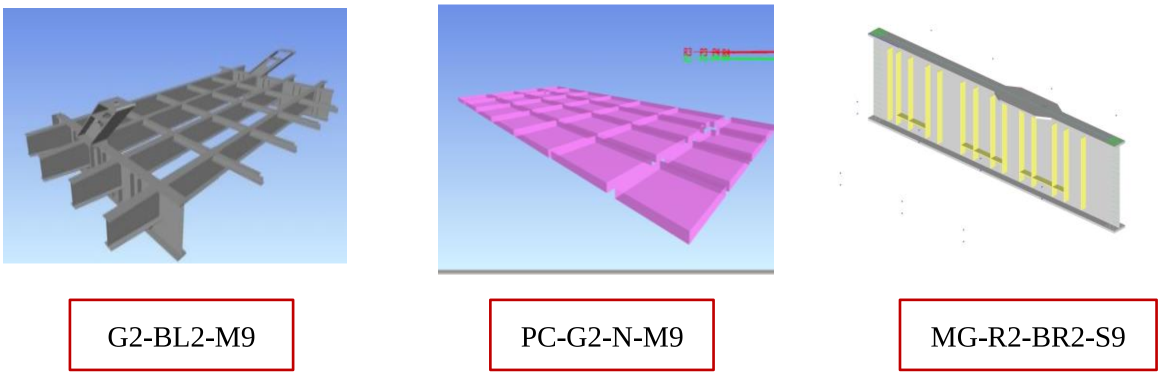

Figure 4: the developed BIM model showing the prefabricated components

Developed Smart Contract

This section shows the development of the smart contract that is associated with the BIM model. The system functions according to lean principles. These included lean principles can be summarized as follows: 1) *One-piece flow*, the developed system facilitates the operator of each station to request products when needed, without relying on a fixed schedule; 2) *Heijunka*, the system levels out the process by mitigating the inventory between stations by implementing the Just-in-time approach; 3) *Quality at bay*, the system allows the participant to submit a notification when a defect is discovered to the other operators. This notification is attached with the element ID, location, description, and deficiency degree. 4) *Poke a yoke*, any submitted quality issue and how it was solved is stored in the system transaction part.

The developed smart contract comprises many operators. Figure 5 illustrates the operators included in the network. Operator one is responsible for the fabrication of the steel girders, and Operator two is responsible for assembling these steel girders into modules. Operator three is responsible for the onsite works, and Operator four is in charge of the fabrication of precast slabs. Three main transportation routings are included in the system: transporting the steel girders from the factory to the yard by truck, shipping modules from the yard to the bridge by ships, and trucking the precast slab to the bridge deck from the offsite slab construction facility.

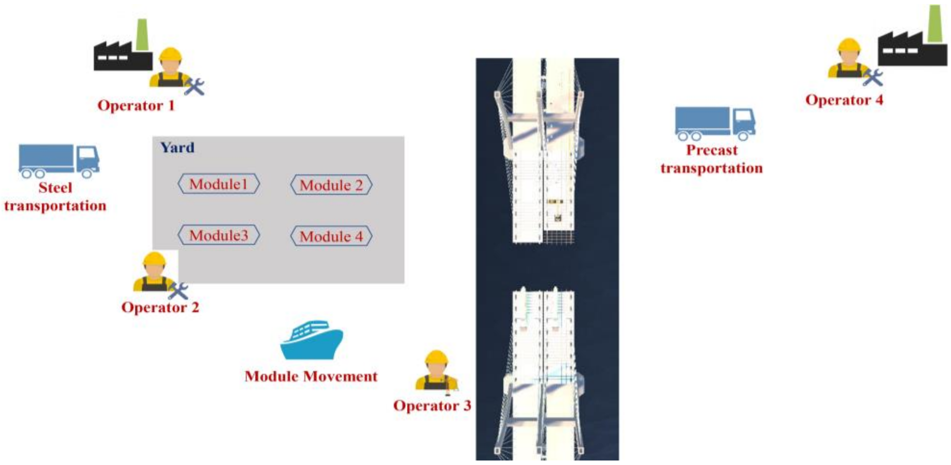

Figure 5: The included operators in the systems

The structure of the developed system uses two main systems: Hyperledger Fabric and Hyperledger Composer. The Hyperledger Fabric is an open permissioned blockchain framework that was developed by the Linux Foundation (Eltoukhy et al., 2022). The system comprised four main elements: participants, assets, transactions, and access control. Figure 6 shows these components in accordance with the proposed system. The participants in the network are all the operators identified above. The assets include the data of the inventory in each inventory. For example, in the operator1-operator2 inventory, the information of the two operators, the current available inventory, and the maximum allowable inventory are defined.

The transactions part includes the following elements: 1) submission of a request for more elements, specifying the quantity and elements IDs; 2) submission of the needed elements by the corresponding operator and update of the ledgers on the system; 3) notify any quality issue (Andon) by an operator; and 4) query of any submitted defect resolution (mistake proofing).

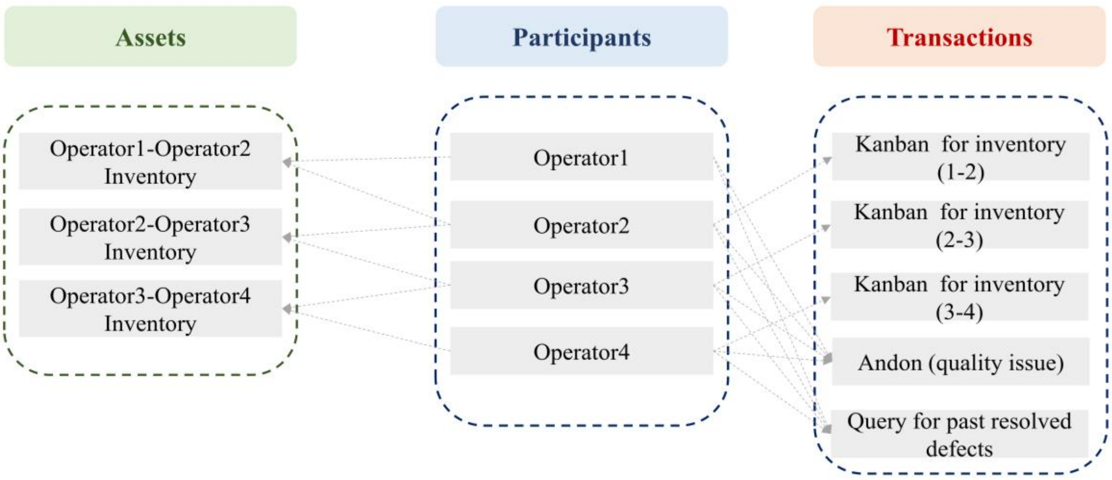

Figure 6: the components of the blockchain system

To implement the above transaction components, a smart contract was developed and deployed in the model script of the Hyperledger Composer tool. JavaScript is the language supported by the tool and was used to write the smart contract. All of the functions of the smart contract, as discussed above, are related to element ID. When participants submit a request to supply or inspect a particular element, they must specify the element ID. Figure 7 shows an ID of a steel module and what it represents.

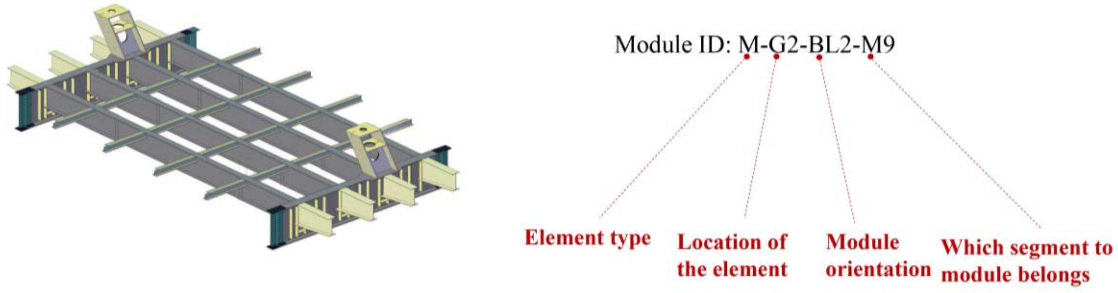

Figure 7: the representation of an element ID

Any transaction made by any participant is timestamped and saved in the transaction with a hash value that is immutable through time. This ensures the security of the network and promotes trustworthiness between participants (Assaf et al., 2022). The transactions available in the system focus on the digital kanbans to request more materials, notification of a quality issue at any time, and a request for a historical record of any issue and its solution method. Figure 8 visualizes how the transactions work in the system.

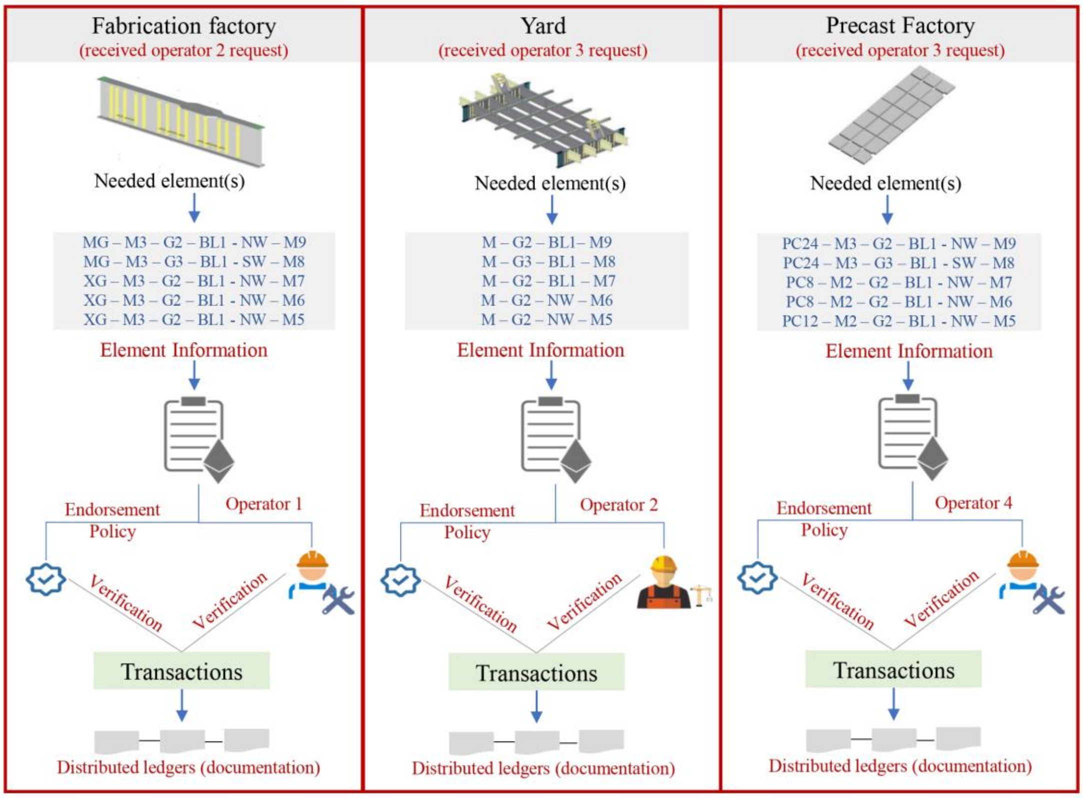

Figure 8: visualization of the functions of the smart contracts

Functionality of the Smart Contract

In this subsection, several scenarios were identified to prove the functionality of the model. First, the model is tested when a material (steel girders) is needed by Operator 2 (the yard) from Operator 1 (the steel factory). Firstly, Operator 1 logs into the system by their digital identity. This operator would have certain access to the system defined by the access control feature (ACL) of the system. Figure 9 shows the network cards that are issued to the participants and allow them to access the system. Operator 2 then selects the transactions section and submits to Operator 1 a digital kanban specifying the following: elements' IDs, quantities, and location. Operator one then receives a notification on the system of the needed items. The smart contract verifies the request first based on an endorsement policy, and then Operator 1 verifies this transaction based on the available data.

Table 1 shows the inventory assets after accepting the submitted request by operator 2 along with the submitted request. The available inventory for Operator 1 will go down by the submitted needed items, and the available inventory for the supermarket between the two stations (factory and yard) will increase by the same amount. In a scenario where the steel factory does not have enough steel girders to cover the operator 2 request, the system itself will notify the operator about the unavailability of the materials. The eligible participant can then view any of the submitted requests at any moment to keep track of the available inventory, as will be shown in the second section.

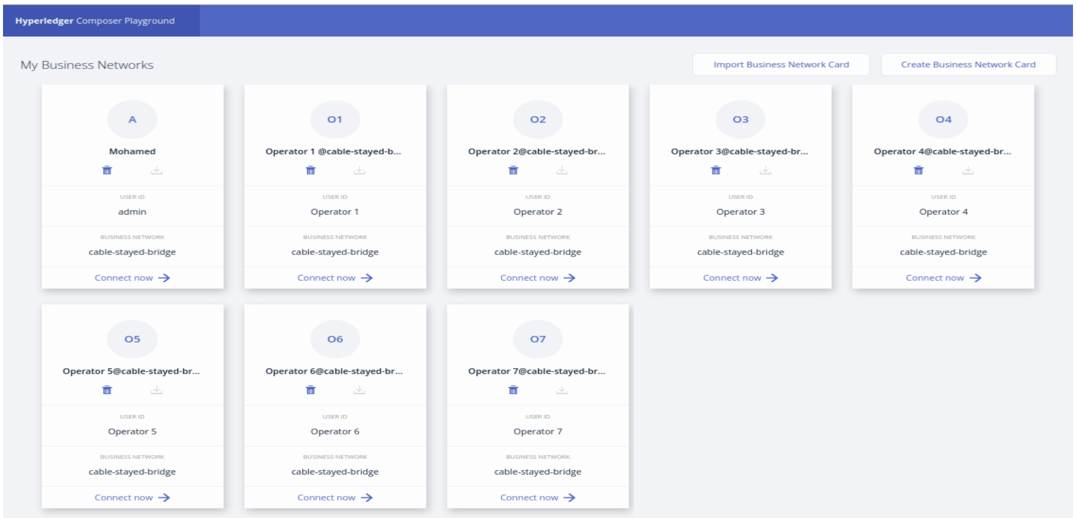

Figure 9: Network cards given to each operator

Table 1: Details of the test scenario

Step	Details
The submitted request by operator one	
The supermarket update after accepting the request	

Besides digital kanbans, the system provides operators with a *Pulling Andon* feature. In a scenario where an operator discovers a quality issue in one or more of the elements, he/she can submit an Andon on the system. The Andon specifies the following data: the element ID, the name of the station, a description of the issue, the Andon pulling time, and the degree of the quality issue (red or yellow). The transaction is visible to all operators in the system. If the issue is not resolved, the operator then submits another Andon with a red deficiency degree, and all operators in the system will stop the work. Further, all of these submitted Andon are documented in the system with its resolving strategies (Poke a yoke). Figure 10 shows a historical submission of an Andon, showing every detail of the quality issue.

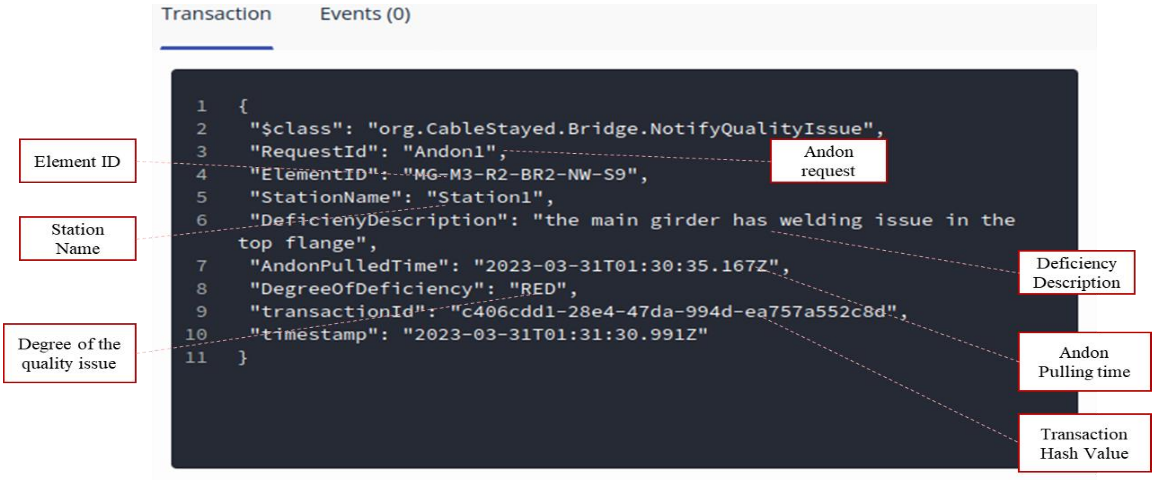

Figure 10: A historical record of a submitted Andon on the system

CONCLUSIONS

This study tackles the challenges in implementing OSC projects through the combination of advanced technologies, such as BIM, blockchain, and smart contracts, with lean principles. The study was motivated by the need to have a holistic framework that addresses the OSC challenges in onsite, offsite, and logistics operations. *Kaizen*, *Heijunka*, *Just-in-Time*, *One-piece flow*, and *Poke a yoke* are the main lean principles that were considered in this study and implemented through the mentioned technologies. Four main areas were addressed in this study. These include an extensive literature review, understanding of cable-stayed processes, providing of improvements, and implementation of the proposed improvements. The application of Value Stream Mapping (VSM) through the current state and future state mapping outlined areas of improvement that the application of BIM was able to exploit. Discrete event simulation was used to observe the impacts of providing these improvements. Further, the study provides a secure information-sharing system based on blockchain technology to fully exploit the benefits of the BIM-Lean approach. The potential incorporation of virtual reality (VR) into this process also is expected to provide an efficient training ability for the operator to be familiar with and train on lean principles.Besides the contribution provided by the current study, it also includes a number of limitations. The developed model future and current VSM do not consider the processes included in the manufacturing factories. Future research may explore the possibility of extending the scope of the presented study. Also, the smart contract system needs the participant to manually specify the element tag number. Future research may explore the full automation of the system.

AN INTEGRATED FACILITY MANAGEMENT SYSTEM SUPPORTED IN VDC AND LEAN

Alvaro Daniel Bazán Montalto [1], Jose Francisco Vidal Quincot [2] and Alexandre Almeida Del Savio [3]

ABSTRACT

The operational costs during the maintenance phase can account for 15% to 70% of a facility's total life cycle expenses, depending upon the type and size of the project. This paper explores the integration of Virtual Design and Construction (VDC) and Lean methodologies, offering practical solutions to optimize the maintenance operations of an engineering laboratory. A comprehensive literature review was conducted to identify common challenges in facility management and assess existing methods and technologies to address these issues. This research introduces the concepts of VDC and Lean within maintenance management, proposing an Integrated Facility Management System (IFMS) that applies these frameworks to the operations and maintenance (O&M) processes. The IFMS aims to harmonize the facility's physical structure, organizational dynamics, and procedural workflows, providing a practical roadmap for facility managers and maintenance professionals. Implemented in an engineering laboratory in Lima, Peru, the IFMS has significantly improved maintenance efficiency. The results include a fivefold reduction in the average time required for corrective maintenance and a 50% decrease in the incidence of such maintenance tasks. Finally, applying VDC and Lean principles to the maintenance phase can yield substantial operational benefits, as evidenced by the data from the implemented IFMS.

KEYWORDS

Facility Management, VDC, Lean, Value stream, Integrated Project Delivery (IPD), BIM.

INTRODUCTION

Despite their innovation, flexibility, and cost limitations, construction products are inherently complex (Nam & Tatum, 1988). This complexity manifests in the organization, the product, and the process. Construction projects involve numerous stakeholders with diverse objectives and interests, leading to fragmentation issues among professionals and organizations (Esa et al., 2014). Moreover, construction products are characterized by many interdependent elements, equipment, and intricate systems that constitute a building (Nam & Tatum, 1988). They are part of a challenging, lengthy supply chain involving numerous internal and external suppliers (Ashworth & Perera, 2015). Some authors correlate this complexity to the construction's heterogeneity and project-based nature (Gálvez-Martos et al., 2018). As a result, construction is ranked the second-lowest sector in adopting information technology (Agarwal et al., 2016).

1 BSc in Civil Engineering, Civil Engineering Department, Universidad de Lima, Lima, Peru, alvbazanm@gmail.com, https://orcid.org/0000-0003-2520-8767

2 BSc in Civil Engineering, Civil Engineering Department, Universidad de Lima, Lima, Peru, josevidalquincot@gmail.com, https://orcid.org/0000-0001-8036-7643

3 Full Professor, Civil Engineering Department, Universidad de Lima, Lima 15023, Peru, delsavio@gmail.com, https://orcid.org/0000-0002-6067-6606

On the other hand, the project maintenance phase represents 15% to 70% of a facility's life cost cycle, depending upon the type and size of the project. Furthermore, corrective maintenance corresponds to this cost more significantly (65% to 85%)(Janjalkar et al., 2023). The consequences of deficient building maintenance entail risks to its users' safety and maintenance cost uncertainty (Shou et al., 2020). These maintenance costs are proportional to the downtime (DT) of the system or an asset. The DT is when equipment/system is down until it returns to normal working conditions. The increase in DT is due to non-value-added (NVA) activities or wastes in maintenance operations (Mostafa et al., 2015).

This research presents a background study on the challenges and problems faced by maintenance management and the methods and technologies proposed for their solution. Moreover, Virtual Design and Construction, Integrated Project Delivery, and Lean concepts are introduced. The hypothesis is that implementing these concepts in the maintenance stage generates substantial operation benefits. Finally, an Integrated Facility Management System (IFMS) is proposed based on VDC and Lean.

BACKGROUND

FACILITY MANAGEMENT

The concept of Facility Management (or Facilities Management) has been around for more than 50 years. According to the International Facility Management Association and ISO 41011:2017, it is "an organizational function that integrates people, places, and processes within the built environment to improve people's quality of life and productivity of the core business" (ISO, 2017). Facility management began as a simple sanitary and cleaning service during the 1970s. Since then, it has constantly been evolving into what is known today as the occupational profession, with millions worldwide involved in managing organizations, their facilities, and services (Drion et al., 2012).

LEAN

Lean management principles are a philosophy that draws on the lessons learned from how Toyota does things. This principle helps an organization manage its operations more efficiently (Liker, 2004). The lean philosophy provides waste minimization methods while creating value for the stakeholders (Denzer et al., 2015). Several studies focus on the effect of lean techniques on maintenance efficiency. These tools are 5S; 5Whys, Total Production Management (TPM), Kaizen, Poka-Yoke, Kanban, Process Mapping (PM), Computerized Maintenance Management System (CMMS)/Computer-Aided Maintenance Management (CAMM), Just In Time, Failure Mode and Effect Analysis (FMEA), standardization of procedures, Value Stream Mapping (VSM) (Dragone et al., 2021). However, VSM is the most frequently applied lean technique for understanding the maintenance process by representing material and information flows (Shou et al., 2020).

VIRTUAL DESIGN AND CONSTRUCTION (VDC)

Virtual Design and Construction is a management methodology that integrates product, process, and organization models (Kunz & Fischer, 2004). The latter is one of his most significant contributions since his approach focuses on integrating a specific work team to achieve the proposed and, ultimately, the client's objectives. Since then, it has evolved into what is known today, with its main components: Client Objective, Project Objective, Integrated Concurrent Engineering (ICE), Building Information Modeling (BIM), and Project Production Management (PPM). The VDC literature shows various implementations in the design and construction phases, with outstanding results in achieving the client's objectives (Balcazar et al., 2023; Barcena et al., 2023; Bustamante et al., 2023; Del Savio et al., 2022; Majumdar et al., 2022; Palpan et al., 2022; Quinteros et al., 2023; Salazar et al., 2023; Tuesta et al., 2022). These results were obtained for projects in the design and construction phase. However, applying the same rationale for maintenance management implies measuring the production objective with some recurrence and not necessarily fixing it in a project timeframe.

INTEGRATED PROJECT DELIVERY (IPD)

Integrated Project Delivery (IPD) is a delivery model based on the collaboration between the project stakeholders in the construction industry (Aslesem et al., 2018). IPD was initially developed to confront the challenges of increased project complexity, high fragmentation levels in the construction industry, and inadequate communication among stakeholders (Ahmed et al., 2021). A multiparty agreement and the involvement of key stakeholders at an early design stage characterize this delivery system. The emphasis is on relationships, collaboration, and pursuing mutual goals. This implies sharing the risks and rewards of the project as an incentive to achieve this mutual goal (Teng et al., 2017; Durdyev et al., 2019).

METHODOLOGY

This paper aims to conduct an explanatory investigation into implementing an integrated facility management system supported by Virtual Design and Construction (VDC) methodology and Lean concepts.

It is hypothesized that integrating VDC and Lean concepts could help fulfill the client's objectives during the building maintenance phase. Based on this premise, a bibliographic review was carried out in indexed databases, such as Scopus, Mendeley, and Web of Science, as well as regulations and standards of good practice, using the following keywords: "Facility Management," "Virtual Design and Construction," “Lean Maintenance” and "Information System."

The methodology follows the Value Stream Mapping method. First, it identifies the target process to improve. Then, the baseline or current state of the value stream map is constructed based on semi-structured interviews with laboratory personnel in charge (identifying the waste). Next, a future value stream map for maintenance supported by the VDC, IPD and Lean is proposed. Finally, a working plan is developed based on that optimized process (Martonen & Baglee, 2019).

RESULTS AND DISCUSSIONS

PROJECT INTRODUCTION

The facility studied in this article is the Laboratories of the Civil Engineering Department (Figure 1) at the Universidad de Lima, located in Lima, Perú (Figure 1). When the Civil Engineering Program began in 2017, the need arose to implement laboratories to provide (i.) technical and academic support to the subjects taught, (ii.) research support, and (iii.) support for the construction industry. In this sense, the direction of the Civil Engineering Department defined a gradual procedure for implementing the laboratories to meet those goals. The following laboratories were identified and implemented: Laboratory of Materials, Soils, Rocks, Topography, Geomatics, Structures, Environmental Engineering, Pavements, Sanitary Engineering, Hydraulics, and Hydrology. The results obtained in this chapter reflect the method proposed to implement the IFMS under a VDC and Lean approaches applied to the Operation and Maintenance stage.

Figure 1: Overall view of the Laboratories of the Civil Engineering Department of Universidad de Lima.

PROBLEMATIC ANALYSIS BASED ON PRIMARY INFORMATION

It was employed semi-structured interviews with stakeholders responsible for equipment maintenance in the laboratory. These interviews facilitated the definition of objectives, identification of critical equipment, mapping of the equipment maintenance process, identification of problems or sources of variability, and proposal of improvements in the maintenance process. The results of these interviews are presented below.

One hundred percent (100%) of the interviewed managers agreed that the value of the investment made in implementing the laboratories is measured in the degree of use of the equipment in academic courses, research, and industry support.

The laboratory managers pointed out 11 critical pieces of equipment, presented in Table 1, organized by the laboratory disciplines. A piece of equipment is considered vital when it meets the following requirements: (1) its operation is essential due to its high demand, (2) its maintenance is complex and laborious or with much variability in the correction period, or (3) that it does not have a replacement available in the local market.

Table 1. Key equipment.

Laboratory	Key Equipment Name
Materials	Uniaxial Compression Machine (Automax) and Multi-testing Machine (600 KN)
Geotechnics	Triaxial Soil System and Direct Cutting Equipment
Pavements	Hamburg Wheel and Servo-Hydraulic Universal Testing Equipment
Structures	Single-ended Hydraulic Actuator
	Uniaxial Compression Machine (3000 KN)
Sanitary, Hydraulic, and Hydrology Engineering	Compact Fluid Mechanics Basic module (HM250) and Flow and Sediment Transport Channel
Environmental	Spectrophotometer Infrared (FTIR)

Based on the interviews, it was mapped the current maintenance process for the laboratories using the Business Process Model and Notation (BPMN) standard. This process is shown in Figure 2. The stakeholders are the laboratory team, civil engineer career team, maintenance team, buy area, and maintenance suppliers.

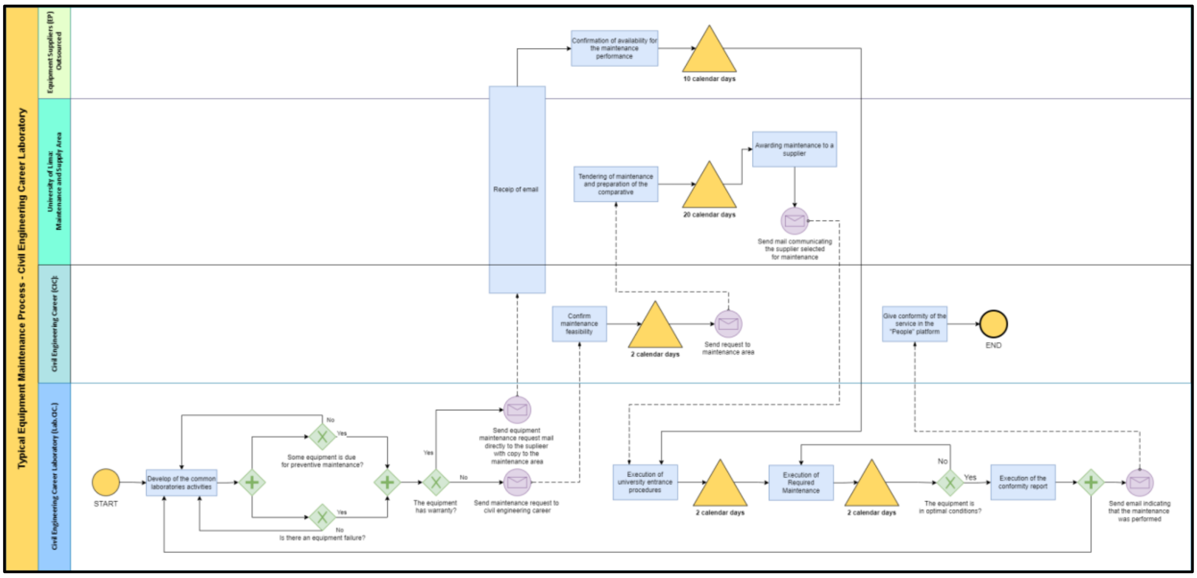

Figure 2 - Current maintenance flow.

The maintenance process is sequential and fragmented. Most communications are made by email. The average duration of the equipment maintenance process depends on two variables: the type of maintenance (corrective or preventive) and an equipment warranty. The equipment inoperability days were increased from 2 days (duration with preventative maintenance and warranty) to 26 days for equipment that did not have a warranty (Table 2). In this sense, strategies are needed to include a more extended warranty.

Table 2. Current maintenance process analysis.

Type of Maintenance	Warranty	Total Process Duration (Days)	Duration of Inoperability (Days)
Preventive Maintenance	Yes	14	2
	No	26	2
Corrective Maintenance	Yes	14	14
	No	26	26

The interviewees identified the main issues with the maintenance process as follows: (1) Latency in communications and deficiencies in following up maintenance requests, (2) variability in the duration of provider selection, (3) the absence of extended warranties, and (4) maintenance information management. Additionally, the laboratory team does not participate in provider procurement. Hence, the duration of the award process and the reliability of the chosen supplier emerge as the primary sources of variability within this process.

The waste analysis and classification were based on the current maintenance flow. In this context, the most impactful wastes are the waiting times and ineffective data management in the entire process. A fragmented approach to maintenance management generates those wastes. The sequential and fragmented process increases communications latency and increments the total cycle time.

As a result, 60% of the interviewed managers reported that some equipment in their laboratory was inoperative due to maintenance, with an average repair time of 130 calendar days for critical equipment (corrective maintenance).

VDC FRAMEWORK ELABORATION

The VDC framework includes explicit specification of client and project objectives and measured performance for the project. This includes specifying a performance objective and a desired performance measured with a specific frequency (Kunz & Fischer, 2020). The proposed VDC framework, presented in Table 3, was based on the stakeholders' interview information and the systematic bibliographic review. Subsequently, the stakeholders validated this framework, and the impact of applying it on the maintenance process was measured. The VDC outputs and production metrics allowed the maintenance process production to be evaluated and compared with a target value.

The client's objective is to guarantee the critical equipment operability in the laboratory. The goal, 95% of operability, was defined considering only one day stop for preventive maintenance per month. It is desired to avoid any equipment inoperability due to corrective maintenance. The project team's (the maintenance process stakeholders) objective is to develop an integrated facility management system to manage the 11 critical equipment and supply the client maintenance needs.

The operability percentage is the core metric of the maintenance process. Two identified problems were the absence of extended warranties and delays in provider selection. As controllable factors, the IFMS includes process mapping and uses collaborative contracts with an IPD scope for maintenance suppliers. This IPD contract implementation has improved the willingness to collaborate and create an open communication culture, integrated information, collaborative goal definition and decision-making, and early involvement of the key participants (Kahvandi et al., 2017; Aslesem et al., 2018). In this sense, the IFMS aims to consider IPD contracts to create long-term collaborative contracts with the maintenance providers and guarantee preventive maintenance and availability for corrective maintenance. This IFMS/IPD contract shall consider sharing the risks and rewards of the year maintenance budget as an incentive. However, this contract should be considered in the early phases of the design process to align better the process needs.

Weekly meetings with the maintenance stakeholders were considered for the ICE component. The communication latency was one of the main problems identified in the interviews. The ICE sessions generated response latency reductions. Hence, the IFMS proposal shall include ICE sessions weekly to keep updated on the maintenance status of the 11 critical equipment. Some important issues were the maintenance provider selection, the information needed to include on the BIM, and a collaborative contract with the selected supplier with an IPD scope.

Another issue was managing maintenance information. The BIM component allows maintenance information to be managed following the COBie standard. As a controllable factor, the IFMS proposes creating a required information checklist for each project. The information needed for the maintenance team may vary per project and organization. The goal for this component is to include all the required information for maintenance in the BIM with the COBie Standard.

Table 3. Proposed VDC Framework.

VDC Framework				
Client Objectives	Guarantee a 95% operability of the critical equipment. (This means only one day stop for preventive maintenance per month)			
Project Objectives	Develop and implement an Integrated Facility Management System (IFMS), which manages the 11 critical equipment of the laboratories.			
Components	**Item**	**Description**	**Metric**	**Goal**
ICE	Production Metrics	Have 100% compliance with the agenda in the sessions (% Agenda Compliance).	$\%Agenda\ Compliance = \frac{\#Items\ Completed}{\#Items\ Scheduled}\ x\ 100$	100%
	Controllable Factors	Send the Meeting Agenda in advance.	Number of days in advance to send the agenda	2
BIM	Production Metrics	Have 100% equipment operation and maintenance information included in the BIM model (With COBie Standard)	$\%\ \text{O\&M}\ Information\ in\ BIM = \frac{\#Inf.\ Included}{\#Inf.Required}\ x\ 100$	100%
	Controllable Factors	Define the information needed for the maintenance checklist for critical equipment.	Required Information Checklist per essential equipment	1
PPM	Production Metrics	Have 95% monthly operability for the 11 critical equipment	$\%\ \text{Operability} = \frac{\#Operating\ Hours}{\#Total\ Hours}\ x\ 100$	95%
	Controllable Factors	Create the VSM for the current maintenance process and optimize it with IFMS.	# of Process Map developed	1
		Create collaborative contracts with the maintenance suppliers with an IPD scope	$\%\ Critical\ Equipment\ with\ a\ colaborative\ contract\ scope = \frac{\#Equip.with\ Contract}{\#Total\ Critical\ Equip.} x\ 100$	100%

IFMS IMPLEMENTATION AND VALIDATION

The maintenance stakeholders validated the IFMS methodological approach. The approach received a satisfaction level of 73% and suggestions for improvement related to developing specific strategies for each piece of equipment and laboratory. Table 4 shows the results of the three-month early adoptions of the IFMS. It can be observed how the average duration for the corrective maintenance was reduced by five times, and the number of corrective maintenance incidents was reduced by half, validating the IFMS implementation.

Table 4. IFMS implementation results.

Process	Baseline Measurement	Maintenance Process with IFMS	Delta	Target
Average Duration of the Corrective Maintenance Process (Calendar Days)	130	22	108 (5 times less time)	2
Number of Corrective Maintenance Incidents	5	2	3 (Reduced by Half)	0

CONCLUSIONS

The main objective of this research was to propose an Integrated Facility Management System (IFMS) based on the concepts and practices given by the VDC and Lean. The IFMS was built based on information from the maintenance process problem identified through semi-structured interviews. This allowed for understanding, validating, and precisely defining the client and project objectives. Also, the systematic review helped to suggest production metrics and controllable factors that support the implementation of IFMS based on the VDC and Lean principles.

With the early implementation of IFMS, the average duration for corrective maintenance was reduced by fivefold, and the number of corrective maintenance incidents was reduced by half. Moreover, this methodology received the acceptance of 73% of the stakeholders. The next step is developing a relational contract with the maintenance suppliers. This will allow us to improve the operability performance of the critical equipment based on collaborative relations.

CAN CHATGPT HELP WITH THE LAST PLANNER® SYSTEM IMPLEMENTATION? AN EXPERT OVERVIEW

Andrews A. Erazo-Rondinel[1], Mauricio A. Melgar-Morales[2], Josep J. Abregu-Gonzales[3], Juan A. Napa-Almeyda[4] and Diego S. Lipa-Mamani[5]

ABSTRACT

In recent years, the construction sector has been influenced by different technologies, which has given way to construction 4.0. One of the elements of Construction 4.0 is the use of artificial intelligence, and in recent years, chatbots have become popular in different industries, including construction. However, the literature on how chatbots can help in construction projects is limited. In this sense, the following article aims to study the degree of reliability presented by a chatbot (ChatGPT) to improve the implementation of the Last Planner® System (LPS). This article begins with a literary review of LPS barriers. From this, 13 main barriers are validated with the help of 10 expert judgments. After that, ChatGPT 3.5 is interacted with to provide possible solutions to the barriers found, which are validated again with eight expert judgments. The results show that 68.27% of ChatGPT responses are “Totally agree” and “Somewhat agree.” The following article will contribute to professionals in the construction sector so that they can evaluate the reliability of chatbots and explore their applications to solve LPS implementation problems and other problems in construction projects.

KEYWORDS

Last Planner, Artificial Intelligence, ChatGPT, construction 4.0, lean construction.

INTRODUCTION

The construction industry faces cost overruns, changes in execution, delays, and low productivity, and one of the main factors for these is the slow technological adoption of the construction industry (Hui et al., 2019). In this sense, Industry 4.0 can transform construction into a technological industry (Kozlovska et al., 2021). Given this, there are efforts to combine Industry 4.0 technologies in construction, which has given rise to Construction 4.0, where technologies such as BIM, virtual reality, mixed reality (Hossain & Nadeem, 2019) and artificial intelligence (AI) are used (Forcael et al., 2020).

One of the elements of Construction 4.0, AI, which is defined as a powerful management tool that provides superior analysis operated by humans, allows time savings in automating

processes and forecasting results (Ayoubi et al., 2023). Its applications occur in intelligent manufacturing and predicting phenomena related to building design, construction, and operation, identification of elements on a construction site, and developing patterns to follow workers' performance (Forcael et al., 2020). The use of artificial intelligence in construction is increasing due to the large amount of data produced by digital transformation, the capacity for data management, and the improvement in computational quality (Baduge et al., 2022).

AI has been explored to generate synergies with the lean philosophy. For instance, Cisterna et al. (2022) explain how AI can leverage the data generated by Lean. In addition to this, in recent years, AI chatbots such as ChatGPT have been developed, which, due to an immense amount of data, training models, adaptability, and learning, are capable of maintaining conversations, understanding the context, and presenting solutions (Yan et al., 2023). This is how its implementation has expanded in different areas, and lean construction has not been the exception. Therefore, interactions between Lean Construction and Chat GPT have a promising future (Hatoum & Nassereddine, 2023). For example, Etges and Fireman (2023) generated a conversation with ChatGPT about the dimensions of lean construction concepts, tools and people and validated them with 14 experts, finding that 77% of ChatGPT responses are "good" or "very good".

In this way, construction 4.0 could support several Lean Construction objectives, such as LPS, Jidoka, and VSM. That is why Hamzeh (2021) mentions that together, these elements could give rise to what is known as Lean Construction 4.0, a new philosophy that uses emerging technologies to streamline processes and promote a culture of continuous improvement, elimination of waste, and respect for people. This new philosophy prioritizes the harmonious integration of people, processes, and technologies.

While there are studies on ChatGPT and lean construction, research on adopting Chatbots within Lean Construction still needs to be explored. Dumrak and Zarghami (2023) highlight that one of the most important gaps is understanding AI's potential in the Lean field and how it can aid in the application and concept practice. Schia et al. (2019) note that one of the benefits of using AI is its ability to automate repetitive processes, thereby reducing human errors and allowing people to focus on value-added tasks. This benefit aligns with the Lean principles of waste reduction and value generation. Despite this, as Cisterna et al. (2022) point out, there needs to be more research that analyzes the synergy between the fields of Lean construction and AI, indicating a significant untapped potential. This untapped potential underscores the importance and urgency of our research in this area.

For this reason, the following article delves into how ChatGPT can help establish practical strategies to mitigate the barriers to Last Planner System implementation. To achieve this, the researchers collect and validate barriers associated with LPS through expert judgment. Then, using the categorized barriers, they ask ChatGPT for strategies to mitigate their impact. Finally, they validate the certainty of the obtained answers with expert judgment, thereby providing concrete insights and strategies for leveraging ChatGPT in Lean Construction, specifically in the context of Last Planner System implementation.

BACKGROUND

ARTIFICIAL INTELLIGENCE AND LEAN

Lean Construction is a construction management philosophy implemented on different continents (Engebo et al., 2017). Thus, in recent years, due to the technological revolution, various technological advances have been generating synergy with construction 4.0, giving rise to the concept of lean construction 4.0, which seeks to combine the technology of industry 4.0 with the people-process-technology lean triad (Hamzeh et al., 2021). Thus, one of the key elements of this synergy is the interaction of Lean Construction with artificial intelligence.

In that sense, Cisterna et al. (2022) mention that implementing AI and Lean together generates synergies that add value to what they would have when applied separately. Likewise, other authors have explored these synergies in different fields. Prieto et al. (2023) study the use of artificial intelligence for decision-making, thus avoiding people's subjective judgment that can lead to waste, such as unproductive actions that do not add value. Dumrak and Zarghami (2023) conducted a classification study on the different categories and AI tools to make an application in lean construction management (LCM) to support its principles.

Likewise, this synergy has extended to the interaction of chatbots such as ChatGPT with Lean Construction. Etges and Fireman (2023) conducted a conversation to obtain the definitions that ChatGPT can provide about the concepts, tools and behavior of people related to lean construction and then be evaluated by experts on the subject. Hatoum and Nassereddine (2023) focused on collecting and summarizing IGLC articles and identifying their trend in research that relates to lean construction and ChatGPT and their ability to educate and train on both theoretical and practical aspects of the application of lean construction.

CHAT GPT AND CONSTRUCTION INDUSTRY

ChatGPT is used in different industries, and the construction industry is no exception. Thus, ChatGPT promises to transform not only the way we build but also the way we imagine the infrastructure of tomorrow (Rane, 2023). ChatGPT can help carry out preliminary designs, structural analyses, and simulations, in addition to facilitating the optimization process and evaluation of the feasibility of each alternative (Aluga, 2023). In addition, it has been used in risk management (Aladağ, 2023) and in project planning, where it has promising results, especially for simple cases, but since it is not a tool designed for planning, it has limitations in the programming of real projects. (Prieto et al., 2023). ChatGPT also helps in the development of intelligent, sustainable, automated cities, BIM models, and choice of materials and technologies, showing that even with the challenges it presents, such as the need for specialized training and possible job changes, it seems clear that ChatGPT will have a central role in the development of the construction industry (Rane, 2023).

PROBLEMS IMPLEMENTING THE LAST PLANNER SYSTEM

The Last Planner System (LPS) tool, a Lean Construction tool, is used for production planning and monitoring to increase reliability and performance while establishing a predictable workflow (Hamzeh et al., 2009). It has been shown that its implementation brings benefits such as improved organizational control (Cerveró et al., 2013), a decrease in variability that translates into greater productivity, and a reduction in costs (Koskela et al., 2010), simplifying thus the production control and planning process (Aziz & Hafez, 2013). Despite these benefits, its successful implementation faces several barriers.

Liu et al. (2020) described the barrier of lack of knowledge about LPS, mentioning that one of the causes is the low effectiveness through which social dynamics are managed in construction organizations, which reduces both absorption and diffusion of LPS. These can be without a solution for a long time.

On the other hand, Venkatesh and Venkatesan (2021) explained that the barriers of "resistance to change" and "Lack of collaboration between project team members" have a relationship between the two because, in the construction industry, there is a late acceptance of the change and one of the main reasons for this is the low participation of various segments deployed in the project.

Lindhard and Wandahl (2015) focus mainly on two barriers: "Partial Implementation" and "Lack of Knowledge of the LPS execution process." In their research, they mentioned that a theoretical and practical study revealed that only parts of the LPS are implemented, and this directly influences the process's reliability. In addition, a lack of knowledge of the implementation can cause reliability problems to go unnoticed.

Based on the literature review, 15 barriers to implementing the Last Planner system were detected, which are presented in Table 1.

Table 1: Barriers associated with the implementation of the last planner system.

Barriers	References*
Lack of leadership and management commitment for the implementation of the Last Planner System (LPS).	1
Lack of Last Planner training to managers to manage the project.	2, 3
Management has a short-term vision in the implementation of LPS in their organization.	4
Lack of knowledge about the LPS System	1, 2, 5, 6, 7, 9
Lack of role definition in LPS implementation	3, 5
Lack of commitment of the team in the LPS implementation	2, 4
Lack of involvement of the last planners	5, 6
Lack of involvement of the members of the production chain (customer, suppliers, subcontractors)	2, 3, 5, 7
Resistance to change	1, 2, 3, 6
Lack of transparency and weak communication in the exchange of information in the weekly meetings	2, 3, 5, 7
Lack of commitment of the whole team in the implementation of LPS	6, 7
Failure to use a gradual process of LPS implementation	9
Lack of self-criticism to take improvement actions during LPS implementation	3, 7
Incorrect use of the information gathered during implementation to create a learning loop	1, 3, 5, 7
Lack of management support for LPS implementation	1

Note: *1. Murugaiyan et al. (2022), 2. Venkatesh and Venkatesan (2021), 3. Murguia (2019), 4. AlSehaimi et al., (2009), 5. Brady et al. (2011), 6. Liu et al. (2020), 7. Tayeh et al. (2018), 8. Lindhard and Wandahl (2015), 9. Perez and Ghosh (2018).

RESEARCH METHOD

Figure 1 shows the phases of the methodology of this research. In the first phase, a literary review of the barriers to the implementation of the last planner system is carried out by searching with the keywords "Last planner" and "barriers" in the IGLC and Scopus databases because IGLC contains the most significant amount of Lean Construction publications (Daniel et al., 2015) and Scopus has a greater range of construction publications than other databases (Mongeon & Paul, 2016). In the second phase, a survey was developed that allowed the main barriers of LPS to be categorized, and the survey was sent to 10 experts using the Likert scale. The surveys were used because they have been used in other lean construction studies, such as those of Murguia (2019).

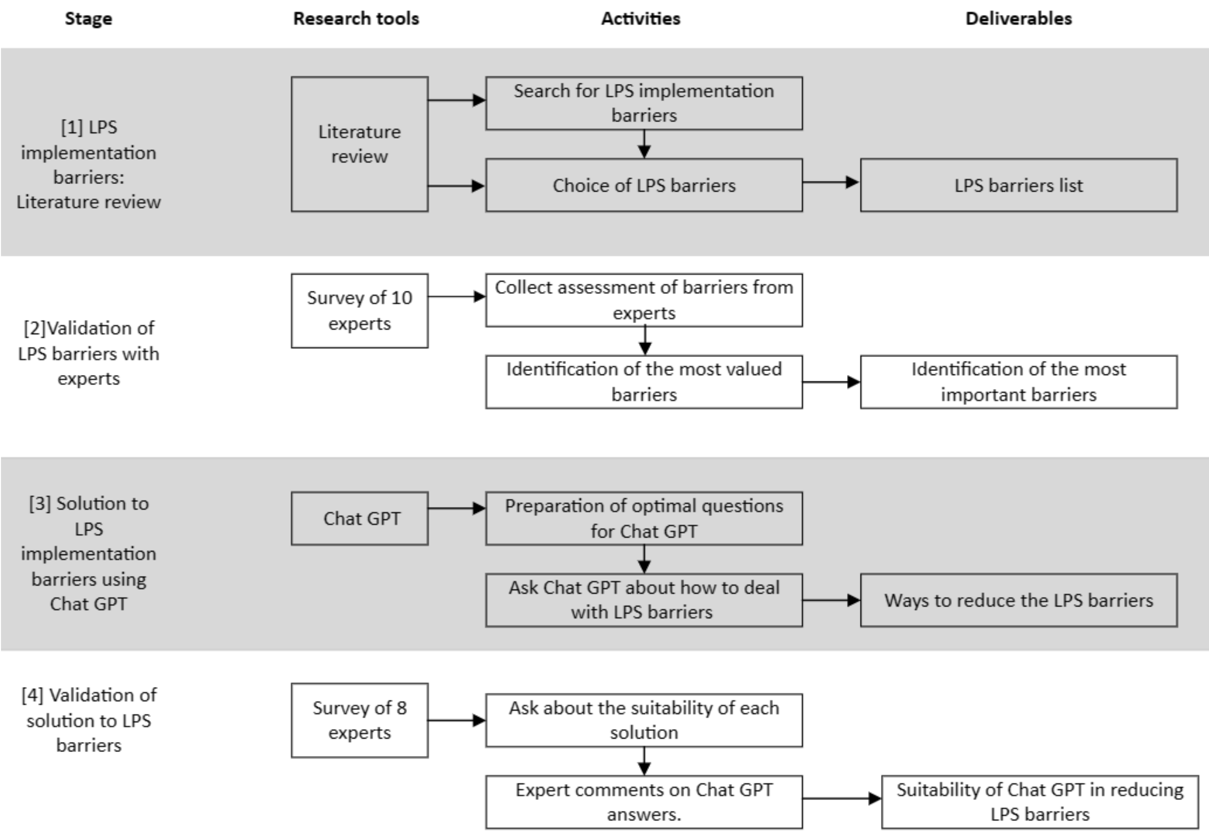

Figure 1: Structure of the Paper.

The selected experts had to be civil engineers with more than five years of experience in lean construction. Table 2 shows their profiles.

Table 2: Profile of the experts who validated the LPS barriers.

Number	Experience	Experience in Lean Construction	Industry/Academic	Business /Interest Area
Expert 1	10-20 years	10-20 years	Industry Participant	Project management
Expert 2	5-10 years	5-10 years	Industry Participant	Construction
Expert 3	>20 years	>20 years	Academic	Research, development and innovation
Expert 4	10-20 years	10-20 years	Industry Participant	Construction
Expert 5	5-10 years	5-10 years	Industry Participant	Construcción
Expert 6	10-20 years	10-20 years	Industry Participant	Project management
Expert 7	10-20 years	10-20 years	Industry Participant	Construction
Expert 8	5-10 years	5-10 years	Industry Participant	Project management
Expert 9	5-10 years	5-10 years	Industry Participant	Construction
Expert 10	10-20 years	10-20 years	Industry Participant	Project management

In the third phase, ChatGPT was used to ask how it would resolve the barriers with an average greater than 4, of which there were 13 and were considered the most important. In the last phase, the answers were sent in a new questionnaire to experts, with the same requirements as the previous validation. They were evaluated using a Likert scale to evaluate how much they agreed with the content and quality of the answers and to write a comment with their opinion. Table 3 presents the characteristics of the experts.

Table 3: Profile of the experts who validated the set of CHAT GPT's answers.

Number	Experience	Experience in Lean Construction	Industry/Academic	Business /Interest Area
Expert 1	10-20 years	<5 years	Industry Participant	Construction
Expert 2	10-20 years	10-20 years	Industry Participant	Construction
Expert 3	5-10 years	<5 years	Industry Participant	Project management
Expert 4	5-10 years	5-10 years	Industry Participant	Construction
Expert 5	10-20 years	10-20 years	Industry Participant	Construction
Expert 6	10-20 years	10-20 years	Industry Participant	Research, development and innovation
Expert 7	10-20 years	10-20 years	Industry Participant	Project management
Expert 8	5-10 years	5-10 years	Industry Participant	Construction

RESULTS AND DISCUSSION

LAST PLANNER BARRIERS

From the surveys with the experts, 13 barriers were obtained, shown in Table 4.

The most important barrier is barrier B1, with an average of 4.6. This shows that a key factor in the successful implementation of LPS is management's support and commitment to it. For this same reason, the B3 barrier does not allow us to achieve the expected results.

It is argued that barriers B2, B4, and B5 exist because the LPS is a tool that requires a good understanding of the principles and their composition to put them into practice and obtain results. Furthermore, barriers B6, B7, B8, B10, and B11 exist because the LPS is a tool that requires collaboration from the entire team (Daniel et al., 2015), so if it is not available, it can lead to problems in implementing this tool. On the other hand, barrier B9 is typical of lean approaches such as LPS despite the benefits it may bring (Pedrosa et al., 2023).

Table 4: Most important Barriers of LPS.

Code	BARRIERS	s.d.	Mean	Rank
B1	Lack of leadership and management commitment for the implementation of the Last Planner System (LPS).	0,70	4,6	1
B2	Lack of Last Planner training for managers to manage the project.	0,71	4,5	2
B3	Management has a short term vision in the implementation of LPS in their organization.	0,88	4,5	3
B4	Lack of knowledge about the LPS System	0,70	4,4	4
B5	Lack of role definition in LPS implementation	0,70	4,4	5
B6	Lack of commitment of the team in the LPS implementation	0,82	4,3	6
B7	Lack of involvement of the last planners	0,79	4,2	7
B8	Lack of involvement of the members of the production chain (customer, suppliers, subcontractors)	0,63	4,2	8
B9	Resistance to change	0,79	4,2	9
B10	Lack of transparency and weak communication in the exchange of information in the weekly meetings	0,67	4,1	10
B11	Lack of commitment of the whole team in the implementation of LPS	0,74	4,1	11
B12	Failure to use a gradual process of LPS implementation	0,67	4	12
B13	Lack of self-criticism to take improvement actions during LPS implementation	0,82	4	13

For reasons of space limitations, the responses provided by ChatGPT are not presented in this research, as this conversation occupied 31 pages of results. However, of the barriers identified in the previous stage, the questions asked to ChatGPT are presented in Table 5. The "act" prompt was used since this instruction guides the artificial intelligence to execute or reproduce a specific set of skills from a group of experts. This research scenario allowed the AI to provide us with solutions based on the answers previously uploaded by lean construction experts to its database. It is observed that the most critical barrier turns out to be barrier B1, with an average of 4.6, which shows that for a successful implementation of LPS, a key factor is the support of management and their commitment to the implementation. For this same reason, the B3 barrier does not allow us to achieve the expected results.

Furthermore, it is important to highlight that at the beginning of the conversation with ChatGPT, the pre-set question "What is lean construction?" was asked because it was observed that ChatGPT provided higher-quality answers by building connections with past answers (Etges and Fireman, 2023).

Table 5: Most important Barriers of LPS solved by ChatGPT.

Code	Questions to ChatGPT	Number of words
B1	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of leadership and management commitment for the implementation of the Last Planner System (LPS)?	396
B2	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of Last Planner training to managers to manage the project?	449
B3	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Management has a short term vision in the implementation of LPS in their organization?	473
B4	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of knowledge about the LPS System?	449
B5	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of role definition in LPS implementation?	460
B6	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of commitment of the team in the LPS implementation?	472
B7	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of involvement of the last planners?	485
B8	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of involvement of the members of the production chain (customer, suppliers, subcontractors)?	495
B9	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Resistance to change?	504
B10	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: lack of transparency and weak communication in the exchange of information in the weekly meetings?	504
B11	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of commitment of the whole team in the implementation of LPS?	504
B12	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Failure to use a gradual process of LPS implementation?	515
B13	Act as a professional in lean construction, how would you solve this barrier to implementing last planner system: Lack of self-criticism to take improvement actions during LPS implementation?	509

The experts' answers are in Figure 2. On average, 68.27% of the responses are in the range of "Totally agree" and "Somewhat agree," which is" close to the 77% obtained in the ChatGPT and lean construction study by Etges and Fireman (2023).

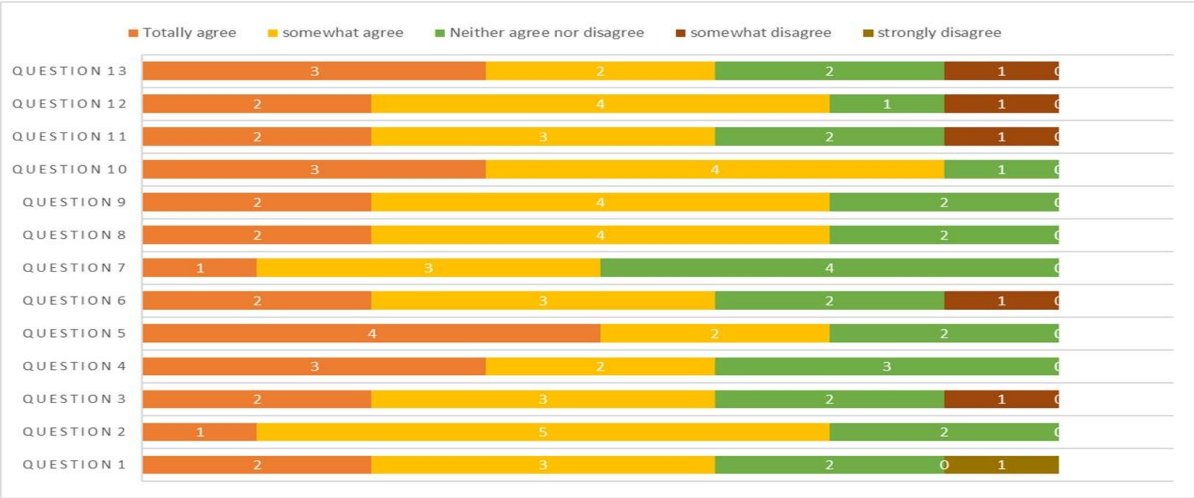

Figure 2: Chart of expert evaluation results on Chatgpt.

Question 10 is where the experts agreed the most, where no expert answered, "somewhat agree" or "strongly disagree." However, they would also propose an appropriate selection of the implementation team, making a better evaluation of the profile and performance of the participants.

Question 7 has the least approval, with 50% answering "Totally agree" and "Somewhat agree." Half of the respondents mentioned that more information was needed from Chat GPT and that, from the experts' experience in practice, they mention that this barrier is also influenced by factors external to those raised in the answer.

The only question with a "strongly disagree" answer was question 1. The expert who gave that rating commented that Chat GPT's answer fits the adoption of a general tool and not a tool with a philosophy of continuous improvement and lean transcendence, such as the LPS, which is consistent with what was mentioned by Etges and Fireman (2023). However, there were also responses in "Totally agree," arguing that good responses were given, such as highlighting the economic benefits to the company, as this will ensure a successful start to implementation and with high involvement of senior management.

In question 2, the experts mention the relevance of training operational managers and project supervisors but not so much that of "managers," pointing out that raising their awareness is enough to improve management with LPS. On the other hand, some criticisms were that knowledge management is more than the application of learning tools; rather, it is a process to ensure the learning achievements that are to be transmitted.

The experts highlight that question 4 is developed using the approach of barrier 2. However, both the question and the answers are more specific. It is also differentiated by the inclusion of "internal champions," who will be the defenders and mentors in the integration of LPS. There are unaware of LPS due to a generational issue, but not because they do not know of its existence.

In question 3, the experts mention that ChatGPT's answers were predictable in the sense of prioritizing that the LPS is oriented with the strategic plans and demonstrating the business benefit of implementing LPS.

Question 5 has the most answers in "Totally agree," and the experts mention that they provide accurate recommendations on role recognition in the implementation of the LPS, but they also mention that there should be more emphasis on the communications management part.

Most experts gave their opinions with a "Totally agree" rating for question 6, showing their interest in a relationship with communications management within the workplace.

In the comments on question 8, they mention that Chat GPT provides general answers to multiple factors, so it would be better to identify the flaws in a project personally and then ask Chat GPT what it would do to solve them.

Question 9 has a generally accepted answer. However, the experts mention that one must look beyond providing training and incentives and worry, for example, about generational change and how to generate change for senior professionals.

For question 11, it was recommended that this barrier can be avoided with better personnel selection and evaluation of profiles and performance of participants so that they are aligned with the work's objectives.

In question 12, the experts mention that adequate points were given in the answer but that the implementation process depends on each problem, so the answers are very general. In addition, they recommend getting more information to ask about a particular case.

Experts mostly agree with the answers provided by Chat GPT. However, some recommend that each problem for LPS adoption be first identified in addition to collecting data. So that Chat GPT has a greater context of the situation and generates better, more precise, and more understandable solutions. Results are consistent with the results found by Etges and Fireman (2023).

CONCLUSIONS

From this research, Chat GPT can be a good tool for providing responses related to mitigating the impact of the barriers associated with the Last Planner System since the specialists agreed with the different measures proposed by ChatGPT in 68.27% of cases.

The authors propose that future research try more interactions between lean construction and ChatGPT, increase the quality of the questions in the present study, and follow the recommendations of the experts to solve LPS implementation problems in a particular case study with ChatGPT so the answers can be more accurate.

The strong approval in question 10 indicates that experts recognize the importance of carefully choosing the implementation team. This finding suggests they value the need for trained and committed personnel to ensure success in applying the LPS. Furthermore, no expert selected "somewhat agree" or "strongly disagree" highlights a consensus on this topic.

The lower approval recorded for question 7 highlights a concern about the need for more information provided by Chat GPT in certain aspects. Experts suggest that a lack of clarity or detail in some areas could be an obstacle to the effective implementation of the LPS. This finding underscores that communication and the availability of complete information are critical elements for project success.

The experts' analysis shows that "Lack of leadership and management commitment for the implementation of the Last Planner System (LPS)" is the main barrier, which indicates the importance of management support and commitment.

DIGITAL MONITORING FOR LEAN CONSTRUCTION: EFFICIENCY IN MAJOR INDONESIAN TOLL ROAD PROJECT

Mardiansyah[1], Agung F[2]., Rizky A. Saputra[3], Gregorius A. Sentosa[4], Amy R. Widyastuti[5], Sastria Wresniwira[6], Achmad Luthfi Naufal[7] and Juniar R. Kusuma[8]

ABSTRACT

The Karangjoang-Kariangau Section 3A Toll Road Project in East Kalimantan, Indonesia, aims to connect Balikpapan City with Nusantara, the New Capital City. This 13.4 km project, primarily involving intensive earthwork, utilizes heavy equipment whose efficiency is crucial for enhancing productivity and reducing costs. Our study examines inefficiencies such as unnecessary equipment motion, transportation delays, and extended waiting times—common challenges in lean construction. We implemented a digital monitoring system to compare its effectiveness against traditional manual methods in improving resource utilization and minimizing waste. Findings indicate that digital monitoring, despite the higher initial costs, significantly helps to boost operational efficiency by providing detailed data, then the data can be used to analyze the core of the problem so that a solution is found that successfully reduces idle time by 37% and increasing equipment utilization by 39%. These results demonstrate the substantial benefits of integrating digital technologies into construction management, suggesting a crucial shift towards digital methods to meet the demands of modern infrastructure development effectively. This study underlines the alignment of digital monitoring with lean construction principles, advocating for its adoption to optimize productivity and cost-efficiency in large-scale projects.

KEYWORDS

Lean construction, waste, digital monitoring, continuous improvement

INTRODUCTION

The Karangjoang-Kariangau Section 3A Toll Road Project, referred to as the "New Capital City Nusantara" called Ibu (IKN), spans 13.4 kilometers and plays a crucial role in connecting Balikpapan City to the New Capital City, Nusantara, in East Kalimantan, Indonesia. Ensuring

efficient and controlled use of heavy equipment is vital due to the project's extensive scope, where precision in monitoring and control are essential to adhere to the project schedule and prevent delays and cost overruns. Challenges such as equipment location monitoring and productivity rate assessments have been identified as key factors contributing to these delays and additional costs. These challenges are often exacerbated by traditional management methods, which typically involve low-frequency monitoring that does not provide real-time data, thus failing to allow timely corrective actions (Nasr E., 2013).

In response to these issues, this study aims to evaluate the impact of implementing a digital monitoring system on the operational efficiency of heavy equipment in the section 3A Toll Road Project. Our objectives include assessing how digital monitoring can enhance real-time tracking, reduce equipment idle times, and support lean construction principles by improving resource utilization and reducing waste. By transitioning from traditional to digital monitoring methods, this research seeks to provide empirical evidence on the improvements in project management that can lead to significant cost savings and efficiency gains. The adoption of a stricter and more sophisticated monitoring system is not just a requirement but a strategic enhancement in line with national strategic project goals.

LITELATURE REVIEW

This literature underscores the evolving landscape of construction technology and sets a foundation for this study's exploration of digital monitoring's impact on lean construction practices in the context of Indonesia's significant infrastructure projects.

LEAN CONSTRUCTION CYCLE PROCESS

Lean Construction is grounded in the philosophy of continuous improvement, influenced significantly by Kaizen, which promotes incremental enhancements to boost efficiency and foster collaborative innovation. The Plan-Do-Check-Act (PDCA) cycle and Lean Six Sigma's DMAIC framework are pivotal methodologies within this realm, enhancing workflow, reducing waste, and improving quality by utilizing structured, data-driven problem-solving techniques (Lean Construction Institute, 2023; IdeaScale, 2023). In line with the Toyota Way's principles, the adoption of new technologies in construction must be reliable and tested extensively to ensure they support continuous operations and enhance worker productivity.

IDENTIFICATION OF WASTE IN CONSTRUCTION

Waste in construction encompasses more than just material waste; it includes inefficiencies in time, labor, and processes that can lead to increased costs and project delays. Classic waste types identified in lean construction include defects, overproduction, waiting, non-utilized talent, unnecessary transportation, excess inventory, and excess motion (Ohno, 1988). Techniques such as Value Stream Mapping (VSM) and the Last Planner System (LPS) are employed to identify and mitigate these wastes by visualizing workflows and enhancing planning reliability (Koskela, 1992; Ballard, 2000). Emerging technologies like Building Information Modeling (BIM) and automated monitoring with drones and sensors have further advanced the capability to identify and reduce waste, particularly in large-scale projects (Smith & Doe, 2020).

DIGITAL MONITORING

Advancements in digital monitoring technologies, such as Global Positioning Systems (GPS) and On-Board Instrumentation Systems (OBIS), represent significant strides in construction management. GPS technology, known for its autonomous operation and real-time data provision, is crucial for monitoring equipment effectively on large-scale construction sites, facilitating better resource management and operational efficiency (Pradhananga & Teizer, 2013). OBIS complements GPS by monitoring mechanical conditions and operational parameters to optimize the productivity of heavy equipment, addressing issues such as equipment idle times and inefficient resource use, critical in projects like the IKN 3A Toll Road (Alshibani, 2015).

METHODOLOGY

The methodology of this study systematically investigates the impact of digital monitoring on enhancing lean construction practices within the Section 3A Toll Road project in the middle of the project (August - October). Our approach combines qualitative and quantitative data to provide a comprehensive understanding of the role digital monitoring plays in waste reduction and process optimization. The research commences with identifying waste through both conventional and digital monitoring techniques to provide continuous improvement. Conventional monitoring serves as a baseline for comparison, while digital monitoring, enabled by a real-time dashboard, allows for a more detailed performance analysis and recognition of dominant waste streams. A comparative analysis between traditional and digital monitoring methods is conducted to evaluate their efficacy in waste identification and reduction. The digital monitoring system, featuring a dynamic dashboard, offers real-time insights and performance metrics that facilitate a continuous improvement cycle. Lean construction tools such as current state value stream mapping (VSM) and Fishbone Diagrams are employed to map out existing workflows and diagnose inefficiencies. This analysis is enhanced through root cause analysis, allowing us to develop targeted countermeasures. A future state VSM then helps to envision improved processes with higher cycle efficiency. The research aims to yield actionable outcomes, including a comprehensive guideline tested and refined through the research process to assist in the implementation of digital monitoring in lean construction & identification of digital monitoring features that contribute to lean construction waste reduction, substantiating the system's effectiveness in improving operational efficiency.

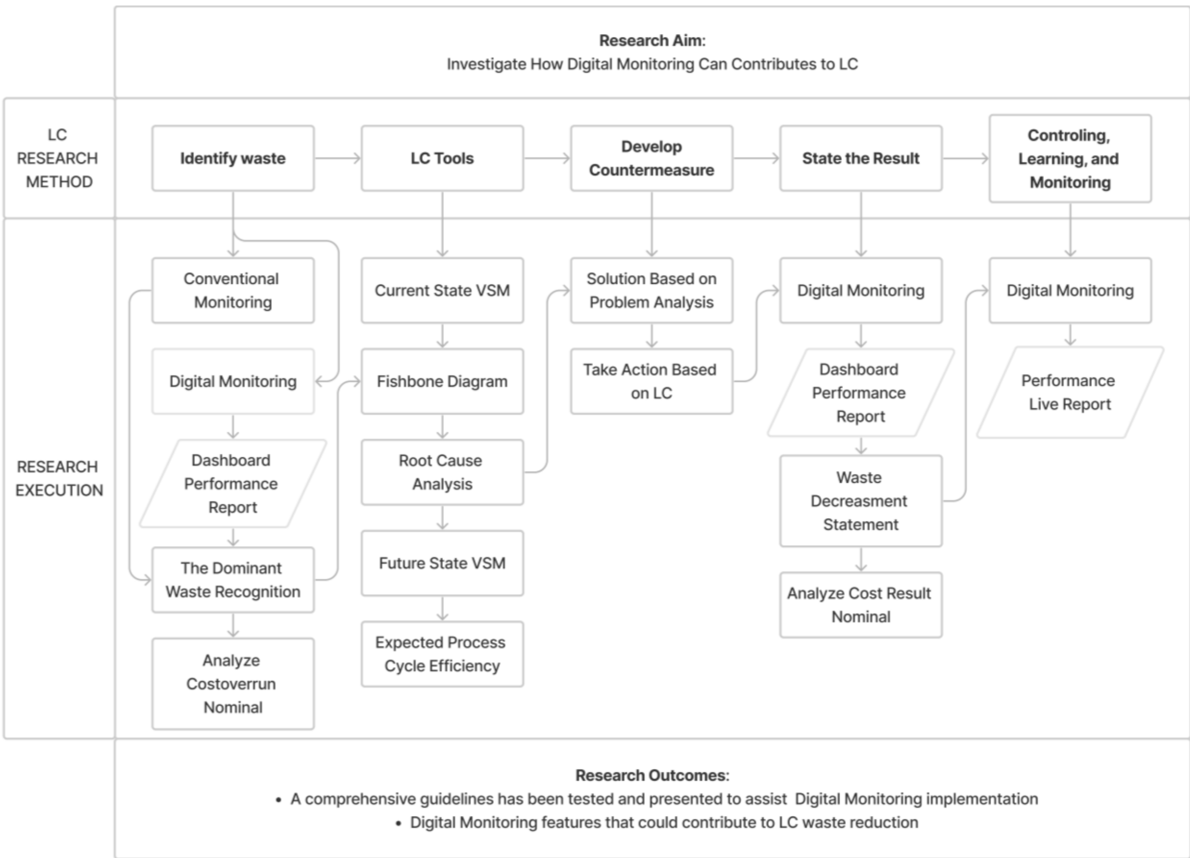

Figure 1: Research Methodology

INITIAL DATA REPORTS COMPARATION

Table 1: Report of Heavy Equipment Timesheet from Conventional Monitoring & Digital Monitoring

Criteria	Month	Idle Time (Monthly)		Driving Times (Monthly)		Total Timesheet (Hour)	Total Cost
		Hour	%	Hour	%		
Conventional Monitoring	Aug	Undetectable		Undetectable		5,880.00	3,80 Bio
Digital Monitoring	Sept	3,134.77	*55.28%*	2,267.12	44.72%	5,401.88	3,48 Bio

The comparative analysis depicted in Table 1 substantiates the advantages of digital over conventional monitoring in evaluating operational activities. In August, conventional methods failed to capture idle and driving times, which stands in sharp contrast to the following month, September, where the digital monitoring system was able to precisely quantify idle time at 3,134.77 hours. This accounted for 55.28% of the total timesheet, surpassing the driving times, which were 44.72% or 2,267.12 hours. The significant proportion of idle time, outstripping active operation, signals a pressing concern for resource wastage, potentially caused by extensive queuing during excavation tasks. Corroborating field observations confirmed these inefficiencies, particularly the protracted waiting periods of machinery, which not only diminish productivity but also elevate operational costs, as indicated by the total cost of IDR 3,487,472,454.74. Of this amount, approximately IDR 1,927,874,772 is attributed to waste. The implementation of digital monitoring thus emerges as a pivotal tool for operational management and cost reduction, providing a clear path to mitigate inefficiencies and optimize resource allocation.

LEAN CONSTRUCTION TOOLS IMPLEMENTATION

CURRENT STATE MAPPING

Advancing from the initial data capture through digital monitoring, applying the Lean Construction methodology to dissect and understand inefficiencies. The deployment of Value Stream Mapping (VSM) is pivotal in this phase, as it provides a visual representation of the current state of operations, laying bare the flow and accumulation of waste. By charting each step in the excavation and construction process, VSM helps us pinpoint where delays occur, where resources lie idle, and where processes diverge from the ideal lean workflow. The Value Stream Mapping (VSM) applied to the Section 3A Toll Road project’s earthwork stages has offered us a granular view of the project's current workflow and efficiency. Based on Figure 2, That illustrates the sequence of earthwork activities for every 100 meters of the construction project, encapsulating the flow of operations from excavation to compaction. The process commences with mobilization of heavy equipment, taking half a day, leading to the excavation phase, which has a value-adding duration of 4 days and a cycle time of 7 days. Subsequent dumping activities contribute 3 days of value-adding and a cycle time of 4 days, followed by grading with 3 days of value-adding and a 5-day cycle time. The final compaction step culminates the sequence with a value-adding time of 5 days and the longest cycle time of 8 days. This VSM, part of a broader project spanning 13.4 km and scheduled for 365 days, is overseen by a project manager conducting daily follow-ups and weekly progress updates. The visualization indicates a total lead time of 28 days for the earthwork process, distinguishing between 15.5 days of value-adding work and 12.5 days potentially available for lean improvement, underscoring the significant opportunity for enhancing operational efficiency and reducing waste.

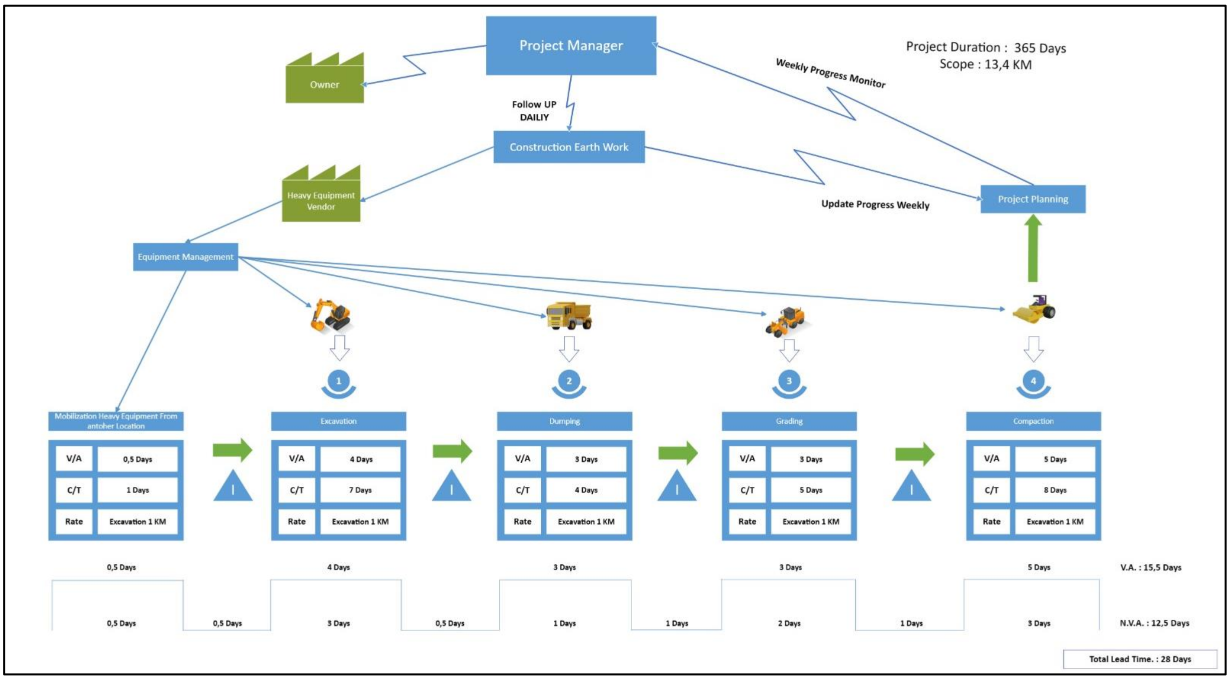

Figure 2: Current State VSM Diagram

With the current state now analyzed through VSM, we shift our attention to the causes of the identified waste. This sets the stage for the Fishbone diagram analysis, which will explore the systemic reasons behind the inefficiencies and pave the way for developing actionable strategies for waste reduction

Fishbone Diagram and Root Cause Analysis

The Fishbone analysis is expected to provide a structured investigation into the complexities of project delays and inefficiency, offering the next critical layer of understanding necessary for implementing Lean Construction principles effectively. In the comprehensive Fishbone analysis conducted for the Section 3A Toll Road project based on Figure 3, systematic exploration of root causes across categories methods, materials, machine, manpower, measurement, and environment has revealed key inefficiencies impacting the project.

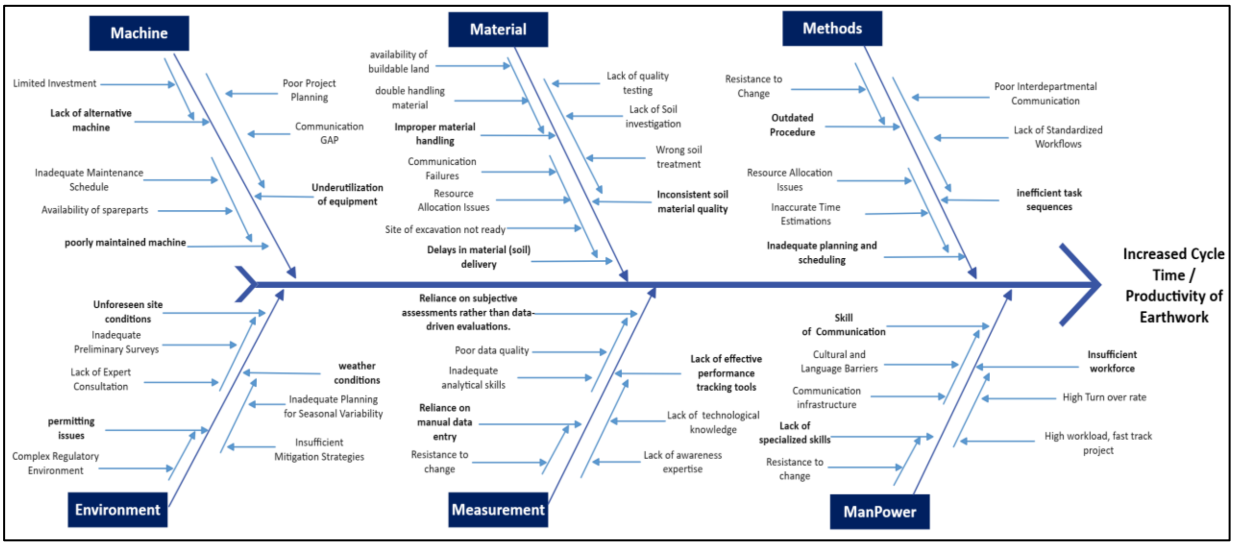

Figure 3: Fishbone Diagram

Based on the Fishbone analysis derived from field reports, several significant issues frequently arise across different categories. Within Methods, the main problems identified include planning and scheduling processes that are inadequate, lacking in detail, and not applicable as field references. For Materials, the soil often used cannot be utilized for earth filling because it does not meet the required criteria. In terms of Machinery, there is a lack of maintenance planning and coordination, leading to significant downtime with many machines remaining idle. Regarding Manpower, there is a substantial communication gap between field staff and management office personnel. Measurement issues persist due to reliance on manual measurement and monitoring systems, resulting in inaccurate data. In the Environment category, the complexity of obtaining excavation permits at the project's commencement poses challenges. Based on the results presented in Table 2, root causes have been categorized and ranked according to the frequency of occurrences over the past two months and the extent of their impact, as discussed in weekly meetings. This was done during periods of both conventional monitoring and digital monitoring. Subsequently, these root causes have been prioritized to determine which issues are most urgent and need to be addressed immediately.

Table 2: Top Root Causes by Frequency and Impact to Productivity

Category	Root Cause	Waste Category	frequence (2 month)	Impact
Methods	Resources Allocation Issue	Waiting, Motion	35 cases	Major
	Schedule not suitable with real condition on site	Waiting, Motion	40 cases	Major
Material	Wrong soil treatment	Defect	12 cases	Major
	lack of soil investigation	Defect, Motion	15 cases	Major
	Double handling material	Transportation, Motion	18 cases	Major
Machine	Availability of spareparts	Waiting	9 cases	Major
	inadequate maintenance schedule	Defect	28 cases	Major
Man Power	Miss coordination between field coordinator	Waiting, Motion	48 cases	*Severe*
Measurement	lack of tecnological knowledge	Non – Utilized Talent	8 cases	Major
	lack of awareness expertise	Non – Utilized Talent	8 cases	Major
Environment	Insufficent mitigation strategies for weather condition	Waiting, Defect	10 cases	Major
	Inadequate planning for seasonal variability	Waiting, Defect	10 cases	Major

COUNTERMEASURE DEVELOPMENT

To effectively address the major root causes identified in our analysis, we have developed and evaluated targeted solutions aimed at preventing ongoing issues and mitigating cost escalations. Table 3 outlines how these challenges were addressed using Lean Construction concepts. By implementing strategic actions grounded in Lean Construction methodologies, we aim to enhance operational efficiency and control project costs more effectively.

Table 3: Solution Based on Lean Approach

Root Cause	Solution
Resources Allocation Issue	Collaborate with the scheduling, procurement, and equipment departments to ensure that resources are prepared in accordance with the planned requirements. This preparation should be informed by the outcomes of previous productivity evaluations. Additionally, involving field coordinators in discussions about heavy equipment needs is essential. Together, develop a more comprehensive pull planning schedule that incorporates insights from all levels of the project team.
Schedule not suitable with real condition on site	Engage with key stakeholders including schedulers, procurement staff, equipment managers, field coordinators, foremen, and vendors. By facilitating a comprehensive discussion among these parties, we aim to develop a new, more dependable Last Planner System. This revised planning approach will serve as a fresh benchmark for ongoing schedule monitoring and evaluation, ensuring that all project activities are aligned and optimized for maximum efficiency.
Wrong soil treatment	Initiate further discussions with planning and design consultants to resolve the issues arising from differences between actual soil conditions and initial design specifications. It's imperative to quickly determine suitable soil treatment solutions to prevent heavy equipment from remaining idle while waiting for decisions.
Lack of soil investigation	Undertake a comprehensive reassessment of the soil conditions and quickly communicate the results to the planning consultants. This will ascertain whether the excavated soil meets the requirements for reuse as fill material or if there is a need to import soil from an external source.
Double handling material	Develop a detailed work plan for excavation and backfill activities, ensuring that every excavation task has a predefined disposal area to prevent inefficient practices such as double handling. Utilize weekly Last Planner System (LPS) planning to strategically sequence the excavation activities, coordinating which sections are to be excavated first and confirming the availability of designated backfill locations.
Availability of spareparts	Develop a procurement strategy for frequently replaced spare parts informed by the Last Planner System (LPS) and pull planning analyses. Should spare parts be unavailable, formulate a contingency plan to borrow heavy machinery from other sites temporarily. This plan requires a reassessment of the project timeline to accommodate machinery availability and prioritizes critical areas to prevent project delays.
Inadequate maintenance schedule	Begin scheduling routine inspections for heavy machinery, particularly during holidays, to ensure that the equipment operates at its maximum efficiency during working periods. This strategy minimizes technical issues with each piece of heavy machinery during operations and mitigates the cost of repairs by addressing potential problems early. Regular maintenance checks can prevent significant downtime and expensive fixes.
Miss coordination between field coordinator	Implement daily coordination meetings between on-site workers and field managers to effectively manage and optimize the utilization of available resources. Use these sessions to track the status of equipment and identify any operational constraints, ensuring that any deficiencies or challenges are immediately reported to the engineering and procurement teams.
Lack of tecnological knowledge	Deploy programs to rapidly and effectively upskill workers on new technologies, enhancing their proficiency and adoption.
Lack of awareness expertise	Develop a skills matrix to identify expertise gaps and implement cross-training programs to broaden the skill sets of the workforce

Table 3 (continued): Solution Based on Lean Approach

Root Cause	Solution
Insufficent mitigation strategies for weather condition	Develop comprehensive risk management plans that include specific mitigation strategies for adverse weather, integrating contingency plans into the project schedule.
Inadequate planning for seasonal variability	Create a construction schedule by integrating historical weather data provided by the local meteorological agency. This data should be carefully analyzed to anticipate potential weather disruptions over the upcoming month. By aligning this information with the project timelines, you can adjust the work schedule proactively to factor in likely weather conditions.

The solutions derived from the Lean approach analysis have been integrated into the current state map to develop a comprehensive future state map. This map projects substantial enhancements in the productivity of earthwork operations and aims to significantly reduce waste. A key focus is on minimizing idle time for equipment, thereby streamlining operations, and improving overall project efficiency. This strategic integration highlights the potential for tangible improvements in project execution and cost-effectiveness.

FUTURE STATE MAP

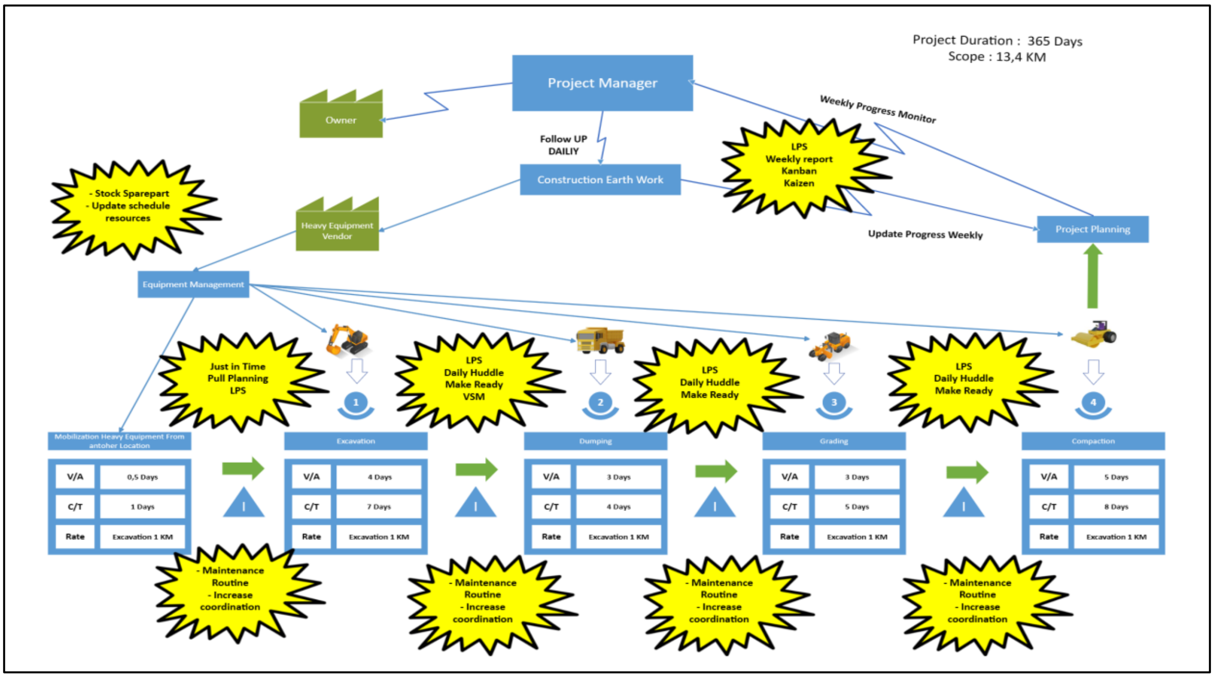

Figure 4: Future State Map

The Future State Map for the Section 3A Toll Road project based on Figure 4 reflects an adoption of Lean practices, integrating lean tools to align resource allocation and task execution with real-time needs. Maintenance is scheduled more effectively with improved coordination to minimize equipment downtime. Weekly reviews incorporate continuous improvement through Kaizen, allowing the project to adapt quickly to changes. A focus on increasing coordination between key person, also maintaining an updated inventory for spare parts and adjusting resource schedules is essential to prevent equipment idleness and boost productivity. This map sets a new standard for operational efficiency by embedding Lean methodologies into the project's processes. This streamlined approach is anticipated to increase non-value-added activities and diminish waste time, setting a new benchmark for operational efficiency and project performance.

DATA REPORT AND RESULTS

After thorough evaluations, the following month saw the deployment of the designed solutions and the Future State Map that had been previously analyzed. Discussions on root cause analyses and corresponding solutions took place in weekly meetings, with updates being made to the Last Planner System. These meetings, attended by representatives across all levels, especially the last planners on-site, were crucial for unifying the understanding and ensuring a coordinated approach to field operations for the next month. Table 4 in the subsequent section will detail the outcomes of applying the Lean tools to the digital monitoring system, showcasing the tangible improvements, notably in increased driving time, indicating a stride toward enhanced operational efficiency.

Table 4: Data Report Recap

Criteria	Month	Idle Time (Monthly)		Driving Times (Monthly)		Total Timesheet (Hour)	Total Cost
		Hour	%	Hour	%		
Manual	Aug	Undetectable		Undetectable		5,880.00	3,800,428,500.00
Digital Monitoring Without Lean Improvements	Sept	3,134,77	55.28	2,267.12	44.72	5,401.88	3,487,472,454.74
Digital Monitoring After Lean Improvements	Oct	1,237.78	18.26	5,589.81	81.74	6,827.59	4,450,175,157.25

Efforts to optimize the capability of heavy equipment by allocating it led to a total timesheet (hours) increase of about one thousand hours, resulting in a total cost increase to Rp. 4,450,175,157.25. Table 5 shows that the driving times before the implementation of lean construction were only at a percentage of 44.72%, unlike after the implementation of lean construction, which reached a percentage of 81.74% driving times. Additionally, from the recap table above, a comparison of idle time percentage between Digital Monitoring After Lean Improvements and Digital Monitoring Without Lean Improvements reveals a percentage decrease from 55.28% to only 18.26%.

Table 5: Waste Improvements

Criteria	Without Lean Improvements	After Lean Improvements	Deviation (Waste Improvements)	Info
Idle Time (Hour)	3,134.77	1,237.78	*-1,896.98*	Idle Time Decrease, Driving Time and Productivity Increase
Waste (%)	58.03%	18.13%	*-39.90%*	Waste % Decrease, Efficiency Increase 39%
Waste Cost / Idle Cost (Rp)	$ 124,787.00	$ 49,745.00	*-$ 75,041.00*	Waste Cost Decrease, Turn into Cost Productivity

The implementation of lean construction based in Table 5 on reducing waste and increasing value, is proven by the impact of corrective actions that have been conducted. There is a decrease in idle time, coupled with an increase in driving time. In other words, there has been a 39% increase in efficiency due to the decrease in waste. This change transforms costs that were previously used for waste into costs that are now used for productivity.

CONTROL AND MONITORING

Following the successful implementation of Lean tools and digital monitoring in October, it is imperative to ensure the continued application of these strategies to sustain the improvements achieved. A critical component of this ongoing effort is the deployment of a real-time monitoring dashboard for heavy equipment, utilizing integrated OBS (On-Board Systems) according to Figure 5. This system allows for the continuous measurement of each piece of heavy machinery's performance. The dashboard not only monitors productivity levels of individual equipment but also quickly identifies issues such as equipment breakdowns or idle times. Immediate identification enables a rapid response to apply Lean principles to diagnose and address the root causes of any discrepancies. This proactive approach fosters a culture of continuous improvement, or Kaizen, ensuring that the project continually adapts and evolves to improve efficiency and effectiveness.

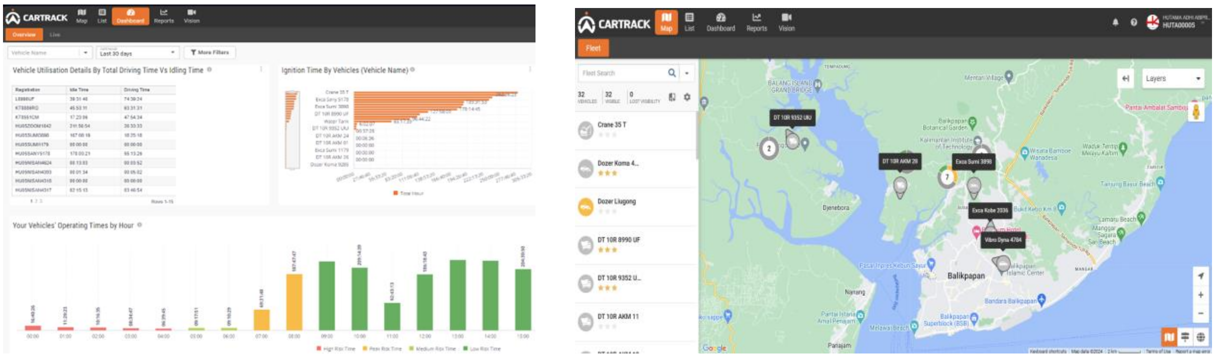

Figure 5: Dashboard in the Digital Monitoring by Cartrack

DISCUSSION

Following the significant improvements detailed in Tables 4 and 5—where driving times increased from 44.72% to 81.74% and idle times decreased from 55.28% to 18.26%—it is evident that Lean construction tools can illuminate hidden operational issues that regular meetings might miss. These tools, integrating with digital technologies, provide the project team with enhanced capabilities to identify and address inefficiencies promptly. future research could focus on several impactful areas. Quantitative assessments could explore the environmental impacts, particularly in terms of reduced fuel consumption and carbon emissions due to enhanced equipment efficiency. A cost-benefit analysis would be valuable, especially considering the reported increase in total project costs to USD 274,393.00 alongside a 1000-hour increase in total timesheet hours. Further studies might include longitudinal tracking to evaluate the long-term sustainability of these improvements, the integration of predictive analytics to optimize efficiency further, and an investigation into workforce adaptation to these changes.

CONCLUSIONS

The primary objective of this paper was to investigate the impact of digital monitoring on waste identification and management in Lean Construction (LC). The findings indicate that digital monitoring is instrumental in detecting and reducing waste, providing teams with the instant data necessary to implement rapid changes for waste minimization. Furthermore, it facilitates effective control measures to sustain improvement efforts and promotes continuous enhancement of processes. The application of digital monitoring in LC delivers a significant advantage by allowing for the prompt identification of inefficiencies that manual methods may overlook. By integrating Lean principles, the approach systematically highlights waste and its root causes, and pinpoints specific equipment that adds to inefficiencies. The analysis demonstrates that digital monitoring enables a structured and precise evaluation process, enhancing the capability to identify underperformance that is not readily apparent through conventional Lean practices. The research has successfully shown that with the aid of digital monitoring, underutilized heavy equipment can be quickly identified, leading to the reallocation of value-added time previously lost to idle periods. It quantifies waste accurately and in real-time, substantially improving the effectiveness and productivity of construction work, as well as facilitating a more informed performance evaluation of individual machinery. The results of this study confirm that the integration of digital monitoring into LC practices fulfills the research aim by substantiating its role in improving the efficiency and reducing the waste of construction projects.

Florez-Perez (Eds.), *Proceedings of the 32nd Annual Conference of the International Group for Lean Construction (IGLC32)* (pp. 731–742). doi.org/10.24928/2024/0185

A REVIEW OF THE ROLE OF DIGITAL TWIN APPLICATIONS FOR WATER SUSTAINABILITY

Mehwish Qureshi[1], Zhenan Feng[2], Vishal Kumar[3], Ruggiero Lovreglio[4] and Mohammed Abdelmegid[5]

ABSTRACT

This paper investigates the convergence of Digital Twin (DT) applications, Lean Construction (LC) principles, and water sustainability. The DT concept, which originated in the 2000s, has gained momentum across various industries. Yet, integrating DT into the construction industry, particularly in water systems, is at an early stage. A comprehensive literature review is conducted to explore the potential benefits of DT in water management, aligning with the principles of LC.

The exploration reveals the integration of DT into diverse water systems, encompassing distribution networks, sewage systems, river and lake management, dam systems, and wastewater treatment plants. The identified benefits extend beyond operational efficiency to water sustainability, addressing climate change adaptation, disaster risk reduction, and resource optimization. The study also explores the tools and technologies employed in DT applications, emphasizing their alignment with LC principles of reducing waste and fostering collaboration.

Nevertheless, limitations exist in the identified tools and technologies, such as data interoperability, computational complexities, and data reliability, underscoring areas for future research to enhance DT application effectiveness. Despite these limitations, the synthesis of DT, LC, and water sustainability holds promise for transforming water resource management.

This study offers guidance on achieving efficient, sustainable, and collaborative water management across various contexts. It provides essential insights for scholars, practitioners, and policymakers, emphasizing the importance of policy support and technological innovation to overcome current challenges. Furthermore, it suggests avenues for future research to evaluate the long-term effects and enhance the effectiveness of DT systems.

INTRODUCTION

The inception of the Digital twin (DT) concept dates back to early 2000 when Professor Michael Grieves introduced it during a Product Life cycle Management Course at the University of Michigan (Grieves, 2005). Since its introduction, DT has gained substantial traction, becoming a cornerstone in various industries. According to Kritzinger et al. (2018), the core of DT lies in the cyber-physical connection, termed the Digital Thread, enabling bidirectional communication between physical and digital spaces.

DT adoption in the construction industry is at a nascent stage; however, it is highly regarded for its significant benefits. It holds the potential to diminish waste through effective decision-making and analysis facilitated by real-time monitoring and control. DT also offers a comprehensive solution that harmonises lean thinking, computing, and monitoring technologies within the construction sector (Altan & Işık, 2023). This technological advancement is in line with the principles of LC, an approach that underscores efficiency, collaboration, and waste reduction throughout the construction process. The integration of DT technology into LC practices can significantly amplify operational efficiency by fostering collaboration among stakeholders and streamlining processes.

Indeed, while lean construction principles may not directly connect to water sustainability projects, their integration into water systems can bring notable benefits. By applying LC principles to water management, efficiency can be heightened, waste reduced, and overall sustainability in water usage improved. Yang et al. (2021) emphasised the need for innovative measures within a diverse social framework, especially those integral to water. Achieving water sustainability entails efficient use of clean water and judicious reuse and treatment of rainwater and sewage water for various purposes. In recent years, water utility planning, operation, and management have seen rapid digitalization and the use of various digital tools to achieve water sustainability. DT, as a transformative tool, is gaining prominence in water infrastructure, water treatment, and networking processes (Matheri et al., 2022).

Notably, prior scholarly works predominantly discuss DT applications in the context of management and operational functions rather than explicitly addressing their relevance to water sustainability. Nonetheless, it is imperative to acknowledge that efficient and intelligent operational and managerial practices significantly contribute to the broader goal of achieving water sustainability. This study endeavours to bridge this scholarly gap by conducting a comprehensive literature review encompassing water systems and their associated DT applications using lean principles.

To guide this exploration, specific research questions were formulated:

1. What water systems have been studied, tested, or evaluated with DT applications?
2. What are the benefits of those DT applications to water sustainability?
3. What are the tools and technologies applied in those DT applications?
4. What are the challenges and barriers of applying these DT applications to water systems?

METHODOLOGY

Research methodology forms the backbone of any study, providing a structured plan that guides the investigation from start to finish. Conducting a literature review is a crucial approach for acquiring insights into the research topic and grasping the current state of knowledge in the field.

This study employs a systematic literature review approach using the PRISMA framework as outlined by Khan et al. (2003), and utilizes the Scopus database as the primary research platform. The literature review encompassed both journal articles and conference papers. The search keywords were “digital twin” OR “building information modelling” OR BIM AND water. We included building information modelling and BIM because these terms are often used interchangeably with DT, ensuring a comprehensive search for relevant literature and studies on the topic.

The second part of the search keywords is: “water”. This search strategy encompassed a broad scope by including "water" rather than "water sustainability". This deliberate choice aimed to capture a wide array of literature concerning water management and its relevance to DT. The keywords were applied to search for titles, abstracts, and keywords.

The search was executed in September 2023, resulting in 1142 initial findings retrieved from Scopus. Using the Preferred Reporting Items for Systematic Literature Reviews and Meta-Analyses (PRISMA) approach (Page et al., 2021), the results were refined as illustrated in Figure 1. Firstly, 33 duplicates (e.g., the same DT application was published in different sources) were removed. Secondly, articles were excluded based on the following criteria: (1) The article has no relation to water and DT. (2) The proposed application in the article was not designed for the water sector. (3) The article proposed theoretical frameworks without practical applications. (4) The article was not in English.

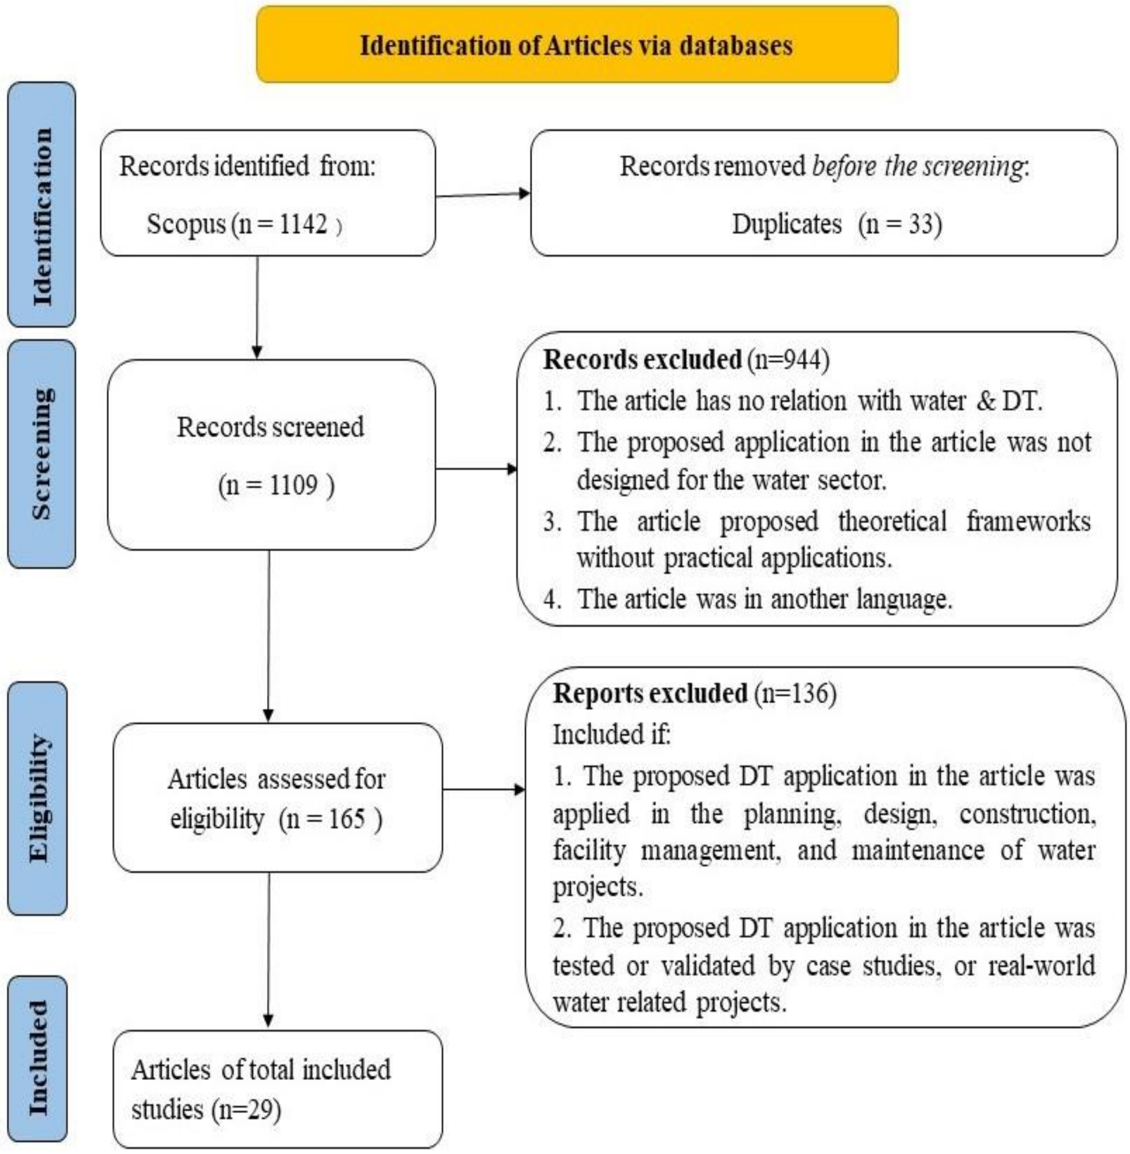

Figure 1 The PRISMA Workflow

During this step, 944 articles were excluded, leaving 165 articles for further analysis. Finally, we scrutinized the full text of these remaining articles, applying the subsequent inclusion criteria: (1) The proposed DT application in the article was applied in the planning, design, construction, facility management and maintenance of water related projects. (2) The proposed DT application in the article was tested or validated by case studies, or real-world water related projects.

This process resulted in 29 articles meeting the eligibility criteria for inclusion in this literature review. Among them, there were 18 journal and eleven conference papers, all published between 2017 and 2023 (Figure 2).

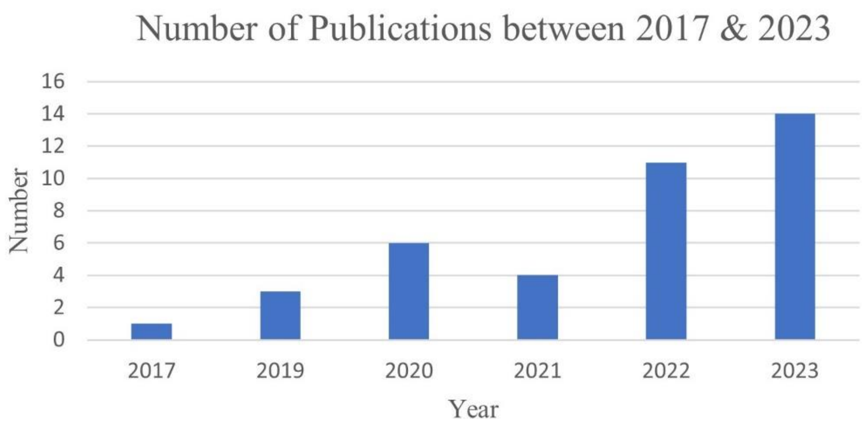

Figure 2 Number of Publications

RESULTS

This study examines the eligible articles to discover the water systems that have been equipped with DT, the benefits to water sustainability, the tools and technologies employed in DT applications, and the challenges and barriers of applying DT.

WATER SYSTEMS

The integration of DT technology into various water systems aligns with the principles of LC, emphasizing efficiency, sustainability, and continuous improvement. These systems encompass water distribution networks, river and lake management systems, dam management systems, sanitary sewage systems, water resource recovery facilities (WRRFs), wastewater treatment plants (WWTP), groundwater management systems, drainage systems, and wetlands (Figure 3).

Conejos Fuertes et al. (2020) explored DT for city management in Valencia, Spain, demonstrating a commitment to lean principles by enhancing daily operations, strategic planning, and responses to unplanned events. Ramos et al. (2023) suggested a DT application for a pumping system in Sta Cruz, targeting a decrease in water demand volume and an increase in renewable energy generation, aligned with sustainable development goals (SDGs). This reflects a lean approach towards resource efficiency.

Fargas and Cornellà (2023) addressed a DT application in managing water distribution pipes for asset management purposes, highlighting the challenge faced by the Tarragona Water Consortium (Consorci d'Aigües de Tarragona - CAT). This application aligns with lean principles, addressing specific challenges and streamlining asset management processes.

Another application of DT towards river, lake, and dam management, presented by Wang et al. (2022), emphasizes lean principles by upgrading conventional water systems to enhance efficiency and reduce energy consumption in the Weihe River Basin (WRB) in Shaanxi province, China. Additionally, Park and You (2023) introduced an innovative DT platform for dam and watershed management, enabling real-time data utilization for flood response and water resource management for Sumjin Dam and its river water system in Korea. This proactive approach embodies one of the principles of LC, which leverages efficient response to environmental challenges.

Moreover, the DT concept was employed to mitigate the impacts of climate change on groundwater levels in distinct water systems. Henriksen et al. (2023) presented a Danish case study introducing the Hydrological Information and Prediction Digital Twin (HIP DT) for Denmark, reflecting a lean focus on climate change adaptation, water security management, and disaster risk reduction.

Three papers specifically focused on wastewater treatment plants and water resource recovery facilities. Bellandi et al. (2022) investigated the DT of an advanced wastewater treatment plant in the Netherlands, aimed at improved performance and water safety. In the context of lean management, this approach enhances operational effectiveness.

Melo et al. (2019) studied the Sanitary Sewage System of Piumhi, a city in Brazil. They applied the framework of City Information Modelling (CIM), a management model leaning on preventive actions and a decision-making process based on accurate information. Payne et al. (2023) used Machine Learning (ML) for surrogate groundwater modeling in Barbados (Caribbean region), showcasing a lean use of technology for efficient groundwater management.

Moving towards natural systems, Ruangpan et al. (2023) explored smart solutions and DT to manage flooding and irrigation systems in the Rangsit Area, Thailand, to enhance urban resilience. Similarly, the environmental improvement project in the Green Water Wetland in the Yangtze River, China, by Huang et al. (2023), integrates technology for lean water system management, emphasizing connectivity, hydrodynamics, and modeling for analysis and verification.

The exploration of DT water management extends to buildings, with Batista et al. (2023) designing a specialized framework for optimizing water efficiency in the Central Market of Belo Horizonte, Brazil. Yang et al. (2021) devised a framework employing advanced technology and algorithms for maintaining water dispensers within campus settings. These frameworks showcase the potential for enhanced water conservation and management, which is a lean approach contributing to sustainable water practices in constructed spaces.

By aligning with lean principles and focusing on continuous improvement, DT technology not only addresses current water management challenges but also paves the way for innovative solutions that could significantly impact resource efficiency and sustainability in both natural and constructed environments.

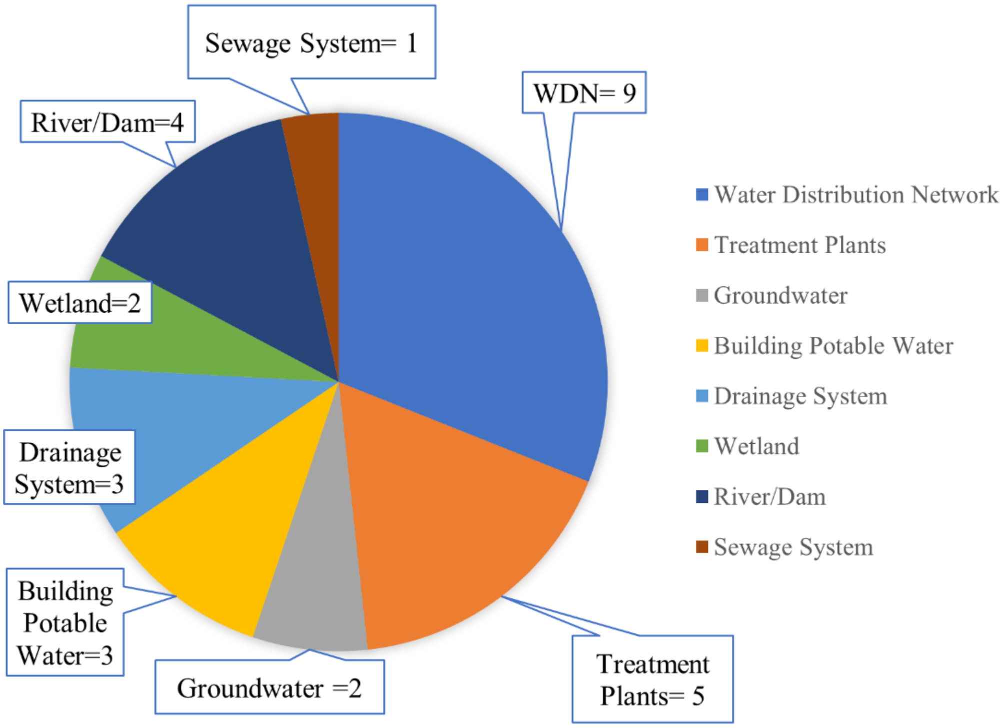

Figure 3 Digital Twin Publications: Water Systems Classification

BENEFITS TO WATER SUSTAINABILITY

The exploration of DTs across diverse water systems presents a multitude of benefits that align with water sustainability and resonate with LC principles. They enhance resilience through proactive monitoring, anticipating, and mitigating challenges. DTs also contribute to sustainability, preserving water quality and promoting long-term sustainable development objectives. For instance, Conejos Fuertes et al. (2020) showcased how DTs contributed to efficient water resource management in city operations, daily activities, and strategic planning. These applications embody LC's emphasis on minimizing waste and optimizing processes.

Similarly, Fargas and Cornellà (2023) highlight the role of DTs in asset management that exemplifies LC commitment to effective asset utilization for streamlined project delivery. DT applications in preserving water quality, flood prevention, and mitigation align with sustainable water practices and LC principles of minimizing inefficiencies (Park & You, 2023; Wang et al., 2022). Moreover, DTs play a pivotal role in adapting to climate change and reducing the risks associated with disasters, as demonstrated by Henriksen et al. (2023). The application of DTs in this context reflects both LC's focus on adaptability and the broader goal of sustainable water resource management.

Treatment plants optimization presented by Bellandi et al. (2022); Remigi et al. (2022) showcase the DT's capacity to enhance overall performance, aligning with LC's principles of continuous improvement. City-specific water solutions proposed by Ramos et al. (2023 a); Ramos et al. (2023 b) reflect a focus on sustainability, renewable energy, and system efficiency. These applications correspond with LC's goal of optimizing resources and improving overall system efficiency.

The use of DTs in groundwater management under changing climates (Payne et al., 2023) aligns with LC's adaptive project management approach. Additionally, the optimization of urban water cycles using Cyber-Physical Systems mirrors LC's emphasis on efficiency (Sun et al., 2020). Smart solutions for flooding and irrigation proposed by Huang et al. (2023); Ruangpan et al. (2023) emphasize resilience and integration of nature-based solutions, aligning with LC's focus on adaptability and resilience in the face of challenges.

Finally, the applications of DTs in buildings by Batista et al. (2023); Yang et al. (2021) optimize water efficiency within commercial structures and campus settings, aligning with LC's principles of efficiency and resource optimization. In summary, the highlighted benefits emphasize the versatility of DT applications, making substantial contributions to both LC practices and sustainable water management. DT technologies significantly contribute to water sustainability, closely aligning with LC principles by optimizing resource use, enhancing resilience, and supporting sustainable development through a wide range of applications across water systems management and infrastructure efficiency.

TOOLS AND TECHNOLOGIES

The eligible articles introduced various tools and technologies employed for developing and implementing DT applications in water management (Table 1). Many of these tools, readily available in the market, have been integrated into new platforms or adapted for use in existing systems to facilitate integration and management.

Conejos Fuertes et al. (2020) extensively detailed the tools and technologies applied in managing the drinking water management system of Valencia, Spain, with the GO2HydNet serving as a foundational platform. The system seamlessly integrated the hydraulic model with various information sources, like Geographical Information System (GIS), Automated Meter Reading (AMR), Computerized Maintenance Management Systems (CMMS), and field data stored by the Supervisory Control and Data Acquisition (SCADA) system. Specialized algorithms facilitated high-efficiency model construction, exemplified by the creation of a comprehensive model with 32,000 nodes in about a minute.

Ramos et al. (2023) employed similar tools but integrated them into the hydraulic model via Artificial Intelligence (AI) algorithms and Information and Communication Technology (ICT). Conversely, Bonilla et al. (2022) utilized Python libraries to estimate pump speed and derive pressure and flow rate information for non-monitored pipes using EPANET 2.2. Fargas and Cornellà (2023) explored the integration of online monitoring technologies such as Acoustics Fiber Optics (AFO) and electromagnetic pipe inspection in the implementation of DT for the Tarragona Water Consortium (Consorci d'Aigües de Tarragona - CAT).

Distinct tools were utilized for managing rivers, lakes, and dams compared to water distribution networks. For instance, Park and You (2023) utilized the K-Twin SJ platform for dam and watershed management, integrating 3D Geospatial Reality Modelling with Aerial LiDAR Survey & Drone, hydraulic and hydrological simulation models. Qiu et al. (2022) developed a web-based interactive twin platform for watershed management using Virtual Geographic Environment, integrating geospatial data with terrain visualization, unmanned aerial vehicle (UAV) tilt photography, and 3D modeling. Furthermore, real-time video monitoring and water quality data were integrated into a 3D scene, enabling a detailed representation of the area and aiding in precise watershed management.

Henriksen et al. (2023) developed a DK-model employing the MIKE SHE-MIKE Hydro software, simulating various hydrological processes, and supplementing it with machine learning (ML) algorithms for enhanced accuracy. The DT for Water Resource Recovery Facility developed by Remigi et al. (2022) comprised components such as MIKE OPERATION for real-time data, WEST model for simulation, and a user-friendly dashboard for operator control. Melo et al. (2019) proposed a combination of technologies for the operation and maintenance of the sanitary sewage system of Piumhi. He utilized GPS GNSS RTK L1/L2 for high-precision positioning survey and designed the sewage network on AutoCAD Civil 3D and QGis.

Various articles explored groundwater sustainability, irrigation and drainage system behavior, wastewater management, and wetland simulations, utilizing software tools such as FEFLOW, MIKE 11, GAMS with CPLEX solver, and Unreal Engine. Huang et al. (2023)

recommended using BIM & GIS as a communication platform during the construction period, while Batista et al. (2023) proposed AquaBIM, a web-based application integrating BIM-IOT-FM for water sustainability within buildings.

This review highlights the diverse tools and technologies employed across various projects, showcasing the versatility of DT applications in the realm of water resource management. Furthermore, the utilization of AI, ML, and streamlined data integration contributes to the lean principles of reducing waste, enhancing productivity, and fostering collaborative decision-making processes. Notably, Geographical Information System (GIS) emerges as the most prevalent technology across these water management systems, employed for managing, analyzing, and visualizing geographic data. Similarly, Supervisory Control and Data Acquisition (SCADA) systems are widely used for control, monitoring, and analysis purposes.

Table 1 Tools and Technologies

Water System	Platform	Tools and Technologies
Drinking Water Management System Valencia (Spain)	GO2HydNet	Hydraulic Model on EPANET, Geographical Information System (GIS), Automated Meter Reading (AMR), Computerized Maintenance Management System (CMMS)
Dam and Watershed Management-Korea	K-Twin SJ Platform	3D Geospatial Reality Modelling, Aerial LiDAR Survey & Drone, Hydraulic and Hydrological simulation Model
Water Resource Recovery facility (WRRF)-Italy	MIKE OPERATION	SCADA, WEST model
Water Distribution Network Madeira Portugal	Big Data Platform	GIS, Sensors, SCADA, Smart Metring, CMMS integrated in EPANET via AI algorithms
Watershed Environment of Chaohu Lake	Web-based platform using Virtual Geographic Environment	geospatial system, unmanned aerial vehicle UAV tilt photography, 3D modelling, video monitor
Hydrological Information and Prediction (HIP) Model Denmark	SHE-MIKE	Supplemented with Machine Learning (ML) algorithm
Water Management systems Belo Horizonte, Brazil.	AquaBIM	Revit Model, Smart Meters

CHALLENGES AND BARRIERS

he authors of the eligible articles have demonstrated various challenges faced by researchers and practitioners in implementing DT within water systems. These challenges span technical, data-related, organizational, and practical aspects.

Conejos Fuertes et al. (2020) addressed challenges related to GIS data integration and model requirements by developing algorithms, ensuring a seamless blend between spatial data and modeling needs. Notably, their proactive approach involved creating supplementary systems to store crucial data, rectifying errors, and modifying EPANET software. This reflects a sophisticated strategy to overcome technical obstacles and enhance the robustness of DT applications.

Tomic et al. (2022) focused on challenges encountered in city implementation, emphasizing the critical role of accurate data. The authors recognized the importance of addressing data challenges for effective DT application, showcasing a meticulous approach to city-level water system management.

In a distinct scenario, Qiu et al. (2022) identified challenges associated with prolonged computational durations in 3D modeling. Their response involved advocating for accelerated approaches in model computation, demonstrating an understanding of the need for agility and efficiency.

Henriksen et al. (2023) viewed establishing explicit project goals, objectives, and comprehensive plans as prerequisites for implementing DT at a national level, emphasizing the importance of clear objectives and efficient resource utilization. The authors recognized the substantial investment in resources and expertise required for national-level DT implementation, showcasing a holistic and strategic mindset.

Similarly, Melo et al. (2019) encountered challenges in surveying the sanitary sewage system and explored alternative surveying methods. Some studies posed challenges and barriers in applying DT in real-world scenarios. Ramos et al. (2023) faced challenges related to the reliability of data used to develop the DT model. They emphasized the need for accurate data related to system configuration. The authors recognized the crucial role of accurate data in the success of DT applications, highlighting the importance of close collaboration between researchers, designers, and municipal management.

Bonilla et al. (2022) rendered challenges in obtaining monitored data on the relative operating speed of pumps. Payne et al. (2023) addressed calibration limitations in spatial coverage of data and challenges in predicting transient groundwater response. Their approach involved advanced calibration technologies, emphasizing accuracy and efficiency in spatial coverage.

Sun et al. (2020) highlighted the challenge of ensuring effective management of routine interactions among subsystems within efficient computational timeframes. Lu et al. (2023) recognized the challenge of collecting data from the extensive Poyang Lake wetland and focused on optimizing data collection strategies.

In the building context, Yang et al. (2021) emphasized challenges in proposing BIM applications for water dispensers' maintenance. Their acknowledgment of interoperability and staff unfamiliarity showcases an understanding of the importance of improved computerization.

Despite these challenges and barriers, innovative solutions and strategic approaches showcased by researchers underline the critical importance of accurate data, streamlined computations, and clear objectives in advancing DT applications for more effective water systems management.

CONCLUSION

This literature review explores the synergy between DT applications, LC principles, and water sustainability. The analysis of diverse water systems demonstrates that integrating DT with LC fosters efficiency and sustainability. The identified benefits, spanning optimized operations and resource management, resonate with LC principles, showcasing a commitment to waste reduction and collaborative decision-making.

Despite challenges in technical, data-related, organizational, and practical realms, the authors exhibit resilience and innovative problem-solving, aligning with the ethos of LC. This synthesis of DT, LC, and water sustainability holds promise for transformative advancements in water resource management. As the confluence of DT and LC principles evolves, this study provides foundational insights for scholars, practitioners, and policymakers navigating the complex landscape of water systems.

The review underscores the importance of incorporating advanced technologies such as AI, ML, and GIS into DT applications, indicating a move towards more nuanced and interdisciplinary approaches. It suggests the necessity for policy development that encourages sustainable practices and allocates resources to surmount technical hurdles, thereby guiding investments in water management technologies.

Additionally, the review points out existing gaps in DT application, such as data integration and model accuracy, suggesting a direction for future research that focuses on closing these gaps to boost DT system efficiency and reliability. The call for longitudinal studies to evaluate the long-term impacts of DT on water sustainability, system efficiency, and environmental outcomes suggests an avenue for future research that could shape the continuous improvement and scaling of DT applications.

ENHANCING LEAN CONSTRUCTION THROUGH INNOVATIVE TECHNOLOGY: A FOCUS ON VIRTUAL REALITY IN CONSTRUCTION

Ali Bidhendi[1], Mani Poshdar[2], Zahra Nahri[3], Ji Won Won[4], Omar A Owais[5] and Kayvan Koohestani[6]

ABSTRACT

This study delineates the integration of Virtual Reality (VR) within Lean Construction, emphasising its application across the philosophy, principles, methods, and tools of Lean Construction. By conducting a systematic literature review, this research considers the utilisation of VR to enhance construction processes, specifically focusing on its role in mitigating waste, maximising value, continuous improvement, and respect for people. The investigation reveals VR's capacity to bridge the theoretical and practical aspects of Lean Construction, offering a novel perspective on its implementation. The results demonstrate VR's potential in advancing Lean Construction practices through its philosophy, principles, methods, and tools. Also, the utilisation of VR, particularly in SCRUM, Set Based Design and Visual Management, underlines a transformative potential for enhancing construction project efficiency and value. The paper concludes by highlighting the contributions of VR to Lean Construction, proposing actionable insights for practitioners and suggesting avenues for future research. This approach provides a comprehensive review for integrating VR in construction projects, aligning with Lean Construction for enhanced project outcomes.

KEYWORDS

Lean Construction, Set Based Design (SBD), VDC, Virtual Reality (VR), Smart Construction.

INTRODUCTION

Numerous essential technologies support intelligent building practices, including big data analysis, robotics, laser scanning, 3D printing, and virtual reality (VR) (Wang et al., 2023). Among these, VR emerges as a notable advancement in the field of smart construction. Smart construction is closely associated with the concept of "Lean Construction," which was

introduced by Koskela, (1992) as a novel production philosophy emphasising principles, concepts, and methodologies within the construction industry. that no longer regard construction as a mere process of converting materials into buildings but rather as a sequence of activities that add value (flow process). This perspective entails identifying problems within the flow and implementing solutions and improvements to address these issues (Wang et al., 2023). VR is one of the promising technologies that can improve the process of design, construction, application, and maintenance in many AEC projects (Safikhani et al., 2022). VR has garnered recognition for its ability to enhance customer satisfaction (Noghabaei et al., 2020), reduce project duration by minimising conflicts, serve as a cost-effective alternative to physical mock-up installations and savings of 15% of capital delivery (Haahr et al., 2019). Moreover, Building Information Modelling (BIM) is one of the VR tools that refers to the creation and utilisation of a computer-based information model that encompasses multiple dimensions. This model is not limited to structural documentation but also includes simulations of the construction and operation of capital facilities (Bidhendi et al., 2023). Increased penetration of BIM, as a manifestation of modern technology in construction, specifically VR, positively impacts resilience and waste reduction in construction (Saeedi et al., 2022). These outcomes stem from VR's ability to mitigate a major factor contributing to waste: deficiencies in communication, collaboration, clarification, and understanding, thereby enhancing the confidence required to accomplish the designated tasks (Getuli et al., 2020; Safikhani et al., 2022; Seyman Guray & Kismet, 2023; Zhang, 2021).

Jacobsen et al. (2021) emphasised the use of a VR-based serious gaming environment to teach Lean Construction concepts, underscoring the potential for collaborative and interactive learning. Liu et al. (2022) explored the socio-technical aspects of Lean Construction, particularly examining the Last Planner System (LPS) and its implementation challenges within an Immersive Virtual-Reality (IVR) setting. Trivedi et al. (2022) discussed the integration of VR simulations with Lean Construction principles to enhance project delivery and achieve high-performance in infrastructure projects. In a slightly different approach, Spisakova et al., (2020) focused on the use of virtual reality in designing safe construction sites, without specifically incorporating Lean Construction principles. Also, Brioso et al. (2019) presented a preliminary methodology for integrating Lean Construction and VR in the planning phase of structural interventions in heritage structures. Lastly, Rischmoller et al. (2018) discussed the use of Virtual Design and Construction (VDC) as a lean strategy for integration in construction projects, without mentioning VR in the context of Lean Construction. While several studies have investigated various aspects of VR applications in Lean Construction, including enhancing learning and training (Jacobsen et al., 2021; Liu et al., 2022), project planning and design (Brioso et al., 2019, Spisakova et al. 2020), and project integration and delivery (Rischmoller et al., 2018; Trivedi et al., 2022), there appears to be a lack of comprehensive research that holistically links the use of VR to the overarching philosophy, principles, and methods of Lean Construction. This indicates a research gap where a structured study could provide a more integrated perspective on how VR can be systematically aligned with and support the broader objectives of Lean Construction.

Our discussions are structured to explore the influence of VR on Lean Construction within projects of varying scales and environments, involving a variety of stakeholders. Accordingly, the research questions are set as follows:

1. How can VR support the Lean Construction Philosophy?
2. How can VR support the Lean Construction principles?
3. How can VR support Lean Construction methods?
4. What tools are offered to implement VR in Lean Construction?

In this paper, a systematic review and integration of literature across various sections are conducted to identify the intersection of VR and Lean Construction. Following this introduction, the paper is structured as follows: first, the research method section details our systematic literature review process and the criteria for selecting relevant studies. This is followed by the results section, where we present findings from the reviewed literature, categorising them into Lean Construction philosophy, principles, and methods enhanced by VR. In our analysis, we provide commentary on all four pillars of Lean Construction: value generation, waste minimisation, continuous improvement, and respect for people (Abdelhamid et al., 2008). Furthermore, we explore value identification, value stream mapping, workflow optimisation, demand-driven execution, and continuous improvement, as guiding Lean Construction principles (Karmaoui et al., 2023). We also have selected SCRUM, Set Based Design, and visual Management as our preferred methods to examine. In our analysis, we specifically examine how VR as an innovative technology can be integrated within the pillars, principles, and methods of Lean Construction to enhance construction project outcomes. The Discussion section then synthesises these findings, examining the implications for current and future Lean Construction practices. Finally, the Conclusions section summarises the key insights, discusses the limitations of our study, and suggests directions for future research.

RESEARCH METHOD

This study utilises a bibliometric approach via a universal library portal that incorporates EBSCO, a prominent supplier of research databases, e-journal and e-package subscription services, book collection planning and procurement management, as well as a significant provider of library technology solutions. This strategy was preferred over direct engagement with databases like Scopus for its broad access to diverse materials, including academic journals, books, and other varied databases. This allows for a more extensive review and analysis of literature across different fields and subjects.

The literature search aimed to systematically identify and select publications that contribute to the understanding of integrating VR into the Lean Construction methodologies. The search strategy was carefully designed to encompass a broad spectrum of databases and sources, leveraging keywords such as "Lean Construction", "Lean Construction Philosophy", "Lean Construction Principles", "Lean Construction methods and tools”, “Virtual Reality (VR)", "Smart Construction", "SCRUM", " Set Based Design", and "Visual Management". These keywords were used in various combinations to ensure a comprehensive retrieval of relevant literature. In identification process, 18 books and 13,662 articles were founded.

The selection process commenced with an initial screening based on the relevance of titles, abstracts, and keywords to the research topic. This preliminary filter aimed to capture studies that directly address the use of VR in enhancing construction processes, aligning with Lean Construction methodologies which 13 books and 152 articles were chosen. Following this, a more detailed assessment was conducted, examining the conclusions, discussions, and methodological approaches of the papers to ensure they provided substantive insights into the research questions where we could select 3 books and 42 articles.

Given the innovative nature of VR applications in construction and the evolving landscape of Lean Construction practices, the study extended its inclusion criteria beyond peer-reviewed journals to encompass conference papers, industry reports, and unpublished studies. This was predicated on the condition that these additional sources were recent, maintained academic validity, and offered substantial contributions to the field.

The selection process culminated in the identification and detailed examination of 23 articles and 3 books that provide a comprehensive overview of the current state and potential of VR in the Lean Construction. The process can be seen in Figure 1. Notably, the selection favoured qualitative insights due to the exploratory nature of the topic, although quantitative studies were also considered to ensure a balanced view. However, it was observed that quantitative research in this specific area remains limited.

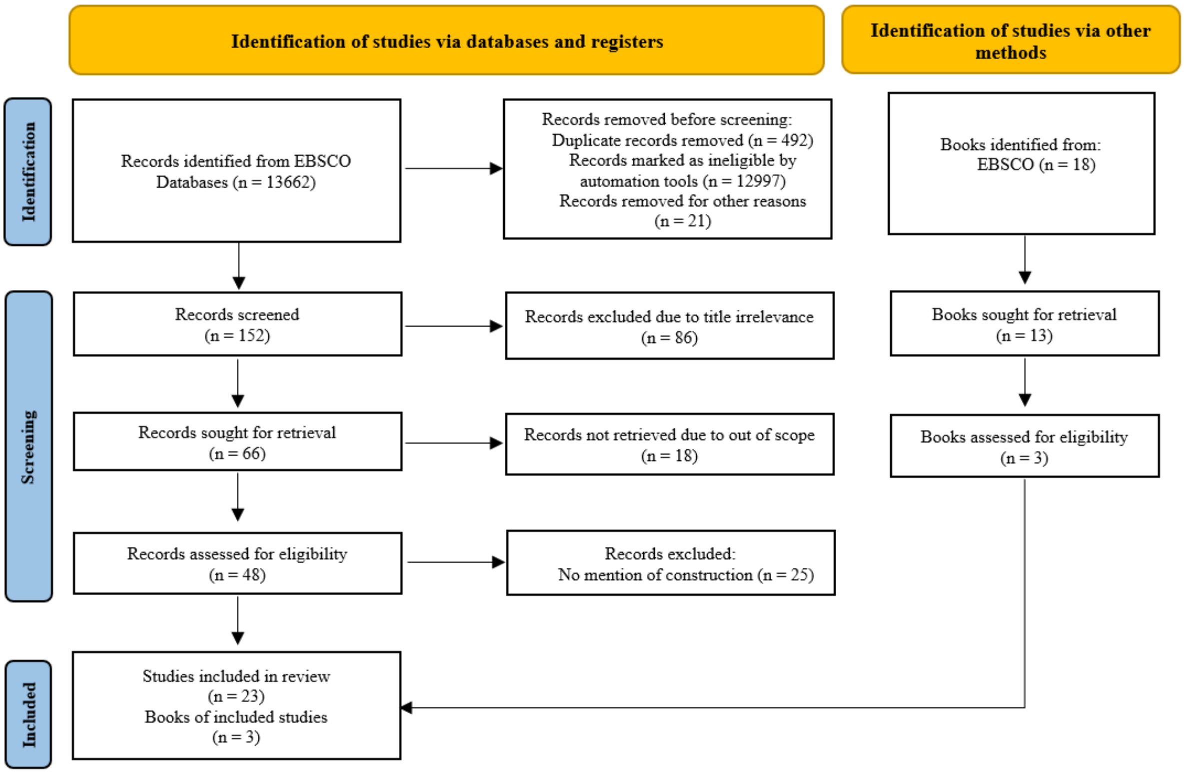

Figure 1. Identification, Screening and Selection process of the systematic literature review

LEAN CONSTRUCTION PHILOSOPHY AND VR

Lean Construction philosophy is based on the principles of lean manufacturing, which originated from the Toyota Production System. This approach focuses on eliminating waste, improving efficiency, and delivering value to customers. Glenn Ballard and Lauri Koskela have conducted extensive research on Lean Construction philosophy. They argue that lean construction is not limited to standardised products or high-volume construction projects. Instead, they believe that Lean Construction can be applied to dynamic projects, promoting innovation and value generation (Ballard & Koskela, 1998). According to Ballard and Howell, Lean Construction philosophy is not about cost-cutting or cheapness. It is about focusing on producing value for customers and eliminating everything else (Ballard & Howell, 2003).

The four pillars of Lean Construction are: Waste Minimisation which focuses on reducing non-value-adding activities and materials in construction processes; Value Maximisation that Emphasises creating maximum value for clients through efficient and effective construction practices; Continuous Improvement which Involves the constant evaluation and enhancement of construction processes to achieve better outcomes; and Respect for People Prioritising the welfare and development of all individuals involved in the construction process (Abdelhamid et al., 2008).

To establish a linkage between the Lean philosophy and VR predicated upon its four pillars, the following connections can be drawn:

WASTE MINIMISATION

VR has a transformative impact on minimising waste in construction, addressing the eight types of waste identified in Lean Construction. Defects are reduced through detailed simulations, allowing for early identification of design flaws (Trivedi et al., 2022). VR aids in accurate demand assessment, which helps prevent overproduction (Jacobsen et al., 2021), and streamlines project timelines to reduce waiting times (Rischmoller et al., 2018). It also promotes the utilisation of talent by visualising every team member's contribution, and assists in reducing unnecessary transportation and motion by enabling precise planning (Noghabaei et al., 2020). Furthermore, VR contributes to maintaining optimal inventory levels and prevents over-processing by allowing teams to finalise designs virtually (Zhao, 2022).

VALUE MAXIMIZATION

As highlighted by Nasirzadeh & Nojedehi, (2013), VR enhances value in construction projects through improved visualisation, aiding in better decision-making and client satisfaction, which are core aspects of value maximisation in Lean Construction. It enables clients to experience and interact with the project before construction, ensuring their needs are accurately met (Trivedi et al., 2022). Furthermore, enhanced communication facilitated by VR leads to a clearer understanding among stakeholders, while also allowing for detailed inspection and quality control (William & Jose, 2023).

CONTINUOUS IMPROVEMENT

VR's ability to simulate various construction scenarios supports the Lean principle of continuous improvement. It allows for iterative testing and refinement of project designs before actual construction, aligning with the ideas presented by Muya et al., (2013). This approach allows for the rapid incorporation of feedback into project plans and aids in performance tracking and analysis for ongoing improvement (Hatoum & Nassereddine, 2023).

RESPECT FOR PEOPLE

Incorporating VR in construction respects and enhances the workforce's capabilities. It offers safer, more efficient, and ergonomically beneficial ways for workers to engage with construction projects, thus respecting and enhancing the workforce's capabilities (McHugh et al., 2023).

Moreover, accidents on construction sites often result from a deficiency in proactive safety measures (Bidhendi et al., 2022). Proactivity, in this context, involves training for safety awareness and the identification of potential risks. To address this, many organisations are increasingly emphasising 'cultural intervention, enacted policies, communication, and induction' (Li et al., 2018). Figure 2 illustrates the efficacy of VR in on-site risk mitigation, as tested and demonstrated.

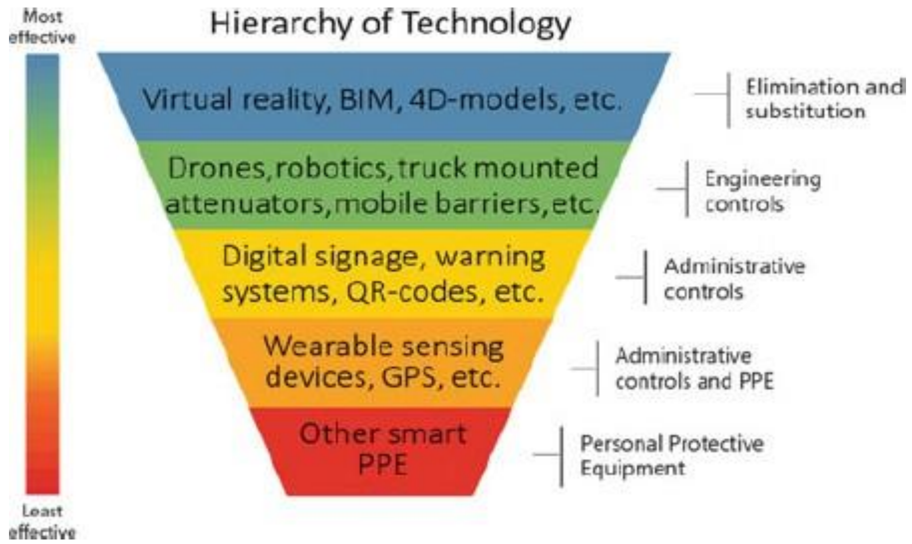

Figure 2: "Technology alternative organised in a hierarchy based on level of risk mitigation effectiveness" (Karakhan et al., 2019)

In the context of Lean Construction, VR aids in the identification and elimination of potential on-site hazards such as spatial collisions. Through VR-enacted site walkthroughs, construction personnel can practice emergency response protocols, bolstering their instinctive reactions to critical incidents (González et al., 2022). Moreover, VR enables the safe visualisation of demolition processes, highlighting potential risks without actual exposure (Seyman Guray & Kismet, 2023).

LEAN CONSTRUCTION PRINCIPLES AND VR

VR is increasingly recognised as a catalyst for enhancing the Lean Construction framework. This section aims to explore the integration of VR with the Lean principles of value identification, value stream mapping, workflow optimisation, and continuous improvement, as these are crucial for advancing construction practices. These principles were selected due to their direct impact on operational efficiency and their ability to be significantly enhanced through technological integration (Karmaoui et al., 2023).

IDENTIFYING VALUE

At the forefront of Lean Construction is the principle of delivering value as envisioned by the client. VR technology serves as a conduit for this vision, providing clients and stakeholders with a tangible representation of project outcomes. Through VR, clients can virtually walk through the construction project, offering feedback that can be incorporated instantly, ensuring that the end result aligns with their expectations (Trivedi et al., 2022). This interactive approach helps in defining the scope more accurately and avoiding costly changes during later stages of construction.

MAPPING THE VALUE STREAM

Value Stream Mapping in Lean Construction is integral to visualising the entire project from inception to completion, pinpointing inefficiencies, and minimising waste. VR can significantly enhance this process by creating a virtual model of the construction value stream, allowing for a comprehensive analysis and optimisation of each step. This digital twin approach not only helps in identifying current waste but also in predicting and preventing future inefficiencies (Sacks et al., 2009).

CREATING FLOW

Creating a consistent and uninterrupted flow of work is crucial to maintaining efficiency on construction sites. VR technology aids this Lean principle by simulating the construction process and identifying potential workflow interruptions. This preemptive analysis allows teams to reorganise tasks and resources to prevent bottlenecks and ensure a smoother flow of operations (Liu et al., 2022).

PURSUING PERFECTION

Pursuing perfection through continuous improvement is a key tenet of Lean Construction. VR allows for an iterative design process where construction scenarios can be tested and optimised in a virtual environment. This virtual prototyping not only enhances the quality and performance of the construction process but also fosters a culture of continuous learning and improvement within the team (Li et al., 2018).

The integration of VR with Lean Construction principles provides a robust framework for enhancing construction project outcomes. By leveraging the immersive and interactive capabilities of VR, stakeholders can achieve a deeper alignment with Lean Construction principles, leading to reduced waste, improved efficiency, and enhanced client satisfaction (Noghabaei et al., 2020).

LEAN CONSTRUCTION METHODS AND VR

This section aims to explore the integration of VR with Lean methodologies like SCRUM and Set-Based Design (SBD). These methods were selected for their potential to significantly benefit from VR's capabilities in enhancing collaborative and iterative processes. Given the scarcity of direct references connecting VR with SCRUM and SBD in existing literature, this document interprets supportive evidence and discusses its potential application to these frameworks.

SCRUM

Recent advancements in project management have seen the integration of SCRUM, an Agile method, into Lean Construction practices to address the dynamic and uncertain environments of construction projects. This integration, conceptualised as 'AgiLean PM', enhances Lean Construction by incorporating SCRUM's agility and iterative feedback processes, proving effective especially in the design phases of construction projects (Bryde et al., 2014).

SCRUM, akin to a relay race featuring brief pauses between each participant, is a highly collaborative method that emphasises continuous review, feedback, progress, and repetition for incremental advancements and superlative quality, all while striving to deliver the highest value swiftly (Arroyo, 2022).

VR facilitates a more profound and qualitative design review throughout the entire project lifecycle by inviting end-users to navigate freely in a virtual environment and provide candid opinions (Spisakova et al., 2020). This heightened engagement enhances productivity by securing each decision-making process, ultimately reducing the need for rework. Given SCRUM's rapid and confident approach, feedback from end-users becomes a crucial resource. For instance, clients evaluating alternative design options can virtually experience the scale of rooms affordably. In another context, researchers found that VR, without additional cost, significantly reduced lighting electricity consumption in commercial buildings by providing options for lighting conditions (Noghabaei et al., 2020). This underscores how VR-enabled design reviews not only add enduring value for end-users but also contribute to ongoing cost reductions.

Moreover, for projects requiring simulations, VR can realize real-time occupancy flow, making it less cognitively demanding for clients (Safikhani et al., 2022). However, if VR settings reveal excessive detail too early in the process, they can become distracting and create false expectations, potentially obscuring the overall project scope (Ventura et al., 2019). With these possibilities in mind, it becomes evident that in the context of VR and SCRUM, effective management necessitates a directive approach to adopting VR and avoiding incremental deviations from the principal task.

SET BASE DESIGN

The foundational design method, Set Base Design (SBD), is characterised by its open-minded approach, keeping design options open until the final stages to better address unpredictable elements through continuous inquiry, analysis, clarification, and selection. SBD relies on a competent and dependable team that can undergo training and eventually operate autonomously toward achieving the project's end goal (Oliveira et al., 2024). This section explores the role of Virtual Reality (VR) in enhancing SBD practices.

In an experiment involving riggers, signal person, and operators, it was found that VR enabled participants to visualise the impact of their decisions on project cost and schedule. It also provided a platform for practicing tasks, boosting confidence, and reducing human error (Safikhani et al., 2022). This led to a significant reduction in decision-making time and the elimination of timidity (Paes & Irizarry, 2018). Additionally, VR proved beneficial in identifying potential clashes in building services (Haahr et al., 2019). A proposed method for on-site training involved setting up a trailer with full equipment capable of hosting virtual meetings, which was found to enhance satisfaction and communication richness compared to non-VR alternatives (Getuli et al., 2020).

While the research acknowledges that the accuracy and appropriateness of meetings were better in a non-VR face-to-face setting, the overall effectiveness of VR in SBD lies in its ability to empower individuals in decision-making. This worker-centered approach, although not necessarily reducing project timelines, influences the occurrence of rework or defects, thus aiding in budget control.

VISUAL MANAGEMENT

Visual Management (VM), defined as 'visual and definitive verification' (Hatoum & Nassereddine, 2023), is a Lean principle adopted in methodologies such as Last Planner System (LPS), SCRUM, Kanban, and others. Research indicates that visual platforms like VM can forecast design conflicts and deficiencies, thereby minimising rework in construction projects (Noghabaei et al., 2020). VM enables the calculation of metrics such as Percent Plan Complete (PPC) by breaking down and making tasks measurable through visual representation.

In the research conducted by Liu et al., (2022), VR was utilised in an LPS setting, incorporating VM elements within their hypothetical project. While VM was not the primary focus of their study, it contained pertinent elements of VM. The Figures below illustrate key aspects of their research.

In Figures 3 and 4, one can observe tables listing tasks alongside adjacent images. The VM environment depicted is reminiscent of actual scenarios, albeit possibly more simplified. Consequently, the study indicates that participants engaged in more negotiations and achieved a higher Percent Plan Complete (PPC) compared to projects managed using conventional methods, even though negotiations in both instances took place within a VR context. The author further suggests that VR contributed to reducing mental stress, fostering clear communication, and enhancing commitment among participants (Liu et al., 2022). This effect may stem from the necessity for discussions to be straightforward or focused, as the visuals in VR are self-explanatory, eliminating the need for complex language usage by those negotiating.

Figure 3: “ In the construction phase, the sub-scene manager on the construction site oversees the work and updates the progress.” (Liu et al., 2022)

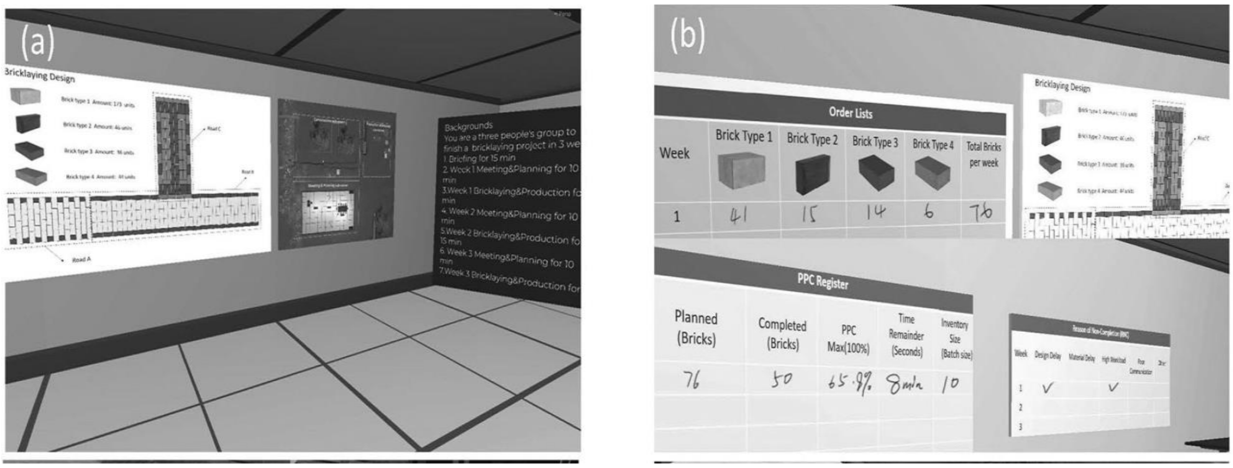

Figure 4: Presenting their VM (Virtual Model) within a VR (Virtual Reality) environment offers a level of detail far surpassing that of conventional methods used in meetings (Liu et al., 2022)

FINDINGS AND DISCUSSIONS

This research comprehensively examines how Virtual Reality (VR) can enhance Lean Construction practices. Our findings suggest that the utilisation of VR, particularly in SCRUM, Set Based Design, and Visual Management, underlines a transformative potential for enhancing construction project efficiency and value. Notably, VR's impact on reducing rework and defects while fostering an environment conducive to innovation and continuous improvement aligns with Lean Construction philosophy pillars. The study further emphasises VR's capacity to enhance Lean Construction's principles: value maximisation, waste minimisation, and continuous improvement. Studies by Jacobsen et al., (2021) and Trivedi et al., (2022) have similarly highlighted VR's role in improving project delivery and training effectiveness. The discussion points to VR as not just a technological tool, but a paradigm shift in construction management, fostering a more collaborative, efficient, and safety-conscious project environment. The integration of VR into Lean Construction not only streamlines project management and design processes but also enhances safety and worker engagement, aligning with the Lean principle of Respect for People. For practitioners, adopting VR could lead to more efficient project outcomes and improved stakeholder satisfaction.

The research identifies a crucial need for quantitative analysis to measure VR's impact, suggesting future studies focus on empirical data to solidify VR's role in Lean Construction. This exploration opens avenues for innovative project management strategies, advocating for VR's broader adoption in the industry.

Despite the qualitative nature of this research analysis, the evidence suggests VR as a pivotal tool in bridging communication gaps. However, the research underscores a critical gap in quantitative studies, pointing to an emergent need for empirical evidence to validate VR's operational benefits comprehensively.

One of the main limitations of our study is its reliance on secondary data, which might not capture the nuanced experiences of implementing VR on construction sites. Future research should focus on primary data collection, including case studies and experimental designs, to validate and extend our findings. Future explorations should aim at quantifying VR's effectiveness in Lean Construction, offering a clearer picture of its return on investment. This study serves as a steppingstone for deeper inquiries into VR's role in smart construction, encouraging stakeholders to consider its strategic implementation for Lean-aligned project outcomes.

Our discussion underscores the transformative potential of VR in Lean Construction but also acknowledges the complexity of its implementation in real-world settings. By addressing these challenges and focusing on empirical studies, future research can pave the way for more effective and widespread use of VR in Lean Construction.

CONCLUSIONS

In conclusion, this study has demonstrated the transformative potential of VR in enhancing Lean Construction practices. Our research systematically investigates how VR supports the four pillars of Lean Construction—value maximisation, waste minimisation, continuous improvement, and respect for people—as well as principles and methods, thereby contributing significantly to smarter construction practices.

Our findings illustrate that VR can act as a powerful enabler of Lean Construction by providing immersive and interactive environments that improve understanding and collaboration among project stakeholders. Through detailed VR simulations, construction projects can reduce waste and enhance efficiency, aligning closely with the principles of Lean Construction. Specifically, methods such as SCRUM, Set-Based Design and Visual Management have shown great potential for integration with VR, offering new ways to manage and execute construction projects that promote both efficiency and precision.

While our study primarily utilised secondary data, the potential for VR in qualitative research remains substantial. Future research could focus on case studies that examine the real-time application of VR in construction sites to provide deeper insights into its operational benefits and challenges. This will be particularly impactful in exploring how VR can further streamline Lean Construction in practice.

The ongoing development in VR technology promises further innovations that could be harnessed to support Lean Construction philosophy principles and methods more robustly. It is imperative for future research to continue exploring these technologies in diverse construction environments to solidify VR's role and optimise its benefits in Lean Construction.

BIM AS AN ENABLER OF LEAN CONSTRUCTION IN THE PUBLIC SECTOR

Guillermo Prado Lujan[1] and Danny Murguia[2]

ABSTRACT

Several governments are mandating Building Information Modeling (BIM) for public construction worldwide. While this top-down approach can be effective in some contexts, the lack of a lean construction perspective within BIM project delivery might hinder the expected outcomes. This paper aims to unpack the interplay between lean principles and BIM adoption that support formal and informal lean construction implementation in the design phase of public construction projects. The study focuses on a Latin American country subject to a current BIM mandate. Qualitative data was collected through semi-structured interviews with senior public sector practitioners. The findings reveal that the BIM practices *informally* align with lean principles, as there is no explicit emphasis on lean implementation within the BIM mandate framework. Drawing on these insights, the discussion compares these results with previous studies and suggests the inclusion of BIM as a facilitator of lean practices in the Lean in Public Sector (LIPS) agenda. The conclusion highlights the current opportunities for leveraging the BIM public policy trend towards lean implementation in public construction projects.

KEYWORDS

Lean construction, BIM, lean-BIM synergy, lean in the public sector (LIPS), public policy.

INTRODUCTION

Lean construction and building information modeling (BIM) have positively impacted the construction industry, and their interaction has been a major topic of discussion in both research and practice. Koskela (1992) defined lean construction as the application and adaptation of the underlying concepts and principles of the Toyota Production System (TPS) to construction. On the other hand, BIM is "a verb or adjective phrase to describe tools, processes, and technologies *facilitated by digital machine-readable documentation about a building, its performance, its planning, its construction, and later its operation."* (Eastman et al., 2011).

Despite being independent efforts to transform and enhance construction as an industry, lean construction and BIM share similarities and differences in adoption and potential outcomes once implementation occurs (Sacks et al., 2010). Bhargav et al. (2013) argued that lean and BIM have four significant mechanisms of interaction: BIM contributes directly to lean goals; BIM enables lean processes and contributes indirectly to lean goals; auxiliary information systems, enabled by BIM, contribute directly and indirectly to lean goals; and lean processes facilitate the introduction of BIM. Andujar-Montoya et al. (2019) found that BIM considerably reduces construction waste in the form of lack of information exchange, poor communication, poor decision-making, and frequent design changes. Moreover, Eastman et al. (2011) stated

1 University Lecturer, Construction Management & Technology Research Group (GETEC), Pontifical Catholic University of Peru, guillermo.prado@pucp.edu.pe, orcid.org/0000-0002-5325-1132
2 Assistant Professor, Construction Management & Technology Research Group (GETEC), Pontifical Catholic University of Peru, dmurguia@pucp.pe, orcid.org/0000-0003-1009-4058

that some of the principles of lean construction can be fulfilled by using BIM, and it will also enable the achievement of other principles.

Considering the interaction between lean and BIM, several studies have proposed frameworks to understand their relationship and guide their adoption. The interaction matrix of lean principles and BIM functionality presented by Sacks et al. (2010) provided examples based on published research on how lean and BIM align. Bayhan et al. (2023) also developed a framework that shows how lean and BIM interact and then validated the more relevant topics of these interactions through five case studies. Similarly, Karatas and Budak (2023) proposed a lean and BIM framework for the construction phase only, which was then validated through a statistical approach. On the other hand, other papers have presented case studies of the lean construction-BIM synergy, such as the ones presented by Khanzode et al. (2006) with Virtual Design and Construction (VDC), Rischmoller et al. (2006) with lean principles in the design stage, and Sacks et al. (2009) with the use of BIM to enhance product and process design. More recently, Eldeep et al. (2022) demonstrated using BIM as a lean tool to minimize construction waste and reduce the number of change orders in an educational project. Similarly, McHugh et al. (2019) combined the use of production planning software to implement lean tools and BIM models to improve visualization and enhance the project delivery phase of a data center. In sum, previous research has investigated BIM and lean interactions, but there seems to be a gap in how these interactions work in public construction.

Several countries have implemented BIM as a public policy to enhance public construction in their regions. Given the interaction of lean and BIM, these public policy efforts represent an opportunity to ask whether *formal* or *informal* lean construction applications can also be implemented. Unfortunately, several BIM implementation policies focus primarily on the administrative aspects of BIM project delivery (e.g. plans and documentation) without consideration of BIM-enabled production management. Consequently, this paper aims to understand the opportunities for lean implementation using BIM policies as an enabler in the public sector. To achieve this objective, this research focuses on the design stage of public projects in the Peruvian public sector, which served as the case study.

This paper is structured as follows. First, a literature review exploring the interactions of lean construction and BIM in public construction is introduced. Subsequently, the research methodology is presented, culminating in the presentation of results, including the alignment of lean principles with BIM use in the design stage. Following this, the discussion section will contrast the findings with prior research and current trends of lean construction. Finally, the conclusion section summarizes the results and proposes avenues for future research work.

LITERATURE REVIEW

LEAN CONSTRUCTION AND BIM

Sacks et al. (2010) presented one of the most acknowledged lean and BIM interaction matrices in the construction management literature. They found 56 interactions between lean and BIM, and 48 of the 56 were supported by practical evidence from industry case studies showing how BIM functionalities (or BIM uses) positively enable the achievement of lean principles. This matrix suggests that an incremental and integrated adoption of lean and BIM can enhance project and organizational results rather than their adoption separately. Oskoui et al. (2012) extended Sacks et al. (2010) interaction matrix by adding more BIM functionalities and lean principles enabled by this new set of BIM uses. These new interactions were found primarily in the operations & maintenance phase of projects.

Bayhan et al. (2023) proposed a lean and BIM framework using an analytical network process to find the most predominant factors contributing to the lean and BIM synergy. The study results showed that production, standardization, and information accuracy are the most critical factors, and they are mainly used to control production during the delivery phase of projects. Similarly, Karatas and Budak (2023) developed a framework to understand the impact of lean and BIM synergy in labor productivity during the construction phase. That study argued that the BIM uses of 4D planning and coordination support achieving lean principles. Furthermore, using 4D models alongside visual management tools such as dashboards significantly impacts construction labor productivity.

The literature also shows many lean and BIM case studies that provide practical evidence of these synergies in various contexts. Vestermo et al. (2016) developed a project on-site hardware called "BIM station," which facilitates the integration of lean construction and BIM, considering the application of BIM solutions to satisfy lean principles, such as visual management. Gerber et al. (2010) presented three case studies on the integration of lean and BIM. All three case studies showed advancements in delivering increased value to clients while significantly reducing waste in time and material. Gomez Sanchez et al. (2019) presented the use of BIM models with lean tools and methods (i.e., lines of balance, visual management, the Last Planner System) as good practices in the Colombian construction industry. In this case, conducting a BIM implementation seems to allow for a "leaner" project as it facilitates a better communication flow to obtain more reliable production plans.

Mollasalehi et al. (2018) developed a lean BIM maturity model to assess the joint implementation of both innovations in construction. That study proposed an integrated BIM and lean maturity model called IDEAL, which adopted the initial concepts of previous BIM and lean construction maturity models. Previous research have provided an extended understanding of the lean and BIM synergy, the frameworks developed to explain it, examples of their implementation, and how to assess their joint implementation. However, most examples are from the private sector. Understanding the challenges of conducting this effort in public projects is a significant gap that this study intends to address.

LEAN CONSTRUCTION AND BIM IN THE PUBLIC SECTOR

Considering the systemic and wide approach of lean construction and its foundation in lean production, the implementation of lean construction comes along with instrumental changes in how public organizations are managed. Several authors have found significant challenges and barriers for implementing "lean" as a way of thinking and as a foundational aspect of the practices in the public sector. Bathia & Drew (2006) conducted a study to implement lean manufacturing techniques in the United Kingdom (UK) public sector, concluding that "*Applying lean is difficult in the private sector, and more so in the public sector. Therefore, successful lean transformations must close the capability gap early in the process so managers and staff can make the transition to a new way of working*."

Andersson et al. (2023) conducted quantitative research that showed some challenges in understanding what "lean" means in several Norwegian public sector workers. Based on that study, lean is perceived mostly as a set of tools instead of a way of thinking or as a mindset that can be beneficial for delivering more value to the end users of public services. This study also showed several misconceptions about lean and the lack of focus on production and flow management, which is inherent to the concept of lean as it was conceived in the 1950s. Having said that, more specific studies use public projects as case studies to showcase lean construction-related concepts, techniques, or principles (e.g. Kuprenas, 1998; Prado, 2021).

Kuprenas (1998) presented the implementation of lean thinking concepts, tools, and processes in the City of Los Angeles Bureau of Engineering due to poor project delivery performance. Kuprenas (1998) explained a holistic perspective of their lean journey, which contains organizational changes, systems optimization training, and implementation of performance metrics that combine production-related metrics and cost and time metrics. Recently, LIPS emerged as an international forum where practitioners share lessons learned during lean transformation in the public sector and non-profit organizations (LIPS, 2024). Currently, based on the LIPS website, their research areas are Lean in Healthcare, Transformation in Transportation, Empowering people in Utilities, Lean Thinking in Education, Future of Infrastructure, and Principles of Lean Services. The specific topic of lean construction implementation in the public sector enabled by technologies such as BIM is not explicitly stated as part of the agenda items of this organization. However, one of the objectives of the 2022 LIPS conference (LIPS, 2022), which was held in Chile, was to inspire Lean initiatives in public programs, including digital technologies/BIM. Therefore, there seems to be a current discussion on integrating lean and BIM in specific projects and several public sector programs to enhance the delivery of public infrastructure.

The current implementation of BIM as a public policy in several countries (particularly in Latin America) could be used as an enabler to implement not only lean in public projects but also change the way of working in public organizations towards delivering more value to the end-users (i.e. the beneficiaries of the infrastructure delivered). Based on the BIM Network of Latin American Governments, the Latin American region intends to pursue a collaborative effort to implement BIM towards accelerating national digital transformation processes (Red BIM Gob Latam, 2024). Considering that this paper uses Peru as a case study, it is important to mention the current state of the BIM public policy in this country. The BIM adoption policies are led by Plan BIM Peru of the Ministry of Economy and Finance as the regulatory public body in charge of disseminating and overseeing this public effort (Plan BIM Peru, 2024). Several pieces of policy documentation have been published, and the ultimate goal is to use BIM for all public projects by 2030 (Ministry of Economy and Finance, 2023).

Despite the apparent positive interactions between lean and BIM, it seems that no piece of policy addresses these two innovations. However, the literature shows that some public organizations have used lean and BIM collaboratively through case studies. For instance, Umstot et al. (2014) presented a public sector case study in which BIM enabled lean construction. This case study was developed thanks to the combination of two factors: (a) the 2008 Californian law, which granted authority to community colleges to use design-build contracting to deliver capital projects exceeding $2.5M, and (b) the decision of the San Diego Community College District (SDCCD) to require all new projects to be designed and constructed using BIM. Umstot et al. (2014) demonstrated how the combination of lean construction significantly impacted change order reduction, schedule reliability, and the completion of sustainability certification. In the case study of that research, the use of BIM allowed the project to achieve several lean principles.

Monyane et al. (2018) included BIM as a lean construction tool to enhance the cost management framework in South African public sector projects. In that study, Monyane et al. (2018) conducted interviews and found that many respondents agreed on the use of BIM to enhance design and construction workflow and the application of BIM uses (i.e., clash detection) to improve design documents. Similarly, Prado (2021) discussed the use of BIM and lean in combination with the Virtual Design and Construction (VDC) implementation process (and its challenges) in Peruvian public projects. Moreover, Prado (2021) stated that the need for a lean approach is instrumental to overcoming several challenges in implementing these innovations.

Given the influential role of the government in the industry, its ability to encourage and empower public organizations is crucial for delivering value throughout the project lifecycle. These studies indicate that integrating lean construction tools, methods, and innovative technologies can enhance performance in public construction projects. Therefore, the application of a framework that integrates these two concepts, such as the lean and BIM framework presented by Sacks et al. (2010), could be used as the theoretical artifact to understand the opportunities for joint implementation of lean construction and BIM.

RESEARCH METHOD

Given the background of the authors of this paper with the Peruvian public construction sector, and the similar approach in BIM implementation in the Latin American region, Peru was selected as the case study. The first step is to develop a version of the lean and BIM interactions framework. Considering the context of the BIM implementation policies in Latin American countries and the lean and BIM interaction matrix presented by Sacks et al. (2010), this study proposes a more specific version of this framework addressing the design phase. The second step is to develop a qualitative analysis process based on semi-structured interviews with public managers. These public managers are required to have experience in managing public projects implementing BIM and have knowledge of lean construction, so the interactions between these two innovations can be found through the interviews. The interviewees were asked questions about the interaction of lean and BIM in the projects they manage and how lean principles are enabled using BIM. The questions were:

- How many projects have you developed with BIM?
- What do you understand as lean construction and lean overall?
- Based on the list of lean principles, which lean principles are enabled by each BIM use implemented in your projects? Could you elaborate on the evidence?

The demographics of the managers are shown in Table 1.

Table 1: Demographics of public managers interviewed

N°	Public organization	# of years of experience	# of projects using BIM
1	Ministry of Housing	20	10
2	Ministry of Education	15	8
3	Ministry of Education	5	5
4	Ministry of Housing	23	20
5	Regional Government of Callao	30	4
6	Ministry of Education	16	9
7	Ministry of Economy	30	25

The third step is to find the similarities and differences in the lean principles (including lean tools and methods) that BIM enables based on the experiences shared by the interviewees. Using the answers of all the interviewees facilitates the construction of a more robust understanding of the perception of public managers regarding how BIM (uses) supports the satisfaction of lean principles and the evidence related to it. This step will lead to obtaining an explanation of how lean principles are enabled by BIM in the public sector.

RESULTS

CASE STUDY CONTEXT

Projects developed under the Peruvian public construction legislation follow a typical design-bid-build (DBB) as the delivery method of choice (Ministry of Economy and Finance, 2018), which mainly focuses on financial accountability, and generates fragmentation among project stages. Additionally, public projects usually involve many actors throughout their phases, and the regulatory body auditing public procurement constrains public managers from innovating if there is no specific piece of legislation that supports that innovation. Consequently, managing public projects is considered a heavily bureaucratic process, and innovation is usually triggered after a policy is released to "shield" public managers who decide to implement it. In this regard, a new BIM policy now allows public institutions to implement BIM uses and conduct BIM implementation (at organizational and project levels). This policy is also included in different types of delivery methods not commonly used in this sector, such as design-build, and legal frameworks that differ from the standard used in the case study, such as the New Engineering Contract (NEC). Considering the interrelated relationship between lean and BIM and the current BIM policy, the case study context has many variables to study that might or might not affect the opportunities for lean principles to be included in the current BIM mandate.

LEAN CONSTRUCTION & BIM INTERACTIONS IN THE DESIGN STAGE

Table 2 shows the outcome of the lean and BIM interactions in the case study. This is shown by aligning lean principles to BIM functionality based on the case study.

Table 2: Lean construction & BIM framework in the design stage of public projects

BIM functionalities (BIM uses)	Lean Principles (validated by the case study)
Visualization of form (Existing conditions records, 3D visualization)	Reduce variability Verify and validate Go and see for yourself Use visual management Ensure requirements flow down
Rapid generation of multiple design alternatives (Design authoring, Design review, 3D Model coordination)	Reduce variability Reduce cycle times Use visual management
Automated generation of drawings and documents (Documentation production, Quantity take-off)	Reduce variability Reduce batch sizes
Collaboration in design and construction (3D Model coordination, 4D Model simulation, Data coordination, 3D Visualization)	Reduce variability Reduce cycle times Increase flexibility Ensure comprehensive requirements capture Verify and validate Decide by consensus considering all options

In the first column of Table 2, the BIM functionalities are drawn from the initial lean construction and BIM interaction matrix, and the associated BIM uses (in parenthesis) are drawn from Plan BIM Peru. This portion of Table 2 shows the “correlation” between the BIM functionality and BIM uses extracted from the two pieces of literature used in this study. This alignment was necessary to ensure a good understanding of terminology during the interviews with the public managers. Moreover, Plan BIM Peru is working on having the same language within the public sector in terms of the terminology used for BIM-related concepts. The lean principles are presented with the same terms as the original interaction matrix. The explanation of these terms was also part of some interviews with the public managers who participated in this research.

The results of Table 2 show that the BIM functionality of Collaboration in design and construction (the combination of the following BIM uses: 3D Model coordination, 4D Model simulation, Data coordination, and 3D visualization) enables more lean principles than the other

BIM functionality for the design phase of projects. This BIM functionality enables six lean principles based on the interviewees' responses. These lean principles are: reduce variability, reduce cycle times, increase flexibility, ensure comprehensive requirements capture, verify and validate, and decide by consensus considering all options. The BIM functionality of visualization of form (the combination of the following BIM uses: Existing conditions records and 3D visualization) enables five lean principles: reduce variability, verify and validate, go and see for yourself, use visual management, and ensure requirements flow down.

The BIM functionality of Rapid generation of multiple design alternatives (combining the following BIM uses: Design authoring, Design review, and 3D Model coordination) enables four lean principles: reduce variability, reduce cycle times, and use visual management. Lastly, the BIM functionality of Automated generation of drawings and documents (combining the following BIM uses: Documentation production and Quantity take-off) enables two lean principles: reduce variability and batch sizes. From a BIM perspective, there are overlaps in the BIM functionality's impact on lean principles (several BIM functionalities impact several lean principles), which shows the complex and multilayered interaction between lean and BIM. Additionally, it seems that the BIM uses combined could also provide more robust support to a combination of lean principles.

LEAN PRINCIPLES ENABLED BY BIM

The results of Table 2 present the relationship between lean and BIM in the public construction sector, specifically in the design phase of the case study. From a lean construction perspective, the BIM functionalities analyzed enable eight lean principles. To facilitate the explanation of the interrelated connections among some of the lean principles and the BIM uses that enable them, some lean principles are going to be presented paired.

Reduce Variability

All BIM uses enable this lean principle, and the public managers believe that *"BIM allows building two times the project, and as a consequence, less waste (fewer sources of variability) will happen when the projects are constructed."* Some of the public managers most knowledgeable in lean construction mentioned that combining early 4D-BIM modeling with lean tools and methods (i.e., target value design and value stream mapping) might allow for reducing even more sources of variability in the early stages of the projects. Furthermore, there is evidence of conducting training programs in specific lean tools and methods, being The Last Planner System the most common one among the training programs in the public sector. Additionally, the contracting methods currently employed in public projects provide greater flexibility for conducting operations management studies and gathering data on the impact of variability, thereby facilitating efforts to mitigate these sources of variability.

Go and see for yourself & Verify and Validate

All the interviewees mentioned their practices of engaging with the team members and seeing the "sources of waste" as part of their duties, as well as how BIM models support this activity by providing a "virtual *gemba* walk." These activities are now considered a collaboration section in the BIM policies, expecting to enable more positive interactions among stakeholders. These lean principles are also validated and improved through BIM by authoring and reviewing design models in the early stages of the project, which enables to understand better future issues and ways to mitigate them. Additionally, these lean principles insert transparency during the project's design phase, and transparency is a major value in public construction. This principle of BIM is a significant cornerstone of the current BIM mandate.

Use Visual Management

The use of BIM models and outcomes of the BIM uses for reporting, and dashboard development in design seems to be the most common interpretation of how BIM enables this lean principle. Obtaining data to feed the project's visuals since the early stages is a current initiative that most public managers are conducting. Additionally, some public managers mentioned including BIM models and BIM deliverables to develop A3 reports, which shows a combination of lean tools and methods supported by BIM uses. They mentioned they learned these lean tools and methods from different sources, which include institutional training. Moreover, the use of 4D BIM models to develop on-time interaction dashboards and evaluate several design options from a constructability perspective were other examples collected through the interviews conducted.

Reduce cycle time

The combination of having different templates to apply BIM uses provided by public clients and process maps for lean tools and methods makes it seem that BIM allows the reduction of cycle times of several pieces of the design scope supported by BIM. This cycle time reduction mainly happens with design documentation production because it facilitates an almost automated documentation standard in each public institution and a standard process for reviewing procedures and submittals within the private sector institutions. However, there was no emphasis on how reducing cycle time is related to production systems optimization when the interviews were conducted. Additionally, it seems that there is no understanding or acknowledgment of production systems, or production management applications in projects, which are foundational concepts in the lean construction body of knowledge.

Decide by consensus considering all options

Public managers pointed out that designers use BIM models to evaluate different alternatives, reducing potential changes because of the previous visualization of potential issues and helping to incur in a set-based design approach. In this regard, the owner's involvement in the project comes with collaborative efforts from both parties, which is stated in the BIM policy. However, the public managers seem reluctant to understand how this collaborative effort might work, considering the current problems related to corruption allegations in public projects. This is a major root cause of the high levels of bureaucracy and poorly managed accountability of public projects.

Ensure comprehensive requirements capture & Ensure requirements flow down

These two lean principles are related as they intend to keep the value throughout the whole delivery phase of the project, considering building standards and end-user requirements, and properly translating these needs into technical decisions. For this reason, implementation of BIM uses such as design review, visualization, and automation through BIM models allows to keep track of the value and benefits of the project to their users and beneficiaries. These BIM uses allow for the overseeing of any potential building standard infraction and the keeping of the "value" intended for the project by visualizing and analyzing the early design during the design review process with BIM models. Furthermore, one of the interviewees mentioned that in one police department project, the designers were able to show the final product to the police officers (beneficiaries) to use the building, and they were able to discuss project decisions thanks to the BIM models. This example highlights how BIM allows to maintain value by facilitating the interaction with the other stakeholders (primarily the ones not related to construction-related disciplines).

DISCUSSION

The findings of this research seek to understand the opportunities for lean construction implementation (*formally* or *informally*) by enabling lean principles within the context of BIM implementation policies. While the findings of this study show several opportunities for lean construction implementation in public projects, some concepts related to lean construction were required to be explained while conducting the interviews with the public managers. This study also did not ask for specific tools and methods (such as the Last Planner System or Target Value Design), but rather for the lean principles embedded in the lean tools and methods. The public manager's misconception of the relationship between lean construction and production management represents a challenge to the application of lean in the public sector. Furthermore, the concept of value in projects, along with its various implications, appears to be complex and is subject to varying interpretations by public managers. Lujan & Murguia (2022) also discussed this concept and how the Lean Project Delivery System can facilitate the definition of value in public projects.

In terms of the BIM uses or BIM functionality, the interviewees showed some confusion with the specifics and implications of each BIM use, such as the digital deliverable required to complete the application of each BIM use. The interviews were facilitated by providing different names for each BIM use depending on the literature used by the public managers. Regardless, the BIM uses table developed by Plan BIM Peru is supposed to be used as the standard for this type of effort. The BIM Dictionary developed by the BIM Excellence Initiative (BIM Dictionary, 2024) is expected to clarify this concern and have only one source, if possible, to obtain BIM-related definitions. This research needed to "cluster" BIM uses to match the BIM functionality stated in the original lean and BIM interaction matrix. Furthermore, obtaining a more granular table between the interaction of lean construction and BIM uses (not BIM functionality) might provide different results from the ones obtained in Table 2.

Previous studies on the interactions between lean construction and BIM for specific principles and functionalities have not used case studies in developing countries. This study shows empirical results on how these relationships emerge in public construction projects. However, since the authors used the preestablished lean principles associated with the BIM functionality in the design phase of projects, there might be more lean principles enabled by the same BIM functionality. Considering a different lean construction and BIM interaction framework, such as the ones proposed by Karatas & Budak (2023), can also provide a different perspective on the implications of lean construction and BIM implementation altogether in public projects.

These results also provide a broader perspective of two significant opportunities. First, the option of enabling lean principles as part of the BIM mandate, considering the benefits of implementing these two construction paradigms together. This can also be useful in setting a new trend in the Latin American region towards an improved construction sector as eight countries follow a similar BIM implementation journey. Second, considering an even broader perspective, LIPS can also include more case studies of the enablement of lean construction in public projects (and public organizations in general) as it represents a very challenging topic to implement lean towards a more holistic approach. This second opportunity is also related to other efforts trying to implement lean-related concepts (not only within the construction industry). An example of these efforts was presented by Bathia & Drew (2006), Monyane et al. (2018), and Andersson et al. (2020) in the literature review section of this paper.

By adding lean principles to the current BIM mandate for public projects, benefits will arise as the interaction of lean construction and BIM are virtuous, and these two innovations support each other. Moreover, this research presented a baseline to understand better the interaction of lean and BIM from a developing country perspective.

CONCLUSIONS

This research aimed to understand the opportunities for lean implementation using BIM as an enabler in the public sector. To achieve this objective, this study focused on the lean construction and BIM interactions presented in the Sacks et al. (2010) interaction matrix to construct a more specific framework, which was then used to interview public managers of the Peruvian public construction sector and validate the enablement of lean principles. The findings show that the implementation of BIM enables eight lean principles uses: reduce variability, go and see for yourself, verify and validate, use visual management, reduce cycle time, decide by consensus considering all options, ensure comprehensive requirements capture, and ensure requirements flow down. Although these lean principles seem to appear "informally" during the delivery of public projects, more practical applications of lean were also pointed out in the case study, such as The Last Planner System, value stream mapping, set-based design, A3 reports, and other lean tools and methods being used in public projects.

This study has some limitations including the project phase under examination and the unique context of the Peruvian public sector. Future studies could conduct in-depth case studies to reveal more insights into the body of knowledge of how lean construction and BIM interact. Moreover, this study reveals new perspectives of a more integrative umbrella for implementing digitalization and production management in construction, which are being exposed in the construction industry through BIM and lean construction, respectively. Therefore, conducting future research considering these wider perspectives could be beneficial to understanding a more integral improvement process of the construction industry.

ACKNOWLEDGMENTS

The authors want to thank the public managers involved in the interviews of this study.

FROM CONCEPT TO CONCRETE: DIGITAL TWINS ENABLING DIFFERENT LEVELS OF LEAN CONSTRUCTION

Omar A. Owais[1], Mani Poshdar[2], Ali Bidhendi[3], Kamal Jaafar[4] and Saad Sarhan[5]

ABSTRACT

The integration of Digital Twins (DTs) in Lean Construction (LC) represents a transformative approach to enhance collaboration, efficiency, waste reduction, and decision-making in construction projects. This paper explores the potential of DTs across different levels of LC through a comparative analysis method, aiming to establish a robust implementation foundation for lean organisations. Firstly, at the philosophy level, DTs foster collaboration, transparency, and respect for people by providing real-time data and virtual representations. They enable value maximisation, waste minimisation, and continuous improvement through visualisation, simulation, and data-driven decision-making. Besides, continuous improvement through monitoring and feedback loop. Secondly, at the principles level, DTs align closely with key LC principles such as value maximisation, continuous improvement, waste elimination, pull planning, continuous flow, and fast switch-over. By optimising processes, enhancing monitoring capabilities, and facilitating collaboration, DTs contribute to efficient project delivery. Thirdly, at the methods level, DTs complement LC methods such as Error Proofing, Value Stream Mapping, Target Value Design, and Last Planner System by facilitating real-time collaboration, visualising workflows, engaging stakeholders early, and providing error prevention capabilities. Overall, the strategic integration of DTs and LC thinking leads to improved project efficiency and value delivery, fostering ongoing innovation and improvement in the construction sector.

KEYWORDS

Lean construction (LC), Digital Twin (DT), Philosophy, Principles, Methods.

INTRODUCTION

In the ever-evolving landscape of construction, digital technologies integration has become a cornerstone for achieving efficiency, reducing waste, and ensuring optimal project outcomes (Tuhaise et al., 2023). One such revolutionary technology is the concept of Digital Twin (DT). It can be defined as an emerged transformative technology, offering a virtual replica of physical objects, systems, or processes (Maksimović, 2023). This means constructing a virtual duplicate

of a physical asset or process, to enable ongoing monitoring, data analysis, and simulation of diverse scenarios. Its applicability spans various sectors, including manufacturing, construction, and the oil and gas industry (Ferrigno & Barsola, 2023).

On the one hand, DTs have significantly lowered the development cost of new manufacturing methods, enhanced efficiency, decreased waste, and minimised batch-to-batch variability (Attaran et al., 2023). On the other hand, DT has emerged in the construction sector to introduce innovative methods of controlling production during projects (Sacks et al., 2020). It combines information from a range of onsite monitoring technological equipment to offer precise and up-to-date information for effectively evaluating and enhancing the entire project process outcome. According to Sacks et al., this can be achieved through the integration of Building Information Modelling (BIM) technology, Artificial Intelligence (AI) functions, DT concepts, and lean construction (LC) thinking to create a data-centric approach to construction management aiming to enhance the overall construction sector. For instance, the integration of these technologies has the capacity to facilitate decision-making and operational processes for general contractors throughout all phases of construction. This leads to several advantages, including cost reduction, improvement in collaboration, efficient information exchange, and the implementation of construction management practices driven by data (Lv et al., 2022).

In the construction sector, DT aims to achieve several objectives. Firstly, it offers live information and evaluation of physical assets, enhancing building design, construction, and performance in architecture, engineering, and construction (AEC) sectors (Nguyen & Adhikari, 2023). Secondly, it facilitates the evaluation of potential business models by utilising stored data, aiding decision-making for future innovations (van der Veen et al., 2023). Thirdly, a DT holds the potential to revolutionise various areas in construction, including virtual design, project planning, asset management, safety, energy efficiency, structural health monitoring, sustainability, quality control, supply chain management (Omrany et al., 2023). Fourthly, its integration in construction offers benefits like improved project management, reduced errors, increased productivity, despite challenges such as initial costs and data management (Nalioğlu et al., 2023). Additionally, DTs synergise with LC, fostering collaborative efforts and aiding in the identification of benefits, costs, opportunities, and risks in LC projects.

Lean Construction (LC) is a methodology designed to reduce time, efforts, and waste of resources while optimising value in production systems (Koskela et al., 2002). It focuses on efficiency, collaboration, and waste reduction across four levels: philosophy, principles, methods, and tools and implementation (Do, 2022). Firstly, philosophy establishes foundational principles of LC incorporating “respect for people, maximising value while minimising waste, and continuous improvement”. Focusing on philosophy initially establishes the fundamental “WHY” of the lean journey. Secondly, the principles constitute the “HOW” concepts, encompassing timeless ideas such as Visual Management, Continuous Flow, Kanban, Fast switch over, Takt, Poka-yoke, etc. Thirdly, method such as Takt Planning, Set-Based Design, Last Planner System (LPS), Target Value Delivery (TVD), Choosing by Advantages, among others, guide LC implementation. Finally, these methods are applied in real-world settings using Lean tools or implementations, categorised as hybrid, analogy, or digital.

Therefore, LC aims to enhance time, cost, and resource management in construction projects by minimising waste, improving communication, and fostering collaboration (Altan & Işık, 2023; Oke et al., 2021). The adoption of LC practices has shown benefits, such as shortened project durations, reduced costs, and optimised resource allocation (Barkokebas et al., 2023). However, Do (2022) emphasised on aligning the three fundamental levels (philosophy, principles, and methods) during LC implementation, a crucial aspect often overlooked by many lean organisations. Moreover, DT is emerging as a transformative technology in construction, aiming to provide real-time data and analysis of physical assets, support decision-making, revolutionise the industry, advance processes, and interact with the LC concept. Therefore, the combination of lean principles and technological innovation might be a powerful tool for reducing waste and uncertainty in the construction operational process (Owais et al., 2023; Sacks et al., 2020).

Problem Statement: Despite its potential, the implementation of DT in construction has not been sufficiently addressed through different levels of lean thinking to establish a robust implementation foundation for lean organisations. Therefore, the aim of this research is to explore how DTs complement various levels of applying lean thinking to achieve their objectives. This investigation encompasses both conceptual and concrete dimensions. Conceptually, the study delves into the foundational philosophy, principles, and methods of DTs and LC, elucidating their collaborative potential in enhancing project efficiency and value delivery. At the concrete level, the research investigates the real-world applications of DTs and LC methodologies, aiming to bridge the future gap between theoretical frameworks and tangible outcomes in the construction sector. Through this comparative analysis, the research endeavours to establish a robust implementation foundation for lean organisations seeking to leverage DTs for optimised construction project management.

RESEARCH METHOD

This study employs a comparative analysis method to explore the integration of DTs into LC thinking. Comparative analysis plays a crucial role in theory development across various fields of research by enabling researchers to compare multiple units of study, identify correlations, and draw meaningful conclusions (Devi, 2023). The following steps have been carefully elaborated to explore the integration of DTs into LC thinking:

1. Data Collection:

- Literature Review (LR): A comprehensive LR was conducted to understand the current advancements in LC levels and DTs. Using specific search parameters such as “Lean Construction,” “Philosophy,” “Principles,” “Methods,” and “Digital Twins” on Google Scholar, journals, conferences, and books, a pool of 148 articles from 2016 onwards was identified. Subsequently, the research team analysed and curated articles focusing on LC levels and DTs, resulting in a final set of 18 articles for detailed examination.

2. Data Analysis:

- Comparative Approach: A structured comparative approach was developed to analyse the alignment between DTs and LC across different levels. This approach enables the systematic evaluation of similarities, differences, and synergies between DTs and LC.
- Categorisation: Data from the LR were categorised based on key themes and concepts related to DTs and LC levels, facilitating a deeper understanding.
- Cross-Comparison: Data from various sources were cross-compared to identify common patterns, trends, and implications, allowing for the synthesis of overarching insights.

3. Findings Interpretation:

- Synthesis of Results: Findings from the comparative analysis were synthesised to draw conclusions on the benefits and implications of integrating DTs into LC levels, highlighting key themes, and discussing their significance as shown in Figure 1.
- Practice Implications: Practical implications, challenges, and future research are provided to enhance construction practitioners and organisations adopting DTs within their LC frameworks, emphasising collaboration, efficiency enhancement, and value maximisation.

In summary, the comparative analysis method employed in this study offers a systematic and rigorous approach to examining the integration of DTs and LC, providing valuable insights and actionable recommendations for advancing lean practices in the construction industry.

DIGITAL TWINS ORIGIN AND CONCEPT

While the use of DT has achieved immense recognition in recent years, the idea itself is not entirely novel. Gelernter (1993) book "Mirror Worlds" introduced the concept of DT, envisioning software systems that simulate reality by integrating data from the physical world. He described DT as creating "Mirror Worlds," allowing users to interact with complex systems digitally. This early anticipation indicated DT's widespread application in diverse fields.

In 2002, Grieves' introduced the Mirrored Spaces Model (MSM) within discussions on Product Lifecycle Management (PLM), marking an unofficial presentation of the DT concept (Grieves, 2005). This model emphasised the connection between actual and virtual spaces, highlighting the importance of data exchange for understanding PLM information. In 2006, Grieves renamed the conceptual model to the 'Information Mirroring Model'(Grieves, 2009), emphasising bidirectional linking between spaces and the use of multiple virtual spaces for a single real space, fostering exploration of alternative ideas. However, practical DT applications faced challenges due to technological limitations, including low computing power, limited connectivity, and data management issues, as well as nascent machine algorithms.

In 2010, the term "Digital Twin" was publicly introduced by the National Aeronautics and Space Administration (NASA) within their collaborative technology roadmap, specifically within Technology Area 11: Modeling, Simulation, Information Technology, and Processing (Shafto et al., 2012). The idea was inspired by NASA's Apollo program, in which two identical spacecraft were constructed to allow the circumstances of one spacecraft to be mirrored during its journey (Shafto et al., 2010). The spacecraft that stayed on Earth was identical to the one that travelled in space.

Additionally, Tuegel (2012) highlighted the US Air Force's adoption of DT technology for aircraft development, repair, and forecasting, following NASA's lead. The aim was to replicate the mechanical and physical qualities of aircraft to predict signs of fatigue or cracks, thus extending their usable life. The concept of creating a digital representation of physical systems for analysis has existed for decades. This approach gained momentum in the construction sector with technological advancements, such as BIM, as observed by Nguyen and Adhikari (2023).

BIM entails creating digital models of buildings and infrastructure, continuously updated with real-time data, enabling better project visualisation and management (Nguyen & Adhikari, 2023). The integration of DTs into construction likely emerged alongside advancements in BIM technology. van der Veen et al. (2023) and Omrany et al. (2023) both note the gradual adoption of DTs in construction for enhanced project planning, design, construction, and maintenance, as part of a broader trend towards digital transformation across industries.

EVOLUTIONARY PROGRESSION OF DIGITAL TWINS IN CONSTRUCTION

Academic interest in DT technology, particularly in construction, has surged, resulting in numerous studies highlighting its benefits. Despite being in early stages, research has extensively examined DT applications, benefits, and challenges. For instance, Rasheed et al. (2020) explored the values, challenges, and enabling technologies of DTs, emphasising their potential to revolutionise industries and societal interactions. Their framework of Virtual Twin, Predictive Twin, and Twin Projection pillars offers clarity, with recommendations for collaborative efforts among stakeholders for successful implementation. Standardisation is crucial for facilitating interactions between DTs in a connected world. The authors thoroughly delve into DTs as virtual representations of physical assets driven by data and simulators, aiming to transform real-time prediction, optimisation, and decision-making processes. Recent advancements in computational pipelines, AI, and big data technologies have elevated DTs into a crucial trend across diverse applications.

Lee et al. (2021) explored merging DT and blockchain frameworks to enhance traceable data communication in construction projects. They addressed the challenge of fragmented information sharing among stakeholders by integrating a DT updated in near real-time through IoT sensors. Blockchain ensured authentication and traceability of data transactions, enhancing transparency and security. Testing in a case project confirmed the framework's ability to trace all data transactions and generate compliance statements promptly. The main contribution lies in promoting accountable information sharing, which could streamline contract execution, payments, and decision-making, fostering better collaboration among fragmented participants.

Akanmu et al. (2021) mentioned, also, DT play a pivotal role in revolutionising the construction industry by bridging the gap between physical assets and their virtual counterparts. This transformative technology, as underscored by recent research findings, enhances safety, efficiency, and real-time control in construction projects. The authors emphasises that the integration of DTs with emerging technologies such as virtual design modeling, sensing, and robotics forms the next generation of cyber-physical systems in the construction. These advanced systems not only improve workforce productivity, health, and safety but also offer substantial potential for lifecycle management of building systems and competency enhancement. Despite challenges, the adoption of DTs emerges as a critical catalyst for the industry's evolution toward enhanced automation and sustainable construction practices.

Yeung et al. (2022) explored the Digital Twin Construction (DTC) concept, a data-driven approach integrating BIM, LC, DTs, and AI in construction management. They emphasised simulation's role in DT, highlighting predictive situational awareness, data-driven continuous improvement, and future autonomous real-time production control. Barriers to simulation in DTC workflows are discussed, with proposed criteria for tool evaluation. The study underscores the empowering nature of DT in construction, enabling planners to optimise decisions based on comprehensive project status information and envisioning a future with autonomous production control systems. The research contributes to prototype simulation tool development within the BIM2TWIN project's virtual Plan-Do-Check-Act cycle.

Arsiwala et al. (2023) addressed the impact of Industry 4.0 on the construction sector, with a focus on achieving net-zero carbon emissions through the use of DTs. Focusing on existing assets, the research introduces a DT solution integrating IoT, BIM, and AI to automate monitoring and control of CO2 emissions. The study underscores BIM and IoT's significance for spatial information visualisation and introduces AI for predicting emissions. It proposes a user-friendly DT architecture, validated through a real-life case study, illustrating its potential in visualising real-time indoor air quality. The authors highlighted the broader implications, such as nationwide digitisation for policy making and emphasisse interdisciplinary collaboration for seamless data exchange standards in the construction industry.

ALIGNING DTS WITH LEAN CONSTRUCTION LEVELS

Technology has found its roots in the construction industry, aiming to revolutionise the sector. Many researchers have examined the emerging potential in construction, seeking to improve project outcomes with the aid of various technologies. Despite DT technology being in its infancy stage, this section will examine the emerging benefits and how DTs aid LC at different levels, including philosophy, principles, and methods. Moreover, Figure 1 will illustrate the integration benefits at the end of this section.

DT's IN SUPPORTING LC PHILOSOPHY LEVEL

LC philosophy emphasises, firstly, respect for people by fostering collaboration, value-driven communication, and a positive work environment. Secondly, it focuses on maximising value while minimising waste through optimising processes to deliver quality results efficiently. Lastly, continuous improvement is considered the central point of encouraging ongoing learning, adaptation, and innovation for enhanced project outcomes and efficiency (Do, 2022). Several studies have examined the potential of DT in LC philosophy as an emerging technology that can aid construction project outcomes.

For instance, Sacks et al. (2020) conducted a study on DTC, integrating BIM, LC, and AI for data-centric production construction management. The research identified four key information and control concepts, delineating DTC's conceptual framework. They proposed a DTC information system workflow comprising information stores, processing functions, and monitoring technologies within three concentric control cycles. DTC is positioned as a comprehensive construction management approach, prioritising closed-loop control systems over traditional BIM tools. The authors stressed the importance of effective DTs in construction, highlighting challenges in collaboration, interoperability, and real-time monitoring. They advocated for a cohesive workflow for DTC planning and control across design and construction phases to achieve optimal project outcomes.

Barkokebas et al. (2023) have similarly advocated for the integration of a DT to enhance production flexibility in Offsite Construction (OSC), where building components are prefabricated and then assembled on-site. The OSC industry faces challenges in adapting to uncertainties, multiple projects, and variable market demands. The proposed DT leverages real-time data to autonomously reassign multiskilled workers, addressing the lack of flexibility in labour-intensive processes. Applying lean thinking metrics, the study quantifies improved production performance by considering waste reduction. Through simulation, various scenarios are assessed, revealing significant enhancements in reducing waiting time, production duration, and overall cost, affirming the DT's effectiveness in managing multiskilled workers in OSC.

Nevertheless, the authors of this research have meticulously examined, analysed, and explored the direct connections between the emerging benefits of DT and LC concept. In their pursuit of a robust implementation, they have focused on linking this emerging technology, specifically, with LC philosophy levels as a first step to address the research gap. This strategic linkage aims to enhance collaboration, efficiency, and construction project decision-making. By integrating DT into LC philosophy, the authors envision a culture that fosters lean philosophy foundation. This approach not only enhances project outcomes but also lays the foundation for a more streamlined and adaptive construction process, ultimately leading to more efficient and sustainable projects. The linkage is as follows:

Respect for People:

Collaboration and Communication: DTs offer a centralised platform that enables real-time access and sharing of project data among stakeholders (Lee et al., 2021). This accessibility breaks down silos between different project teams, fostering seamless collaboration. Team members can readily communicate, share insights, and coordinate efforts more effectively. By leveraging DTs, LC practices can be enhanced as the technology supports a collaborative environment that values everyone's expertise and contributions. This aligns with lean thinking, emphasising the importance of leveraging collective knowledge and skills to improve project outcomes.

Transparent Information: DTs ensure transparency by making project data readily accessible to all relevant parties (Rasheed et al., 2020). This transparency fosters open communication, ensuring stakeholders are well-informed about project developments and decisions. Transparent information sharing promotes trust among stakeholders, reducing misunderstandings or conflicts arising from incomplete or outdated information. Moreover, it enables stakeholders to contribute their perspectives to decision-making, leading to informed and consensus-driven decisions. This alignment with lean philosophy optimises project outcomes by leveraging stakeholders' collective intelligence.

Maximising Value While Minimising Waste:

Visualisation and Simulation: DTs offer a virtual representation of construction projects, enabling teams to visualise detailed project aspects before physical construction (Tuhaise et al., 2023). Through simulation capabilities, teams can explore diverse scenarios, test design alternatives, and optimise workflows. Early identification of issues and inefficiencies in the virtual environment allows proactive risk mitigation and waste reduction during actual construction. This capability aligns with lean philosophy by promoting continuous improvement and eliminating non-value-adding activities, ultimately enhancing project efficiency and value delivery.

Data-Driven Decision Making: DTs collect real-time data from sensors and IoT devices deployed across construction sites (Tuhaise et al., 2023). This data encompasses project progress, resource utilisation, environmental conditions, and equipment performance. Analysing this data provides valuable insights into construction process performance, enabling teams to identify improvement areas and make informed decisions for optimising project outcomes. Data-driven decision-making minimises waste by addressing inefficiencies, reallocating resources effectively, and optimising schedules and workflows to maximise value delivery. This approach aligns with lean philosophy, emphasising data-driven continuous improvement and waste elimination throughout the construction lifecycle.

Continuous Improvement:

Real-Time Monitoring and Analysis: DTs facilitate continuous, real-time monitoring of construction processes and performance through data collection from sensors, IoT devices, and project management systems (Omrany et al., 2023). This data encompasses key metrics such as project progress, resource utilisation, quality, and safety. Analysis of this data enables project teams to identify bottlenecks, areas for improvement, and opportunities for optimisation. Real-time monitoring empowers teams to proactively address issues, optimise workflows, and enhance project efficiency. By integrating DTs for continuous monitoring and analysis, LC projects can identify improvement opportunities and implement iterative changes, fostering continuous improvement throughout the project lifecycle.

Feedback Loop: DTs establish a constant feedback loop by continuously updating project information and providing timely insights into project performance (Rasheed et al., 2020). As data is continually updated and analysed, teams can learn from DT-generated insights and adjust processes accordingly. This feedback loop enables teams to adapt to changing conditions, address emerging issues, and implement improvements iteratively. By leveraging DT insights, project teams make data-driven decisions, continually enhancing project outcomes. This iterative approach aligns with lean philosophy, emphasising ongoing learning, adaptation, and refinement to optimise processes and deliver maximum value.

DT'S IN SUPPORTING LC PRINCIPLES LEVEL

The integration of DTs into the construction process aligns with several LC principles, which constitute the HOW concepts focusing on enhancing quality, value, and efficiency while minimising waste in construction projects. LC is a management-based approach that aims to deliver better value to owners by eliminating material, time, and effort wastage (Fennema, 2022). Several studies have explored the benefits of DTs at the LC principles level.

For example, Martinez et al. (2022) investigated how DTC influences LC principles, focusing on production planning. They identified challenges in construction decision-making, such as limited real-time data access and regulatory complexities. Using a matrix, they correlated operational decisions, freedom of action, and professional roles within the DTC framework, revealing its transformative potential. The study highlights DTC's role in optimising construction operations by improving decision-making aligned with LC principles. By enhancing situational awareness and decision-making, DTC demonstrates practical benefits for the construction sector.

Altan and Işık (2023) investigated the integration of DT within LC to manage escalating construction project complexity. They emphasised the collaborative nature of these approaches and analysed the synergies between them. The study identified significant obstacles and enablers in this integration by examining the Benefits, Costs, Opportunities, and Risks (BOCR) associated with DT adoption in LC. Altan and Işık underscored the crucial role of DT in reducing the cost of skilled labour and capitalising on waste reduction opportunities within the LC framework. Their research offers valuable insights into the potential enhancements DT can bring to LC principles, providing a foundational understanding for industry practitioners and guiding future research initiatives. The authors of this research focused on aligning the following LC prominent principles with DT, as a second step in bridging the research gap:

Value: DTs optimise construction processes, foster collaboration, and enhance project efficiency (McHugh et al., 2023), aligning directly with lean principles emphasising value maximisation and waste minimisation. By utilising DT, construction teams identify and eliminate non-value-added activities, thus improving project outcomes and customer satisfaction.

Continuous Improvement: DT implementation provides real-time monitoring and data analytics, enabling construction teams to gather insights for continuous improvement (McHugh et al., 2023), reflecting lean principles focused on refining processes for enhanced efficiency and quality. Analysing performance data from DT allows teams to identify optimisation areas and make iterative improvements over time, aligning with lean's principle of continuous improvement.

Waste Elimination: DT reduces waste by enhancing resource utilisation, planning, coordination, and decision-making throughout construction (Seppänen, 2022), which aligns with LC's aim of eliminating waste in all forms, including time, resources, and effort. Leveraging DT streamlines processes and enhances decision-making, minimising waste, and maximising efficiency, aligning with lean principles.

Pull Planning: DT's real-time monitoring and simulation support pull planning by providing updated information on construction activity status (Omrany et al., 2023). Pull planning, a key LC technique, aims to align production with customer demand. With DT, teams adjust plans based on actual demand and progress, enabling efficient resource allocation, and reducing unnecessary work, aligning with lean's pull planning principle.

Continuous Flow: DT implementation offers a centralised platform for collaboration and communication, enhancing coordination among project teams, suppliers, and stakeholders (Ferrigno & Barsola, 2023). Effective communication and teamwork are LC fundamentals, emphasising collaboration's importance for efficient project goal achievement. DT enhances collaboration and communication, aligning efforts and streamlining workflows, in line with LC principles.

Fast Switch-Over: DTs enable fast switch-over by providing live data and simulations, allowing teams to adapt quickly to project requirement changes or conditions (Jungmann et al., 2023). LC prioritises responding swiftly to changes and disruptions while maintaining project flow and efficiency. With DT, teams assess change impacts and adjust plans to minimise downtime and maintain momentum, reflecting lean principles of agility and flexibility in project execution, ultimately improving overall performance.

DT'S IN SUPPORT LC METHODS LEVEL

LC methods represent a strategic approach to streamline project delivery in the construction industry, emphasising efficiency, waste reduction, and continuous improvement. Grounded in Lean thinking principles, these methods prioritise value creation for clients while minimising resources and time (Do, 2022). They serve as the practical means to achieve LC thinking after adopting its principles, representing the final step in bridging the research gap. These methods include SCRUM, Takt Planning, Reliable Promises, Set Based Design, Choosing by Advantages, TVD, LPS, etc. LPS and TVD, specifically developed and implemented for the construction sector, were highlighted by Do. Moreover, emerging DTs as advanced technology can enhance LC methods by providing a technology-driven infrastructure that fosters collaboration, efficiency, and decision-making throughout the building lifecycle. Several studies have explored the potential of emerging DTs in LC methods.

For example, Mao et al. (2022) highlighted significant research findings on integrating DT technology into LC methods. Their meticulous review identified key constituents crucial for efficient constraint management. They explored DT's fusion with constraint management, pinpointing potential constituents. The research emphasised the importance of: (1) Information technologies like BIM, Global Positioning Systems (GPS), and Automated Data Collection (ADC) for precise constraint modelling and data traceability; (2) Swarm Intelligence and Genetic Algorithm for addressing spatial and resource constraints during construction scheduling; (3) Semantic Web technologies, particularly ontology, enabling advanced constraint modelling; and (4) Lean-based methods such as LPS, WFP, and AWP for structured constraint resolution processes. These insights provide a roadmap for leveraging DT technology to optimise LC project efficiency and productivity.

Ramirez et al. (2022) tackled slow decision-making in multi-family building projects, especially in countries like Peru, causing economic losses and inefficiencies. Their solution integrates LC 4.0 methodologies, blending DTs and visual management. A Lima case study illustrates how DTs enable detailed project analysis, remote stakeholder involvement, and enhanced decision-making in quality controls. The LC and Construction 4.0 synergy proves effective, with over 70 per cent acceptance, validating LC 4.0’s technical feasibility and efficiency for improved global construction project execution and decision-making.

McHugh et al. (2023) investigated the integration of LC methods and digital tools in construction, focusing on a data centre case study. Through action research, they highlighted the LPS in establishing centralised digital command rooms. Digital tools, aligned with lean methods, enhance transparency, collaboration, and innovation. The study emphasised the importance of correct data management and skilled workers. Findings showcased how digital platforms improve communication, visibility, and collaboration, fostering a continuously improving project environment.

Recent research has underscored the emerging role of DT in LC methods. DTs provide virtual representations of physical assets and processes, aiming to revolutionise the construction industry. Within the context of LC methods, DTs hold the potential to enhance efficiency, reduce waste, and improve overall project outcomes. This discussion will explore how DTs complement prominent LC methods, drawing insights from the authors’ research of this paper. Their findings emphasise the significant impact of DTs on LC methods, suggesting the potential for DTs to revolutionise traditional LC approaches, as follows:

Last Planner System (LPS): DTs enable real-time collaboration by centralising a platform for project data among stakeholders, including designers, contractors, and clients (Rasheed et al., 2020). They provide access to live project data, such as schedules, progress reports, and design iterations, fostering effective communication and decision-making. For example, a DT platform can integrate scheduling software with real-time construction site data, allowing stakeholders to monitor progress, identify bottlenecks, and adjust accordingly. Teams can use the DTs to visualise the project schedule, allocate resources effectively, and coordinate tasks among different trades. This enhances communication and coordination, ultimately improving the reliability and efficiency of the LPS.

Value Stream Mapping (VSM): Integrating DT offers visual representations of construction processes, helping teams identify non-value-added activities and optimise workflows (Tuhaise et al., 2023). For instance, DT can simulate materials, equipment’s, and manpower flow, enabling teams to identify inefficiencies, such as excessive waiting times or unnecessary movement of materials and implement strategies to streamline processes. DTs with simulation capabilities can also help teams evaluate different scenarios and determine the most efficient layout or sequence of tasks to reduce lead times, aligning with VSM goals to streamline processes and eliminate waste.

Target Value Design (TVD): DTs facilitate early stakeholder engagement by providing virtual models for assessing design alternatives and their impact on cost and value (Adade & de Vries, 2023). They enable the alignment of project goals with budget constraints and client needs. For instance, architects and engineers create DTs of building designs, utilising parametric modelling to explore various configurations or materials. Stakeholders can visualise the model to evaluate the implications of design decisions on cost, schedule, and project value.

DTs promote collaborative decision-making, enabling teams to iterate on design concepts and align project goals with budget constraints from early stages, ultimately optimising project value in line with TVD principles.

Error Proofing (Poka-Yoke): DTs aid error prevention by simulating and validating construction processes before physical construction starts (Ferrigno & Barsola, 2023). Teams, for instance, can use DTs to simulate assembly sequences, equipment operation, or installation processes to identify potential errors or safety hazards. By analysing the virtual simulation, teams can proactively address issues such as clashes or structural weaknesses, minimising errors during construction. DTs offer a platform for virtual testing and validation, allowing teams to refine plans and ensure compliance with quality and safety standards, aligning with error-proofing and continuous improvement principles in LC methods.

Overall, Figure 1 below explores the outcomes of integrating DTs with different LC levels.

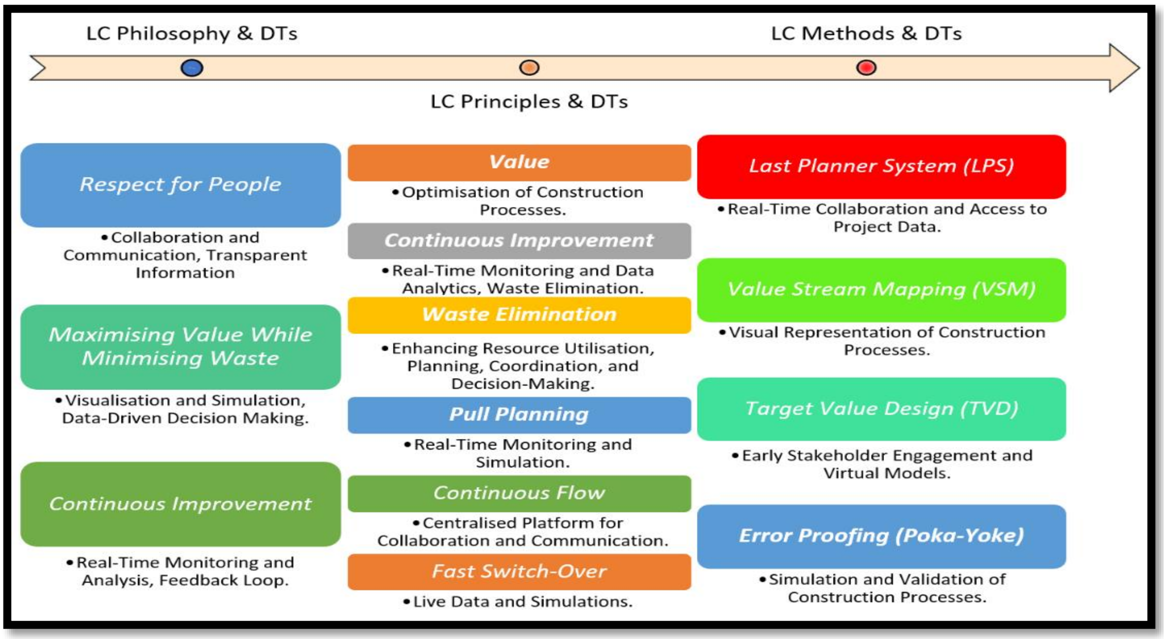

Figure 1: Benefits and Implementation of Integrating DTs into LC Levels

As a result, it is important to encompass the three identified levels of LC while integrating DTs. This is to establish a solid foundation for organisations aiming to adopt DTs within their LC frameworks, emphasising collaboration, efficiency enhancement, and value maximisation.

CONCLUSIONS

The integration of DTs into LC aims to revolutionise collaboration, efficiency, waste reduction, and decision-making in construction projects for optimal outcomes. However, DTs are still in their infancy stage and have not been sufficiently addressed across different levels of LC. Therefore, this research aims to fill the identified gap by revealing DTs' potential in supporting various levels of LC thinking, including philosophy, principles, and methods. The ultimate goal is to improve project outcomes for efficient and sustainable construction practices by establishing a solid implementation foundation for lean organisations.

At the philosophy level, DTs foster collaboration and communication among project stakeholders, promoting transparency and a culture of respect while maximising value and minimising waste through real-time data and virtual representation, aligning with the core thinking of LC through visualisation, simulation, and data-driven decision-making. As well as continues improvement through real time monitoring, analysis, and feedback loop. This philosophy extends to the principles level, where DTs closely adhere to LC principles such as value maximisation, continuous improvement, waste elimination, pull planning, continuous flow, and fast switch-over, contributing to efficient project delivery by optimising processes, enhancing monitoring capabilities, collaboration and communication, simulation, and enabling data-driven decision-making. At the methods level, DTs complement LC methods such as the LPS, VSM, TVD, and Poka-Yoke, facilitating real-time collaboration, workflow visualisation, stakeholder engagement, and error prevention, ultimately leading to enhanced project efficiency and value delivery.

Nevertheless, the integration of DTs with LC faces various challenges, including technological complexity, data privacy concerns, integration barriers, and limited industry adoption. Thus, future research endeavors should concentrate on simplifying DT solutions for the construction sector, addressing privacy and security issues, overcoming integration barriers, and exploring factors influencing adoption to unlock DT's full potential in LC.

In conclusion, integrating DTs into LC embodies a synergistic approach toward achieving lean objectives in construction projects. By harnessing DTs' capabilities to support collaboration, transparency, and data-driven decision-making, construction teams can streamline processes, reduce waste, and deliver greater value to stakeholders. This strategic integration lays the groundwork for more efficient and sustainable construction practices, fostering ongoing innovation and improvement in the industry. This conclusion is drawn from a comparative analysis method aimed at bridging the gap by revealing the linkage between DT and various LC levels.

DIGITAL LAST PLANNER SYSTEM IMPLEMENTATION: CRITICAL SUCCESSFUL FACTORS

Shang Gao[1], Toong-Khuan Chan[2] and Phil Hendy[3]

ABSTRACT

Last Planner System (LPS) is the most popular and most widely adopted lean construction (LC) practice in the LC community. The growing maturity of LPS software encourages the implementation of digital LPS in-lieu of traditional analogue methods. With the boom in infrastructure investment in Victoria, Australia, this study aims to explore the critical factors for implementing digital LPS on Australian infrastructure projects. The study undertaken on one of five program alliances established to carry out rail and road level crossing removal projects. Adopting a case study approach, qualitative data was collected from 19 participants from two projects (Projects A and B). The findings indicate that the critical factors that underscore the successful adoption of digital LPS falls under a combination of technology, people, and organisational aspects. This includes using a suitable digital LPS platform, having LPS champions, getting employees' buy-in, putting organisational support in place, and many others. This study also confirmed the roles that people and organisations play in driving successful adoption of digital LPS. Given this, the implications for roles such as LPS champions at project level and supporting roles within organisations are discussed. Although these are unique contextual factors, it is anticipated that this success story of adopting digital LPS will prove transferable to the Australian construction sector when the critical factors are in place.

KEYWORDS

Lean Construction, Digital Last Planer System, Australia, Infrastructure projects, Critical success factors

INTRODUCTION

It is commonly acknowledged that manufacturing and construction differ in many ways, but the lean movement from manufacturing has become an aspiration for construction. The term Lean Construction (LC) literally means the application of lean principles and practices in construction, aimed at minimizing waste and maximizing value. This approach is gaining popularity globally. Despite the fact that the last planner system (LPS) is the most popular and most widely adopted lean construction (LC) practice in the LC community (Daniel et al., 2015), there is little evidence to indicate LPS has been adopted in Australia's construction industry. A quick search of the IGLC database provides little information. Early studies include Hackett et al. (2019), which developed LPS guidance principles based on a longitudinal research spanning over 18 months investigating LPS adoption on seven sequential refurbishments of a liquified natural gas plant in North West Australia. Fauzan and

Sunindijo (2021) noted the implementation of a few basic lean tools, including LPS, is adequate but this study was based on a very small sample in Sydney, Australia. The question remains of whether Australia really is lagging in terms of deploying LPS practice. We set this study in Victoria and in the context of level crossing removal projects. This is because Victoria is currently in a transport construction boom, with an $90 billion investment delivering over 165 major road and rail projects across the state. For example, the Victorian government is committed in removing 110 dangerous and congested level crossings across Melbourne by 2030, the largest project of its kind in Victoria's history. With the boom in infrastructure investment in Victoria, Australia, this study aims to explore the critical factors for implementing digital LPS in local infrastructure projects. This adds to the body of knowledge of LPS implementation, not only in terms of its adoption in a relatively new geographical location, but also sheds light on adoption issues with the digital platforms that enables LPS.

LITERATURE REVIEW

DIGITAL LPS

The Last Planner System is a construction-based lean practice that might not be well-known outside of the construction industry. On account of its unique feature of bringing frontline crews in to discuss plans in a collaborative fashion, LPS is also known as collaborative planning in the UK (Daniel et al., 2015). Much has been written about LPS—from what it is and its origins (Ballard, 2000), to its principles, fundamentals, and how to use it effectively (Ballard & Tommelein, 2021). Additionally, the positive impact of LPS on performance (Liu et al., 2010; Tezel et al., 2018), and the barriers to implementing LPS (Perez & Ghosh, 2018) have been well documented. There are many case studies of LPS implementation across the globe, from developed countries like the UK (Daniel et al., 2016) to developing countries like India (Bhatla et al., 2016), allowing readers and even practitioners to find a relevant one to suit their local context. A point that may be worth reiterating here is that the term Last Planner refers to whoever makes the work assignment, often someone close to the site and in the lower levels the hierarchy. It is thus a bottom-up process instead of a way of pushing plans to frontline workers. As a system, it is structured in a tiered way comprising master planning, phase planning, look-ahead planning, and finally weekly production planning.

One area that is relatively less well explored is discussion of digital applications for implementing LPS. There is no doubt that digital LPS is becoming more popular thanks to a few driving forces. First, the increasing maturity of the technology with cloud computing (which many digital LPS platforms operate on). The logic is straightforwardly that of moving the traditional physical white board plus sticky notes to a digital environment. Second, the spread of COVID globally, together with stringent rules from government, is 'forcing' contractors to adopt more flexible systems that support remote working. In this context, digital LPS platforms serve that purpose. Gao et al. (2023) reviewed a few digital LPS applications from multiple case studies, and concluded a number of key requirements for digital LPS including: a reality capture strategy (McHugh et al., 2021), engaging stakeholders (McHugh et al., 2021), IT infrastructure associated with visual management (Hua & Schwartz, 2021), and a low user threshold (Thorstensen et al., 2013). Gao et al. (2023) discovered key barriers to digital LPS implementation include: little support from the supply chain partners, increasing planning efforts required, high staff turnover, and many others.

CRITICAL FACTORS

A critical success factor (CSF) for LPS, is a strategic action or activity necessary for an organisation seeking to promote increased adherence to the use of LPS. The literature notes a long list of CSFs for LPS implementation, falling under four groups:

- Behavioural factors: Research suggests that LPS users are required to respond to a number of enabling behaviours that are related to or promoted by LPS in order to secure successful implementation (Fauchier & Alves, 2013).
- Organisational factors: Organization plays a critical role in LPS implementation, where numbers of enabling factors are identified supporting the use of LPS. Paez et al. (2005) emphasized that organisations should provide recognition to promote the required behaviour change, as mentioned in previous section, together with the enabling factors allow focus on organisation strategy.
- Procurement factors: Research found that procurement methods have an impact on the application of the LPS, but that no single procurement method is a certain way leading to full application of the LPS process on a project. The use of collaborative procurement methods facilitates greater integration among project stakeholders through increased involvement of site teams (Daniel et al., 2018) in order to achieve better performance (Samudio & Alves, 2012).
- Contractual factors: Together with the procurement method, the selection of contract is also critical if the LPS to be well implemented (Daniel et al., 2016).

METHODS

RESEARCH DESIGN

This study is set in the context of Melbourne, Victoria, where the city is investing in and upgrading the road and rail network to accommodate population growth. One of the Victorian government's key transport infrastructure projects is the Level Crossing Removal Project (LXRP) (Victorian Auditor-General, 2017). The delivery model for achieving these is to use a programme alliance-based model. The Program Alliance model allows LXRP to break mega-projects into smaller more manageable packages, enabling more time and effort to be applied in front-end engineering, planning and development. The government established five on-going programme alliances to deliver the work packages within the programme. The first and second authors have worked closely with one of the programe alliances - Western Programme Alliance (WPA) when the Continuous Improvement and Innovation Manager introduced the digital Last Planner System to Project A as a pilot, and later rolled it out to other projects, including Project B. By the time the fieldwork commenced, WPA, was working on five level crossing removal projects. The level crossing removal projects will make road and rail travel easier, faster and more reliable for Melbourne. Instead of using the traditional white board plus stickie note styled LPS, the case projects used digital LPS for reasons like large complex projects, overwhelming information that will make the stickie notes on white board hard to update. This study aims to explore the critical factors of LPS implementation.

There is no shortage of explorations of the critical success factors of Lean implementations or the last planner system, in particular. However, there is one fallacy worth commenting on here: in some research, participants are asked about their perspectives on critical successful factors of LPS adoption, without confirming whether the lean practices or LPS were actually being implemented. To address this particular shortcoming, the present study is based on a case study (Projects A and B) that has witnessed successful digital LPS adoption. We then used the qualitative approach to understand the critical factors associated with the digital LPS implementation. This resulted in more reliable perspectives from research participants—the end-user of the digital LPS platform.

We carried out a comprehensive literature review capturing a long list of critical factors that which can be used for the survey, but we did not do so because we were reminded that potential respondents may not appreciate lengthy survey items of critical success factors. Instead, we alternated our fieldwork strategy by asking three simple questions:

- Do you think implementing LPS is a success?
- What are the critical success factors that drive successful implementation of digital LPS?
- What support is available and needed to improve future implementation of digital LPS?

INTERVIEWS

The research team interviewed 19 end users of digital LPS platform. They were from two WPA projects: Project A and Project B (see Table 1). Each interview lasted approximately 60 minutes. Five interviews were conducted in person, the remainder online through Microsoft Teams. The most experienced interviewee had 21 years of experience, the least, 1 year, and an average was about 10 years. It is interesting to note that, according to Table 1, the average LPS experience is low, except for Interviewee A1, who had previously worked in America, where LPS adoption is more mature. Most interviewees were engineers (11 out of 19), including project engineers, site engineers, and junior engineers. Four supervisors, two superintendents and two construction managers took part in the interviews. From a hierarchical point of view, the superintendent manages supervisors, and project engineers report to the construction manager.

Table 1: Interviewee demographics

Participants	Position	Experience in construction (No. of years)	Experience in project Alliance (Nr. of years)	LPS software (Nr. of years)
Interviewee A1	Superintendent	21	4	8
Interviewee A2	Project Engineer	10	1	1

RESULTS

SUCCESSFUL INITIATIVE

When asked if they thought the LPS implementation was a success, in general, all interviewees at Project A noted a positive YES. The majority at Project B also agreed that it is a successful initiative, except for some slight reservations from a few interviewees, which are listed below:

- Interviewee B4 (site engineer) indicated a "maybe", noting that digital LPS should not be used as a booking tool.
- Interviewee B7 (junior engineer) indicated "yes to a degree", noting that digital LPS performs its function but that there are many areas where it could improve.
- Interviewee B8 (supervisor) commented that it was "not a failure", noting that "*it has a good start, and gets better as more people use it, embrace it and learn the functionality of it*".

CRITICAL SUCCESS FACTORS (CSF)

Given the positive perception of the introduction of digital LPS, the follow-up question was: *What enables the success of such an initiative?* This hoped to identify the CSF that supported the digital LPS implementation thus far. Table 2 lists the factors, in the form of keywords, that were captured from the interviewees' responses. There is no weighing to it, but the frequency recorded at the bottom row of Table 2 shows the more significant ones than others. The following paragraphs describe the points mentioned most by interviewees: they are digital LPS itself (10), champions (5), buy-in (5), and support (5).

Table 2: CSF of digital LPS implementation

No.	Commitment	Champion	Trust	Organizational Support	Buy-in	Less interface	Team efforts	Digital LPS itself
Interviewee A1	X		X	X			X	X
Interviewee A2		X						
Interviewee A3	X

Total	**4**	**5**	**2**	**5**	**5**	**1**	**4**	**10**

Note: Interviewee B10 did not comment on CSF.

The digital LPS platform

The digital LPS platform was the most frequently mentioned CSF, particularly in interviewees from Project B, where the conversation on CSF was more focused on the features of the digital LPS platform than on an end-user perspective. We have masked the name of the digital LPS platform. It was highlighted that: *"All the good advantages of digital LPS contribute to the success of implementation" (Interviewee B8).* A closer examination of the comments on the technology—the features that end-users perceived as success factors—points to the following factors:

- Ease of use – the interviewees had good experience particularly with the offline environment functions and interface. One commented "*the offline environments was so convenient that we could start practising it and getting it right*" (Interviewee B1).

Another (Interviewee A6) noted "*Easy interface to use for most team members. No need for a huge amount of training*."

- Shows benefits quickly: one interviewee acknowledged that "*Everyone seem to be able to understand the benefits of the digital LPS platform…*" Interviewee B6 emphasized that especially "*Activities from different teams are all visible in the digital platform.*"
- Functioning: interviewees from Project B acknowledged that the digital LPS "*does its function, but there are lots of areas to improve on*" (Interviewee B7) whereas others noted that it was acceptable "*as long as it is doing its job*" (Interviewee B3).
- Facilitate behavioural change: "[allowing] *more communication with engineers*" (Interviewee B9) and '*making people more accountable for their scope and resources booked in…. it could be used for interfaces*" (Interviewee B6) were also welcomed.

Champions

Having a champion (or champions) was the top CSF suggestion of Project A interviewees. Project A's superintendent[4] (anonymised as 'XX' in Table 3) was applauded as a passionate champion and strong believer in LPS. More than half of the interviewees mentioned that superintendent's name when answering this question (see Table 3).

Table 3: comments noting importance of having a champion

Interviewees	Comments
Interviewee A2	"Having a champion to drive, follow the process"
Interviewee A4	"XX drives it well"
Interviewee A5	"XX firm on implementation, being supportive" and "XX also trains late entrants"
Interviewee A7	"XX's passion for it really drives the whole system. Jason managed all the resistance from engineers"

Organisational support

Apart from a champion who drives implementation on the ground, support from the organisation is also essential. The Continuous Improvement and Innovation Manager oversees the roll-out of digital LPS platform across all WPA projects, and his support represents the organisational support. His support in the beginning, helping the team set up and use the digital platform, is of particular importance, and his continuous support along the way is crucial. One interviewee (Interviewee B11) recalled "*I was on the phone with him more or less daily when we first started digital LPS at project B*". However, one comment noting "*Leave the Continuous Improvement and Innovation Manager to generate reports*" seems to suggest there was an over-reliance on the Continuous Improvement and Innovation Manager supporting LPS on projects. It is reasonable to assume that the site would quickly slip back to how things were previously planned if it were not for these key people's support.

Buy-ins

The next CSF is the buy-in from the ground. This was echoed by many interviewees, including: *"buy-in from our supervisory team, and engineers as well."* (Interviewee A6) *and "People are committed."* (Interviewee A3). Several interviewees noted that at the start it was not easy because of resistance. As Interviewee A5 echoed, *"resistant from the team at the start but after seeing the results, all settled"*. However, one of the ways to overcome resistance and get the

[4] Project A's superintendent's name is masked here for anonymous purpose.

team's buy-in is to demonstrate the benefits of using digital LPS to them and to help the end users understand the benefits.

Team efforts

Team efforts were also acknowledged, thanks to the digital LPS platform, which allows everyone to be involved and plan the works on the digital platform. As one interviewee noted, "*this is the platform that allows everyone to contribute; everyone in the team should put tickets in"*. In the dashboard, the team's participation and activities are visible. In Project B, there are eight team members who had developed more than 100 tickets. There are other indicators, such as "ticket update" and "plan views", which are useful indicators demonstrating the team's engagement and contribution.

SUPPORTS ALREADY IN PLACE AND FOR FUTURE

The research team also investigated what support is already available and what support is required for future roll-out. Two broad forms of support are made available: training and catch-ups.

Training

Perceptions vary across different levels in projects (see Table 4).

Table 4: perceptions/experience about training

Superintendent/supervisors	Engineers
• Coached by our Continuous Improvement and Innovation Manager and online support from the digital LPS provider (Interviewee A1) • Introduction to what LPS is and then focus on software training (Interviewee A7) • Some people showed me how to add tickets (Interviewee B8) • I haven't had any training on digital LPS software. Only engineers showed me what to do in it. I have seen some emails about it over the last year and a half. But I am busy to get to one of the sessions (Interviewee B9) • I didn't get any training from anyone. I am able to do all I need to do on it. So, if I needed to do anything further, I'd probably look for the training. I just need to know how to add a ticket and show that it has been completed as planned (Interviewee B10) • Our Continuous Improvement and Innovation Manager set up a few training sessions, initially a couple of hours, every two days, and breakaway to weekly. And the same training session for supervisors and engineers. When the team become self-sufficient the team will train the rest (Interviewee B11)	• Initial support from Continuous Improvement and Innovation Manager, together with our superintendent, who talks about adding tickets and does constraints (Interviewee A5) • Late entrant – will do some basic training (Interviewee A8) • Not aware of training; not aware of LPS guide – (Interviewee B2) • No training for me. But can apply to get training from the Continuous Improvement and Innovation Manager. Just read a guide and went ahead, self-explanatory (Interviewee B2) • Not aware of any. Not formally trained; only briefed by manager (Interviewee B3) • Some training and guidelines; teach new engineers how to use the digital LPS software (Interviewee B4) • Some formal training previously (Interviewee B7)

Catch-ups

Regular catch-up were mentioned by several interviewees from both projects, including "our Continuous Improvement and Innovation Manager organises regular session to check the use of digital LPS and potential opportunities for improvement" (Interviewee A6) and "Regular catch-ups and some formal training previously" (Interviewee B7).

WHAT SUPPORT MAY BE REQUIRED

When asked what other support is required in the future, most interviewees indicated that something could be done to improve the implementation of LPS across WPA projects. Interestingly, '*more training*' (mentioned 10 times) and '*site visits and best practices*' (mentioned 7 times) were mentioned most frequently by interviewees. Table 5 provides a summary.

Table 5: More support needed

No.	More trainings	Site visits and best practices	Support and tips from Continuous Improvement and Innovation Manager and	Buy-in from everyone	Workshop and session t	Make it business as usual	Discussion with all key construction leaders
Interviewee A1	X	X	X			X	X
Interviewee A2	X	X					
Interviewee A3	X						
Interviewee A4	X						
Interviewee A5				X			
Interviewee A6		X			X		
Interviewee A7		X					
Interviewee A8							
Interviewee B1							
Interviewee B2					X		
Interviewee B3	X						
Interviewee B4		X					
Interviewee B5						X	
Interviewee B6		X					
Interviewee B7	X				X		
Interviewee B8	X	X					
Interviewee B9	X						
Interviewee B10	X						
Interviewee B11	X		X				
Total	**10**	**7**	**2**	**1**	**3**	**2**	**1**

More training

From superintendents to engineers, there is a consensus that more training is desired. The training is expected to be formal, sufficient, basic, and targeted. Interviewee A2 elaborated "*a more formal approach is needed to train new staff, and internal and external users, as well as subcontractors*." Interviewee A4 also highlighted training can minimise people's resistance to change. Those motivated end users of digital LPS platform such as Interviewees B3 and B8 expected to learn all the features of digital LPS, including the high-level advanced functionality.

- "need formal training and learn all digital LPS features" (Interviewee B3).
- "some basic training of how to use it to everyone will do. People who want to learn more can learn more high-level functions." (Interviewee B8).

Site visits and best practices

Site visits and sharing best practices were also strongly agreed upon. A few typical comments include: *"See actions from another project, dial into their weekly or look-ahead planning sessions in another ongoing project"* (Interviewee A6), and hear from people involved in the project the whole way. See what other people thinks that contribute to the success will be interesting" (Interviewee A7).

DISCUSSION AND CONCLUSION

This study uncovers the critical success factors arising from the successful roll-out of digital LPS in infrastructure projects in Victoria, Australia. This study points out that the critical factors that underscore the successful adoption of digital LPS can be categorised under a combination of technology, people, and organisational aspects. This includes using a suitable digital LPS platform, having LPS champions, getting employees' buy-in, putting organisational support in place, and many other aspects. The most cited critical factor in this study is the digital platform of LPS itself, which, understandably, was not a critical factor in traditional LPS practice as described by previous literature (Abusalem, 2020). This study further uncovers a number of features of digital LPS platform such as 'ease of use', 'show benefits quickly', 'functioning' etc. for practitioners to weigh in on when they are thinking about LPS adoption. This echoes to several studies (Hua & Schwartz, 2021; Pikas et al., 2022) examined digital LPS that acknowledging its power functions. Each feature aligns with the common factors normally discussed in the technology adoption model (TAM) (Davis, 1989), which explains the influencing factors for technology adoption. The other critical factors, especially the people and organisational related ones, aligns with previous research (O. AlSehaimi et al., 2014; Watfa & Sawalha, 2021). Not surprisingly, this study confirmed the roles that people and organisations play in driving successful adoption of digital LPS. Given this, the implications for roles such as LPS champions at project level, and supporting roles within organisations, can be stated as follows:

Firstly, an LPS champion should be nominated at the project level. A few key qualities of LPS champions are worth considering here; these are based on the findings of the study. Champions should (1) be able to drive the implementation and be firm on the implementation; (2) be able to manage resistance; (3) lead by example; (4) be able to pass knowledge onto team members, including late entrants; and (5) be approachable for catchups. Secondly, in addition to having an LPS champion on the ground, organisational support is also valuable: this includes helping the project team set up the implementation process, and providing training, coaching, and mentoring. Organisational support is evident in the two projects where the role of Continuous Improvement and Innovation Manager is highly appreciated. However, the study revealed that although training was provided, the level of penetration differed. Whereas the managerial level may well receive the necessary training, the junior/site engineers, who are the ones adding the tickets to the digital whiteboard, noted they had not received adequate training. Instead, Project B adopted a people-train-people strategy assuming that firstly, digital LPS is self-explanatory and easy to use, and that secondly, the engineers may only need to know how to add the tickets as their primary function, perhaps not needing to understand the advanced features. We therefore recommend that there should be prerequisite or induction-styled training in the use of digital LPS. This aligns with many studies (Hua & Schwartz, 2021; Pikas et al., 2022) which acknowledged the importance of training and support the team members as a lesson learnt in digital LPS adoption. The people-train-people approach seems to prepare new entrants to be onboarded quickly but knowing how to create tickets (e-stickies) in the digital system is far from being competent at working with digital LPS and getting the best out of it.

Having examined a successful adoption of digital LPS with critical factors highlighted leads us to infer that LPS has made its debut in Australia's construction sector but is still far from its counterparts in the USA or the UK. This study has laid the foundation for future work on LPS and Lean construction research in the Australian context. However, the study does have a few unique contextual features, or even limitations.

Firstly, WPA embarked on the LPS journey with a particular digital LPS solution provider. Each digital LPS platform has unique features. Some are highly sophisticated and can be integrated with other technology such as BIM. In this study, some of the features of the particular digital LPS platform were highly commended by the end-users. It will be interesting to compare the perspective of various digital LPS tools in order determined whether technology is indeed a critical factor in driving digital LPS.

Secondly, the local LPS champions and the Continuous Improvement and Innovation Manager are also unique in this context, as they happen to be strong believers in LPS and have great passion in driving it. It is hard to imagine what the results of this study would be like if these two roles were absent. Conversely, if there were more active champions and supports across the team, one might assume and even greater adherence and performance may have been achieved.

Lastly, the projects were undertaken in the Alliance arrangement, where innovation and continuous improvement are heavily encouraged. Continuous Improvement and Innovation Managers are constantly seeking and testing innovative practices in order to learn and continuously improve the existing processes. Without this culture, it would be challenging to see digital LPS being selected as a new way of managing project production with medium-term and short-term planning.

Although these are unique contextual factors, we remain hopeful that this success story of adopting digital LPS will prove transferable to the Australian construction sector with the benefit of knowing these critical factors to put in place.

QUANTITY TAKE-OFF IN ROUGH CONSTRUCTION OF HIGH-RISE BUILDINGS BASED ON CAD AND BIM METHODOLOGIES: A CASE STUDY

Walter Meléndez[1], Rodrigo Saavedra[2] and Gonzalo Garcés[3]

ABSTRACT

Building Information Modeling (BIM) prepares the quantity take-off (QTO) of the construction elements, helping in the management of the design and construction process and preparing the 3D visualization of the construction phases. BIM increases efficiency and gives users more control over construction-related tasks. This study identifies the New Cycle building as a Case Study, in which inconsistencies were detected in the QTO, compared to the real quantities of budgeted materials, so the interested parties decided to implement BIM in the use of QTO as a mechanism of control. The central question addressed was: If BIM had been implemented at the tender stage, could it have provided benefits to the project? To do this, various parameters were evaluated to conduct a comparative analysis between the results obtained through the use of the CAD and BIM methodology in the same project. Using the Analytical Hierarchy Process (AHP) method, it was possible to evaluate and compare the two alternatives, CAD and BIM, in order to determine which of them would have been more effective in satisfying the objectives set in the project. The results obtained offer a valuable and informed vision for making informed decisions for future construction projects, contributing to a change in perception about the adoption of new work methodologies.

KEYWORDS

Building Information Modeling; quantity take-off; work flow; collaboration.

INTRODUCTION

Lean Construction is the delivery process that uses Lean theories, principles, techniques and tools to maximize stakeholder value and minimize waste by emphasizing team collaboration on a project. The goal of Lean Construction is to drive productivity, profits and innovation in the industry, enabling the entire construction project lifecycle to benefit from the application of many Lean principles.

BIM (Building Information Modeling) is a well-known tool to improve the design and construction of buildings. It is based on the digitalization of all project information, which allows better control and monitoring of the project. BIM not only changes the technology used, but also the way of working. This is a cultural change that involves all the agents participating in the project, from architects and engineers to builders and owners. Although these approaches are different initiatives, there are synergies between Lean and BIM that are most effective when implemented together and not separately (Garcés & Peña, 2023; Michalski et al., 2022; Sacks

[1] Department of Civil Engineering, Universidad Andrés Bello, Chile, w.melndezbernardo@uandresbello.edu
[2] Department of Civil Engineering, Universidad Andrés Bello, Chile, r.saavedraortega@uandresbello.edu
[3] Faculty of Engineering, Universidad del Bío-Bío, Chile, gegarces@ubiobio.cl

et al., 2017). The precision of BIM and the Lean approach to eliminating errors minimize the costs associated with rework and modifications. The combination of Lean Construction and BIM in the early stages of the project allows you to optimize the design and construction processes, eliminate waste and generate a more efficient, profitable and sustainable project.

LITERATURE REVIEW

While BIM addresses the reliability of information in construction projects, Lean addresses the reliability of processes to reduce or eliminate waste (Fosse et al., 2017; Nguyen & Akhavian, 2019; Garcés & Peña, 2022). Regarding the use of building information models (BIM) in design and construction projects, which cover work processes and team organization, it is worth highlighting the pioneering work of the Center for Integrated Facilities Engineering (CIFE) of the University. from Stanford. This center developed a new concept called Virtual Design and Construction (VDC), which is based on the integration of new BIM technologies with Lean philosophy and practices (Kunz & Fischer, 2020). VDC tools can be very effective in achieving Lean Production Delivery System (LPDS) objectives (Aslam et al., 2021).

In this sense, BIM (Building Information Modeling), VDC (Virtual Design and Construction) and Lean Construction are three methodologies that overlap and complement each other to significantly improve the efficiency and success of the construction project (Fosse et al., 2017; Nguyen & Akhavian, 2019; Aslam et al., 2021). For example, 1) BIM provides the database and platform for the integration of VDC and Lean; 2) VDC uses the BIM model for simulation, planning and project management, and 3) Lean guides the implementation of VDC and BIM to eliminate waste and optimize the process. This overlap improves communication and collaboration between different disciplines, reduces errors and costs during design and construction, optimizes project planning and execution, improves project quality, safety and sustainability, and reduces delivery time and project costs.

That said, in the construction industry, effective cost and time management is crucial to achieving project success, which is why various investigations have addressed it through the BIM methodology and Lean Construction techniques and tools. Where, timely completion, cost control, and compliance with quality and performance requirements define achievement (Parsamehr et al., 2023). Improving work and production processes is essential for this success. Construction project stakeholders, including owners, architects and general contractors, are increasingly aware of ways to reduce time and costs, including cost estimating using BIM, as the architecture, engineering and Construction (AEC) adopts building information modeling (BIM) in its construction (Gholizadeh et al., 2018; Jin et al., 2017). Compared to conventional estimating methods, research studies have shown that using BIM for estimating reduces work time and errors and improves estimator performance (Kim et al., 2019; Peterson et al., 2011).

However, the use of BIM estimation comes with several challenges, including: (1) a lack of knowledge and understanding of BIM on the part of the estimator; (2) implementing data sharing between various applications such as estimating software and BIM creation tools; and (3) limitations in maintaining relationships between cost information and construction elements modeled in three-dimensional (3D) objects (Aibinu & Venkatesh, 2014; Kim et al., 2019).

BIM is characterized by being a methodology that optimizes performance and productivity in construction projects, achieving greater efficiency and collaboration in the processes. This methodology allows architects, engineers and builders to develop projects effectively throughout their life cycle, which, in turn due. An inconsistency in the quantity extracted from building components can make the quantities calculated difficult. This is because the quantities used to prepare a budget during the design phase serve as a basis for calculating the tender price, and evaluating the suitability of construction cost when deciding on a general contract, therefore, accurate measurements must be made to reduce the possibility of the total construction cost increasing or decreasing during construction (Ashworth & Perera, 2015; Hyari, 2016).

Due to the lack of investigations of real cases of quantity take-off (QTO) of high-rise buildings, this research compares the results of QTO based on traditional methodology, such as CAD, and on BIM methodology through a case study, which is a 16-story building plus two basements. The QTO of concrete, reinforcing steel bars, and formwork, prepared through CAD for the budget of the New Cycle project, is referred to as “QTO CAD”; and the QTO using the BIM methodology for this research is called “QTO BIM”.

Combining various studies and analyses, this research assessed whether Building Information Modeling (BIM) would present advantages or benefits to the Computer-Aided Design (CAD) in a specific case study. The aim was to identify the best approach for achieving accurate quantity take-off (QTO) results and minimizing material waste. To make this complex decision, the Analytical Hierarchy Process (AHP), a structured technique for evaluating multiple factors, was employed.

The AHP Method is a useful tool for making complex decisions with multiple factors to consider. It is based on decomposing the problem into a hierarchy of elements and then comparing them pairwise (one against one) to determine their relative importance (Darko et al., 2019). The AHP Method has the following steps: 1) Define the problem: What decision do you want to make?; 2) Decompose the problem: Identify the different factors that influence the decision; 3) Organize the factors in a hierarchy: Create a structure that groups the factors by levels of importance; 4) Compare the factors: Compare each pair of factors at each level of the hierarchy to determine which is more important; 5) Calculate priorities: Assign numerical values to comparisons to determine the relative importance of each factor; 6) Synthesize the results: Combine the priorities of the different factors to obtain a final decision. AHP is a powerful tool for making complex decisions with multiple factors to consider. It is simple to understand and use, and can help you make more informed and objective decisions.

CASE STUDY

The present research focuses on the comparative analysis of the uses of CAD and BIM in QTO of the core work of the New Cycle building, located in the city of Concepción, Chile. During the developing of this research, New Cycle has been in the construction and completion stages. This case study consists of a residential building for apartments. In addition, its design includes 16 floors, 2 basements and various spaces for uses and services (see Figure 1).

BIM Model of the New Cycle Building | Render of the New Cycle Building | Simulation of the construction process

Figure 1: BIM model and render of the case study building.

The Real Estate Company that manages New Cycle made a 3D model of the building, in the early stages of the project, which was more linked to the architecture, so it was used only as a rendering of the building. Given this, the project's Construction Company decided to remake the model, integrating all the specialties, where the concrete modeling was considered.

For the structural part, a new 3D model was developed, given that its design characteristics required different skills that the construction company´s modeling area did not have. They were developed in collaboration with modeling contractor companies specializing in the design and installation of steel bars. Finally thanks a "plugin" (PROISAC-encofrados) allowed obtaining the m^2 of formwork based on the concrete model BIM. The objectives set with this structural model were: 1) optimize the purchasing process, 2) identify incompatibilities of the reinforcing steel bars project, and 3) increase efficiency in execution, since, if the bars are designed to be easily sized and installed, the purchasing process would be faster, thus avoiding delays in the execution of the heavy work process due to the high latency in the response of the estimator, and on the other hand, the amount of steel on the ground would be reduced, avoiding the performance of repetitive work, thus increasing the work efficiency of workers.

With this, at New Cycle BIM was implemented with 2 models: one to manage the control and execution of the installation of steel bars and another model that integrates and coordinates the specialties, in order to keep track of both modifications and real-time progress of the project.

PROBLEMATIC

Due to differences in the budgeted QTO of materials versus the actual ones used, the need arises to create a quantity control mechanism, including the modifications that may bring about changes in requirements and design. Given this, the use of CAD methodologies in the case study for the QTO is evaluated to contrast it with the QTO obtained through BIM models (QTO CAD vs QTO BIM), in order to study the impact on the project if BIM had been implemented at the beginning, over the traditional applied work methodology, this is CAD. To study the impact on the difference in quantities of materials, the bulk construction stage is analyzed exclusively, The integration of BIM in the construction industry presents a comprehensive solution to enhance material usage efficiency, notably curbing waste across projects. By enabling precise and detailed planning, BIM facilitates surplus minimization and efficient inventory management, thereby fostering a cleaner and more sustainable work environment.This approach closely aligns with Waste Management principles in construction, where waste reduction and value maximization stand as pivotal objectives in enhancing sectoral efficiency and sustainability, resonating with Lean Construction principles, which prioritize waste elimination and process optimization towards achieving more efficient and profitable outcomes.

The main items within the gross construction work are concrete (m^3), reinforcing steel bars (tons) and formwork (m^2) (Choi et al., 2015; Garcés & Molina, 2023; Liu et al., 2022; Olsen & Taylor, 2017; Whang & Park, 2016), and correspond to the instances that require more time and costs, therefore, the QTOs carried out and studied correspond to these three items.

SOFTWARE USED

The QTOs were made with CAD files (Autodesk AutoCAD) with which the building project was budgeted. The information collected from plans was transferred to Excel spreadsheets for data processing. The entire model was made in Revit, only the ironing machine model was made by TSC Company in Tekla Structures and then transferred to the Trimble viewer through an IFC format. Finally, for the application of the AHP method as a decision maker to determine the best alternative for QTO, the Total Decision software was used, a program specialized in the matrix development of this method.

Certain ranges of percentage differences based on current industry references were established to define how acceptable the results obtained are when comparing the QTO in CAD and BIM of the New Cycle building with the QTO carried out in this research, these are: (1) <2% acceptable; (2); 2-5% moderately acceptable; and (3) >5% not acceptable.

ANALYSIS OF RESULTS

To carry out the QTO comparison, three parameters were considered: (1) the QTO of Concrete, reinforcing steel bars and formwork, made using CAD with which the New Cycle project budget was developed (hereinafter "CAD NC"), delivered at the bidding stage of the construction project; (2) and the QTO of Concrete, steel bars and formwork, using New Cycle BIM models (hereinafter "BIM Research"). Thus, with these QTO parameters, through the comparison "CAD NC vs BIM Research" you can know the differences between what was budgeted and what was required in the execution of the project. It should be noted that these are geometric calculations without considering the waste of execution. See Figure 2.

QTO comparisons are presented using results by level, from the foundation slab, basement -2 and -1 and floors 1 to 16.

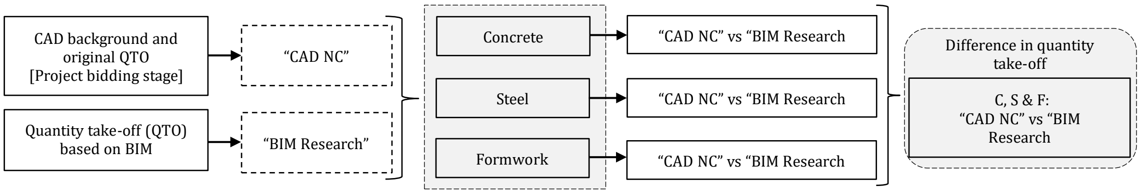

Figure 2: Quantity take-off of the New Cycle (NC) building.

CONCRETE: "CAD NC" VS "BIM RESEARCH"

Table 1 shows that "CAD NC" calculated 5856.00 m³ of concrete, while "BIM Research" recorded 5719.87 m³. The totals differ by 136.13 m³, representing a 2.32% percentage difference. The high level of detail in the "BIM Research" models provides a more precise and realistic estimate of the volume of concrete required for the New Cycle project. In the foundation slab and basement -2 and -1 the differences are negative, indicating that "CAD NC" quantities of concrete were underestimated. Under the acceptability criteria, the foundation slab presents an unacceptable difference, while both basement have moderately acceptable differences between CAD and BIM applications. On the other hand, for Floors 1 to 16, the differences are considered unacceptable, which implies that "CAD NC" calculated a volume of concrete above the real needs of the project.

"CAD NC" carried out the calculation by elevations, considering the total lengths of each level. In addition, "BIM Research" takes into account empty spaces where concrete is not required, such as shafts, which contributes to a calculation adjusted to reality.

It is important to mention that the difference that occurs on the 16th Floor is due to a redesign on said floor, reducing its area, and therefore, its amount of concrete. This modification was not considered by "CAD NC".

Table 1: Concrete CAD and BIM Results

	CAD NC	BIM Research	Difference	% Difference
TOTAL	5856.00 m³	5719.87 m³	136.13 m³	2.32%
Foundation slab	1394.84 m³	1665.94 m³	-271.10 m³	-19.44%
Basement -2	445.81 m³	455.81 m³	-10.00 m³	-2.24%
Basement -1	470.40 m³	487.53 m³	-17.13 m³	-3.64%
1st Floor	244.05 m³	219.12 m³	24.93 m³	10.21%
2nd Floor	227.90 m³	186.99 m³	40.91 m³	17.95%
3rd Floor	234.85 m³	214.91 m³	19.94 m³	8.49%
4th Floor	234.85 m³	214.89 m³	19.96 m³	8.50%
5th Floor	234.85 m³	215.40 m³	19.45 m³	8.28%
6th Floor	234.85 m³	215.63 m³	19.22 m³	8.19%
7th Floor	234.85 m³	215.69 m³	19.16 m³	8.16%
8th Floor	234.85 m³	215.79 m³	19.06 m³	8.12%
9th Floor	234.85 m³	214.78 m³	20.07 m³	8.55%
10th Floor	234.85 m³	214.50 m³	20.35 m³	8.67%
11th Floor	234.85 m³	214.68 m³	20.17 m³	8.59%
12th Floor	234.85 m³	210.51 m³	24.34 m³	10.37%
13th Floor	234.85 m³	215.25 m³	19.60 m³	8.35%
14th Floor	234.85 m³	187.35 m³	47.50 m³	20.23%
15th Floor	211.24 m³	131.97 m³	79.27 m³	37.52%
16th Floor	43.53 m³	23.13 m³	20.40 m³	46.87%

STEEL BARS: “CAD NC” VS “BIM RESEARCH”

The observed differences caused problems in terms of project processes and costs. There is a difference of -61.93 tons of iron, which represents a discrepancy of 10.02% compared to the amount budgeted by “CAD NC” (see Table 2). Both positive and negative differences are identified in Floors 3 to 14, but all of them are within the acceptable and moderately acceptable range. However, the foundation slab, basement -2 and -1, and Floors 1, 2, 15 and 16 present differences that are not acceptable according to the established criteria. It is important to highlight that the greatest differences are evident in basements -2 and -1, where “CAD NC” considerably underestimated the amount of steel bars required compared to “BIM RESEARCH”

“BIM Research” considers all the elements of the steel bars, even those that do not have a structural function, but are necessary from a construction point of view, such as extra locks, splices and hooks, to support slabs, and master bars, among others. These additional elements are not detailed in the plans, but are required during the installation of the steel bars. This difference in the consideration of non-structural elements explains why “BIM Research” shows superior steel QTO results than “CAD NC”.

Table 2: CAD and BIM results of reinforcing steel bars

	CAD NC	BIM Research	Difference	% Difference
TOTAL	617.88 Ton	679.81 Ton	-61.93 Ton	-10.02%
Foundation slab	64.14 Ton	70.82 Ton	-6.68 Ton	-10.41%
Basement -2	44.05 Ton	81.45 Ton	-37.40 Ton	-84.89%
Basement -1	43.19 Ton	67.45 Ton	-24.26 Ton	-56.17%
1st Floor	39.85 Ton	52.06 Ton	-12.21 Ton	-30.65%
2nd Floor	44.68 Ton	40.76 Ton	3.92 Ton	8.78%
3rd Floor	36.09 Ton	34.53 Ton	1.56 Ton	4.33%
4th Floor	32.42 Ton	33.45 Ton	-1.03 Ton	-3.17%
5th Floor	30.85 Ton	30.14 Ton	0.71 Ton	2.31%
6th Floor	29.58 Ton	30.31 Ton	-0.73 Ton	-2.47%
7th Floor	28.33 Ton	27.86 Ton	0.47 Ton	1.65%
8th Floor	27.96 Ton	28.53 Ton	-0.57 Ton	-2.03%
9th Floor	26.68 Ton	26.66 Ton	0.02 Ton	0.07%
10th Floor	26.43 Ton	27.15 Ton	-0.72 Ton	-2.71%
11th Floor	26.02 Ton	25.77 Ton	0.25 Ton	0.97%
12th Floor	26.00 Ton	26.66 Ton	-0.66 Ton	-2.56%
13th Floor	25.37 Ton	25.32 Ton	0.05 Ton	0.19%
14th Floor	24.56 Ton	25.62 Ton	-1.06 Ton	-4.31%
15th Floor	24.38 Ton	20.90 Ton	3.48 Ton	14.28%
16th Floor	17.31 Ton	4.39 Ton	12.92 Ton	74.64%

It is important to note that there was modification to design of the 16th floor that decreased the buildable area and was not considered by “CAD NC”, which shows that the amount of steel was greater than that actually required for that level.

The “BIM Research” study shows the superior precision of BIM for calculating the QTO of steel. Including non-structural elements in BIM is crucial for accurate estimating, resulting in better project management and transparency in real cost. The literature on BIM and construction project management supports these findings. Furthermore, the inclusion of non-structural elements in BIM is crucial for accurate estimation of steel QTO, and the lack of these elements in CAD NC underestimates the QTO, which can lead to problems during construction. Therefore, BIM offers greater precision in material estimation, which makes real cost transparent and optimizes project management.

FORMWORK: “CAD NC” VS “BIM NC”

Between the results of “CAD NC” and “BIM Research” there is a difference of 229.36 m² of formwork, which translates into a differential of 0.81% between what was budgeted and what was used (see Table 3). The total difference turns out to be very slight, with various differences, positive and negative, existing in the calculations for each level of the building. in foundation slab, basement -2 and -1, floors 1, 2 and 16 the differences are negative, that is, what was budgeted was less than what was required. The "not acceptable" results are offset by the results that are "moderately acceptable", finally having a total difference categorized as "acceptable" between the CAD and BIM methodologies in formwork QTO.

Table 3: CAD and BIM results of formwork

	CAD NC	**BIM Research**	**Difference**	**% Difference**
TOTAL	28421.00 m²	28191.64 m²	229.36 m²	0.81%
Foundation slab	112.80 m²	126.47 m²	-13.67 m²	-12.12%
Basement -2	2154.24 m²	2482.91 m²	-328.67 m²	-15.26%
Basement -1	2294.80 m²	2583.88 m²	-289.08 m²	-12.60%
1st Floor	1490.60 m²	1577.68 m²	-87.08 m²	-5.84%
2nd Floor	1551.16 m²	1813.38 m²	-262.22 m²	-16.90%
3rd Floor	1582.69 m²	1502.75 m²	79.94 m²	5.05%
4th Floor	1582.69 m²	1508.76 m²	73.93 m²	4.67%
5th Floor	1582.69 m²	1507.23 m²	75.46 m²	4.77%
6th Floor	1582.69 m²	1503.03 m²	79.65 m²	5.03%
7th Floor	1582.69 m²	1505.59 m²	77.10 m²	4.87%
8th Floor	1582.69 m²	1506.66 m²	76.03 m²	4.80%
9th Floor	1582.69 m²	1506.18 m²	76.51 m²	4.83%
10th Floor	1582.69 m²	1499.78 m²	82.91 m²	5.24%
11th Floor	1582.69 m²	1506.78 m²	75.91 m²	4.80%
12th Floor	1582.69 m²	1507.38 m²	75.31 m²	4.76%
13th Floor	1582.69 m²	1472.15 m²	110.54 m²	6.98%
14th Floor	1582.69 m²	1507.26 m²	75.43 m²	4.77%
15th Floor	1462.26 m²	1204.45 m²	257.81 m²	17.63%
16th Floor	362.90 m²	369.34 m²	-6.44 m²	-1.78%

The difference with "CAD NC" vs "BIM Research" comparison is minimal: 0.81% (229.36 m²). This reinforces what was previously stated, that the formwork QTOs do not require a major analysis for the calculation of areas.

It should be noted that in order to obtain the quantities in m2 of the formwork, it is necessary to use a "plugin" given that the formwork is a temporary element that cannot be obtained directly from the BIM models.

AHP METHOD

Analytic Hierarchy Process (AHP) is a decision-making method in which alternatives are evaluated using a mathematical model, based on a series of criteria, to define which best meets the objective of a process (Darko et al., 2019). In this research, AHP is applied to define which alternative, CAD or BIM, best satisfies the requirements to develop QTO in the bidding stage.

To develop the AHP, the objective must be defined ("Define whether the CAD or BIM methodology is the best alternative to perform QTO and budget calculations in the bidding stage of a construction project"), and the criteria and alternatives (CAD and BIM) to make the best decision. The criteria were established based on input from experts consulted during the assessment phase of the Analytical Hierarchy Process (AHP). Six criteria are presented in Table 5 along with their corresponding sub-criteria. The first 4 criteria consider technical aspects that have direct implications in the use of CAD and BIM methodologies. Criteria 5 and 6 respond to qualitative aspects, which consider perceptions of barriers to overcome for the adoption and use of software related to work methodologies.

Due to the complexity of decision-making in construction projects, the AHP methodology emerges as a robust approach (Darko et al., 2019). It offers a systematic framework for evaluating and comparing multiple criteria, facilitating an informed selection between alternative methodologies such as CAD and BIM. The flexibility and adaptability of AHP allow for customization to address the specific needs of the research, ensuring a comprehensive evaluation that encompasses both technical and qualitative aspects (de Paris et al., 2022). Furthermore, in comparison to other decision-making methods like Cost-Benefit Analysis (CBA), AHP excels in its ability to consider a broader range of factors beyond purely monetary considerations (Arroyo et al., 2020; Natarajan et al., 2022), thus providing a more holistic and nuanced approach to decision-making in construction projects (Razi et al., 2019).

Table 5: AHP criteria and sub-criteria

N°	Criteria	Sub-criteria
1	Precision in quantity take-off	• Ability to identify elements in plans/models • Accuracy in the quantity of the elements identified
2	Efficiency in the quantity take-off process	• Speed of the QTO process • Degree of automation of the QTO process
3	Compatibility with other systems	• Ability to import and export data to other systems • Interoperability with other systems
4	Resource availability	• Availability of personnel trained in the use of the software • Availability of technical support and updates
5	Investment cost	• The initial cost of licenses • Cost of maintenance and updates
6	Easy to use	• Level of technical knowledge required to use software • The friendliness of the software interface

The first step to develop the AHP method in Total Decision is to enter the already established objective, criteria and alternatives. The criteria are then compared to each other, one by one, using ratings that indicate their degree of importance. With this process, the weights of each criterion are obtained in order to define the hierarchy between them, knowing which criteria are the most relevant within the analysis. The evaluations to compare criteria and alternatives based on the objective obey scores from 1 to 9 as presented in Table 6.

Table 6: AHP rating scale

Equal Importance	Moderate importance	Great importance	Very great importance	Extreme importance
1	3	5	7	9

The ratings entered into the software are based on information collected from interviews with experts. From this, each criterion was scored, understanding the degree of importance that each one has when carrying out the QTO, both by QTO CAD and QTO BIM. In this stage, the hierarchy of criteria is established, obtaining that the “Investment cost”" criterion is the one with the greatest weight, followed by the “Precision in QTO” criterion as the second most relevant. This indicates that the “Investment cost”, although not a technical aspect, is the most important criterion when making decisions about which work methodology to adopt to carry out QTO. Furthermore, the two main criteria are followed in the ranking by: “Efficiency in the QTO process”, “Compatibility with other systems”, “Resource availability” and, finally, “Easy to use”.

The next step is to evaluate each criterion concerning each of the alternatives. The same assessment scale used previously is used to rate the performance of each alternative based on the objective, as shown in Figure 3.

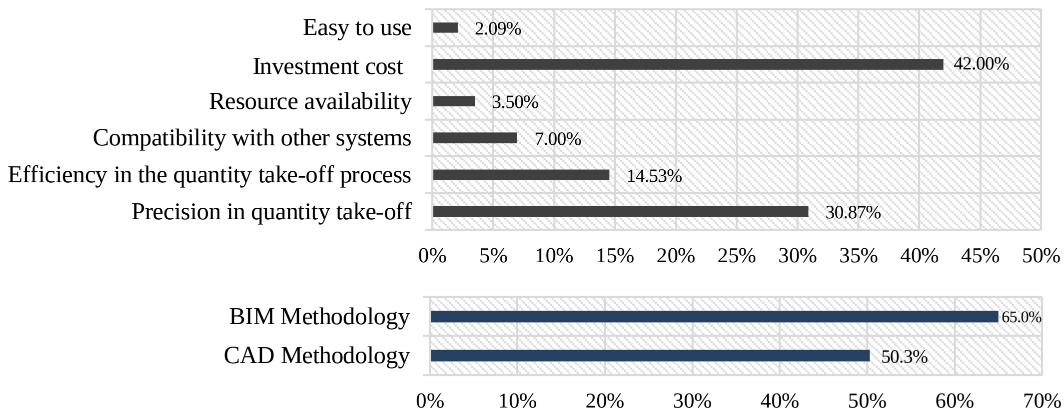

Figure 3: AHP structure of hierarchies.

These evaluations provide a measure of the performance of each alternative in relation to the objective. The evaluations are developed by matrixly ordering the results for each comparative instance. From each matrix, the eigenvectors are obtained that indicate the relative weights of each comparative pair. By obtaining all the eigenvectors, a global decision matrix is constructed with which, finally, the alternative with the greatest weight for decision-making can be obtained. This entire mathematical process was carried out using the Total Decision software.

Finally, with the AHP Method, through the calculation software, it is concluded that the best alternative to perform QTO and budget calculation in the bidding stage of a project is the BIM methodology over CAD.

Given that the “investment cost” criterion has high relevance in the study, considering that the costs associated with BIM are higher compared to CAD, the gap between alternatives may not turn out to be completely representative. That is why by carrying out the same study without considering the “investment cost” criterion, the decision-making is decisively more conclusive, defining BIM as the alternative with almost ideal performance to satisfy the objective, as shown in Figure 4.

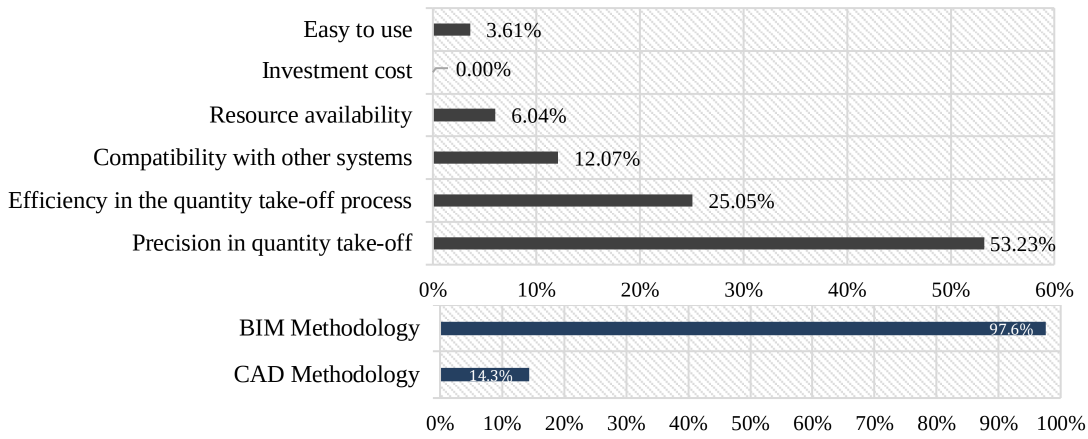

Figure 4: AHP sensitivity analysis - Simulation of results without Cost criteria.

This supports that the "investment cost" variable has a fundamental role in quantifying the best decision. However, in both cases, the BIM alternative presents the best performance, based on the criteria and its hierarchical analysis, to satisfy the objective of defining CAD or BIM as the best alternative to carry out QTO and budget in the bidding stage of a project.

QTO with CAD, unlike BIM, is based on individual 2D or 3D drawings, requiring manual calculation or using additional tools. This leads to errors due to the lack of integration between elements, making it difficult to update the calculation in the event of changes in the design. Instead, BIM creates an intelligent 3D digital model, allowing an automatic and precise calculation of materials from the model, minimizing errors and enabling rapid updating in the event of changes. This efficiency is applied to the calculation of concrete, reinforcement and formwork, optimizing the use of resources and collaboration between teams.

It is important to consider that the AHP method provides precise results after a mathematical development that integrates and weights various variables, delivering solid outcomes. By way of analysis, it is also important to understand that the use of AHP in decision-making can be affected by biases and limitations that must be addressed to ensure reliable results (Darko et al., 2019; Munier, N., & Hontoria, E. (2021). The judgments of experts, crucial in AHP analysis, may be influenced by personal preferences, limited knowledge, or external influences, which could bias evaluations (Liu et al., 2020). Additionally, the quality and availability of information for experts may vary, requiring measures to ensure equitable and comprehensive access to relevant information. The rating scales used in AHP analysis may be subjective and require validation to ensure accuracy (Darko et al., 2019). Faced with all this, it is necessary to carry out iterative processes and sensitivity analyses to evaluate the effectiveness of these scales and their impact on analysis results.

CONCLUSIONS AND RECOMMENDATIONS

The comparative analysis between the QTOs carried out with "CAD NC" and "BIM Research" has revealed important information regarding the precision and accuracy of the results. In the case of concrete, it is observed that "BIM Research" provides a real and precise quantity, avoiding overestimation of quantities, while "CAD NC" shows a tendency to overestimate volumes. This demonstrates the advantages of BIM in terms of obtaining accurate information and avoiding deviations in project processes and costs, and it could make projects more competitive by using them in earlier stages. Similarly, when comparing the QTO of steel bars, it is again evident that "BIM Research" offers a more detailed and complete analysis for the required elements, considering even those that do not have structural purposes but are necessary for construction. On the other hand, "CAD NC" presented discrepancies and errors in the study of plans, which generated imbalances in the processes and associated costs. It is important to highlight that the errors detected in the QTO are related to CAD, which supports the need to adopt more advanced methodologies such as BIM to avoid carryover of errors and detect incompatibilities early; This generates claims for defects in the design, which then end up being awarded to the client or assumed as a loss. In the case of the formwork, the results were quite similar in the totals, however, this required the help of a plug-in to have the calculations in BIM per floor, where the differences are within the moderately acceptable margins. described as criteria.

The study, using the AHP method, found that BIM (65%) outperforms CAD (50.3%) for performing QTO at the bidding stage. This is based on six criteria: accuracy, speed, ease of use, flexibility, collaboration and integration. The percentages are not absolute, but rather represent the relative performance of the alternatives. The AHP performs an independent analysis between alternatives.

While BIM is the best option, cost is a major barrier to its adoption. The implementation risk must be considered against the benefits of structuring, parameterization and process optimization that BIM offers. For construction professionals it is recommended: 1) Consider BIM as the best option for QTO in the bidding stage; 2) evaluate the cost of BIM implementation compared to the long-term benefits; and 3) seek strategies to mitigate the risk of BIM implementation. For researchers in this field, it is recommended: 1) Develop studies that demonstrate the value of BIM in terms of ROI (Return on Investment); 2) investigate strategies to reduce the cost of BIM implementation; 3) study the risk perception of BIM in the construction industry.

BIM adoption faces obstacles such as the need for training, investment in hardware and software, and adaptation to new work processes (Olanrewaju et al., 2022; Sriyolja et al., 2021). However, it is crucial to demystify the idea that BIM alone improves a project. While BIM offers great benefits, efficient processes are required to make the most of them. Resistance to change and lack of technological updating are also barriers that must be overcome (Shin & Kim, 2021). It is necessary to change the perception of BIM as something expensive and risky, and see it as an investment in improving the efficiency and quality of construction projects.

To overcome the challenges of BIM implementation, it is crucial to integrate the Lean Construction philosophy. Lean focuses on waste elimination and continuous improvement, which improves the efficiency of the BIM process and optimizes project performance. The integration of Lean and BIM offers benefits such as: 1) Reduction of costs and time, eliminating unnecessary activities and optimizing planning; 2) improved quality, minimization of errors and greater precision in construction; 3) greater collaboration among stakeholders, and 4) more effective decision making, based on accurate and up-to-date information and more effective decision making. Therefore, by integrating Lean into BIM from the early stages of the project, you boost competitiveness and ensure greater success in BIM implementation, optimizing overall project performance and minimizing waste.

Florez-Perez (Eds.), *Proceedings of the 32nd Annual Conference of the International Group for Lean Construction* (IGLC32) (pp. 807–818). doi.org/10.24928/2024/0127

IMPLEMENTING LEAN PRACTICES AND A MODERN CONSTRUCTION METHOD IN A SOCIAL HOUSING PROJECT

Sergio Kemmer[1] and Leonardo L. Marin[2]

ABSTRACT

The paper aims to explore the implementation challenges and advantages of utilising lean practices along with a modern construction method, i.e. timber frame prefabricated system, to accomplish a challenging goal in a social housing project in Brazil.

It presents a case study on the construction of 518 housing units, which were built in a short period to help victims of a climate catastrophe relocate. Data was collected through semi-structured interviews, participant observation, site visits, and documental analysis. The findings suggest that relying on a single lean practice or a modern construction method may not be enough to achieve demanding project objectives, such as completing a construction project within a tight deadline. Instead, it is the appropriate combination of these initiatives that will result in a better outcome.

Moreover, the study contributes to a particular issue that has not been adequately addressed by the lean community. Specifically, it sheds light on the connection between a project objective, lean concepts and managerial tools that can be used to accomplish it.

KEYWORDS

Lean practices, Last Planner® System, off-site construction, prefabrication, prototype.

INTRODUCTION

In February 2023, during the Carnival festival, the coastal city of São Sebastião in the state of São Paulo, Brazil, experienced the worst rainfall ever recorded (G1, 2023). Within less than 24 hours, approximately 600mm of precipitation fell resulting in dozens of fatalities, extensive damage to local highways, and hundreds of people left homeless (Figure 1).

After the disaster, the local government quickly relocated the affected population to sports arenas and provided temporary housing. They worked on a permanent solution and decided to construct 518 housing units within a short period of 10 months to allow the displaced people to move into their new homes and begin rebuilding their lives.

In order to achieve this challenging goal, the local government decided to utilise a modern construction method to ensure quick completion of on-site work. The modern construction methods promote a shift from fragmented project delivery methods to a more controlled environment. (Taylor, 2010). Specifically, the timber frame prefabricated system was chosen, which is one of the methods outlined in the Modern Methods of Construction Definition Framework (MHCLG, 2019). To minimize waste and add value to the population affected by such catastrophic climate event, lean practices were also applied in the design, planning, and

construction processes. The project was led by Brazil's top company in efficient and sustainable social housing.

Figure 1: The damage caused by a catastrophe resulting from heavy rainfall. (G1)

This study explores the challenges and advantages of using lean practices and a modern construction method to complete the construction project within a tight timeframe. Moreover, it highlights the relationship between a project goal, lean concepts (i.e. conceptual ideas related to the lean construction philosophy), and managerial tools.

LEAN AS A SYSTEM

The key to successfully applying and sustaining Lean Construction concepts and tools lies in a thorough understanding of the fundamentals and consistent practice (Koskela et al, 2002).

The Toyota Production System (TPS) has served as an inspiration for the development of the Lean Construction theory (Koskela, 2000). It changed the paradigms of production management, bringing to light simple and innovative ideas based on a common goal: increasing production efficiency by eliminating waste consistently (Ohno, 1997). The following figure, known as the TPS House, shows the basic elements of the system.

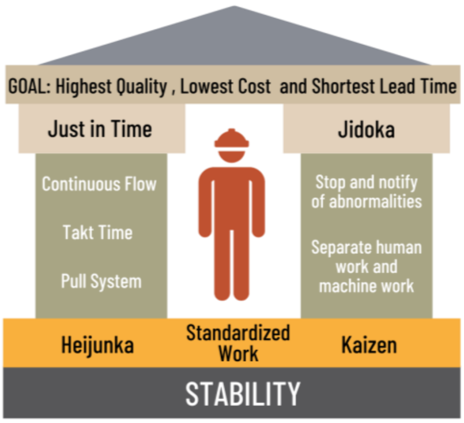

Figure 2: Toyota Production System House (Adapted from Lean Enterprise Institute).

On the roof of the house are the TPS goals (highest quality, lowest cost, and shortest lead time). Just in Time and Jidoka are the system's support pillars. Stability is the foundation. The person at the centre represents respect for people. Understanding the meaning of each of these elements is a mandatory task for anyone who wants to embark on a Lean transformation journey. It is also worth highlighting the idea of a system brought by the TPS House, that is, for the expected results to be achieved, all parts need to be applied. Systems thinking is essential.

Furthermore, the TPS House (Figure 2) indicates the initial step in a lean implementation, namely, the achievement of production stability, which is represented as the foundation of the house. The creation of a stable workflow is a prerequisite for the deployment of more advanced lean concepts (e.g. continuous flow) that will enable the achievement of project objectives (e.g. compression of lead time).

The Last Planner System® (LPS) is a well-known lean tool in construction for production planning and control (Ballard and Tommelein, 2021). LPS aims to promote stability in production flow and facilitate rapid learning (Ballard, 2000). Therefore, it is advisable for construction companies to start their lean journeys by implementing LPS (Koskela et al., 2002).

It is worth mentioning that the LPS is not the only lean practice available for supporting the creation of stability. There are many other initiatives that can be employed during design and planning processes with the purpose to remove uncertainties associated to the product and its production process such as the early involvement of cross-functional teams (Ballard et al., 2002; Laurent and Leicht, 2017; Laurent and Leicht, 2019), Design for Manufacturing and Assembly (Rankohi et al., 2022), Building Information Modelling (Sacks et al., 2018), First Run Study (Saffaro, 2007; Hackett et al., 2015; Aslesen et al., 2023), and Production System Design (Ballard et al., 2001; Barth et al., 2020). The literature on these management practices is extensive and it is assumed to be well-known and thus omitted from this section.

THE PROJECT

This paper presents research conducted as part of a project to reconstruct housing for those affected by landslides. The construction involved 518 housing units, which were distributed across 30 four-story blocks. Each floor of the blocks contained four apartments, with an average area of 47.29m². In addition, there were 38 houses, each averaging 44.16m². In total, the entire project spanned over an area of 24,377m².

Three companies were hired by the São Paulo State Government to undertake a project. Each company was responsible for a specific aspect of the project, which was divided into infrastructure, assembly and installations, and finishes. The industrialised timber frame panels were manufactured in a city located 500km away from the site. A total of 6,124 panels were then transported by truck to the assembly location. During the 10-month operation, approximately 450 people worked on the project, which covered the period from the beginning of the first excavation and manufacturing to the delivery of the housing units to the residents.

In addition to the challenges related the tight timeframe, the project attracted significant media attention due to its status as a public work contracted by the government, employing a construction method considered innovative in the country.

RESEARCH METHOD

A case study was carried out to investigate the implementation issues and benefits of utilising lean practices along with a modern construction method, i.e. timber frame prefabricated system, to construct 518 housing units within a short period of 10 months. The research was structured in three phases: diagnostic, training, and implementation. The objectives set for each phase along with the methods used in this investigation is presented in the following table.

As shown in Table 1, the first phase of the study was exploratory. Data was collected prior to the commencement of works on site through semi-structured interviews (engineering manager, production planning and control coordinator, head of operations, process engineering coordinator, quality manager and site agents), direct observation of works on the prototype built offsite, and documental analysis (production plans, production rates, and problems faced in previous projects).

Table 1: Research process.

Items	Phase 1 (Diagnostic)	Phase 2 (Training)	Phase 3 (Implementation)
Objectives	(a) understanding the characteristics of the project and typical issues faced in previous projects (b) discussion on which managerial tools should be implemented to compress project lead time	(a) raising the awareness on lean fundamentals (b) practical application of lean concepts and tools such as Takt Planning, Production System Design, Last Planner System	(a) discussion on the implementation issues and the benefits reaped through the application of lean practices
Research methods	Semi-structured interviews, direct observation, documental analysis	Training sessions delivered to the project team	Participant-observation in planning meetings, documental analysis

The second phase involved training sessions on lean fundamentals such as value, continuous flow, and continuous improvement. Besides, production system design, takt planning, Last Planner System® were also addressed throughout the sessions through practical exercises.

The deployment of the lean practices was conducted in a collaborative fashion during the third phase. A cross-functional team involving the the engineering and innovation director, project manager, design representatives, procurement manager, site agents, safety coordinator and planners were engaged to promote collaboration in order to ensure a successful implementation. Follow-up meetings were led by the production planning and control coordinator on a fortnightly basis to discuss the implementation issues, project progress, opportunities for improvement and the benefits reaped through the application of lean practices.

Due to the objectives set for this study, the findings reported in this paper are focused on phase 1 (i.e. discussion on which managerial tools should be implemented to compress project lead time) and phase 3 (i.e. discussion on the implementation issues and the benefits reaped through the application of lean practices).

ON THE INITIATIVES TO COMPRESS PROJECT LEAD TIME

Several initiatives were taken to shorten lead time as this was the aim of this project. The first decision made in this regard was the selection of a construction method appropriate for a project with a tight timeframe. The timber frame prefabricated system was chosen because it increases the efficiency of the construction process as opposed to the artisanal process traditionally used in Brazilian construction sites. The timber frame panels are produced off-site in a controlled environment with the support of an automated production line, thus increasing the levels of quality, safety, and productivity. The panels are sent to site fitted with electrical and plumbing installation kits and windows, hence simplifying the construction process by reducing the number of steps to be done on site.

Besides the choice of a suitable construction method, lean concepts and tools were deployed across project phases (Figure 5) to ensure that works on site was completed as quickly as possible. To achieve a design solution that would help the production teams to avoid stoppages on site as well as increasing product quality and safety during installation, the DfMA (Design for Manufacturing and Assembly) approach, BIM (Building Information Modelling) and a physical prototype were adopted. In the planning phase, a Production System Design was conducted by a cross-functional team with the support of BIM Models to remove uncertainties in order to promote a stable production workflow. Takt Planning was also applied to create a continuous flow that would help shorten production lead time. In the construction phase, the

Last Planner System® was implemented to ensure works on site were conducted as planned along with Visual Management and a Continuous Improvement approach to enable agility in dealing with deviations from the original plan. The following figure summarises the lean practices implemented across the project phases. Further details on the implementation of these initiatives are provided in the next sections.

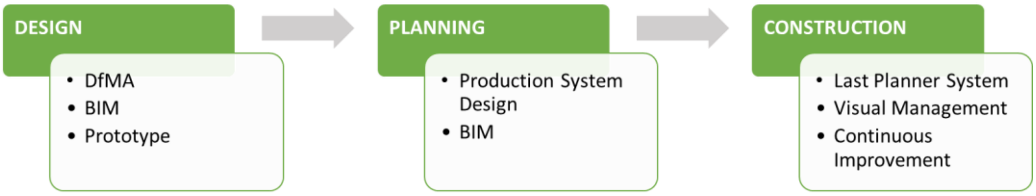

Figure 3: Lean practices implemented across project phases.

DfMA

The DfMA principles, which DfM involves minimizing the number of components whereas DfA focuses on streamlining assembly (Gao et al., 2018), were introduced to the engineering teams after the conclusion of the conceptual design phase and prior to the creation of detailed drawings. This collaborative effort involved design engineers, the safety manager, as well as production and assembly coordinators and analysts. The primary objective was to streamline and optimize production and assembly operations with a focus on safety.

During this phase, two four-hour meetings were conducted, engaging all team members. The initial focus was on defining the manufacturing and assembly sequencing to ensure the most efficient operational utilization. Subsequently, following the initial planning, 15 new subproducts were identified and categorized as potential project risks. This identification prompted the necessity to prototype these elements, encompassing 2 structural components, 2 roof-related elements, 5 installations, and 3 external finishes.

BIM

The application of BIM was undertaken with a focus on industrialisation, with a view to achieving a high level of detailing and fidelity to reality through the use of a specified Level of Development (LOD). The resulting model was then analysed to validate solutions and interfaces, providing the basis for informed discussion and decision-making involving people, technology, processes, and policies to ensure the achievement of business objectives, during the production process. – as it is common when BIM is applied as a working methodology.

As highlighted by the Engineering Manager, "developing a design for an emergency project that requires rapid delivery demands a high level of decisiveness in engineering decision. There is no room for error during construction, which makes decisiveness even more crucial when it comes to industrialisation and repetition of the same typology. Even a minor error can easily become a systemic problem, which is why the use of BIM is essential. By utilising BIM models, clashes between different disciplines can be detected at an early stage, design solutions can be better assessed and discussed, construction stages are properly defined, training sessions can be delivered in a higher quality in order to get the operational team ready in the best way possible. This ensures that there are fewer issues due to design omissions or project failures". Also, the information contained in the modeled objects allows for an accurate quantity takeoff, thus making it easier to achieve assertive purchases and providing better on-site inventory control.

Prototype

To validate design and engineering solutions as well as reducing the risk of unexpected issues (e.g. time waste) on site, a two-story prototype with a roof was erected within two weeks. It was an accurate full-size mock-up of the building. All electrical and plumbing installations were executed, and a complete dwelling was finished. Figure 4 shows results from the prototype implementation.

Figure 4: Two-Story Prototype built off-site.

The development of the prototype was a collaborative effort involving the engineering manager, operations manager, project coordinator, manufacturing and assembly teams, and the electrical and plumbing subcontractors. Upon its completion, a thorough assessment of the prototype revealed the existence of 16 non-conformities. These issues were attributable to either flaws in the product definition or errors during the execution process. A depiction of these non-conformities is illustrated in Figure 5. Subsequently, measures were taken to address and mitigate these issues before commencing the mass production phase.

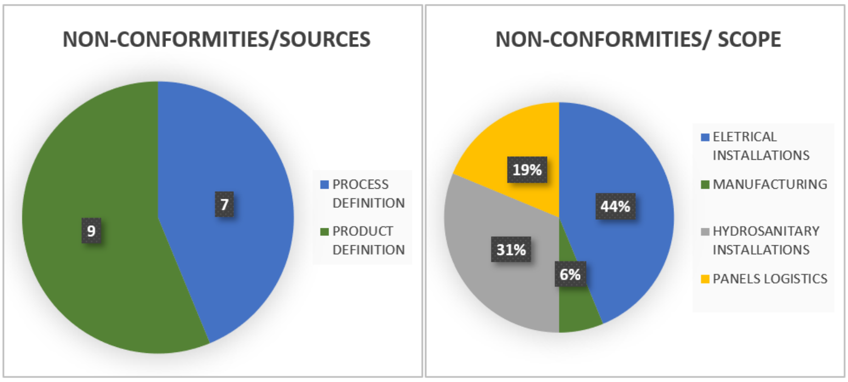

Figure 5: Number and type of non-conformities.

The oversight conducted by the project team facilitated the validation of the hourly schedule for the execution of electrical and plumbing installation activities. These activities were deemed critical due to the significant number of non-conformities identified. The project coordinator emphasised that the prototype provided valuable insights such as the importance of carrying out all activities until their completion and ensuring the precise measurement of parameters such as production rates and materials.

Production System Design and Takt Planning

The Production System Design aimed at organizing the production system by establishing a structure that served as a reference for production planning, control, and improvement. The scope of decisions involved: definition of work packages, production sequence and activity durations, analysis of the workflows of crews on site, definition of the project execution strategy, capacity analysis of production resources, site layout and logistics planning. The Takt principle was also applied with the purpose of enabling continuous flow, hence allowing the compression of project time. The engineering and innovation director, project manager, design representatives, procurement manager, site agents, safety coordinator and planners were involved in this phase.

Four meetings of four hours each were necessary to conclude the work. They were structured according to the scope of works abovementioned, namely, the first and second meetings focused on work structuring and sequencing as well as production flow analysis whereas the third and fourth meetings addressed the definition of project execution strategy, capacity analysis of production resources, site layout and logistics planning. These collaborative sessions were held in the headquarter of the general contractor prior to start of works on site. The main outcome of this work was the development of the strategic production planning, which was represented in a line of balance. The work packages and resources (labour and equipment) required to carry out the production tasks were also sorted by the team.

LAST PLANNER SYSTEM®

The Last Planner System® was deployed with the purpose to stabilize production workflow to allow the implementation of continuous flow as well as promoting a culture of continuous improvement. Two pull planning sessions were carried out to specify handoffs and conditions of satisfaction of two key processes defined by the team, namely, electrical installation and plastering. Lookahead meetings were conducted on a fortnightly basis. Weekly meetings were held for assessing production progress as well as learning from mistakes. Daily huddles were also implemented to allow front line supervisors to share commitments completed as well as making clear what commitments need help with or cannot be delivered. These daily meetings happened at the end of the day and lasted 30 minutes approximately.

VISUAL MANAGEMENT

Visual tools such as line of balance and charts displaying attributes related to production planning (e.g. Percent Plan Complete, reasons for task non completion, countermeasures, etc.) were deployed on site to increase process transparency and allow the project team to quickly identify deviations from the plan. Furthermore, a Big Room was set up on site to foster communication and collaboration among project participants as well as supporting management routines such as daily huddles and weekly meetings. It is worth mentioning that visual aids such as BIM Models and wallcharts with sticky notes were also used during the development of the production system design and takt planning.

CONTINUOUS IMPROVEMENT

A continuous improvement approach was implemented by identifying and analysing the root causes of problems. The 5 Whys technique was used for this purpose. The project team applied countermeasures to promote stability and improvement in processes, which were reviewed daily during huddles at the end of each workday. Weekly meetings were held to assess project progress. The continuous improvement approach was also applied during the design and planning phases of the project, with management practices such as DfMA, prototyping, and production system design prompting changes to improve performance.

DISCUSSION

In this section, the authors describe the implementation challenges and advantages of utilising lean practices and a modern construction method, i.e. timber frame prefabricated system, to accomplish the construction of 518 housing units in 10 months. This analysis is structured according to the project phases, namely, design, planning, and construction. Furthermore, the connection between project objective and the lean concepts and managerial tools that can be used to accomplish it are also discussed by the authors of the paper.

DESIGN PHASE

A relevant issue faced in this phase was the short time available for developing and validating the design. As this project had a particular feature, namely, it was a response for a catastrophic event where people had been displaced from their homes, the engineering team had to develop the design solution faster than what they usually do in traditional projects in order to releasing the production of prefabricated panels to be shipped to the construction site. According to the Engineering Manager, the design development for a new building normally takes 60 to 90 days. However, due to the tight timeframe, the engineering team decided to use a design solution that had already been tested before. Consequently, only a few minor enhancements were made, therefore reducing the design lead time to less than 30 days.

Another important challenge was to start the production of prefabricated panels as soon as possible to meet the on-site demand. The ideal approach would be to produce a prototype first, validate its components, and then proceed with further production. According to the project coordinator "it's important to fully validate each component of the prototype, including time, execution processes, and materials used, before moving on to further production. If any component is only partially validated, it may result in waste generation". However, it was not feasible to produce all the required timber frame panels within the given timeline due to the limited production capacity of the factory. As a result, some of the panels were manufactured beforehand and kept in storage offsite. This led to rework on site due to technical problems discovered only at the end of the prototype evaluation phase.

It is important to note that despite the challenges mentioned earlier, the virtual model created using BIM, along with the physical prototype, proved to be effective in helping the team to evaluate potential issues, refining solutions and ultimately achieving a high level of precision and accuracy throughout construction. Besides, it helped validate some key factors for the project. This includes the validation of engineering assumptions and the production rates for electrical and plumbing installation activities. These activities were found to have a higher number of inconsistencies in design specifications and constructability, and were identified as the most critical, making them the focus of special attention during the planning and construction process.

PLANNING PHASE

The main issue faced during the planning phase was the lack of collaboration between the three main contractors hired by government to undertake the project. The company responsible for carrying out the infrastructure services, which was a basic requirement for allowing the assembly of timber frame panels, did not participate in the meetings held to carry out the production system design. There was no commitment to the dates considered in the strategic production planning hence affecting the work conducted by company responsible for installing the prefabricated timber panels.

Another relevant issue faced by the project team was the lack of reliable data on production rates to perform the Takt Planning. Without a sound database it was difficult to adjust the level of work to achieve the production pace set for the project. Although some data were gathered during the execution of the physical prototype (e.g. electrical and plumbing production rates), there was no information available for all services required to be carried out on site. Besides, the data collected in the prototype did not consider the site conditions where material logistics was more difficult to be handled than what was faced during the simulation conducted in the prototype built in a controlled environment. Hence, adjustments had to be made on site after the construction of the initial blocks, but this exposed the project to a risk of having to allocate extra resources to cope with the production pace originally planned. Hiring additional crews in a timely manner to work in an underway project located in a remote area was not an easy task. This issue ended up having a negative impact on the works on site due to the dependencies among services. The delay in one task affected the start of the next and this created an undesirable effect, namely, deviation from the original plan.

The production system design meetings prompted the early involvement of cross-functional teams from the company hired to install the timber frame panels. People from different departments such as engineering, supply, quality, safety, production (factory), operation (site agents), besides the engineering and innovation director worked in a collaborative fashion to create an effective production plan. The presence of a senior-level leader along with a multidisciplinary team improved the quality of the discussions as well as the commitment to the plan because people felt appreciated to take part in its development.

Another benefit noted during the production system design meetings was related to the use of BIM models to speed up the process of quantitative take-off. This information was required for calculating the amount of work that needed to be done by the crews on site. These quantities are an important input for Takt Planning, hence calculating them in an automated manner saved time and increased accuracy.

CONSTRUCTION PHASE

The lack of consistency in conducting the routines established by the Last Planner System® (LPS) was one of the main issues faced during the construction phase. According to the production planning coordinator, this was due to the lack of training on the fundamentals of LPS for the subcontractors engaged later in the project. This problem was tackled by a three-day training session held on the construction site to raise awareness on basic lean concepts with a focus on the implementation of LPS. As a result, the engagement of the subcontractors increased and their behaviour during the planning meetings improved, i.e. they became more collaborative. Another important action taken to improve the commitment to the planning process was the provision of a financial incentive for achieving goals. The team received a bonus when production targets were achieved. It is noteworthy that the LPS training was not carried out for the three main contractors hired by the government. Only the company responsible for installing the timber frame panels and its subcontractors were involved in the lean implementation.

The application of LPS resulted in a more stable production flow. This condition enabled the implementation of the takt principle and allowed construction processes to be carried out in a nearly continuous flow, hence contributing to the accomplishment of the project deadline. The daily huddles had an important role in in providing agility in the resolution of issues found out on site. The use of visual aids in the Big Room displaying the production targets against the actual performance was also instrumental to enable the rapid identification of deviations from the original plan, hence prompting improvement actions in a timely manner. Equally important was the use of a software tool for modelling the line of balance as it allowed a more agile approach to project control during the weekly planning meetings.

THE LINK BETWEEN PROJECT OBJECTIVE AND THE LEAN CONCEPTS AND TOOLS

The compression of lead time was the main goal of the project investigated in this research due to the context mentioned in the introduction section of this paper. Therefore, the selection of lean practices aimed at achieving that specific objective. The following figure summarises the rationale applied by the authors.

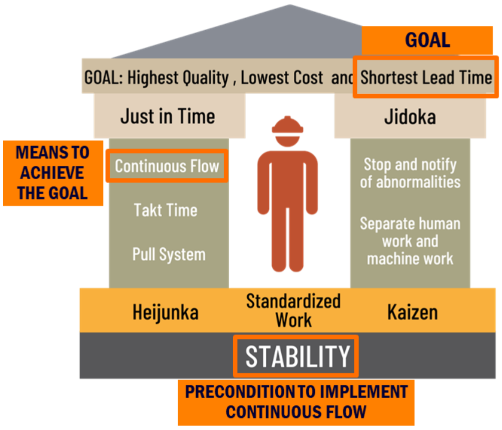

Figure 6: Connection between the elements of the TPS House.

Based on Figure 6, it can be argued that there is a logic behind the sequence of actions taken to achieve the project goal. If one wants to compress lead time (goal), then applying the principle of Takt is an effective way to attain continuous flow (means to achieve the goal), which in turn will lead to the achievement of project objective. However, there is an important precondition to implement continuous flow, namely, stability. Therefore, the selection of lean practices to be applied in the project aimed at creating a stable workflow on site to enable the implementation of a continuous flow and, hence, the compression of lead time. Visual management and continuous improvement practices were also adopted to support the identification of deviations from the original plan, project stabilisation, and rapid learning.

CONCLUSIONS

This study demonstrates that the application of lean practices across different project phases (i.e. design, planning, and construction) coupled with a modern construction method (i.e. timber frame prefabricated panels) can be an effective approach for delivering an emergency construction project in a tight timeframe. It leads to efficiency gains, waste reduction, and value to the customer. The main evidence of such benefits was the achievement of the challenging goal set by the government, namely, the delivery of the 518 housing units in 10 months.

Among the implementation issues described in the paper, it is highlighted the lack of integration between the three main contractors responsible for undertaking the project. Only the company responsible for installing the timber frame prefabricated panels and its subcontractors engaged in the lean implementation whereas the other two main contractors had not adhered to that. This undermined a better performance of the project as a whole since there were dependencies between those companies.

Another key issue noted in the study was the lack of a reliable database on production rates, which have impacted the quality of the production system design and exposed the project to unnecessary risks. Prototyping was an important initiative for helping with this issue and the knowledge on site status was deemed as critical for adjusting the data collected offsite.

Finally, regarding the selection of lean practices to be applied in the project, an important lesson was learned by the managers of the company. Lean should be seen as a system. Thus, having a solid understanding on the relationship between the lean concepts and choosing appropriate lean tools is crucial to achieving project objectives. Systems thinking is vital!

ANALYSING THE ALIGNMENT BETWEEN LEAN CONSTRUCTION AND CIRCULAR ECONOMY IN PREFABRICATED CONSTRUCTION

Jaeden Mourmourakis[1], Wenchi Shou[2], Jun Wang[3] and Yu Bai[4]

ABSTRACT

With the recurring challenge of resources scarcity in the world, the construction industry needs to shift its attention towards sustainable practices. Prefabricated construction (PC) or modular construction has become increasingly popular in recent with its potential solution for the challenges faced, through increase of efficiency and reduction of waste. Some researchers have explored the integration of lean construction (LE) and circular economy (CE) into PC projects and highlights the benefits. However, they conclude that the implementation is in its early days and require a need for research as it holds significant potential in transition into a sustainable industry. This paper aims to exploring the alignment between CE and LC in PC through relevant resources to understand the full extent on this topic. The paper presents the research findings of 25 relevant publications that met the inclusion criteria in a statistical manner. This is to identify and summarise the known body of knowledge relevant to the topic. It shows that there is a strong link between focusing on the whole process for design, construction, and end-of-life of a building. Content was examined to discover what type and application of PC and relevant benefits and/or limitations.

KEYWORDS

Lean construction, circular economy, prefabricated construction, alignment, review.

INTRODUCTION

Generational waste and high consumption of natural resources is a global issue that the construction industry is currently facing due to its contribution from traditional construction methods (Akhimien et al. 2021). Factors include minimal exploration, lack of research and reluctance in embracing new sustainable concepts that the industry can transition into (Ayarkwa et al. 2022). However, as newly emerged methodologies and concepts arise, there has been interests in all parties to the possibilities and adaptations from just thinking of sustainability practices as recycling. A focus is seen on lean construction (LC) principles and circular economy (CE) applications through prefabricated construction (PC) (Luo et al. 2021).

PC is a process where components of a building are manufactured in specialised facilities (off-site) other than the site location, then specifically designed to be transported and assembled on-site (Ferdous et al. 2019; Innella et al. 2019). The integration of the two concepts is compliable as they aim to reduce waste and shorten the project life cycle, resulting in a more efficient and sustainable way (Du et al. 2023). It optimises the production process and has a high potential to effectively address resource wastage and inefficiency (Ferdous et al. 2019). The research found that various LC tools aim to cut waste and shorten project cycle have been used in lean prefabricated construction, they were: (1) kanban that is a visual card system displays steps and materials, (2) value stream mapping (VSM) which is a visualisation of a process and, (3) last planner system (Du et al. 2023; El Sakka et al. 2016; Innella et al. 2019). Furthermore, Caldarelli et al. (2022) conceptualised the application of LC and PC through focusing on modular construction as a hybrid production system. It treated off-site construction as a manufacturing system, as it reorganised the sequences of the construction as a layout of stages, which led to reduction of waste and efficient usage of time. However, it also mentioned that this concept is within its initial stages. Nahmens and Ikuma (2012) identified the effects of LC on modular homebuilding, where the barriers faced in widespread application of sustainable construction is the high initial costs, lack of education in the industry and applications of technologies. It was found through seven case studies that LC resulted in reduction of material waste by 65% and production hours by 31%. Innella et al. (2019) reviewed application of lean methodologies and indicated that techniques to modular construction has the potential to reach new levels of productivity while has yet to be achieved. It highlighted that the challenges faced is how to fully integrate lean strategies to all production process stages of PC. Du et al. (2023) pointed out future direction of the integration of LC and PC through a new concept called lean prefabricated construction. Although there is limited research on the application of the integration of LC through PC applications, they all aim to aid practitioners with an overview of potential benefits and suggest further research is needed.

CE concept derived from the opposed of traditional economy which has not evolved since the industrial revolution (Benachio et al. 2020). The traditional model or linear economy uses the concept of take-make-disposal, where raw materials are extracted from the environment, processed, and are transformed into products and discarded once they have reached their end of life or no use of them (Afteni et al. 2021). Pomponi and Moncaster (2017) stated that although the implementation of CE model is within infancy in the construction industry, there is momentum and support, and examples can be drawn from the Netherlands where European nations are at the forefront of circularity. Benachio et al. (2021) and Munaro et al. (2020) concluded that the CE was involved within the industry which shine a spotlight on research themes, findings, and gaps. In result, they found that there was a need for standardised practices to benchmark the concept and government incentives to promote CE models.

The integration of the CE practices and PC is compliable as PC has the potential to reduce costs and times, whereas CE promotes building resilience and reducing waste (Zairul 2021). Xu and Sun (2019) found that PC have contributed to green building literature through integrating CE applications. Although the integration of CE in PC is a newly emerged concept, there has been research conducted on how the alignment can not only achieve circularity but an efficient construction process. Dams et al. (2021) suggested a framework towards on how the built environment can transition into circularity through integrating modular construction as an application for CE. 15 guidelines were created tailored around achieving Sustainable Development Goals that foster the applications of CE to buildings. Furthermore, Machado and Morioka (2021) extended the idea of integration through how modular construction can further contribute to CE benefits and the link between them has become more evident. It found that most research papers did not mention circular economy directly, but rather the benefits within the implementation of modular construction practices. Zairul (2021) investigated the recent trends within the built environment on PC with the integration of CE. The paper identified that there is an absence of research of the integration as the concept has recently emerged. The research objective of this paper is to investigate the alignment between LC & CE in PC and the potential synergies, challenges and opportunities of integrating in the industry.

The existing body of literature highlighted the importance of the LC and CE concepts and how they can be integrated into PC to achieve further sustainable benefits. The main agreement in the literature displayed that each concept has benefits individually but can be achieve further from integrating them as a collective. Gaps exist such as minimal research and full integration of these theoretical concepts to be implemented practically in the built environment. There is area for future research in collecting data, applying, and implementing the researched ideas in a project. These concepts require additional exploration and how to manage the industry being reluctant to apply these ideas.

RESARCH METHOD

A systematic literature review is a research methodology that identifies, selects, and critically evaluate material to address a specific formulated question. This is thought to be an effective strategy to execute extensive review and identify the research gaps on the topic(Innella et al. 2019).

DATA COLLECTION

For the literature research, the Scopus database has been implemented as it is one of the most accurate, high quality, creditable, and peer-reviewed databases. A three-stage criteria was developed to accurately capture relevant data, which aimed at focusing on papers that demonstrated strong contributions to the three concepts and topic.

In Stage one, the research was conducted using keywords in 'Article title, Abstract, Keywords' field and limited to articles and review papers. The keywords that were implemented in the research field was "Lean Construction* AND Modular* OR Prefabrication* OR circular*". The search result found that there was a total of 223 documents matching these keywords. The research was limited for publication years for a 10-year range between 2023 to 2013 to ensure relevant literature for the topic. There were 158 documents matching the research parameters. The research was further refined through subject area, in this case the relevant area is "Engineering", "Environmental Science" and "Business, Management and Accounting" reducing the number of articles to 138 documents.

In Stage two, the 138 papers were reviewed by evaluating the title and abstract to discover relevant papers concentrating on the alignment of LC and CE in PC within the built environment. A total of 90 publication which do not contain the key terms in titles, author keywords and abstracts were excluded or was not accessible to the public.

In Stage 3, the remaining 48 papers were deeply analysed by reading the full paper to fully understand the relevance towards completing the research aim. A total of 16 paper were found that had relevance towards the paper. Additionally, a manual search was conducted to include the possible omission of CE, LC, and PC archive by the search engine. There are 9 papers were added to the total number of research papers from references. As shown in Figure 1 of the flowchart of data collection, 25 papers were selected for review and analysis.

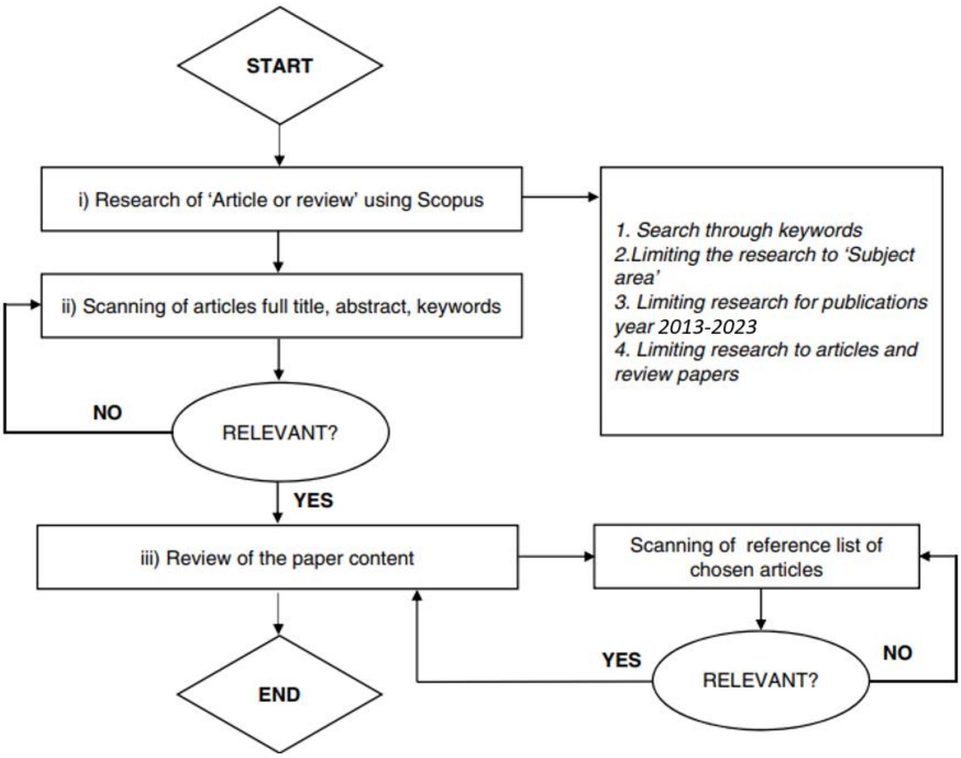

Figure 1: The Flowchart of Data Collection

DATA ANALYSIS

A content analysis was conducted to determine the presence of certain words, themes or concepts surrounding the papers titles. As shown in Table 1, this paper explored the interactions between lean and modular, modular and circular, lean and circular, and the integration of three concepts and the barriers of the integration. The table below

Table 1: Code of Analysis

Code	Definition of code
Alignment of themes	Research contribution and connection and/or explicitly stated in the source.
Analysis of barriers	Addresses or explores the barriers that the concepts may face.

RESEARCH FINDINGS

The researching findings subheading and tables were established to directly address practical challenges of waste cause, stringent construction programmes and budgets involved with traditional construction.

ALIGNMENT OF CE & LC IN PREFABRICATED CONSTRUCTION

A table of alignment was created to explore the alignment of LC principles and CE practices. As shown in Table 2, it is structured to present key components of LC principles and CE practice, along with the specific life cycle stages of a building that the integration has applied. The purpose of the table is to create a visual representation of the relationships between the alignment of these concepts, which allows for a clear understanding of where they overlap and how they complement one another. The life cycle stages, depicted below in the first column represents the different stages that a building undergoes, from a concept to a tangible operative building, to the deconstruction of a building. There are four main stages of a building's construction, project design, construction phase, operations, and end-of-life.

From the created matrix it is possible to obtain a series of results to help understand the relationship between the studied subjects. The number of occurrences refers to when a paper mentioned the alignment between the two areas, regardless of if positive or negative. The alignment of LC principles and CE practices which has the most interactions were "focus on the complete process" with 11 occurrences for LC principles and "deconstruction, reuse, waste management" for CE practices. This was mentioned almost two times than all other alignments. This was followed by "focus on the complete process" with 6 occurrences for LC principles and "prefabricated construction, disassembly and adaptability" with CE practices. The alignment that occurred the least was "Build continuous improvement" with 1 occurrence for LC principles and "prefabricated construction, disassembly and adaptability" for CE practices. Similarly, the life cycle stage that occurred the most was "End-of-life" with 17 occurrences collectively, followed by "Project Design" with 12 occurrences collectively, showing that these are the vital stages where the alignment appears. Whereas the least occurred life cycle stage was operations with 0 (zero) occurrences. This furthers supports how the operations stage of a building is not considered for LC principles and CE practices can be applied to.

Table 2: The Alignment of LC Principles and CE Practices in Lifecycle Stages

		LC Principles			
Life Cycle Stage	**CE Practices**	**Reduce on non-valuing adding activities**	**Reduce cycle times**	**Focus on the complete process**	**Build continuous improvement**
Project Design	Prefabricated construction, disassembly, adaptability	3	2	6	1
Construction	Reuse, waste reduction, off-site construction	2		5	
Operation	Minimise maintenance				
End-of-Life	Deconstruction, reuse, waste management and refurbishment	2		11	4

Table 3 was created to show the alignment between LC principles and CE practices as they are applied to PC. The table lists the alignment that occurred within the Table 2 and outlines their corresponding connections and how they are applied further in PC.

Table 3: the Alignments of LC&CE in PC Application (data extracted from the 25 filtered papers)

Number of publications	Alignment of LC & CE	PC Application
11	Focus on the complete process & Deconstruction, reuse, waste management and refurbishment.	Focusing on the manufacturing process to reduce steps needed while applying disassembly design and allowing the use of reuse materials
6	Focus on the complete process & Design for disassembly and adaptability.	Mapping out the entire process of the production process (Waste & material handling) and focusing on modular and standardized components
5	Focus on the complete process & Reuse, waste reduction and off-site.	Evaluating and refining the off-site prefabricated process layout and activities to implement reclaim materials and waste management
4	Build continuous improvement & Deconstruction, reuse, waste management and refurbishment.	Adopting a life cycle approach to manufacturing methods of PC which achieves waste reduction.
3	Reduce on non-valuing adding activities & Design for disassembly and adaptability.	Optimising a production process of modular construction through eliminating unnecessary transport or material usage.
2	Reduce cycle times & Design for disassembly and adaptability.	Shorting the design phase of PC through standardising the designs and incorporating disassembly principles
2	Reduce on non-valuing adding activities & Reuse, waste reduction and off-site.	Removing activities through the off-site manufacturing production of modular panels, where exact amounts of materials are ordered.
2	Reduce on non-valuing adding activities & Deconstruction, reuse, waste management and refurbishment.	Optimising the production process through eliminating nonvalues activities within the prefabricated construction process and reuse of reclaimed materials in a controlled environment
1	Build continuous improvement & Design for disassembly and adaptability.	Designing modular building components that can be removed and producing them in an offsite location where it is easier to introduce continuous improvement.

BENEFITS AND LIMITATIONS OF THE INTERACTIONS IN PREFABRICATED BUILDINGS

Table 4 shows the main benefits that were mentioned within the papers. The papers were analysed completely and any main points taken regarding the benefits were noted. The results showed that the benefit of PC was “Shorter construction time” and “Design for disassembly” occurred the most frequency with the occurrence of 2. Whereas the least mentioned was the “Higher quality of work”.

Table 4: Definition of identified benefits

Benefit items	Definition	No.
Higher quality work	Refers to fabricating building components with precision and accuracy with small tolerances which results in a consistent quality product. This can be strong, durable, uniform dimensions higher resistance items. In the context of PC refers to: precise dimensional accuracy, consistent finishes, improved safety and stringent quality control.	1
Shorter construction time	Refers to the reduction in time in which is needed to construct or complete a project. In the context of PC it refers to using off-site fabrication in a controlled environment.	2
Design for disassembly	Refers to designing a building to be disassembled at the end of the life of the building. In the context of PC refers to modularisation sections such as façade panels.	2

Table 5 was structured to present the three main limitations mentioned, which was captured from the filtered 25 papers. The results showed that the limitations of PC were “Limited Knowledge known in the field / Uncertainty” had the most frequency with the occurrence of 3. Whereas the least mentioned was “Design Restriction”.

Table 5: Definition of identified Limitations

Limitation items	Definition	No.
Limited Knowledge known in the field / Uncertainty	Refers to a situation where there is lack of information or understanding about a certain topic or element. In this context, PC.	3
Design Restriction	Refers to the limitations or constraints that the designer must consider while creating a product or system. This can include cost, material availability, and aesthetics.	1
Need for business model innovation / Lack of technology	Refers to the necessity in which a business needs to develop new strategies and approaches to either have a competitive advantage or maintain their position. Whereas lack of technology refers to where businesses or individuals have limited access, or unable to utilise, modern tools and processes.	2

DISCUSSION

THE ANALYSIS OF THE ALIGNMENT OF LC & CE IN PC

Analysing the created matrix of the alignment of the interactions of LC and EC and how these can be applied to PC results, it is possible to interpret what those results mean for the relationships of the alignment and applying it to PC in the built environment.

First in the table 2, shows the alignment of LC application and CE practices had the greatest number of mentions of interaction with “Focus on the complete process" & “Deconstruction, reuse, waste management and refurbishment” with 11 occurrences throughout within the 25 papers. This happen mostly because they are interrelated and are crucial for promoting circularity and achieving sustainable construction practices. A comprehensive approach or focusing on the complete process guarantees that every phase of the building process, from design to demolition, is efficient and optimises minimisation of waste and use of available resources (Benachio et al. 2021). Reuse, deconstruction, waste management, and refurbishing are examples of circular economy techniques that are crucial for reducing waste and fostering resource efficiency (Akhimien et al. 2021). Table 3 and the supporting citations further support and explain how this interaction of aligning LC principles and CE applications can be optimised to construct sustainable and efficient buildings through utilising resources and focusing on the complete process.

The other alignment of LC application and CE practices had the second highest number of interactions with "Focus on the complete process" & "Design for disassembly and adaptability" having occurred 6 times throughout the 25 papers. This happened because they are essential to implementing life cycle optimisation and resource efficiency in the built environment. By focusing on the entire process ensures that all the stages of construction process from design to disposal are streamlined to optimise reduction of waste and improve overall resource utilisation (Ghisellini et al. 2018), whereas, designing for disassembly and adaptability is an essential part of CE practices to promote the effective use of resources and reducing waste. This is through creating structures and building systems that are simple to disassemble and reuse at end-of-life stage or when buildings no longer fulfil their purpose. By aligning this LC principle and CE practice they can work together to opposite the goal of resource utilisation and waste generation can be minimised.

The other alignment of LC application and CE practices had the third highest number of interactions with "Focus on the complete process" & "Reuse, waste reduction and off-site" having occurred 5 times throughout the 25 papers. This happened because they are both essential in optimising resource utilisation and reducing waste generation in the built environment. As mentioned previously, focusing on the complete process is an essential part in achieving maximisation of resources used and in reducing waste production. Whereas, reuse, waste reduction and off-site construction focuses on the construction process by minimizing on-site waste generation, promoting efficient resource utilization, and reducing the carbon footprint (Parker et al. 2023). While these practices are essential for encouraging sustainability in the built environment, they have a less effect than procedures such as deconstruction and refurbishment that lead to more optimal resource utilisation (Johns et al. 2023). Additionally, off-site construction may contribute to the reduction of on-site waste, and it can have an impact of increasing transportation of module components which relate emissions produced, thereby partially offsetting the benefits. In result, the synergy between the alignment of LC and CE remains a crucial part to reducing waste generation and promote sustainability, hence why there is less emphasis than the other alignments ranked higher.

THE BENEFITS AND LIMITATIONS

Table 4 lists out three benefits of PC that were found within the analysed 25 papers and the occurrences of them. It is noted that not all 25 papers explored nor mentioned PC in them. The highest occurrence of the benefit of applying PC in the built environment was both "shorter construction time" and "design for disassembly" with 2 occurrences. Shorter construction times occurred the most as prefabrication enables the manufacturing of components off-site, whereby contractors can put together the structures simultaneously on-site without interfering with other on-site activities. This happened because PC components are constructed off-site away from the site location and generally in enclosed environments, enabling works to be completed favourable without weather-related delays, leading to less delays. The controlled environment of a warehouse eliminates weather rated interruptions such as rain, heat and other extreme conditions that would stop works using conventional techniques on site, as they are deemed unsafe for workers that frequently contribute to delays. Although there are allowances within the construction program for weather delays, this factor is unpredictable as weather conditions can vary (Purchase et al. 2022)**.** This leads to more controlled and predictable delivery programs, ultimately contributing to accurate constructions times. Additionally, using PC streamlines the site process, thus reducing the time of equipment and materials movement on site. Traditional on-site construction can vary from project to project as how the site is operated is up to the Principal Contractor. However, items such as Crane time, Manitou bookings and delivery slots are all items that can contribute to delaying materials for workers to be able to install/build. Therefore, factories can design layouts specifically for assembling components to reduce non-valuing adding activities such as material movement on site and deliveries. Design for disassembly occurred the most as it has become a popular concept of PC in the built environment as it promotes the ideology of considering a buildings whole life cycle not just its purpose during the operation stage. This happen because all contributors in the built environment such as architects, engineers, consultants, clients, and principal contractors are more conscious of the negative impacts construction has to the environment and how resource extraction is not sustainable. Designing for disassembly has been seen and applied within the Australian construction industry, through Design for Manufacturing and Assembly (DfMA). A principal contractor, Built Pty Ltd, has implemented DfMA in a recent project for a 200-worker office for Sydney Metro and who is delivering the new airport project. Built incorporated CE thinking, through an innovative modular structure design. This allowed the building to be disassembled and reassembled (relocated), providing a successful example of the possibilities and opportunities of PC (Graham 2023).

While prefabricated building provides numerous advantages in the built environment, there are certain drawbacks that must be addressed. Understanding and managing these constraints can lead to more successful and efficient construction projects. This talk will delve deeper into some of the key constraints of using prefabricated building in the built world. Table 5 lists out three limitations of PC that were found within the analysed 25 papers and the occurrences of them. It is noted that not all 25 papers explore nor mention PC in them. The limitation that had the most occurrences was "Limited Knowledge known in the field / Uncertainty" having occurred 3 times throughout the 25 papers. A significant limitation in the application of PC to the built environment is the lack of knowledge and uncertainty surrounding the field. This is because although the PC method is a sustainable solution to reduce labour and materials demand, PC methods are less preferred over conventional construction. This results from a lack of understanding regarding the advantages, restrictions, design, and construction of PC within the industry. From the lack of knowledge and experience about PC design, logistics and installation of PC and influenced by the lack of technical standards, contributes to the limitation of implementing this method in the built environment (Navaratnam et al. 2022). Due to the lack of knowledge and experience of PC within the built environment, it can cause clients and stakeholders wary of the concept and result in oversights or omissions in implementing it.

CONCLUSION

Through the systemic review, this paper collected, analysed, and interpret the credibility of academia and industry materials. This process provided a comprehensive understanding of the current state of knowledge regarding the alignment of LC and CE principles in prefabricated construction within the built environment. The research paper, as a result of this review, successfully identified the key benefits and limitations associated with the integration of lean and circular economy principles in prefabricated buildings. The research findings succinctly presented the most frequently occurring alignment of LC principles and CE applications concerning various stages of a building's life cycle. This information was utilised to determine how the alignment influences prefabricated construction applications, thereby contributing to the strengthening and evolution of prefabricated construction practices within the industry.

However, it's crucial to recognise the inherent limitations of a systematic literature review. The effectiveness of such a review is contingent upon the quality of the research it incorporates. Despite the availability of various techniques for quality evaluation, this paper utilized Scopus as a singular source to obtain filtered papers, employing several steps to refine the selection. While Scopus is a reputable source, it is not without potential limitations. Human errors or the unavailability of all relevant resources from this single source can introduce biases. Additionally, the process of selecting materials meeting the paper's requirements might inadvertently include or omit low-quality resources, impacting the overall validity of the study's conclusions.

Future research should focus on examining specific materials or elements of prefabricated construction that could benefit from circular economy approach while meeting lean construction principles. Here are some areas to be considered for further research and avenues:

Case Studies: Conduct case studies on prefabricated construction projects that integrate the concepts of lean construction and the circular economy. Such case studies can provide insights into the practical application of these ideas in real building projects.

Comparative analysis: Contrast prefabricated construction projects applying circular economy and lean concepts with traditional construction projects to demonstrate the advantages of each strategy and identify potential areas for improvement.

Integration of life-cycle assessment: Explore the inclusion of life-cycle assessments (LCA) in the examination of lean construction and circular economy principles in prefabricated buildings. LCA allows for a comprehensive evaluation of the environmental impact of a system or product throughout its entire lifecycle.

Sustainability assessment: Further investigate the sustainability benefits of incorporating lean and circular economy concepts in prefabricated construction. Evaluations could assess the advantages in terms of the economy, society, and the environment, including reduced waste, lower material usage, and increased productivity.

Furthermore, recognising the potential and difficulties in aligning lean and circular principles could direct the creation of creative solutions to integration roadblocks. The potential effects of applying lean and circular economy principles to prefabricated construction within the broader context of sustainable construction practises could also be explored in more detail. This would highlight the chances to cut waste, boost efficiency, and improve the environmental, social, and economic impact of the construction industry.

INSERTION OF MODULAR CONSTRUCTION ALIGNED WITH LEAN PRINCIPLES: A CONCEPTUAL MAP MODEL

Marcos Henrique Bueno da Silva [1], Elisa Atália Daniel Muianga [2], Kaio Pimentel Rego de Oliveira [3] and Ariovaldo Denis Granja [4]

ABSTRACT

The construction industry presents increasing levels of competitiveness among sectors, increasingly demanding products with higher value-added and sustainability. However, problems such as: production capacity, product quality, meeting deadlines, cost control and low productivity are always in evidence for this industry. Therefore, this work aims to present strategies for inserting modular construction in projects in the housing sector. This constructive method allows the application of innovations, increased productivity, control of costs and deadlines, products with greater added value, as well as the development of lean principles in the sector. Due to the complexity involved in the theme and the limited academic development and market for the application of this construction method, this work presents a conceptual map with strategies for inserting modular construction, offering a synthetic vision for companies in the sector that wish to follow the path of modular construction can better understand the main opportunities, barriers, risks and strategies. Market externalities and alignment with lean principles are also presented. For this purpose, the Design Science Research methodological approach was used.

KEYWORDS

Conceptual Map Model, Modular Construction, Lean Construction, Real Estate.

INTRODUCTION

The construction sector is important throughout the world economy. Due to the high competition, project-oriented industries such as the construction industry need to introduce more efficient systems (Toosi & Chamikarpour, 2021). The sector coexists with the design of complex products and has some peculiar characteristics, inherent to its environment (Koskela, 1992).

Efforts to promote innovation and modernization into the construction sector are in development, however, less than other sectors, classified as a low-technology sector in research, development, or innovation practices application (Reichstein et al., 2005). It is perceived as a sector constantly at risk, given the reduced profit margins, high production costs and little

concern for the end customer, also considering its slowness in adopting new knowledge (Seaden & Manseau, 2001). The lack of knowledge induces the use of conventional materials, products or services, inhibiting the use of innovative construction technologies.

In scenarios where real estate heats up and increases in input and labor costs, construction companies are forced to look for alternatives to conventional construction systems. In this sense, the use of off-site construction elements can be considered a path (McKinsey and Company, 2020).

Modular construction (MC) has shown superior results in terms of efficiency, when compared to the results of traditional construction. However, MC presents barriers that should be considered and overtaken, such as knowledge gaps regarding the high initial cost, the requirement for an innovative design process, the complexity of the supply chain and social perception (Broadhead et al., 2023).

Another fact that should not be unconsidered when thinking about the transition of traditional construction systems to MC is the growing need to produce housing units around the world. The world population grows at a rate of approximately 200K inhabitants per day in large urban centers (WEF, 2016). This growth imposes the need to provide adequate housing infrastructure. Considering the issue of productivity and conventional technologies, it is unlikely that the production of housing units will be able to meet this growing need for new buildings.

MC can help reduce the housing deficit, given the characteristics of such a constructive mode. Providing off-site prefabricated components with precision, efficiency, controlled cost, quality, safety and functionality increases the overall productivity of architecture, engineering and construction (AEC) industry. Countries such as the United States, United Kingdom, Sweden, Australia and China have been adopting modular construction to solve the housing deficit (Bello et al., 2023).

The use of industrialized construction methods may help solve important and historical construction problems, such as workflow instability, low productivity, lack of punctuality and delays (Deakin et al., 2020). These problems are also solved by applying lean practices. The benefits of applying lean concepts in MC have been documented in various case studies (Velarde et al., 2009; Nahmens and Mullens, 2012; Yu et al., 2013; Heravi and Firoozi, 2017). The main benefits are increased productivity; reduced waste, especially costs; improved safety conditions; increased job satisfaction and improved sustainable solutions.

The MC industry has an affinity with the manufacturing industry. This increases the synergy between lean concepts and MC, without forgetting the challenges that MC brings, such as the need for product customization, variable market demand and the involvement of the supply chain (Höök and Stehn, 2008). Thus, lean practices can be incorporated into the entire production flow of MC, involving the application of lean design management, lean supply chain management, lean production management, lean transportation management and lean site-assembly management (Innella et al., 2019).

The main questions of this work are: What is the contribution of MC in the construction sector?; What are the main barriers, opportunities and risks for expanding the use of MC in line with lean principles and how to consider them in viability studies?

The path to be taken by companies in the civil construction sector, which seek to align and implement modern and sustainable construction methods (such as MC) still has numerous barriers and doubts. Therefore, this work aims to present the beginning of a solution to this problem, with the aim of facilitating, through a conceptual map, the choice of the best path for the insertion of MC.

MODULAR CONSTRUCTION

DEFINING THE CONCEPTS AND PURPOSES

MC is a different way from the traditional building system and can be defined as an industrialized construction system compatible to be transported between the factory and the construction site (De Carvalho & Scheer, 2019). In this construction mode, work at the final construction site is minimized and prefabrication is maximized. Technologies are employed that facilitate off-site manufacturing and the transport to the assembled site, like a Lego® (BCA, 2022).

The term used for MC may suffer considerable variations. The definition is different in distinct parts of the world, as it considers different views and interpretations, more or less complete. The following terms are found in the literature: prefabrication, pre-assembly, modular construction or off-site construction, which can make understanding difficult (Gosling et al. 2016). Other terms may still exist: prefinished volumetric construction, permanent modular construction, prefabricated modular construction (Doermann et al., 2020). These terms are used interchangeably and encompass a variety of different approaches and systems (Bertram et al., 2019).

Industrialized construction is the rationalization of the work process in the construction industry to achieve cost efficiency, greater productivity and quality (Girmscheid and Scheublin, 2010). Off-site construction is the planning, design, manufacture and assembly of construction elements in environments outside the construction site (Australia, 2022). In this work, the definition adopted is that modular construction is the process in which a building is constructed off-site, under factory plant conditions with a controlled environment, using materials, codes and standards that resemble conventionally built facilities (MBI, 2019).

In addition to the definition of MC, this can be considered as the pinnacle of prefabrication, involving the most integrative measures of modules made in a factory with greater added value (Pan & Hon, 2020). It refers to the manufacturing and assembly of modules in a location other than the final installation location, after which such modules are sent to the installation location and assembled to form a complete building (Doermann et al. 2020). In general terms, modular construction involves the production of standardized components of a structure in an off-site factory, for subsequent assembly at the final construction site (Bertram et al., 2019).

STRATEGIES TO MODULAR CONSTRUCTION

Modularization, prefabrication of subsystems, standardization and industrialization of processes, increasing product value and making processes more efficient in terms of resources and time (Jonsson & Rudberg, 2013). Strategies to modularization of construction have recently attracted interest from academics and professionals in the sector. However, there are few studies that comprehensively classify different strategies. These must be suitable to develop innovative design solutions, improve the quality, cost, schedule performance of a project, allow flexibility in the use and maintenance of a building (Peltokorpi et al. 2017).

Modular product design is at the heart of any effort to utilize modularization in the production system. A "modular" design differs from the conventional strategy in that it includes a discrete mapping of functional elements to product components and specifies interfaces between them (Ulrich, 1995). Modularity becomes an attribute of the product (activity of structuring a product into modules). Coupling between modules allows product variants to be created, mixing and matching components according to the functions each user needs (Bask et al. 2011). Functions are hierarchical and that a single component must implement a specific "package of functions" rather than a single specific function (Peltokorpi et al. 2017).

To the production strategy, decisions regarding the necessary equipment are required, as well the factory layout, the level of automation required, production organization and planning methods (Ravn et al., 2015). Therefore, attention must be paid to this issue from the beginning of the project, considering the competitive priorities defined for investment in the enterprise (Jonsson & Rudberg, 2013).

Peltokorpi et al. (2017) presents four paths to modularization, according to the degree of product standardization and off-site production, with traditionally constructed buildings at the lower end evolving to the upper end with fully modular buildings. The paths are: – a. modular buildings (3D - pre-assembled volumetric units, composed of whole or connected modules, meaning the highest degree of off-site production and standardization); b. volumetric pre-assembly (building modules are produced off-site and assembled at the final construction site inside an independent built structure – example – the insertion of a bathroom or a kitchen; c. non-volumetric pre-assembly (2D - pre-assembled elements that do not create usable space – example – wall panels, floors or roofs); d. conventional buildings (raw materials and components, such as bricks and mortar, are used in construction at the final building site, indicating a high degree of customization and a lower degree off-site production and standardization).

The set of the first three categories provides a good basis for investigating modularization strategies, since the distinction between them is based on the hierarchical "packaging" of functions embedded in a single component. Understanding the different dimensions of MC, their interconnections and possibilities for achieving various objectives may support professionals select the most appropriate strategies for a specific context (Peltokorpi et al. 2017). Such strategies, for this work, are defined in three: construction with panels (2D), volumetric (3D) and hybrid (2D + 3D).

OPPORTUNITIES AND BARRIERS TO MODULAR CONSTRUCTION

In general literature on this topic, similar impressions from different authors, from different schools and parts of the world are found (BCA, 2022; Bello et al., 2023; Bertram et al., 2019; Broadhead et al., 2023; Deakin et al., 2020; Doermann et al. 2020; McKinsey and Company, 2020; Pan & Hon, 2020). In one hand, the main opportunities for MC: accelerated construction cycle, increased productivity, increased quality, safer and healthier working conditions, enables cost control, reduced volumes of construction components to be stored, improved sustainability (reduced waste of materials, the generation of dust, noise and carbon emissions, water consumption, as well as the possibility of greater recycling or relocation of such modular buildings). In other hand, the main barrier are: high initial costs for production and training, more complex of transport and logistics, production capacity limitations, market vulnerability, lack of technical knowledge, adversarial/resistant culture of potential customers, inadequate business model and supply chain configuration, lack of specific standards, codes and regulations, government support, lack of qualified professionals.

LEAN PRINCIPLES IN MODULAR CONSTRUCTION

Lean principles have greatly evolved through the Toyota Production System (TPS). When developing their products, companies must seek greater competitive advantage, launching better products onto the market more quickly, with attractive prices for their potential buyers and eliminating waste in production.

Since the origins of this new production paradigm, several sectors have made efforts to apply it. The pioneering work to introduce these principles in civil construction was Koskela (1992). Since then, researchers and companies have sought to interpret and adapt to this environment, as well as discussions and case studies can be found in the International Group for Lean Construction papers (Picchi, 2003).

However, lean principles became known worldwide through the publication of Womack et al. (1990), where briefly, the objective is to produce more value for the customer with less waste. Some of the lean tools are present in the AEC industry, like: Last Planner System (LPS), Value Stream Mapping (MFV), Integrated Project Delivery (IPD) and 5S. The benefits linked to their application are improved quality, reduced waste, increased productivity, increased safety and health at work (Almeida & Picchi, 2018).

Considering the five lean principles proposed by Womack & Jones (1997), disseminated and adopted in several industrial sectors, this work seeks to present their alignment with strategies for insertion of MC – a. Value: understand what value is for the customer and offer greater added value; b. Value Stream: identify and eliminate waste throughout the value chain; c. Flow: production in stable flow, without interruptions; d. Pull: produce only when demanded by the customer or previous process; e. Perfection: continuous improvement through rapid detection and resolution of problems at the base. Lean principles aim to continually improve the competitiveness of companies in the sector, employing methods that seek to reduce waste and meet customer requirements. Issues involving sustainability are important lean guides (Koskela et al., 2010). Through methods and tools, we seek to mitigate common problems in the sector, such as the high environmental impact and lack of efficiency in production (Almeida & Picchi, 2018).

Some of the main impacts and benefits arising from the implementation of lean principles may be collected in publications: standardization of work, improvement in productivity and working conditions, focus on value, formation of specialized teams, improvement in planning and control of work, transfer of knowledge between projects, collaborative project, integration with suppliers, reduction of lead time, reduction of waste and costs, greater customer satisfaction, increased company competitiveness (De Freitas & Costa, 2017).

The existing literature about modular construction addresses dispersed points of view. It is common for MC to be approached with individual factors such as design, planning, coordination, automation or benefits and barriers. At the same time, the literature about the synergy between lean principles and MC is also dispersed. Each work usually evaluates the specific use of a concept or tool. So, there is a gap in the understanding of the alignment of these concepts in a systematic way. Thus, the main constructs of MC are dispersed, especially when related to lean principles. For this reason, this work uses concept maps to define and relate the main constructs of the subject. This creates a logical sequence between the constructs to guide the adoption of MC by organizations.

RESEARCH METHOD

Design Science Research (DSR) was applied as a research methodology. DSR is a method which seeks to solve a specific problem, develop innovations, methods, models, product and process improvements (Dresch et al., 2015).

The objective of DSR is to develop concepts for solving complex and relevant problems in a given context, often based on a multidisciplinary study. DSR combines description and prescription (Aken & Joan, 2004). This approach is seen as a way of producing scientific knowledge that aims to lead to innovative solutions and artifacts to solve real problems and, at the same time, contribute to the evolution of theory in the area in which it is applied (Cole et al., 2005).

The literature provides guidelines for the DSR process (Shrestha et al., 2018). DSR presents six phases summarized from: development of a relevant practical problem; definition of objectives and expected results; development of a artifact (models, methods, constructs, instantiations, and design theories); demonstration of artifact effectiveness; evaluation; and diffusion (Dresch et al., 2015).

This research is part of a doctoral research, in which it is expected to formulate a complete model for the insertion of MC in the sector. Thus, the research we sought to understand the alignment of the MC concept and its contribution to the construction sector. For this, a literature review was developed to understand and identify MC strategies, and opportunities for its application. Studies on MC were assembled and data were collected to construct the conceptual map model.

ARTIFACT - CONCEPTUAL MAP MODEL

The development and use of a new theory may present some challenges to ordinary understanding. Conceptual maps, among many other tools, may be used to clarify the understanding of a new theory. Such maps present a visual structure that can graphically explain what is being studied (Maxwell, 2012).

Concept maps can be created for a variety of purposes, such as: making information from existing theories visible, clarifying an existing theory (allowing implications and limitations to be observed), developing a theory (helping to observe connections) and identifying gaps or contradictions, helping to find better solutions for a particular theory (Maxwell, 2012).Concept mapping has been shown to help learn, create new knowledge, structure and better manage organizations (Novak & Cañas, 2008).

Although concept maps may seem like just a graphical representation of information, understanding this tool and using it properly will lead the user to see that this is a powerful tool. The organization of concepts with connecting words can be simple at the same time, but also full of complexity and important meanings. A conceptual mapping was developed in this research to understand the concept of MC and its association.

MODULAR CONSTRUCTION CONCEPTUAL MAP MODEL

The Conceptual map model (Figure 1) presented the main characteristics, limitations and points of attention for each of the strategies considered, as well as seeking to relate the main barriers, opportunities, risks and externalities that surround MC. The tool (Figure 1) is composed of two parts: the first, which involves the concepts contained in boxes, and the second, which involves the relationships between these theoretical concepts. Furthermore, it also presents connectors, words that connect concepts and express relationships between them (Novak & Cañas, 2008). In line with each of these aspects, connections with lean principles were also presented.

As a way to guide the good understanding and application of the conceptual map model, a brief explanation of its use and the main themes involved is interesting. The MC is organized through six strategies: opportunities, risks, externalities, 2D MC, 3D MC, hybrid MC, which are associated with lean principles. For each strategy, information gathered in literature to construct the conceptual map are presented, as follows.

OPPORTUNITIES

Control
Safer
Quality
Sustainability

Initially, the opportunities of MC are verified, such as control and reduction of construction deadlines, cost control, healthier and safer working conditions, better control of quality standards and the possibility of developing a more sustainable environment. The deadline to execute these works is shorter than those for conventional works, and significant reductions can be achieved (McKinsey and Company, 2020). Cost control comes with the possibility of increasing productivity, due to better defined construction standards. This connects with the lean principle of standardization of work applied to construction and can increase performance with the use of lean cost management, the Target Value Design (TVD) (Koskela, 1992; Ballard, 2011). Regarding working conditions, there is less physical workload and fewer workers at the final construction site, improving the general organization and increasing work safety (Deakin et al., 2020). Lean practices address the concept of safety in its essence, bringing it from the theory of the Toyota Production System to lean construction (Koskela, 1992). Sustainability is also improved, being perhaps one of the greatest benefits of opting for MC, with the reduction in consumption of energy sources and natural resources, carbon emissions, waste generation, and general impacts on communities around to constructions (Bertram et al., 2019). The use of lean principles improves the sustainability of products, especially with the use of Value Stream Mapping (VSM) (Rosenbaum et al. 2013).

RISKS

Construction Standards

Business model

Suppliers

There are additional risks mapped, collected through the authors' work experience in construction and literature. To insert MC, it is necessary to develop specific standards, codes and regulations for this type of construction (Bello et al., 2023), without which, linked to incentives from government entities, the dissemination and encouragement of industrialized construction cannot be advanced. There is also a need for a new business model for companies in the sector and the adoption of a collaborative project, including the required digital transformation and improvement of relationships with suppliers. This can be achieved through the effective use of the value stream principle, using the VSM, for example.

EXTERNALITIES

Traditional methods

High competition

Resistant culture

Value understanding

Resource

Delimitation

Previous studies (Deakin et al., 2020; Bello et al., 2023; Doermann et al., 2020) have demonstrated that the main externalities and challenges focus on issues involving market conditions and the culture of potential customers to the MC. This collaborates with the first lean principle, which deals with value. It is necessary to evaluate the value chain, especially considering customer requirements (Womack & Jones, 1997). The high competition between companies in the sector and the preference of agents in the production chain for traditional methods, has an arrow indicating the box that the decision by MC, since these are aspects that must be considered in the decision. Searching for improvements in the production system and breaking away from the use of traditional methods is related to the lean principle of perfection, which involves the search for continuous improvement (Womack & Jones, 1997). Regarding the opposing culture and understanding the value propositions of potential customers, it was decided to indicate the opposite direction for the indicative arrows, since they are basic and conditioning aspects and must be analyzed even before any intention to the construction method. Finally, we have the challenges related to financial resources for production - which are considerably higher, since it is assumed the need to install and maintain production in an off-site manufacturing environment (Deakin et al., 2020) and price delimitation that keeps the product competitive compared to the market in general (De Mello et al, 2015). For these last two, a two-way relationship was used, as it is understood that they are necessary for the decision of the MC insertion, as well as being feedback with information within the process. Thus, the use of lean concepts and principles can reduce these challenges by eliminating waste and optimizing resources, as has been widely presented in lean literature.

2D MC

Design process
Workforce
Needs
Capacity
Flexibility
Entry, Cost

When evaluating the 2D strategy, a simpler modular construction method, it appears that it is quite attractive as a gateway to this world. Transport costs are lower, since the panels are two-dimensional, allowing a greater number of elements in loads. Like all labor involved in MC, it requires workers with greater training compared to traditional construction. It is important to highlight the production capacity of panel suppliers, a large quantity of flat elements are required.

3D MC

Impacts
Resources
Productivity
Construction speed
Specialized labor
Flexibility

As MC strategies are considered, when evaluating the 3D strategy, a greater number of considerations are made. This construction mode, even today, is disruptive, with almost all construction being off-site. Issues relating to logistics and transport stand out, given the size of the volumetric modules, transport conditions and costs, as well as the need for large equipment for lifting and coupling the modules. In this scenario, there is a greater need for initial resources in the manufacturing units to enable the construction of modules (Bello et al., 2023), on the other hand, there is difficulty in obtaining resources from financial institutions, both to finance production and to finance potential buyers of the units, who have a much shorter period of time to amortize payment for the product during the construction phase (which in many cases is a fraction of the time compared to traditional construction). There is also low architectural flexibility and great difficulty in changing the project on site, which requires more sophisticated and integrated projects, in addition to more specialized labor.

HYBRID MC

Flexibility
Vulnerability
Optimisation
Workforce, Areas, MC use
Impacts

As for the hybrid strategy (2D+3D), at the current stage of MC knowledge and application, it can be considered the most ideal scenario. Combining flat and volumetric elements optimizes transport and logistics, as well as allowing wider use of off-site elements. These factors lead to medium architectural flexibility, allowing greater customization of buildings.

The lean principles are indicated in the conceptual map model, linked to the constructs, in order to indicate the principle evaluated as most adherent and aligned. What can be seen is that most of the alignment of lean concepts are related to "value", where one must seek to understand what value is for the customer and offer greater added value through the chosen strategy. This is in line with customer resistance, one of the main barriers to adopting modular construction. By analyzing, managing and delivering value, the customer reduces their resistance. Reducing customer resistance can increase the procurement of modular products, bringing a gain in scale. Increased scale helps to reduce other barriers, such as direct and indirect costs and financing. For some constructs, lean principles were not aligned, due to the difficulty of establishing the most appropriate principle or because this establishment was not possible.

The main contributions of this research were the following: (i) Classification of the MC concepts into strategies groups and associations between them; (ii) Proposal with opportunities of MC context with inclusion of different models (iii) Results of the organization and relationships between the constructs, within of a group of strategy. The conceptual map classifies and organizes the main constructs of MC and evaluates their relationships with each other. The map includes the relationship of the constructs with lean principles and presents the externalities that impact the main constructs.

With the conceptual map, the Architecture, Engineering & Construction sector may identify possible paths for adopting MC, evaluating different modularization strategies based on their needs, conditions and points of attention. With the externalities, organizations can structure strategies to overcome the challenges pointed out. The MC may contribute to MC adoption perspectives, considering externalities (barriers) and main opportunities in each strategy.

Overall, the conceptual map provides a basis and direction for decision-makers to choose paths for adopting MC, taking into account the requirements and resources needed for each path. This leads to a more conscientious and informed adoption, with well-defined paths.

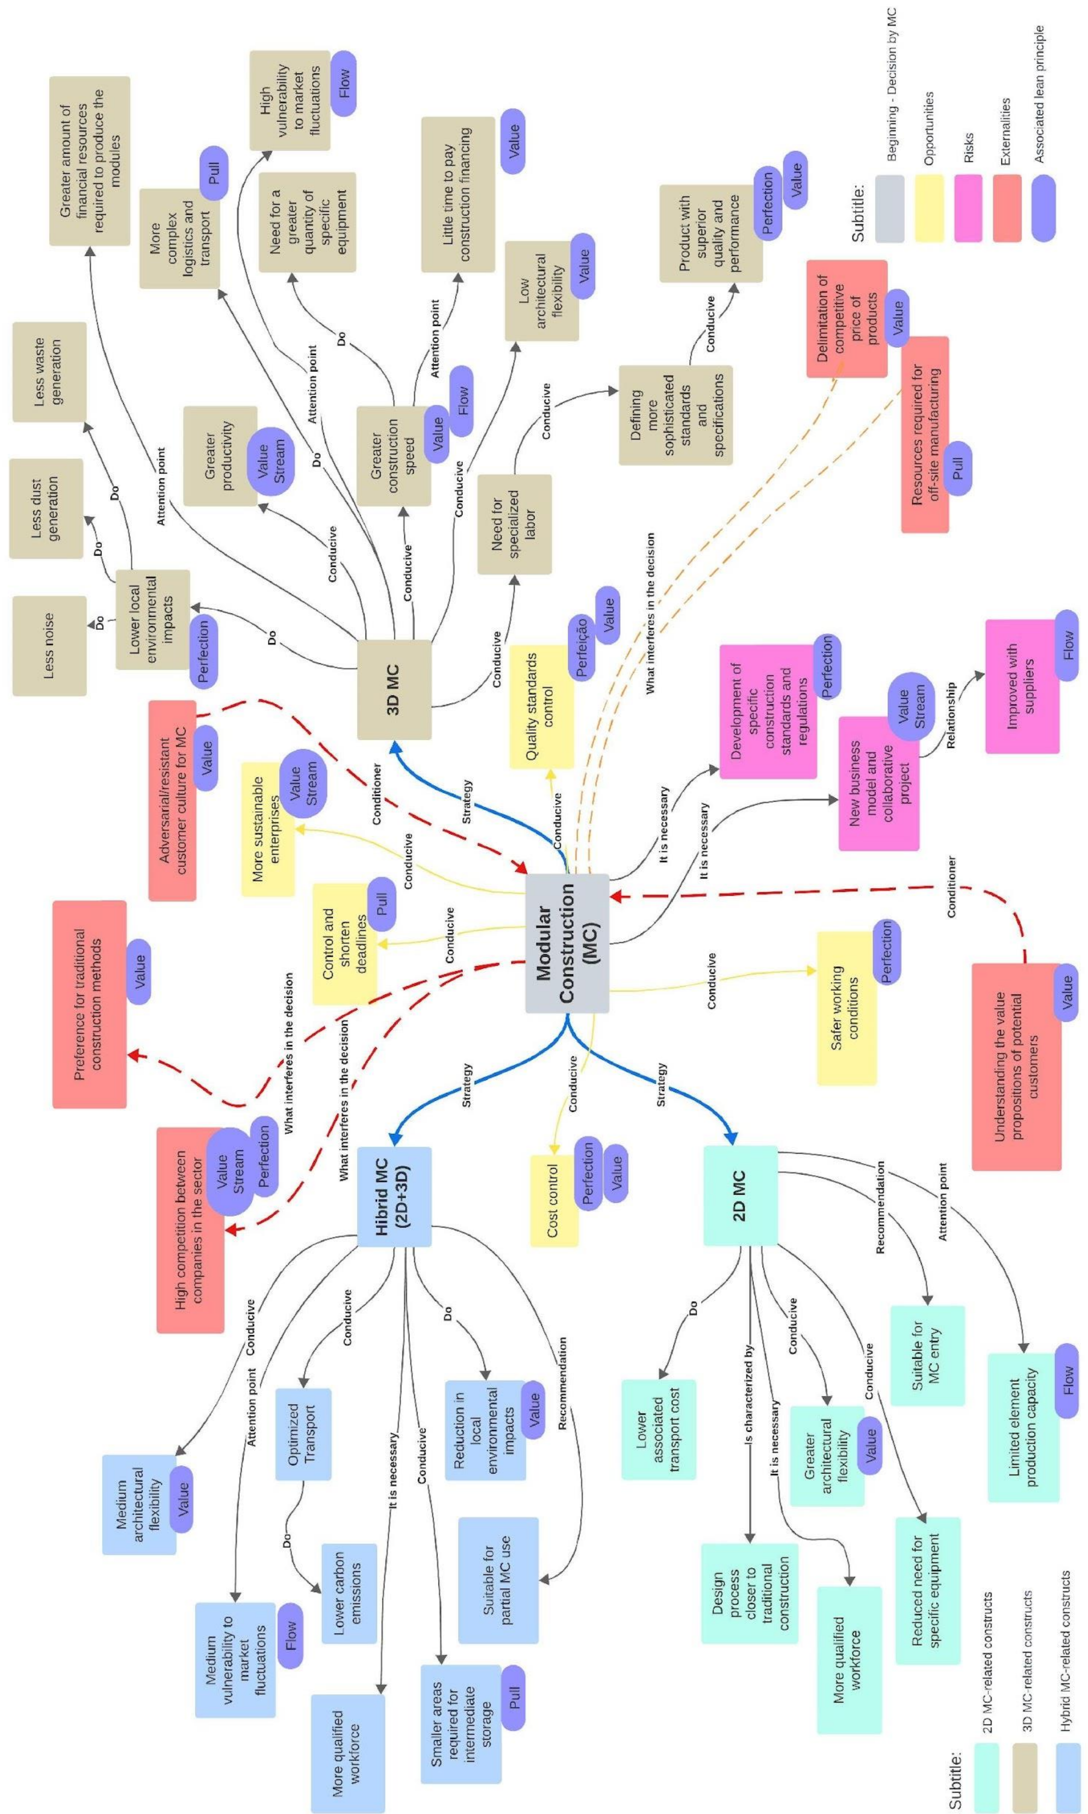

Figure 1: MC Conceptual map model. Source: The Authors.

CONCLUSIONS

Lean principles allow complete alignment with MC, since it is a mentality already widely spread in the manufacturing industry, as well as bringing new paradigms, applicable to the business, involving the development of the product as a whole and the relationship between agents of the production chain.

Precisely because MC requires that construction companies, markets and potential clients have new conceptions about this construction method, the application and alignment of lean principles allow choosing the best paths to be followed for the insertion and expansion of employment of this constructive way, considering the necessary reviews of project flows, supplies and execution of works, as well as the production and business model of each company in the sector.

The conceptual map model presented facilitates the understanding of possibilities and paths through the synthetic visualization of alternatives. Each one of the constructs presented can be analyzed in more detail, allowing one to choose the most appropriate MC strategy for each company or enterprise.

The lack of studies that analyze the MC application through different strategies, in different contexts, mainly where traditional construction models are more effective limit the analysis of MC applicability in a real context. Thus, future and complementary work may explore each MC strategy, adapting and analyzing the particular ones in light of the main opportunities and barriers identified. As for lean principles, specific works may study each alignment proposed for each construct present in the conceptual map model. Increased studies in this area will certainly lead to the development of more innovative, sustainable construction techniques with greater added value.

ACKNOWLEDGMENTS

The authors would like to thank the academics who participated in this study, providing important insights to construct the conceptual map model. DEFINING INTERFACES TO FACILITATE BUILDING MODULE CHANGE

Peter Zieth[1] and Cecilia Gravina da Rocha[2]

ABSTRACT

Modular construction in the building industry remains largely misunderstood, despite numerous studies on the subject. With confusion around what constitutes a module, how it is defined and differentiated from other modules, and how they interface. This study examines interface characteristics; types, standardization, and reversibility (three measurable categories based on Fixson (2005) function-component allocation (FCA) tool for product architecture assessments) and assesses product architecture interfaces to apply them to building product architecture. The intent of this examination is to understand the interface's role in any transfer of module functions across modules. Defining interfaces to better differentiate building modules from each other should ultimately facilitate the identification of what specific functions of the building component modules that need to be designed, manufactured, assembled, changed, and disassembled. From the examination, the discussion arising seeks to advance on how a building spatial module function designation might transfer functions at an interface, to provide clarity on the functional requirements for component modules to meet.

KEYWORDS

Modular construction, prefabrication, flexible manufacturing, interfaces.

INTRODUCTION

Modular construction in the building industry remains largely misunderstood, despite numerous studies on the subject. With confusion around what constitutes a module, how it is defined and differentiated from other modules, and how they interface. In the context of product architecture (or product modularity) each component, or module, can be made up of modular sub-components, or connected subassemblies. Likewise, each module, when connected, forms a product (Ulrich, 1994). Further explained in the referenced authors' study, these connections, or interfaces, can be coupled, such that a change to one component requires a change to the other (e.g., changing a ball hitch size on a car requires a change to the hitch on the trailer which is to be attached) or de-coupled (Figure 1) where no such dependency exists (e.g., a mobile phone and protection case). While a modular architecture includes one to one mapping of the function to the component (e.g., for a car trailer, the function being the transfer of a load to the road is mapped to the wheel component), an integral architecture includes complex mapping of functions to components (e.g., a car chassis) (Ulrich, 1994).

As has been studied, those interfaces may be 1) coupled (nuts and bolts), tightly coupled (welded joints), decoupled (furniture in a room), or loosely coupled (door hardware and door

leaf) (Sanchez, 1995; Schilling, 2000; Ulrich, 1994), or 2) an interface type across families of modules (doors to walls across room types) (Pine, 1999; Salvador et al., 2002). Both sets of interface types have applicability in building modularity.

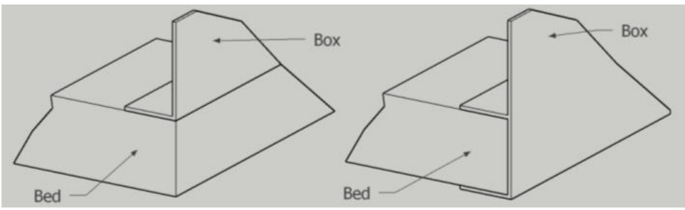

Figure 1: De-coupled Interface, left, Coupled Interface, right.
(Adapted from Figure 4 in Ulrich, 1994)

Using Ulrich's definition of a module, a study (Fixson, 2005) looked at (i) what is a function, (ii) what is a component, and (iii) how the function was allocated to a component. While the first part of the Fixson study is important in framing a discussion on modules, how a function is allocated to a component (modular or not) could apply to a product and a building product equally and is therefore not the focus of this study. Understanding interface characteristics though and their role in the functional allocation transfer from one component to another potentially has the greatest ability to facilitate building module decoupling and change.

Ulrich proposed six motives for change in products (upgrades, add-ons, adaption, flexibility, wear, and consumption) (Ulrich, 1995). Changing, making, and unmaking a building product is of particular interest since buildings are typically designed and constructed to serve a specific function for an expected period (Askar et al., 2021), namely, its design (or service) life. When applying Ulrich's motives for change to the design life of building product components, they could be organized into three groups: (i) replacement (wear and consumption), (ii) retrofit (add-ons and adaption) and (iii) change in use (flexibility and upgrades).

Regardless of the mechanism initiating change, design strategies (specific plans of action to accomplish an objective or set of objectives) which increase the flexibility of a building, and allow for change to be easily carried out, have been studied (Gosling et al., 2013; Keymer, 2000; Slaughter, 2001). These include strategies grouped into; the use of interchangeable system components, increased layout predictability, improved physical access, dedicated areas for systems, among others, but do not examine a process designers can use to facilitate these strategies. Other authors have looked at the absence of initial design consideration for potential change that leads to different levels of disruption in building operations once component parts of a building need to be changed (Gleeson et al., 2011; Grussing & Liu, 2014; Knyziak et al., 2017). Indeed, occupants can be subjected to a diminished use of the building in normal day to day activities once changes need to be performed (Tokede & Ahiaga-Dagbui, 2016). One of the studies (Gleeson et al., 2011) categorized disruption and demonstrated that different levels of disruption are connected to the complexity/extent of change (intervention), and highlighted the importance of identifying change potential to guide the design of components and the relationship to adjacent components. What the components do, what their interfaces are, and their arrangement with the rest of the product is referred to as the product architecture (Eppinger & Ulrich, 1995; Fixson, 2005; Gershenson et al., 2003; Ulrich, 1995; Vickery et al., 2015). What these studies don't do, and is needed, is to provide a consolidated process for designers to use that lead to design outcomes that can facilitate change activities while limiting disruption.

The second part of the Fixson study examined product interface characteristics, types, the degree of interface standardization, and the interfaces' role in making, changing, and unmaking (disassembling) the product (its reversibility). When considering a building as a product, it becomes important to understand the definition of an interface between modules to better identify the type of coupling, what is the level of modularity (modular or not), and what the modules are. The aim being to evaluate an alternative interface definition to help identify and distinguish building modules more clearly so they can be manufactured and assembled, while also facilitating change, the speed of construction, disassembly, maintenance activities, and environmental outcomes for material reuse and recycling.

Conducting desktop research of literature identified an issue with applying a definition for interfaces from product modules to building modules. The literature review looked at the basic differences between building product architecture as compared to product architecture before examining how building module interfaces are identified between building modules. This review conceptually examined how interfaces might be used to facilitate change. The study then considered parameters that define an interface, before devising and applying an alternative conceptual interface definition to the Fixson study, specifically when conceptually applied to buildings. Particular attention is given to the interface characteristics of type, reversibility, and standardization before a conclusion is drawn and implications are identified. The developed knowledge from the research and analysis will help to better identify and differentiate one building module from another and can be further tested using more analytical research methods.

BUILDING PRODUCT ARCHITECTURE

When applying the concepts of product modularity to buildings, there is a key difference between buildings and products. Buildings utilize components to create spaces typically occupiable by people, whereas products typically involve only the physical components (C. Rocha et al., 2015). An obvious exception may be cars, that contain spaces occupied by people, but differently, buildings are anchored/founded on a specific piece of land. Buildings also typically have longer life cycles and involve multiple different stakeholders influencing their change over that period (Menassa & Baer, 2014), and they often remain occupied while changes occur to them. Whereas modular (or integral) products, like a car, tend to be deactivated completely while change occurs (e.g., changing a wheel, or a battery). It also implies that if a building typically remains occupied while changes occur to it over time, there is a potential high degree of change variability inherent due to the diversity of potential stakeholder input. Whatever those changes are should also facilitate the ability for occupants to remain while the changes happen to the affected components, and those components should be made to be easily changeable to limit the disruption to occupants.

BUILDING MODULE INTERFACES

To facilitate the potential for change to modules in buildings, there must be an initial recognition of the differences between product and building modularity. Examining the concept of product modularity levels (a chunk, divided into sub-chunks), and how they could be divided, as applied to buildings, was a study (C. G. da Rocha et al., 2018) that focused on modules being spatial voids (rooms) with components being used, or not used, to create spaces (with walls and doors, for example, being used to differentiate one module family from another, Figure 2). There are two outcomes of this study worth highlighting: (i) components are not needed on all sides to define a space, but the interface connection between spatial modules is, and (ii) spatial voids are formed by at least six surfaces (the latter logically assumes rooms are cuboid).

The Rocha and Koskela (2018) study conclude there are interface connection surface problems at the junction between two modules. In this case, the interface connection surface is a single shared wall of two different spatial modules like a Bedroom (Room B) and a Bathroom (Room A) on either side of the wall in Figure 2. With the interface connection problem being where the two modules have potentially different requirements for that shared wall, like the location of a door that necessitates changes to the components forming another module like the

Bathroom cabinet in A1 to B2 modules in Figure 2. It implies the interface may not be correctly identified or located between modules.

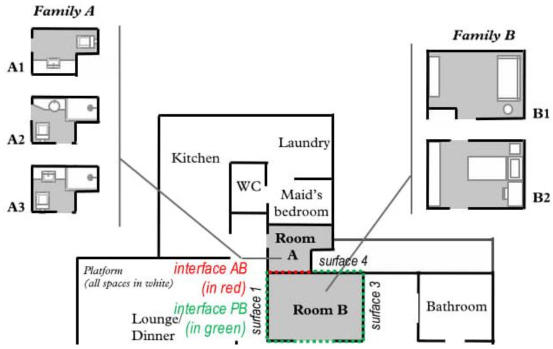

Figure 2: Example of building module component variances from the differing positions of fixtures, doors and windows, and services. (Adapted from Figure 2 Rocha and Koskela 2002)

The Rocha and Koskela (2018) study considered spatial modules to also contain building components such as walls surrounding a spatial void, along with other associated doors, windows, and fixtures. While component-oriented building modules are not always bounded by components on all sides, due to the arrangement of boundary components, a change to one module necessitates a change to an adjacent module. The result implies these modules are more integral and requires clarity of the interface definition if a modular outcome is desired.

Maintaining the assumption that spatial void modules are cuboid and formed by at least six 'surfaces' implies that modules are limited in their ability to be universally adaptable (sectional modularity) with other modules since the surfaces (including doors, windows, fixtures etc.) of a particular module are fixed. Hence that module is limited in its ability to be universally adaptable for use with other modules because of the location of those features that conflict with the adjacent module at that interface. Further a module interfacing with another module along the length of a shared wall, between Rooms A and B in Figure 2, points to potential difficulties of constructing, manufacturing, and coordinating individual modules to facilitate a connection.

However, the interface surface problems could be resolved if modules are more clearly differentiated by viewing and defining the interface differently. Firstly, a building product architecture could be a combination of both component-oriented and space-oriented modules. This is not a new concept, but it needs to be described to understand the second point. A building module could be a component (door, wall, window, floor) and it could be a spatial void (room) (Figure 3) to make the appropriate scale of these module interfaces invariant. While a component may be an object, like a wall, a spatial void could also be considered a component because a function can be mapped to it. For example, placing a bed in a room implies the function of a room is for sleeping and is therefore a Bedroom. Applying this perspective to building modularity means that every surface of a spatial void (room), and every surface of an object component (wall), all being different modules, could interface with each other.

Secondly, if the proposal was that spatial voids are formed by at least six 'planes' (e.g. boundaries without physical mass between two spatial voids) instead of 'surfaces' (e.g. associated with a solid mass such as a wall), then there is flexibility in the definition of a building module to allow for interfaces with other modules that are not dependent or linked to a surface. This approach places emphasis back onto the role and characteristics of the interface.

The notion that a module could interface via a 'plane' with either a component that has surfaces (i.e. physical mass), or another spatial void constituting any number of 'planes' (i.e. voids), provides a more appropriate product architecture module definition to a building. It allows, for example, walls, portions of walls, or the absence of a wall (the void that might otherwise be occupied by a wall defined by its 'planes'), all to be modules, and rooms (or voids) to be modules, with or without walls.

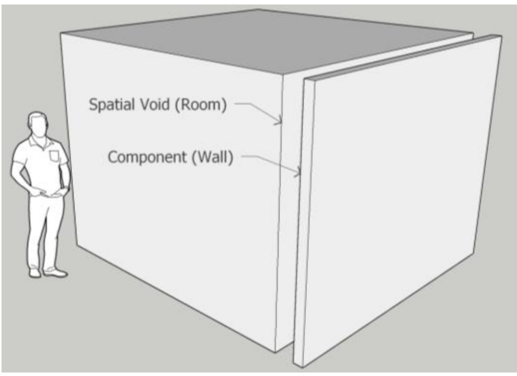

Figure 3: Component-oriented (wall) and Space-oriented (room) building modules where every surface of each module is an interface.

By extension, if consideration of the spatial void definition is applied to a component, then, a component, having surfaces that are co-located with a plane means that all building modules, be they spatial voids or components, are bounded by planes (having no physical mass). This means that all building modules have planes that interface with other planes. Simply, the building module plane is the interface, regardless of it having a surface or not.

BUILDING MODULE INTERFACE DEFINITION

The concept of product modularity initially focused building modularity on being spatial voids (rooms) with building components being used, or not used, to create the spaces. Further analysis of literature resulted in concluding that a product architecture module definition for a building could be that (i) a module (spatial or component) could interface with either a component, that has surfaces, or a spatial void constituting any number of planes, and (ii) while components are not needed to define a space, and a space could itself be a component, an interface connection between modules is required. This definition raises two questions 1) if a module could interface with either a component that has surfaces, or a spatial void that has planes, would it be simpler to refer to the component surfaces as planes, and 2) if components are not needed to define a space (ceiling or walls for example), is there a limit to the number of adjacent components required in order for that space to be considered a component module?

If a module's surface coincides with a plane, then the first question is addressed. However, if the second question was not addressed, it could be surmised that a cubic void of air not within a building could be considered a building module. While there are practical benefits to defining exterior air 'space' as a module when allocating functions from that space to a building module to address (wind, radiant heat from the sun, rain, atmospheric pressure, humidity, for example), this interpretation is useful only in allocating those atmospheric functions to the building and its constituent component parts. Namely, from an overall building module set of functional requirements allocated to the rooms and wall modules being examined here. Maintaining the limitation of applying building modularity to physical buildings, and not outdoor natural environments, it therefore implies that a building module must be bounded by components: a built environment having a floor at least. How people perceive a defined space is not the subject of this paper, however, the purpose of the distinction is to clarify a revised product architecture module definition for a building. That definition being that a building module (i) constitutes any number of planes that coincide with component surfaces and spatial void boundaries, and (ii) an interface connection between modules is required. A building module could therefore be either a spatial void that has met certain boundary conditions, or a component, and requires an interface connection. This conclusion is reinforced by a study (C. Rocha et al., 2015) that aimed to adapt product modularity to be used for house building that concluded solid mass components (walls, roof, floors) create spatial voids for the activities of the people within.

Returning to Ulrich's concept that a modular architecture includes one to one mapping of a function to the component, and an integral architecture includes complex mapping of functions to components (Ulrich, 1994), requires examination of the application of functions to building modules when considering the module interfaces. Using Ulrich's definition of a module, a study (Fixson, 2005) looked at (i) what is a function, (ii) what is a component, and (iii) how the function was allocated to a component. As referenced previously, while the Fixson study is important in framing a discussion on modules, it is the interface characteristics and role in the functional allocation transfer from one module to another that potentially has the greatest ability to facilitate change of building spatial or component modules. It is the examination of product interface characteristics, types, the degree of interface standardization, and the interfaces' role in making, changing, and unmaking (disassembling) the product (its reversibility), that is of interest, and applying them to a building product architecture to see if they can facilitate change.

The result of the Fixson study was the development of a tool (a device or implement to carry out a particular function) for assessing interface linkages between the product, process, and supply chain of different designs of similar products. This tool, albeit intended for manufactured products, could be adapted for application to assessing building modules and is the subject of what is tested in this study. The intent of adapting the tool would then be to reverse engineer it for possible use to define adjacent component modules more clearly for manufacturing purposes.

To assess how the tool could be adapted for application associated with building modularity, an understanding of the interface role needs to be examined against the product function for its nature and intensity as applied to a building using the definition of an interface being a plane. For the purposes of demonstrating the concept as applied to building modularity, I will use a building in the form of a six-sided cuboid that contains a series of cuboid forms (room spatial modules) linked together and separated by other, narrower cuboid forms (walls and floors component modules) like those of other studies (Ching, 2023; C. Rocha et al., 2015). Figure 4. For further simplification and clarity, the exterior boundary cuboid forms (exterior walls, floor, and roof component modules) will not be used in the demonstration and can be examined in further studies. Using two adjacent room component modules of similar function, for example, a bedroom-to-bedroom relationship, there are characteristics (privacy, insulation, visual amenity, for example) of the component function (bedroom 1) that must be transferred through the interface plane (interface characteristics) into the component function of another product (wall) for that product to perform (opacity for privacy, insulate for warmth, color and texture for visual amenity, for example) prior to transferring through another interface plane (interface characteristics) to another component function (bedroom 2) for it to perform (opacity for privacy, insulate for warmth, color and texture for visual amenity, for example) and vice versa. Figure 5.

The Fixson study (Fixson, 2005) assessed three different interface characteristics: (i) type (the interfaces role for the product function), (ii) reversibility (the interfaces role for making, changing, and unmaking the product), and (iii) standardization (the interfaces role regarding substitutes). These will be recapped below with interpretations of how they might be applied to a building product architecture.

TYPE

According to the Fixson study, the type of interface is initially determined by (i) their number and distribution across the product, (ii) their nature, and (iii) their intensity.

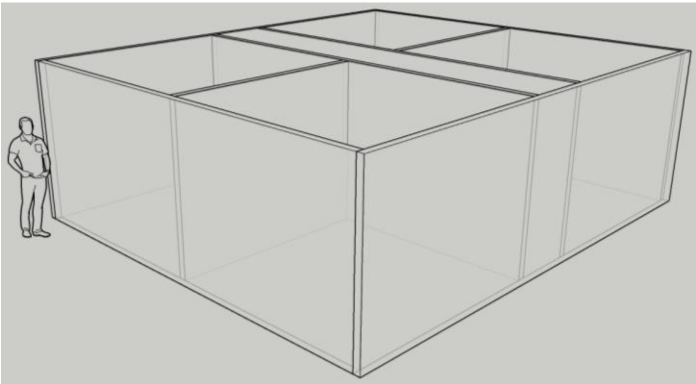

Figure 4: Cuboid that contains a series of cuboid forms (room component modules) linked together and separated by narrower cuboid forms (walls and floors component modules). Roof/Ceiling removed for visual simplicity.

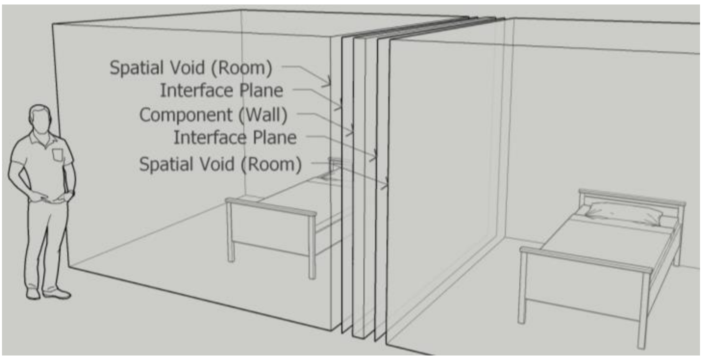

Figure 5: Bedroom-to-bedroom component function (bedroom 1) transfers through the interface plane into the component function (wall) to another interface plane to component function (bedroom 2) and vice versa.

Determining the number involves a simple counting of the interfaces. In the example, these interfaces are the boundary planes. A room component module shown in Figure 5 has primarily six; the ceiling, the floor and four walls. This number could be expanded if there was a window component module in one wall and a door component module in another, for a total of eight. Honing the example, for a wall separating the other room, there is only one interface plane to each adjacent component, the room to wall, or two interface planes if you add a door. Services (electrical, ventilation, communications systems, for example) interfaces are not referenced here for simplicity. They are sub-components for this example and an outcome of how the interfaces of the room to adjacent components are managed and functions are allocated.

Distribution examines if a component interface interacts with a limited or significant number of other components (relative to the total number of components) (Fixson, 2005). If the interface does interact with a significant number of other components, the component may be general or central to the functionality, indicating if the product architecture is not very modular but fragmented. Fixson postulates that a fragmented product architecture is more likely to have many components that show interactions with many other components. This also generally applies to a building since the room component modules generally interact with a variety of other adjacent modules (walls, floor, ceiling, doors, windows, other rooms, and services of varying types) through their interface planes and is consistent with Ulrich's Integral product architecture. However, this is not the focus of this study.

It is the function of a room module that distinguishes it from another room module. At a very basic level, a Bedroom is called a Bedroom because it has a bed in it and is used for sleeping. A Dining Room has a table and chairs used for eating at. That is not to say that either of these examples cannot be used for other functions, but those other functions influence the functional allocation of that space, and hence the transfer of those functions to the interfaces for the adjacent components to meet, or not. Hence, the functional allocation has the potential to affect the adjacent component being manufactured.

Fixson's tool utilizes the outcomes of another study (Pimmler & Eppinger, 1994), that combines the nature of the interface (reflecting the physical effects that occur for the interface to play its intended role), and its intensity (its strength and desirability with respect to its nature), to assess the interface between components. At the component level, the tool assesses four types of interactions: (i) a spatial interaction (the need for adjacency or orientation – room to room adjacency for functionality, room to wall), (ii) an energy interaction (the need for energy transfer – room to wall for insulation, of heating), (iii) an information interaction (the need for information or signal exchange – room lighting activation), and (iv) a material interaction (the need for an exchange of materials – the passage of people through a door, or wind through a window opening). These interactions are further assessed by their importance and desirability levels. Each of these four interactions, at the interface, apply to building modularity and can be tested accordingly as was studied by da Rocha et al. (C. Rocha et al., 2015).

REVERSIBILITY

Considered to be an advantage of modular product architectures reversibility is the ability to change products over the product life, such as upgrades, add-ons, adaptation, wear, consumption, or reuse, and depends on the interface. The ability of a module to change depends on the difficulty to disconnect at the interface, and the interface's position in the overall product architecture (wall to floor being more inaccessible than a wall to room interface). In the example, the ability to change the room function, from Bedroom to Living Room, will be dependent on the ability of the interface planes reversibility with boundary components. Changing from one spatial module type to another requires changing function allocations at an adjacent wall component interface plane. If the wall component module meets the requirements of the interface, then reversibility conditions have been met. However, if the wall needs to be replaced due to it not meeting the performance requirement needed, then the ability to remove and replace the wall as facilitated by the wall components other interface planes (floor, ceiling, and adjacent wall component modules) is a measure of the components reversibility. For a wall it is not just one interface plane that is required to be reversible, but six. An example of low-level of reversibility of a component module might be a wood framed gypsum board wall that requires destructive removal of the gypsum board to expose stud framing nailed to the floor, that also needs destructive removal. Refer to the left side of Figure 6. A high-level reversibility might be a prefabricated wall finish panel clipped onto a wall frame that is bolted to a floor and ceiling. Undoing these clips and bolts facilitates removal and replacement without the levels of destruction the former example necessitates, as shown to the right side of Figure 6.

Fixson uses two measurables for reversibility; (i) the interfaces' own technical specifications (skill and equipment requirements to change the component), and (ii) how deep the component is 'buried' in the product. In the former, the room (spatial module) to wall (component module) relationship requires the interface plane to require the room function to be accommodated by the wall component function through the interface plane exchange and vice versa. What those requirements are will be the subject of further study. For the depth a component is buried, the room module is entirely accessible, however the wall component has other interfaces (the joints to the floor, ceiling, and other walls), that are less accessible. It may be easier therefore to change the function of a room module for technical and depth reasons, but harder to change the wall module since the wall to floor interface is connected and hidden.

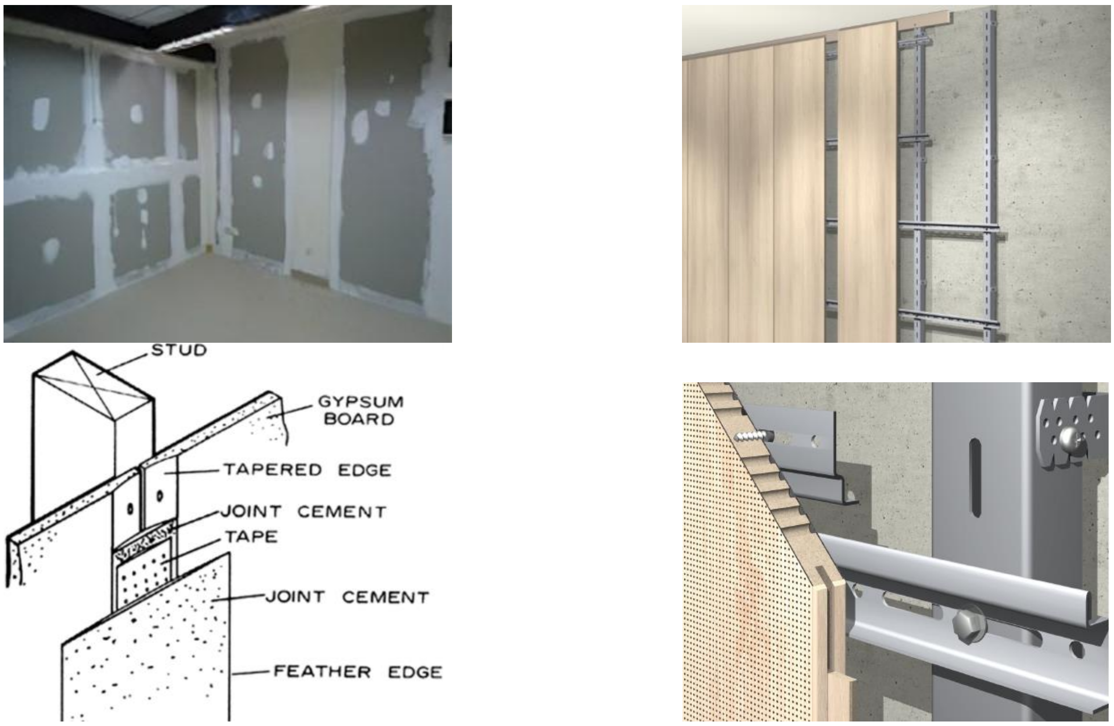

Figure 6: Left: Low-level reversibility wood framed gypsum board (Adapted from Civilguidelines.com images), and Right: high-level reversibility prefabricated panelized wall finish (Adapted from Ambienta Architectural Systems images)

STANDARDIZATION

The third characteristic Fixson describes, standardization, relates to the interface's role regarding substitutes. Considered to be critical for product variety, interface standardization measures the interfaces' role to facilitate module substitutes (components and spatial voids) and, in this case, building module component product families (room/spatial void types, wall modules, floor modules, ceiling modules, for example). Room types, like student accommodation rooms, or hotel rooms are highly repeatable, while a railway control center room is often a one off. For sub-components making up a module, the junction between a wall lining and the supporting wall is often a standard system (regardless of the degree of reversibility) as represented in both examples in Figure 6, versus a one-off rammed earth wall.

Standardization describes the degree to which an interface facilitates the swapping of components on either side of the interface. While standardization could be easily confused with Reversibility, a building example distinction for a component would be the difference between a nail and a screw. Both could be standard, but a nail does not facilitate reversibility, while a screw facilitates reversibility. Fixson clarifies that 'component swapping modularity and component sharing modularity do not describe the interface itself, but rather the alternatives that exist on either side of the interface.' The distinction being that component swapping, is usually where the larger component remains in the system, like a room, and the interface allows the exchange of the other one, like a wall. In our example of a room and wall, the larger component is exchanged by changing the function of the room from Bedroom to Living Room, hence it would be considered component sharing (the wall is shared), provided the wall component interface (the plane separating the two components – wall and room) with the room can accommodate the change of function. As a plane, this might seem straightforward for the interface between the two. However, the interface must be capable of exchanging all critical functions. Using the wall as the example, if the wall was acoustically rated for 40 dB (Decibels), and the Living Room requires separation to another Bedroom of 60 dB, the interface (plane) has failed to transfer the functional performance requirement since the wall component has only managed to address 40 dB of the interface requirement. The result being that the interface requirements must be maintained, and therefore the wall component module needs to be changed with another wall module type that meets those requirements.

Since interface planes in a building are similarly common across component types within a family, room to walls, for example, the interface systems are considered to have bus modularity. If the interface planes become standardized to the point they facilitate connection of every component with every other component, they would be considered sectional modularity. Looking at the types of interfaces at various similar module levels, rooms (spatial voids) to walls (components), for example, is where Fixson's Lego standardization example is fitting.

CONCLUSION

This study has taken a view from product architecture that a building could be a combination of both component-oriented and space-oriented modules. A building module could be a component (door, wall, window, floor) and it could be a spatial void (room) to make the appropriate scale of these module interfaces invariant. Further, spatial voids are formed by at least six 'planes' (e.g. boundaries without psychical mass between two spatial voids) instead of 'surfaces' (e.g. associated with a solid mass such as a wall). A building module plane is the interface for both spatial and component modules, regardless of having a surface or not. This view gives greater flexibility in the definition of a building module to allow for multiple interfaces with other modules that are not dependent or linked to a surface.

By applying product modularity definitions to building modularity, testing interfaces through a different lens to what other literature has used, and applying them to Fixson's tool, this study suggests the tool can be adapted and applied for use in building product architecture to define component module requirements. Following Ulrich's (1995) product architecture definition, after the function of the spatial void (room) is determined (and arranged in a floor plan), the functions can be mapped to the adjacent physical components (walls, ceiling floor, for example), through the interface plane connecting those components. Where interface planes (having interface characteristics, but no physical mass or thickness) are defined between spatial (rooms) and component (walls, floors, ceilings) oriented modules, with functions allocated to them from those modules, a clearer, more succinct set of component modules for manufacture and assembly can be defined.

IMPLICATIONS

The implications being that interface parameters assigned by the functional allocation from the spatial voids can be applied to an invariant interface database parametric management tool to be used for module component identification, selection, and meet functional spatial performance criteria. If used by designers initially, this tool, once developed, should provide building owners and maintainers greater certainty that the building designed will perform as intended, and can be maintained and changed easily while limiting disruption to occupants.

To inform an interface database functional allocation tool, more analytical research needs to be conducted into the design life of various components in various building types that make up assemblies, along with identifying the various change frequencies. This research will help inform the level in an assembly a modular or integral component might need to be. Additional research also needs to be conducted into the levels of disruption tolerable to building occupants in the various building usage types to help organize the modules.

The next step would be to define building module function categories (performance standards) from room requirements. These would be mapped to the interface characteristics (type, reversibility, and standardization) for transfer from a spatial module (rooms) across an interface plane to a component module (walls, floors, ceilings) and vice versa.

ABSTRACT

Prefabrication of mechanical, electrical, and plumbing (MEP) systems seems to be an obvious choice to some, while others are struggling to reach the same conclusions. Most of the literature is focused on benefits, implying prefabrication is an obvious choice. To understand reasons why different conclusions are reached, we studied two cases where one decided against, and one decided to use MEP prefabrication. While some reasons can be contributed to differences in project type, there are general conclusions to be drawn. Reluctancy to use prefabrication seems to correlate to first time experience of prefabrication, namely overestimation of direct costs, and underestimation of indirect benefits (obstacles). Moreover, in the second case, prefabrication was used as a tool to enable lean practices such as short takt time, low amount of waste, levelled production, and efficient flow of materials. The key difference between the two cases is, Case 2 uses prefabrication to reach a valued goal while Case 1 evaluated its utility without a real problem that could be solved by prefabricating. Based on the two studied cases prefabrication becomes a more attractive alternative when it is used as part of a systemic change to achieve a valued goal.

Prefabrication, Choosing by Advantages (CBA), Lean construction.

INTRODUCTION

The construction industry is far from other industries if measured by industrial revolutions (Lasi, 2014; Sharma and Singh, 2020). If compared to factory environment, construction industry has passed Mechanisation (Industry 1.0) and has entered to Electrification (Industry 2.0). As an example of current state, the workstation lighting is an essential part of electrification but is often not a normal part of the site's working conditions. For construction, Automation (Industry 3.0), Digitalisation (Industry 4.0) and Personalisation (Industry 5.0) are still waiting for realisation. Construction is done on-site by craftsmen as opposed to work being divided into manufacturing and assembly operations as in Industry 3.0. Womack et al. (2007) describe craft production of 1890's as follows: workforce was highly skilled in machine operations and fitting, organisations were extremely decentralised, although concentrated within a single city, general purpose machine tools were used, and production volume was very low. Same applies to on-site production in construction industry. Lean methods towards industrialisation are applied as isolated solutions, and the need for systemic change is often overlooked or not understood.

Prefabrication of mechanical, electrical, and plumbing (MEP) systems is an example of such an isolated Lean method. It has been suggested to solve the problem of low productivity and poor quality in construction. The term prefabrication does not have a clear-cut definition, but in general, it means moving work from construction site to factory environment, thereby reducing installation time on site. Documented benefits associated with prefabrication include lower time and material waste, better ergonomics, shorter lead time, fewer accidents, improved productivity, and better quality (Easmann & Sacks, 2008; Poirier et al., 2015; Lavikka et al., 2018). In addition to these non-monetary benefits, direct cost savings have also been reported, although evidence is contradictory (Khanzode et al., 2008; Jang and Lee, 2018). Decision-making frameworks have been developed to make non-monetary benefits visible for project members, as direct costs are easier to evaluate. Based on these previous results, adoption of MEP prefabrication seems like an obvious choice. However, the adoption rate in Finland and other countries remains low.

Studies have documented multiple obstacles hindering or preventing the adoption of MEP prefabrication. The following obstacles in adoption of MEP prefabrication have been reported by Lavikka et al. (2021) and Lopez et al. (2022):

- Prefabrication requires detailed designs earlier in the process, necessitating early design freezes. In traditional procurement, designs are not detailed enough for bidding prefabrication accurately.
- Lack of prefabrication procurement knowledge and resistance to change.
- Direct costs are the main bidding criteria.
- Lack of detailed modular designs due to lack of capabilities and the custom of designing one-of-a-kind buildings.
- Contract and union agreement boundaries.
- Lack of flexibility (design revisions).

Obstacles of prefabrication are making its adoption difficult but not impossible. Objectively balancing benefits and obstacles to decide whether to prefabricate is not simple, hence various evaluations methods have been introduced. Based on previous research Chauhan et al. (2019) proposed a Choosing by Advantages (CBA) based method for evaluating MEP prefabrication. Their proposed model answered to the need for transparency in evaluating non-monetary benefits in addition to direct costs. The need for such a framework was derived from the overemphasis on direct costs and the difficulty in translating other benefits to monetary benefits reliably. In CBA method, these non-monetary benefits are ranked between on-site and prefabrication alternatives to determine their relative advantage over each other. Finally, prefabrication is compared to on-site construction by combining the direct costs and relative advantage in one figure(Suhr, 1999; Arroyo, 2012).

Research literature lacks an explanation of why some companies choose to implement MEP prefabrication, and succeed in it, while others deem it unprofitable or impossible. In this research, two cases are evaluated. One decided to construct on-site and another decided to prefabricate. Differences in reasons contributing to these decisions are evaluated. The following research question is answered:

RQ: What are the differences in decision-making processes and motives resulting in the adoption and rejection of MEP prefabrication?

Prefabrication has the potential of being a more interesting alternative to a more significant number of projects by demonstrating why some choose to prefabricate. Broad adoption of prefabrication has the potential to significantly increase the quality and productivity of construction industry by enabling adoption of other Lean methods like takt production.

METHODS

Two case studies were conducted to determine differences in decision-making leading to different outcomes related to MEP prefabrication. Workshops, interviews, document reviews, and site visits were used as part of case study research. Case study research was selected to study differences in decision-making processes retrospectively.

New construction of an educational building was studied as Case 1, where the main contractor was interested in studying possibilities of cost savings by using MEP prefabrication. The main contractor had started the project using traditional on-site construction. They were interested in studying the possibility of MEP prefabrication for the current project and with future projects in mind. The phase of the current project would have enabled utilisation of some prefabrication. The company decided against prefabrication due to higher cost.

Renovation of residential buildings was studied as Case 2, where the main contractor had chosen to implement MEP prefabrication. The case company uses prefabrication for competitive advantage. They had decided to prefabricate before the study.

CASE 1

Three workshops were arranged to evaluate potential applications for MEP prefabrication and related benefits. The workshops were organised by the first author on initiative of the main contractor, having interest in studying possible advantages of MEP prefabrication.

In the first workshop, the project was introduced to all participants and a prefabrication programme was drafted listing all possible use cases for the project. Then positive and negative effects for project were listed for all alternatives, including effects on designing, schedule, additional responsibilities, and purchasing.

The second workshop focused on choosing two most attractive options for further assessment and determining of non-monetary benefits for both on-site and prefabricated solutions. This evaluation was done by utilising choosing by advantages method.

The third workshop was focused on determining costs for two application comparisons and comparing the combined effects of monetary and non-monetary factors in parallel. Possible implementation of prefabrication and reasons for these decisions were discussed.

The case project was a large new construction of an educational building with various use purposes. None of the participants had any significant previous experience in prefabrication, and they were all experienced professionals. Table 1 lists the participants. During the workshops construction was ongoing while designing and customer requirements were still developing.

Table 1: Workshop participants and their roles in Case 1.

Workshop participants	Role in project
MEP foreman 1	Electrical
MEP foreman 2	HVAC
Project manager 1, GC	
MEP designer	Design project manager
MEP expert, GC	Initial design
Construction manager, GC	
Project Manager 2, GC	

CASE 2

Case 2 was a renovation of an apartment building where the general contractor had chosen to implement MEP prefabrication. To study the prefabrication process and to document the reasons for adopting prefabrication, interviews, site visits, and document reviews were conducted. The interviewed people are presented in Table 2. The interviews were semi structured interviews focusing on reasons for adopting prefabrication and specific methos of implementation of prefabrication. Document review and site visits were used to study the process of designing and manufacturing prefabricated assemblies.

Table 2: Interviewed people and their roles in Case 2.

Interviewees	Role in project
Construction worker	MEP (on-site)
Construction worker	Prefabrication
Designer	MEP (prefabrication and site installations)
Team Leader	Foreman on-site (workers)
Group Leader	Foreman on-site (team leaders)
Development Manager	Development

RESULTS

CASE 1, COST IS KING

In the first workshop, a prefabrication programme was drafted recognising 15 possible use cases of MEP prefabrication in the case project. This included discussions of design scope, requirement for special prefabrication contractor, site and design schedule, material acquisition, site logistics, safety, and contractor capabilities. At this point, none of the alternatives were deemed impossible, while schedule of designing and construction was seen problematic in many cases. This was due to planned element installation during frame erection, which was not possible due to the project and design schedule.

In the second workshop, two most potential alternatives, a ventilation shaft with HVAC systems and a fully equipped door frame with Electrical systems, were selected for detailed CBA analysis. The ventilation shaft would consist of a supporting structure containing all ductwork within the shaft and be either one or two floors high. These elements would be installed during frame erection and manufactured in a separate location by the selected contractor. The door frame would include electrical installation in the panel adjacent to the door, including lighting switches, sensors, displays, and indicators. Both installations are typically made on-site.

The CBA compared onsite construction to prefabrication separately for both alternatives. For both evaluations, the prefabricated alternative was decisively preferred over on-site construction in the case of non-monetary factors. In the case of the ventilation shaft, 5 out of 7 benefits were assigned for prefabrication alternative. In CBA analysis, prefabrication had 270 importance points against 90 for on-site. For the doorframe, all benefits were assigned to prefabrication alternative, the total importance points being 320. The three most important factors in both evaluations were assessed to be safety, ergonomics, and material waste. The detailed evaluation is presented in Tables 3 and 4 for ventilation shaft and door frame respectively.

Table 3: CBA analysis of ventilation shaft, prefabrication versus on-site construction.

Factors	Prefabricated ventilation shaft	Imp.	On-site ventilation shaft	Imp.
Material waste	Attribute: Causes less waste. Better utilisation of cut pieces. Cleaner storage and handling. Adv: Causes less waste.	40	Attribute: Causes waste due to unused cut pieces and damaged ducts. Waste in insulation also.	-
Safety of workers and environment	Attribute: Risks in lifting of the elements. Decreases working in areas with a risk of falling. Adv: Smaller safety risks overall.	100	Attribute: More work in open shafts, risk of falling or dropping tools and materials.	-
Ergonomics	Attribute: Possibility to work in positions of better ergonomics and horizontal installation of ducts. Adv: Better working positions.	60	Attribute: Working in high and cramped spaces. Especially insulation is challenging, very small spaces.	-
Quality	Attribute: Supports and insulation are easier to install in steel frames. Adv: Fewer quality issues.	50	Attribute: Support of ducts need to be designed on site to fit the local conditions, variation to installation.	-
Flexibility of designing	Attribute: Design changes are more expensive or impossible.	-	Attribute: Design solution can be changed for as long as the installation is made, installation later compared to prefabrication. Adv: More flexible solution.	50
Logistics	Attribute: Lifted immediately to the right location and installed. Less site storage. Adv: Ready installation quickly from delivery.	20	Attribute: Hauling large ducts from site storage to shafts is challenging.	-
Design schedule	Attribute: Designing must be completed significantly earlier and takes more time due to increased LOD.	-	Attribute: Later installation and lower LOD, more available design time. Adv: More time for designing and, therefore, more flexibility for designing.	40
Total		**270**		**90**

Table 4: CBA analysis of door frame, prefabrication versus on-site construction.

Factors	Prefabricated door frame	Imp.	On-site equipped door frame	Imp.
Material waste	Attribute: Smaller risk for damage, affects waste, a significant factor. Adv: Elimination of broken equipment during installation.	90	Attribute: More waste caused by equipment broken during installation.	-
Safety of workers and environment	Attribute: Fewer accidents. No working in high places. Cleaner site. Adv: Fewer accidents.	80	Attribute: Many openings drilled on site to high locations. Causes debris to surroundings.	-
Ergonomics	Attribute: Possibility to work in an ergonomic position and use industrial methods. Adv: Better working ergonomics.	50	Attribute: Working in high places. Unergonomic working positions.	-
Maintenance and flexibility for changes	Attribute: Door frames equipped with extra conduit pipes, allowing for easy addition later. Adv: Better flexibility during the life cycle.	60	Attribute: Only what is needed will be installed; changes later are more difficult.	-
Logistics	Attribute: No need to store or transfer equipment on site. Adv: Less logistics and storage on site.	40	Attribute: Need to store equipment on site close to doors when door frames are opened.	-
Total		**320**		**0**

The third workshop focused on determining direct cost differences and adding the cost component of CBA. For the ventilation shaft, the direct cost of prefabrication was estimated to be 6% more expensive. Respectively for the door frame the prefabricated version was estimated to be 11% more expensive. Costs related to factors evaluated in CBA were not calculated due to the lack of an objective method for determining costs. The resulting CBA analysis is presented in Figure 1. In both cases, the prefabricated alternative scored significantly higher and was only slightly more expensive.

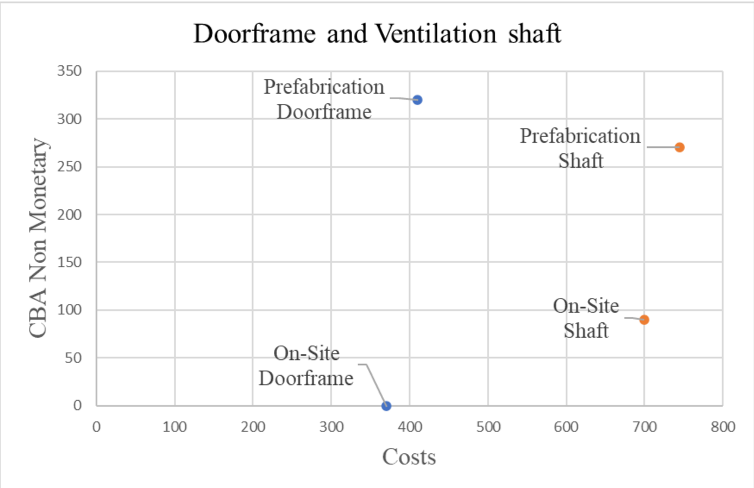

Figure 1: Effects of monetary and non-monetary factors of prefabricated and on site manufactured for ventilation shaft and doorframe with electrical installations.

All participants agreed that based on these results, on-site would be favoured in both cases. Competition for contracts being solely based on total cost was given as the reason for this choice. Participants acknowledged that quality and safety affect costs. They had ranked these as important factors. However, they did not trust the cost savings to be sufficient in comparison to direct cost without calculations. Without experience in prefabrication, they found it difficult to estimate the magnitude of cost saving. While there were no barriers preventing prefabrication, some aspects were found to hinder its adoption. These were designer capability (detailed modelling and schedule), construction schedule (designing concurrent to construction), and difficulty in evaluating possible savings from CBA factors in advance.

CASE 2, PREFABRICATION ENABLES INDUSTRIAL CONSTRUCTION

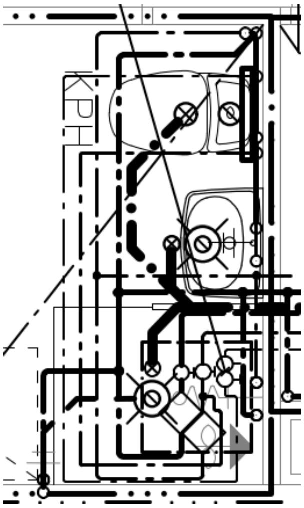
The case company prefabricated MEP systems for apartment building renovation. Prefabricated products included water, sewer, ventilation, electrical cables, heating, and suspended ceilings. The company had a goal of achieving competitive advantage by shortening lead times and improving quality by introducing practices of industrial construction. The company is considered a pioneer in the application of flow and takt production in Finland.

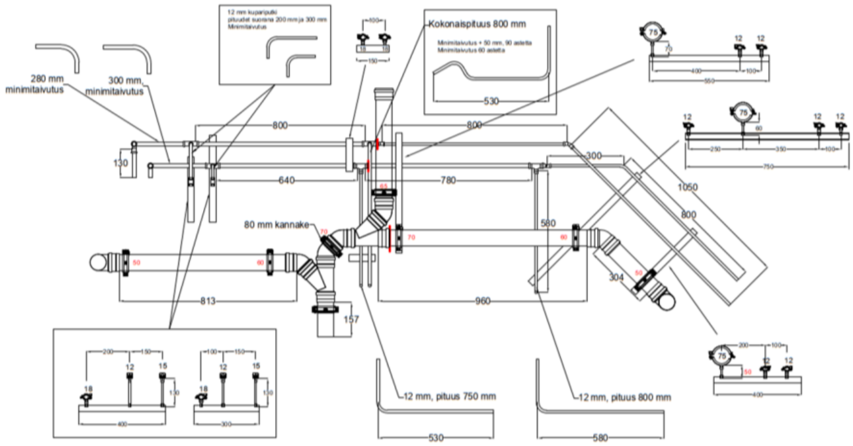
The business unit in question first adopted the Theory of Constraints (ToC) and Alliance business model but, in 2019, switched the production system to using Constant Work in Progress (CONWIP). This transformation was based on large amount of variability and difficulty of creating an efficient flow by using outsourced processes with multiple subcontractors. Additionally, the project team implemented a business model change by separating materials from work and using standard partners for work instead of per-project bidding. These standard partners were contracted on an hourly base as opposed to traditional contract work and quotas. The interviewees reported adopting these methods in stages during 2020-2022 in accordance with the Toyota organisation model (Liker, 2020) and Deming principles 11-14 (Deming, 1991).

Applying CONWIP enabled examining workflows in a high level of detail. Used parts, materials, work methods, and work sequences were documented at a minute level. As a result, traditional construction drawings and their low level of detail were abandoned. Instead, the company aimed at a standardised product by standardising work and materials using Manufacturing Bill of Materials (M-BOM). Knowing the exact M-BOM at each location made it possible to implement four-hour takt and move to precise takt logistics by utilising the Plan for Every Part concept described by Harris et al. (2011).

After standardizing work and drafting accurate M-BOM, increasing flow and shortening takt times require moving work from construction site to a separate workshop. Prefabrication was first adopted 2021. This separation of manufacturing from assembly was a transition towards industrialisation. Tests by the case company indicated a 23-46% time saving in total installation time by using prefabrication. Large-scale adoption of prefabrication with advanced on-site logistics further led to the shortening of takt times from four hours to two hours to realise shortened lead times. The effect on lead times was significant as the company reported having increased their yearly production rate from 150 to 320 apartments/year, while number of personnel has grown by 20%.

In the prevailing construction mode contractors bid both materials and work as fixed price (black box purchasing), based on construction drawings. These construction drawings, however, are not buildable, and as a result installers are responsible for installation designing. This undocumented designing by installers leads to significant variation in installations of identical apartments. The following installer, wagon in takt production, must take this variation into account and adapt, leading to ever increasing variation. Examples of traditional construction drawings and designs for manufacturing are presented in Figures 2 and 3.





Figures 2 and 3: Figure 2 (left) is a traditional construction drawing for water and sewer installation (LOD below 200). Figure 3 (right) is a design for prefabrication (LOD 400) containing three sub-assemblies (separated by red lines in drawing).

As traditional construction drawings do not enable the creation of M-BOM due to their low level of detail, separate designs for manufacture and assembly are needed. A detailer drafted high LOD designs using AutoCAD and their own library of manufacturer-specific parts. All support systems were also designed, and possible clashes were resolved. These assembly drawings contained millimetre-level cut lengths. Reuse of designs from project to project reduced design time as the number of projects increased. Figures 4 and 5 show the manufacturing and installation of underfloor heating.

Figures 4 and 5: Cardboard template (1:1, prototype design) for laying underfloor heating pipes in one bathroom type and later installed prefabricated module (white pipes on steel net).

Fabrication was scheduled according to a takt schedule, and work was divided into packages per takt area for one day. Team leader presented the fabrication schedule on a white board for workers in daily huddle. Team leader also either solved with the construction workers the arisen problems or escalated them to group leader in team leader's daily huddle. The logistical takt was based on on-demand deliveries of materials and parts with a two-day buffer. Figures 6 and 7 show subassemblies of pipes ready for transportation and installation itself. Four different consolidation points (wholesale, factory, site warehouse, and workstation) were in use, and logistics were carried out by specialised personnel.

Figures 6 and 7: Prefabricated pipe elements for vertical ascent in shaft ready for transportation (left) and connecting horizontal pipe elements with shaft elements (right).

DISCUSSION

Prefabrication was evaluated in Case 1 to win in almost all non-monetary factors and to be slightly more expensive. While most of the non-monetary criteria have a cost reducing effect, reliably evaluating their magnitude is difficult. As a result, the case decided against prefabrication. Since cost was the deciding factor, companies would benefit from an objective tool for assessing monetary benefits in case of non-monetary criteria. For Case 1, even relatively small cost savings could have favoured prefabrication over on-site construction. When determining direct costs for Case 1, the participants were able to assign additional costs to prefabrication (e.g., higher design cost or higher cost of manufacturing) but were unable to see monetary benefits from shortened lead time or fewer quality issues.

For Case 2 prefabrication allowed shortening lead times, improving quality, and profitability. Case 2 was focused on adopting Lean practices, one piece flow, takt production, and industrial construction where prefabrication was eventually used as a mean to achieve these targets. Case 2 shows all the obstacles identified by Lavikka et al. (2021) and Lopez et al. (2022) can be overcome. When construction drawings were not suitable for prefabrication, M-BOM was created, and a detailer was employed to draft construction drawings. It was also shown that the detailer does not need to have formal training in MEP engineering, but understanding of installation methods is required.

The decision-making processes for the two studied projects were very different. For Case 1 the process started with the question “Can prefabrication save us money?”. This question was eventually answered by difference in estimated direct cost compared to on-site construction. For Case 2 the process had started years ago with the goal of improving flow and shortening lead times, eventually resulting in competitive edge by being able to bid at a lower cost and complete more projects during the same time. Eventually through gradual lean implementation the company was in a position where transition to prefabrication was the natural next step to further improve, and they had gained the necessary knowledge for smooth implementation. Conversely, in Case 1 adoption of prefabrication would have been the first step towards industrialisation and would have caused the need for rapid development of culture, logistics, schedule, and designing, all at the same time.

While the projects in cases 1 and 2 were of different type, both companies operate in the same Finnish market and compete for projects in a market where contracts are won or lost based on cost. The two cases have differences in design schedules. Apartment renovations are bid on ready construction drawings. In larger projects designing is more concurrent with construction. This difference becomes less significant with the observation that construction drawings for bidding must be completely redesigned for prefabrication (Case 2) causing eventually similar concurrency as in larger projects.

The studied cases also differ in contracting. In case 1 the main contractor uses a separate MEP contractor. In Case 2 the company had previously used similar subcontracting business model but had observed that change to industrial construction necessitated removing subcontracts. This allows the case company 2 to control material acquisitions and logistics and efficiently lead the work of installers contracted on hourly basis, as opposed to fixed price contracts. Keeping prefabrication in-house drives costs down and prevents partial optimization by minimizing the cost of every subcontract. For example, in Case 1 the main contractor would certainly get higher bids for MEP contracts if asking for prefabrication since they would have to invest in capability. This gives the impression of saving money by choosing the cheapest non prefabricating bidder. When prefabrication is implemented by an experienced main contractor, keeping costs down and developing the process are more important compared to an independent subcontractor.

Bidding based on construction drawings is not necessary for prefabrication to be possible. Both customer and prefabrication will benefit from bidding with more schematic designs. This removes rework as detailer does not have to redraw all systems. As a result, customer saves money by reduced design costs for bidding phase and lower overall cost as the detailer does not spend time fixing original designs.

Based on our findings, similarly to O'Gorman et al. (2023), we suggest that only considering MEP prefabrication and direct costs related to it is not recommended. Contrary to O'Gorman et al. (2023), we however argue, that this is not due to lack of cost savings from prefabrication, but the incomplete question framing where prefabrication is considered alone without all other necessary transformations towards industrial construction. The only way for prefabrication to succeed is to implement and improve it over time as part of other methods of industrial construction. For example, a study by Chauhan et al. (2018) demonstrated that takt production and prefabrication benefit from each other. Simply suggesting to only consider non-monetary aspects is not feasible when contracts are won or lost based on the cost only.

This study is limited by low number of cases, which limits the reliability of drawn conclusions. Further investigations to a larger number of cases is needed to confirm the results and determine how project type affects the decision-making process. Additionally, these cases represent the situation in a predominantly non prefabricating market, and differences could be found from countries of advanced application.

CONCLUSIONS

The two studied cases highlighted fundamental differences in reasons motivating the use of MEP prefabrication. To answer our RQ about differences in decision making processes the following can be concluded. Participants of Case 1 were keen to study if prefabrication can be used to obtain cost benefits and Case 2 decided to use prefabrication to enable short takt time, short lead time, and increased quality, eventually translating to increased profitability. The main difference being instrumental use of prefabrication for immediate realisation of cost savings (Case 1) as opposed to a far-reaching cultural change towards industrial construction with prefabrication as part of it (Case 2).

Based on the observations of advanced lean adoption in Case 2 it is necessary to acknowledge the need for large cultural changes in moving towards prefabrication. Gradual transformation towards prefabrication through other lean adoptions increases the likelihood of success.

ACKNOWLEDGMENTS

This work has been supported by Talotekniikan esivalmistussuunnittelu (Designing for MEP prefabrication) project funded by Building 2030 Consortium. The Building 2030 consortium includes Aalto University and 21 companies from the Finnish construction sector.

BUSINESS MODELS EMERGING FROM INDUSTRIALIZED CONSTRUCTION ADOPTION

Alejandro Vásquez-Hernández[1], Luis Fernando Alarcón[2] and Eugenio Pellicer[3]

ABSTRACT

Industrialized Construction (IC) has been recognized as a promising approach to improving project performance. However, its benefits are not evident in the building as an entity. The background of IC reveals approaches limited to production methods, overlooking issues related to process, collaboration, supply chain, and market. IC represents a novel strategic approach for the construction sector, introducing a business logic distinct from that of project-based companies, which is timely to understand within the context of managing IC adoption. Business models (BMs) are constructs that can be employed as tools to describe and analyze such business logic. This article aims to identify in the literature the constructs proposed for analyzing BMs associated with IC adoption, their approaches, and business-configuring elements, and to identify the business models associated with cases reported in the literature. A systematic literature review and content analysis were conducted. The results revealed fourteen proposed BMs frameworks and two approaches to IC BMs. Furthermore, following the analysis of reported cases, thirteen BMs were identified, associated with seven groupings based on the roles and value chain clustering strategies linked to IC adoption.

KEYWORDS

Industrialized construction, modular construction, off-site construction, business model.

INTRODUCTION

The construction industry can mitigate the adverse effects of its relatively unstable production environment in two ways: by minimizing its peculiarities to leverage methods developed in other industries, or by developing techniques within the sector itself to address its dynamic nature (Vrijhoef & Koskela, 2005). These two approaches are closely related in the pursuit of lean construction, as aligning construction with manufacturing logics is a conducive scenario for lean (Egan, 1998). In turn, minimizing construction peculiarities involves achieving the lean objective of controlling processes (Vrijhoef & Koskela, 2005). Industrialized construction (IC) serves as a structural means for the former approach by adopting project-independent strategies and transferring site activities to the supply chain. However, the expected benefits of this approach have not yet been fully realized in the case of buildings as entities (Richard, 2012).

The background of IC reveals a focus that is limited to production methods, neglecting aspects of process, collaboration, supply chain, and market issues (Lessing, 2015). Many emerging problems in IC implementation experiences relate to adoption processes under a conventional context, in terms of organizational structures, project development models, working methods, and procurement methods (Ahamad et al., 2020). IC represents a new strategic approach for the construction sector (Hall et al., 2022). Its business logic differs from that of conventional construction companies, which are project-based (Lessing & Brege, 2015). Therefore, it is timely to understand how companies that have adopted IC operate. Business Models (BMs) are constructs that can be used as tools for such descriptions and analyses (Lessing & Brege, 2015). BMs are mechanisms through which a company's strategy is translated into a model of the logic for making money (Osterwalder et al., 2005) (Zott & Amit, 2008), emphasizing a systemic perspective on conducting business and aiming to explain both value creation and capture (Pan & Goodier, 2012). In this sense, it constitutes a unit of analysis in addition to product, company, industry, or network levels (Pan & Goodier, 2012).

In light of the above, this article seeks to identify in the literature the constructs proposed for the analysis of BMs associated with the adoption of IC, their approaches, and business elements. Furthermore, by understanding business models as configurations of business elements (Brege et al., 2014), this study aims to identify the business models associated with reported cases in the literature of companies adopting IC, through the analysis of patterns in how the different configuring elements of BMs are presented.

RESEARCH METHOD

A systematic literature review was conducted to identify the frameworks for analyzing BMs of IC and to identify case studies of companies adopting IC based on BM frameworks. Using database searches in electronic databases Scopus and Web of Science, a targeted search was carried out to identify related papers. The selection criteria for these databases were their extensive coverage in the research field (Chadegani et al., 2013). The search terms included "business model" combined with "industrialized construction," "industrialized building system," "modular construction," "off-site construction," "modern method of construction," or "prefabricated construction." Additionally, an exclusion criterion was applied to remove irrelevant articles, specifically those not including a BM analysis framework or descriptive reporting of BMs of IC-adopting companies identified empirically through case studies. A complementary search was performed using backward snowballing (Webster & Watson, 2002) to ensure thorough coverage of relevant literature.

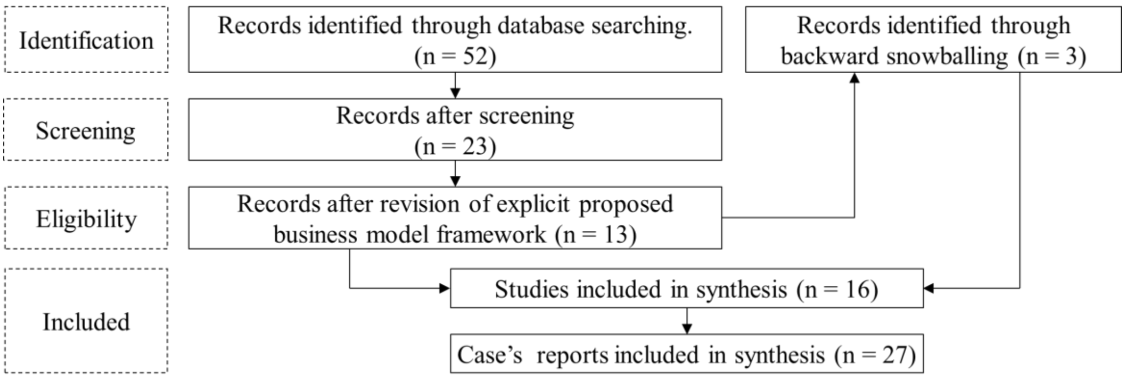

Figure 1. Information collection record. PRISMA Flowchart.

A content analysis approach (Krippendorff, 2004) was employed to examine the data gathered from the literature. Various frameworks for analyzing BMs of IC proposed and/or used by researchers were identified and analyzed. Different approaches and specific constituent elements of each BM analysis framework in IC were identified. Based on the identified BM elements, an analysis framework was adapted for characterizing the identified case studies. Through the identification of patterns in the presentation of different BM configuration elements in the case studies, the various business models of the analyzed cases were identified.

BUSINESS MODELS IN INDUSTRIALIZED CONSTRUCTION

From the literature review, sixteen studies were identified. These studies, along with their country of origin and the identifiers of the case studies they report, are presented in Table 1.

APPROACHES AND ELEMENTS OF BM

The set of elements that constitute BMs and their involved relationships allow for the articulation of a particular company's business (Osterwalder et al., 2005). There are differing viewpoints among researchers regarding the specific constituent elements of a BM (Brege et al., 2014). However, the offered value proposition and the way in which the offered value is configured and delivered are two aspects commonly held (Höök & Stehn, 2014).

Magretta describes BMs as "stories that explain how enterprises work" and suggests that a good business model answers the questions: Who is the customer? What does the customer value? How do we make money in this business? What underlying economic logic explains how we can deliver value to customers at an appropriate cost? (Magretta, 2002). Building on this, the configurative elements of BMs can be classified into four groups that respond to the question: What? Whom? How? And how much? These groups account for the company's value offering, the targeted customer, the way value is configured, and the benefits equation.

Furthermore, there are varying perspectives on whether adopting IC acts as a driving force in forming new BMs or if the IC adoption fits within established BMs. Figure 1 presents the BM configuration frameworks as a combination of elements proposed by different authors in their approaches to analyzing BMs in IC contexts, their associated elements with the mentioned questions, and the approaches identified.

In the exploration of BMs within the realm of IC, a diversity of approaches has been discerned. These approaches delineate the strategic frameworks proposed by researchers to understand the interplay between IC adoption and BM innovation. Presented herein are the varied perspectives unearthed from the analysis, each underscoring distinct facets of business model configuration in the context of IC.

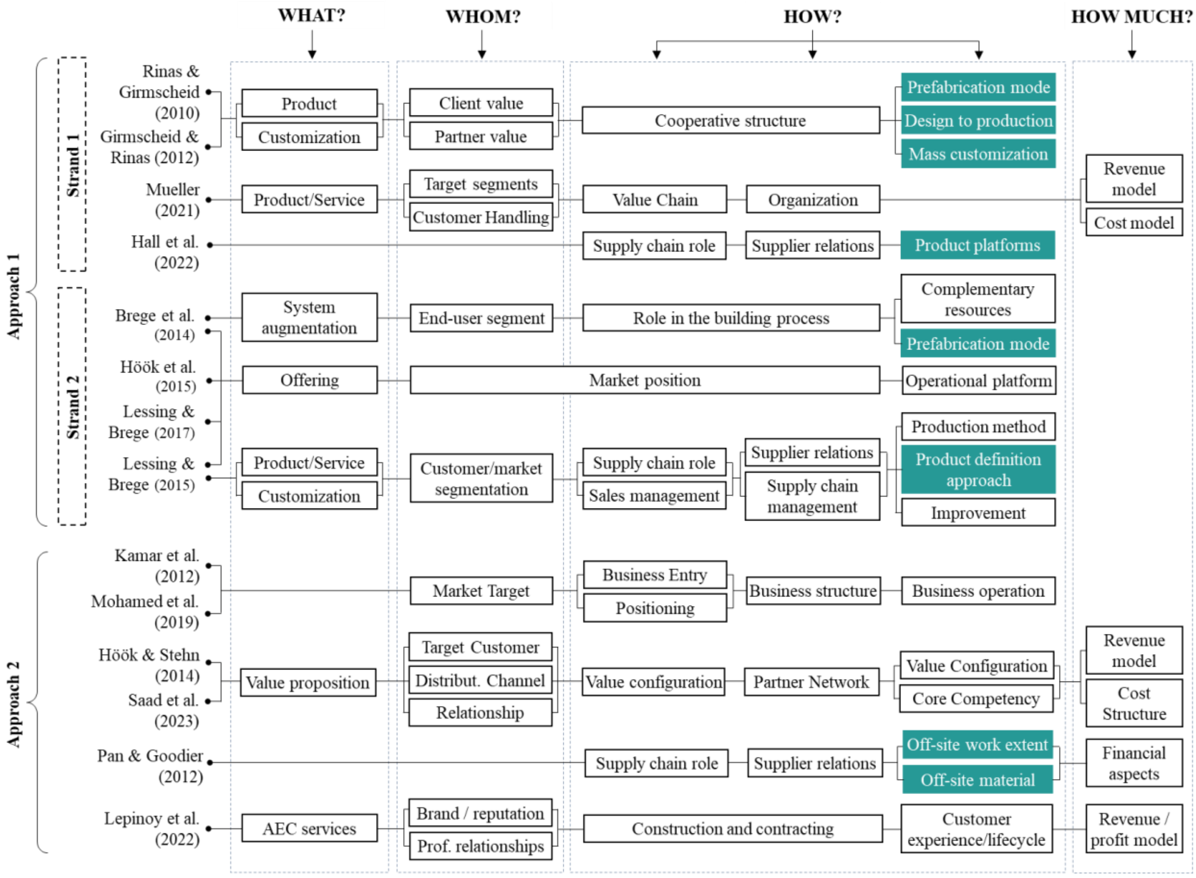

Figure 1: Approaches and elements of BM

Approach 1: IC as a driving force in the formation of BM

This perspective views IC as a driving force in the creation of new or modified business models (Brege et al., 2014). This view is echoed by Lessing et al. (2017), who highlighted that production strategies, business models, and company organization should be specifically designed and structured for IC to reap the benefits of industrialization. From this viewpoint, a clear demarcation exists between project-oriented BMs, which are traditional models for constructing unique projects using on-site methods, and product and/or process-oriented BMs, which are based on prefabrication strategies and product platforms characteristic of IC adoption (Lessing & Brege, 2015). From this approach, two strands were identified:

Strand 1: BM as a supply chain aggregation strategy. Contrasting with the extreme fragmentation characterizing the construction industry, where independent companies temporarily organize to design and build a new project, IC is seen as an effort to reorganize and build continuous production systems (Hall et al., 2022). New business models within this approach represent efforts to deliver buildings in a more integrated manner throughout their lifecycle (Hall et al., 2022), spurred by the adoption of IC methodologies. While this approach also touches upon product ranges and market goals, the BM focus is on models of actor integration; hence, the identified business models are configured based on these variations.

In this direction, the framework proposed by Rinas & Girmscheid (2010) advocates for a cooperative approach, viewed as promising for linking complementary competencies and providing holistic solutions. This model emphasizes cooperation among various actors, such as prefabrication companies, local architects, and other partners, to bolster IC. It includes two cooperative dimensions: one oriented towards production, encompassing development and manufacturing, and another towards sales, covering assembly and sales. Furthermore, Mueller (2021) introduces a framework to categorize the spectrum of IC approaches from a business strategy perspective. This framework conceptually outlines six dimensions classified in pairs on scales: market vision (targeting segments and solution characteristics), the underlying business model (value chain position and value chain organization), and technological approach (scope of industrialization and level of pre-specification). As such, market elements and strategic focus are regarded as distinct strategic dimensions apart from the business model, which incorporates value chain elements. Additionally, Hall et al. (2022) suggest that the new BM for IC is characterized by longitudinal continuity, as opposed to a project-based orientation. It is the focus on IC that facilitates this novel form of longitudinal continuity, through the development of product platforms, providing a mechanism for continuously establishing and enhancing organizational knowledge about the construction technical system. Products not manufactured by the company are sourced through long-term partnerships within the supply chain, rather than through competitive bidding.

Strand 2: BM as a construct supported by three pillars: offer, market position, and operational platform. Beyond efforts to reorganize the value chain, this line of approaches supports the understanding of BMs from the construct proposed by Brege et al. (2014), which is predicated on three pillars: offer, market position, and operational platform. This framework articulates a clear distinction between strategic effectiveness and operational effectiveness, with market platforms indicative of the former and operational platforms denoting the latter.

This analytical framework is further explored in the works of Höök et al. (2015), Lessing & Brege (2015), and Lessing & Brege (2017). Within this framework, Brege et al. (2014) and Lessing & Brege (2015) delineate the foundational element for model construction from an IC perspective, alongside the necessary complementary elements. Brege et al. (2014) posit the level of prefabrication as the model's central element and identify four essential complementary elements: system enhancement (offer), end-user segments (market position), roles in the construction process (market position), and complementary resources for design and on-site construction (operational platform). Conversely, Lessing & Brege (2015) posit the product platform as the inception point for BM design and as the principal resource of the operational platform. This product-oriented approach is considered complementary, extending the scope of investigation to encompass construction companies not necessarily tethered to specific productive resources at the outset of BM design.

Furthermore, Lessing & Brege (2015) distinguish between IC business models: production-oriented and product-oriented BMs. Product-oriented BMs are characterized by their reliance on a product-based offer, anchored in a product platform, serving as the foundational or initial point. Conversely, production-oriented BMs prioritize off-site production methods as the starting point, concentrating on the production facet of novel construction concepts.

Approach 2: IC fits into established BMs

The proposals within this approach are predicated on the notion that IC does not inherently introduce distinguishing attributes between BMs. The proponents of this viewpoint concentrate on how IC adoption aligns with, or necessitates adaptations to, pre-existing BMs.

Some researchers investigating BMs in IC leverage the Business Strategy concept, drawing on the foundational ideas of Porter, who articulates strategy as the crafting of a unique and valuable position through a distinct set of activities (Porter, 1996), and Thompson et al., who envisage strategy as management's action plan to grow the business, secure a competitive market position, attract and satisfy customers, compete successfully, conduct operations, and achieve targeted objectives (Thompson et al., 2006). The analytical framework employed is delineated by Kamar et al. (2012), encompassing five key elements: business entry, business positioning, market target, business structure, and business operation. This framework was utilized by Kamar et al. (2012) in examining IC adoption among large contractors and by Mohamed et al. (2019) among small and medium-sized construction enterprises.

Höök & Stehn (2014) and Saad et al. (2023) ground their models in the framework developed by Osterwalder et al. (Osterwalder et al., 2005), known as the Business Model Canvas. This model is structured around four foundational pillars—product, customer interface, infrastructure management, and financial aspects—and articulates nine interconnected elements: Value Proposition, Target Customer, Distribution Channel, Relationship, Value Configuration, Core Competency, Partner Network, Cost Structure, and Revenue Model.

Similarly, Pan and Goodier (2012) base their approach on the BM categorizations proposed by Ball (Ball, 2010), specifically tailored to the UK housing construction sector. These categorizations are developed with a focus on the construction process and its associated activities, highlighting the role of the company within this framework. Through an analysis of the practices of leading private home builders in the UK, who are progressively embracing IC, the authors pinpoint innovative procurement and supply chain strategies that emerge or are catalyzed by the adoption of off-site construction methodologies. Likewise, Lepinoy et al. (2022) introduce an analytical framework supported by four pillars: value proposition, generating demand, fulfilling promises, and sustaining growth. These pillars are paired with six elements: architecture, engineering, and construction services; revenue and profit model; brand and reputation; professional or other influencer relationships; construction and contracting; and customer experience and lifecycle. This framework aims to provide a comprehensive understanding of how IC can be integrated into existing business models, emphasizing the strategic and operational adjustments necessitated by this integration.

IDENTIFICATION OF BMS

Some of the studies included in the analysis (50%) feature case reports associated with companies that have adopted IC (see Table 1). To analyze these case studies, a common analytical framework was established to integrate the information reported and to identify the types of BMs associated with the different cases. The defined framework is an adaptation of the proposal by Bregue et al. (2014), which is the base framework associated with Strand 2. The choice of this framework is based on two premises: *(i)* the number of case studies reported using this analytical framework; 37.5% of the articles that reported case studies used this framework as a basis and the case studies reported in these articles account for 51.8% of the total. *(ii)* It explicitly includes IC as a driving force in the formation of new or modified BMs.

The framework by Bregue et al. (2014) was adapted in terms of elements in two ways: the inclusion of the element 'supplier relations', as adapted by Lessing et al. (2015), to explicitly outline the value chain reorganization strategies, which are the focus of the frameworks associated with Strand 1. Furthermore, the inclusion of 'predefinition level,' as adapted by Lessing et al. (2017), as a complementary element to 'prefabrication level' in the IC approach.

Accordingly, the analytical framework employed for examining the case study data is anchored in three core pillars: Offering, Market Position, and Operational Platform. It further is delineated by six elements: Scope of Offering (pertaining to Offering), Marketplace Role and Value Chain Role (relating to Market Position), as well as Value Chain Relations, Predefinition Level, and Prefabrication Level (associated with Operational Platform). Each of these components is elaborated upon as follows:

Offering: It embodies the company's value proposition (Lessing & Brege, 2015). It encompasses the amalgamation of physical products and services provided to customers and is often conceptualized as a blend of hardware, software, and services, sometimes coupled with a revenue generation model (Brege et al., 2014).

- Scope of Offering: It represents the breadth of the offering in terms of added value, manifested in the combination of the level of prefabrication and the company's role in the value chain (Brege et al., 2014).

Market Position: It delineates the company's role within the market and value chain.

- Marketplace Role: It describes the customer segments to which a company aims to deliver value (Osterwalder et al., 2005). The spectrum of segments ranges from variable concepts of offering with broad market coverage to niche market orientations with highly standardized and specific solutions.
- Value Chain Role: The company's position in the building process, which is associated with the level of control it exercises over the value chain (Lessing & Brege, 2015).

Operational Platform: Company's internal resources and competencies, alongside complementary external resources from suppliers and partners, and how these elements are organized and utilized.

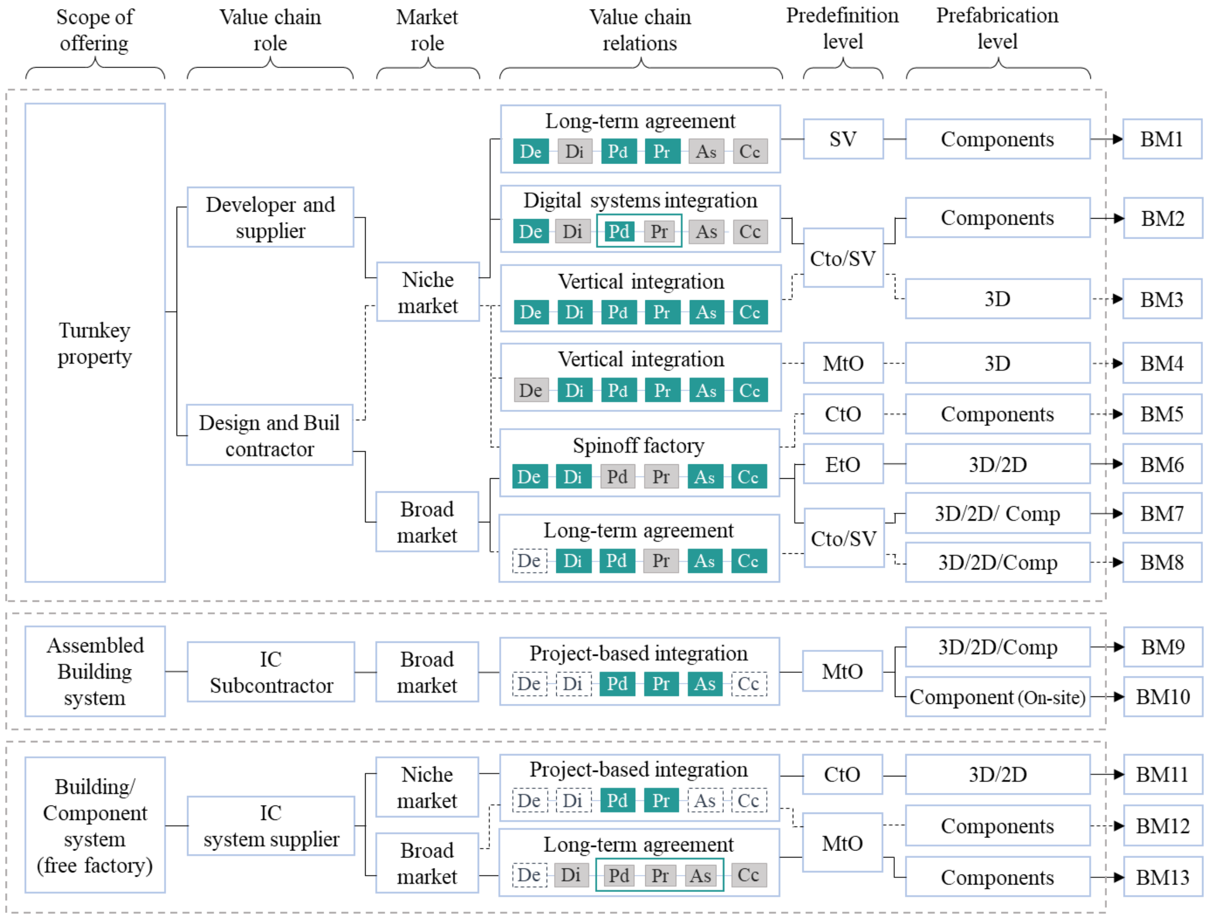
- Value Chain Relations: Access to external resources from suppliers and partners involves five strategies: *Vertical Integration*, referring to companies that maintain control over product architecture and processes internally (Hall et al., 2022); *Digital System Integration*, where long-term relationships with partners in design, procurement, manufacturing, and assembly stages are built through digital platforms (Hall et al., 2022); *Spinoff Factory*, related to the creation of a new factory or business line originating from an existing project-based company (Hall et al., 2022); *Long-term Agreement*, linked to long-term commercial and collaborative agreements with external companies, not limited solely to the project scale; *Project-based Integration*, associated with formal and informal integration strategies confined to the project scale.
- Predefinition level: Indicates the standardization level and defines the entry point for design customization (Mueller, 2021). Following Hvam et al. (2008), Lessing and Brege (2015) outline four levels: *Engineer to Order (EtO)*, employing industry norms as starting points in client-controlled project design; *Modify to Order (MtO)*, using established technical solutions and predefined geometries for essential components within project-specific designs; *Configure to Order (CtO)*, employing set parts and modules in a uniform configuration approach; and *Select Product Variant (SV)*, achieving near-final construction with predetermined variations, significantly reducing the need for project-specific designs by pre-setting most details (Hvam et al., 2008).
- Prefabrication level: Three levels of prefabrication in construction systems are identified: 3D elements, 2D elements, and component systems, all associated with off-site production. Additionally, within the component systems level, a distinction is made between off-site prefabricated elements and those associated with mobile factories, where the process occurs on-site. This distinction is highlighted in two of the case studies reported by Mohamed et al. (2019).

BMs of IC identified

Through the analysis of patterns in the various combinations or configurations of elements presented in the reported cases of companies adopting IC, thirteen BMs were identified, as depicted in Figure 2. These identified BMs can be categorized based on similarities in roles and value chain aggregation strategies adopted. The categorizations are outlined as follows:

(i) Contractor-developer and owner of the construction system and manufacturing facilities (BM3 and BM4). The value chain is integrated vertically, whereby contractors maintain complete control, allowing them to directly reap the benefits associated with repetition and systematic improvement. This strategy fosters horizontal, vertical, and longitudinal integration

but requires taking on the risks associated with the development and deployment of fixed capital assets, as well as the costs of operating and maintaining manufacturing facilities. In the studied cases, the companies adopting this strategy are contractors that have embraced IC from their inception, offering turnkey property solutions and prefabrication at the 3D element level. However, this approach is observed in companies targeting specific market niches with high levels of predefinition (CtO/SV) (BM3), as well as in companies aiming for broad market coverage with low levels of predefinition (MtO) (BM4).



De = Project development; Di = Project design; Pd = Product design; Pr = Off-site production; As = Assembly; Cc = Construction and coordination.
■ = In-house; ■ = Partner/Long-term relation; ⬚ = Outsourced.

BM1: case 16; **BM2:** cases 17, 21; **BM3:** cases 1, 6, 8, 9, 10a, 10b*, 11a, 12, 15; **BM4:** case 23; **BM5:** case 20; **BM6:** cases 19, 27; **BM7:** cases 3, 4, 22, 25; **BM8:** cases 2, 7**; **BM9:** cases 13b; **BM10:** cases 24, 26; **BM11:** cases 5, 11B; **BM12:** cases 13a, 14a***, 14b; **BM13:** case 18.
*In addition to turnkey property, the company's offer includes the operation (build-to-own).
**The company established a joint venture agreement for off-site production.
***The company offers technical support in the design and on-site production/coordination phases, which implies having complementary resources.

Figure 2: Identified BM´s

(ii) Contractor-developer of construction systems and manufacturing facilities via spinoff (BM5, BM6, and BM7). This strategy is employed by 100% of the studied cases where the company is a conventional contractor adopting IC. These project-based contractor companies integrate system development and off-site production phases through a new product/process-oriented business line. This approach allows project-based companies to balance project demands with the need for longitudinal continuity centered around the factory. However, the integration achieved is partial and depends on an internal integrator agent continuously updating and educating the existing supply chain about the new factory's capabilities (Hall et al., 2022). This strategy is linked to turnkey property solutions. It is adopted by companies targeting specific market niches with a high level of predefinition (CtO) and component-level prefabrication, as

well as by companies offering low levels of predefinition (EtO/MtO), covering various prefabrication levels, aimed at broad market coverage.

(iii) Contractor-developer and owner of externally manufactured construction systems (BM8). This model is utilized by contractor companies that establish long-term agreements to integrate the off-site production phase. The prefabrication of construction systems is conducted off-site and outsourced to external industrial suppliers, yet the contractor remains the developer and owner of the construction system. The primary rationale behind this approach is that contractors seek to control the design of the construction system while avoiding the risk of fixed capital investments in manufacturing facilities. Although off-site production is outsourced, it necessitates commercial relationships that extend beyond individual construction projects and framework agreements that ensure a steady supply of construction systems at the required rate. Such agreements are also vital for industrial suppliers, providing them with a guarantee of consistent demand, thereby reducing the investment risk in capital goods. This arrangement also facilitates early-stage involvement of the industrial supplier (Andersson & Lessing, 2017). In the cases studied, companies adopting this strategy are contractors that have incorporated IC from their inception, offering turnkey property solutions, low levels of predefinition (MtO), covering various prefabrication levels, and aimed at broad market coverage.

(iv) Contractor as purchaser of IC goods and services (BM9, BM10, BM11, and BM12). This strategy aligns with IC implementations in value chains characterized by minimal integration, stemming from a fragmented process dominated by short-term relationships (Cox & Ireland, 2002). Contractors procure construction systems developed and manufactured by external entities, subcontractors in the case of BM8 and BM9, which include on-site assembly, and free factory system providers in the case of BM11 and BM12. Relationships with these subcontractors and suppliers are limited to the project scale, hindering effective cooperation, efficient information exchange, and innovation drives, leading to suboptimization and productivity losses (Winch, 2010). To mitigate the impacts of this fragmentation, the company associated with case 14a, implementing BM12, provides technical support in design phases, construction, and on-site coordination, requiring additional resources. However, the achieved integration remains informal (Hall et al., 2022). The studied cases include adoption of this strategy with offerings both aimed at specific market niches, with construction systems of high predefinition level (CtO) and prefabrication at the 3D and 2D element levels (BM12), and broad market coverage offerings, with construction systems of low predefinition level (MtO) covering various prefabrication levels (BM9, BM10, and BM12). BM10 features a unique aspect regarding the mode of prefabrication, observed in cases where industrial suppliers do not have a permanent manufacturing facility but rather a mobile factory that is commissioned per project to save on logistics costs.

(v) Project developer and supplier of own construction system manufactured in-house (BM1). These are project-configuring companies that own a construction system developed and manufactured in-house, within their own facilities. Assembly, construction, and on-site coordination tasks are performed by long-term collaborative partners. The associated offering is turnkey property solutions, with component-level prefabrication, high predefinition (SV), and targeted at a specific market niche.

(vi) Project developer and supplier of proprietary construction system manufactured externally (BM2). These companies are project configurators owning a construction system developed in-house. However, instead of establishing their own production facilities, they partner with specialized manufacturers and suppliers. Local contractors carry out the assembly. The company retains ownership of the concept, managing and orchestrating the delivery of component kits to project sites. Value chain integration is achieved through a digital systems integration approach, allowing for the manufacture of parts through peripheral supply chain partners (Hall et al., 2022). Digital platforms enable the building of long-term relationships with

partners in design, procurement, manufacturing, and assembly stages. This strategy enables growth by establishing new partner networks without the need to invest in creating their own production facilities. The associated offering is the supply of a component system (free factory) with a high level of predefinition (CtO, SV), targeted at a specific market niche.

(vii) Supplier of own construction system manufactured externally (BM13). The company supplies a construction system with a low level of predefinition (MtO), targeting broad market coverage. The prefabrication level is component-based, and the company-owned structural system can be adapted for various building configurations. The company also partners with subsystem suppliers to integrate them into the complete building system. Product design, production, and assembly are all outsourced, aligning with the company's strategy to avoid high-capital investments and specific manufacturing commitments. This BM is defined by subcontracting as a fundamental principle, suitable for companies with limited internal resources. Close relationships with partners ensure access to external product development, production capabilities, and market presence, all while maintaining minimal financial risk (Lessing & Brege, 2017).

CONCLUSIONS

A systematic review of the literature on BM analytical frameworks within IC was undertaken, and a content analysis oriented to identify the distinct constitutive elements of a BM, the approaches, and the BMs associated with documented instances of IC adoption by companies. This inquiry uncovered fourteen proposed BM frameworks and delineated two approaches to BMs in the context of IC. Furthermore, 27 case reports detailing the operational practices of companies that have implemented IC, framed within a BM analysis, were found. Analysis of these cases led to identifying thirteen distinct BMs, which were categorized based on their roles and the strategies they employ for value chain integration within the realm of IC adoption.

The identified frameworks present two main perspectives: considering IC as a driving force in creating new business models and viewing IC as not defining attributes that necessitate new models but rather fitting into conventional BMs or deriving adaptations from them.

An adaptation of the model proposed by Brege et al. (2014) was presented, enabling the integration of information from reported cases. This adaptation faced limitations related to the integrated elements. The customization element is crucial for categorizing both a company's offering and the market standard it targets. However, only three of the discovered frameworks included explicit descriptions of this aspect, thus not constituting a common element that would allow for a joint characterization of the identified cases.

Seven BM groupings were identified based on the roles performed and the value chain aggregation strategies: *(i)* Contractor-developer and owner of the construction system and manufacturing facilities; *(ii)* Contractor-developer of construction systems and manufacturing facilities via spinoff; *(iii)* Contractor-developer and owner of externally manufactured construction systems; *(iv)* Contractor as purchaser of IC goods and services; *(v)* Project developer and supplier of own construction system manufactured in-house; *(vi)* Project developer and supplier of proprietary construction system manufactured externally; and *(vii)* Supplier of own construction system manufactured externally.

LIMITATIONS AND FUTURE RESEARCH

The cases analyzed originate from six countries, with a notable concentration of 55% coming from Sweden. This uneven distribution may introduce inherent bias, particularly considering that most Swedish literature on BMs of IC focuses on residential construction. This bias limits the generalizability of the findings to other geographical contexts and market sectors. It is recommended that future research explores BMs of IC from a broader perspective, including other market sectors and business practices from different regions.

MASS CUSTOMIZED PRODUCTS FOR INDUSTRIALIZED CONSTRUCTION: CHALLENGES AND OPPORTUNITIES

Manoela Conte[1], Iris D. Tommelein[2], Carlos Torres Formoso[3] and Randall Miller [4]

ABSTRACT

Developing mass customized products for industrialized construction (IC), including single- and multi-family modular housing, requires multidisciplinary, collaborative, and iterative approaches from the first stages of product development. Despite this, decisionmaking based on data pertaining to companies' capabilities and increasing diversity of customers' needs in IC is still in its infancy. Catalogs of houses are often extensive yet fail to take advantage of IC strategies (such as mass customization (MC), product platform, modularity, and product families), thereby undermining the competitiveness of IC against traditional construction. An opportunity exists to enhance communication among stakeholders, fostering decisions about catalog offerings based on clear understanding of their requirements, robust data analysis, and continuous improvement. This paper discusses practices, challenges, and opportunities related to the development of products and integration among stakeholders in the IC context. The research method comprised three steps: developing theoretical understanding, conducting two ongoing studies in Brazil and the United States, and leading a workshop with experts to identify practices, challenges, and opportunities regarding the development of IC products. The preliminary results indicated the imperative need for stakeholders to work together on improving product development and production system, fostering a more competitive IC industry.

KEYWORDS

Mass customization, industrialized construction, modular construction, product development, collaboration.

INTRODUCTION

Early developments of industrialized construction (IC), especially in the house-building sector, were strongly based on the Mass Production paradigm, resulting in a negative perception from customers due to the high degree of standardization, focus on cost reduction, and poor quality of products (Nadim & Goulding, 2011). More recently, Mass Customization (MC) has emerged as an approach to improve value delivery in house-building projects (Noguchi, 2003). MC aims to provide a certain degree of flexibility, while keeping production cost and delivery time within

acceptable limits (Pine, 1993; Da Silveira et al., 2001). It seems that recent developments in IC, combined with the adoption of MC represent an opportunity to achieve high levels of efficiency in the building industry (Larsen et al., 2019) and, at the same time, to accommodate different customer requirements (Yashiro, 2014).

Product platform, modularity, and product families are key concepts in MC to respond to the diversity of demands (Salvador et al., 2009; Khalili-Araghi & Kolarevic, 2018). Those concepts can change the way in which new products are developed in the construction industry, e.g., by pre-defining a range of modular components to be used and creating a certain degree of process repetition (Brege et al., 2013). This allows the delivery of a limited variety of product solutions while sharing parts and production steps within the manufacturing capabilities, achieving economies of scale and scope (Robertson & Ulrich, 1998; Tseng et al., 2017).

The development of this type of solution requires early identification of stakeholders and collaboration among them, so that both customers and operations' requirements are considered in the definition of a finite solution space (SS) (Piller, 2004; Ferguson et al., 2014). The SS is a limited or stable space in which customization offers can satisfy the needs of customers (Piller, 2004). This involves the alignment between three MC areas: (1) customer integration, (2) product design, and (3) operations management (Rocha, 2011; Ferguson et al., 2014), with information exchange and knowledge dissemination between them being critical (Hentschke et al., 2020). The capacity of combining these elements in a meaningful way may have a strong impact on competitive advantage (Piller, 2013; Schoenwitz et al., 2017).

Companies apparently fail to understand how relevant information can support decisionmaking for SS definition (Hentschke, 2021) at a strategic level. There is often a lack of integration among different stakeholders in IC, such as developers, designers, manufacturers, general contractors, and regulators, and solutions are often defined considering the perspective of only a single one (Rocha, 2011). Only a few previous studies have addressed this fragmentation (e.g., Jiao & Zhang, 2005; Rocha, 2011; Ferguson & Olewnik, 2014; Andújar-Montoya et al., 2015; Schoenwitz et al., 2017; Khalili-Araghi & Kolarevic, 2018; Sjobakk et al., 2018; Hentschke, 2021; Popovic et al., 2021). The lack of understanding of market- and customer demand prior to the definition of a building system causes the need for later adaptations to projects, resulting in problems related to poor quality, occurrence of waste, and failure to implement continuous improvement. Manufacturers end up absorbing the issues resulting from the lack of refinement of design solutions which results in limited process efficiency (Popovic et al., 2022). Therefore, the development of solutions for capturing, analyzing, and presenting information about customer requirements, together with the understanding of operations management constraints may improve decisionmaking in product design, resulting in an effective way of developing and adjusting the SS (Sjobakk et al., 2018).

The aim of this paper is to report on a study to identify practices, challenges, and opportunities related to development of mass customized products in the IC context. The topic was approached from the perspective of the MC areas and their integration, which depends on the collaboration among stakeholders. This paper is distinct from previous research due to the emphasis on the need of deeply understanding customers' demands. This study is based on a literature review, two ongoing Empirical Studies, one in Brazil and the other in the United States (US), and insights from a workshop involving leading IC experts from California, US.

LITERATURE REVIEW

MASS CUSTOMIZATION (MC)

Trading off standardization desired by IC against flexibility required by customers is challenging (Schoenwitz et al., 2012). Nevertheless, MC attempts to fulfil these contradictory requirements (Pine, 1993). The level of customization allowed in the SS (Von Hippel, 2001) depends on the analysis of customers' requirements and existing operational capabilities (Da Silveira et al., 2001), and it is defined at the customer order decoupling point (CODP) (Rudberg & Wikner, 2004). In construction, it is not uncommon to have more than one decoupling point (Rocha, 2011), which allow different levels of customization of the same production system, depending on the market segments.

For MC to be feasible, a fixed- but still flexible SS is necessary (Ferguson et al., 2014). Differently from personalization, in MC value must be delivered with no need to reinvent products or processes for every new customer (Piller, 2004). Although customers may get the impression that the product is customized, several standardized components are being used in project delivery (Gibb, 2001). The definition of SS must be based on customer requirements, which are captured, analyzed, and translated into product specifications (Piller et al., 2004). Product solutions must also respond to the regulations, site, and climate conditions of different locations (Popovic et al., 2021). According to Otto et al. (2013) it is necessary to design products for specific market segments or customer clusters, instead of defining a general product that tries to meet all possible needs.

Maximizing repetition helps MC to achieve efficiency and lead-time reduction not only in production, but also in sales, design, and logistics (Tseng & Jiao, 2001). Economies of scale and scope are reached through commonality and reusability of both design and process capabilities across modules, tools, knowledge, processes, components, and specific market segments with respect to repetition in customers' needs (Tseng & Jiao, 2001). The reuse of solutions furthermore allows continuous improvement to be pursued, and facilitates the dissemination of practices within the company (Kotha, 1996).

DEVELOPMENT OF MASS CUSTOMIZED PRODUCTS FOR IC

The development of products for Industrialized House-Building (IHB) should be very different from traditional construction (Jansson et al., 2014). Structured solutions to handle multiple projects simultaneously, integrated decisionmaking, short lead-times, and adoption of new concepts, such as MC, modularity, and platform (Meyer & Lehnerd, 1997; Thajudeen, 2023), and a large number of engineering design activities, are necessary for manufacturing and site assembly (Lennartsson et al., 2021). These solutions may help companies that use MC reach competitive advantage (Hvam et al., 2008).

Product-platform and modularity concepts have been used to manage product variety in many other sectors (Hvam et al., 2008; Salvador et al., 2009) by sharing parts and production steps (Robertson & Ulrich, 1998). However, the application of those concepts requires much product development[5] effort (Bonev et al., 2015), involving several stakeholders throughout several project stages (Lessing, 2006). There is a need to shift to multidisciplinary product development from the early design stages (Jansson, 2013).

The term product platform refers to the collection of assets that are shared by a set of products (Robertson & Ulrich, 1998) or production lines (Meyer et al., 2018), allowing companies to offer products that show front-end variety based on back-end commonalities (Eriksson & Emilsson, 2019). These assets can be divided into components, processes, knowledge, people, relationships (Robertson & Ulrich, 1998), subsystems and technologies (Meyer et al., 2018). Lessing (2006) suggests that IHB development should include a Technical- as well as a Process Platform. The first consists of modularized solutions for building parts with interfaces that allow interchangeability and parts that can be combined to create a variety of end-products. The latter includes modules for collaboration, logistics, and information flow. Lessing also states that collaboration in multidisciplinary teams is a powerful way to develop solutions, methods, and tools designed to fit together.

[5] Product development is a set of activities to create, design and market a product (Ulrich; Eppinger, 2000).

The modularity concept is used to decompose complex products and processes into smaller and simple parts (Hvam et al., 2008). The ability to modularize a catalog of products is of great importance to offer a wider range of solutions for customers (Hofman et al., 2006). Voordijk et al. (2006) pointed out three different types of modularity: product-, process-, and supply chain modularity. The distinction between a modular- and an integral architecture is associated with the flexibility of the system to absorb changes. The first allows changes to impact only one component, whereas the second may see changes reverberate globally to several components of the system (Ulrich, 1995), making it harder to adapt products for diverse customers' needs without incurring penalties in product development costs and lead times.

RESEARCH METHOD

The point of departure of this investigation was a literature review on the management of information in the development of IC products, including the capture, processing, analysis, dissemination, and use of information to support decisionmaking among MC different areas. Our investigation also draws on learnings from two ongoing studies conducted in IHB companies (Table 1). Each case study involved two companies. The difference is that in Empirical Study 1, product development is carried out by the manufacturer, while in Empirical Study 2, it is carried out by the seller and real estate developer. In both studies, the companies delivered single-family houses. Those companies were chosen because they had been implementing some Lean Construction concepts, and also were interested in implementing an integrated approach in product development strongly based on the concept of modularity.

Table 1: Empirical Studies 1 and 2

<tr><td>Operations Management</td><td>Company D
(manufactures and assembles)</td></tr>
</table>

Multiple sources of evidence were used in both Empirical Studies, including open- and semi-structured interviews with companies' staff, direct observation on construction sites and manufacturing units, analysis of existing database of customer profiles (Empirical Study 1), participant observation in meetings, and seminar participation for discussing results.

The literature review and the learnings from both Empirical Studies grounded the proposition of the questions about product development in the IC context that guided the discussions described in this paper. These questions were presented for discussion in a workshop with expert practitioners and academics selected based on their practical or academic experience in recent developments in IC in California and also for their complementary backgrounds (Table 2). This study is part of a collaboration between the Federal University of

Rio Grande do Sul in Brazil, and the University of California, Berkeley in the USA. The goals of the workshop, held at UC Berkeley, were to create a collaborative learning environment and provide an opportunity for IC representatives to share thoughts, convey practices, and suggest opportunities to overcome industry challenges.

The workshop started with a presentation with the aim of (1) sharpening the understanding of MC strategy and key concepts related to the IC context, e.g., product platform, modularity, product family; (2) reporting the research gap regarding the integration between MC areas in the development of IC products; and (3) introducing the practical problem based on insights obtained from Empirical Studies 1 and 2. A set of questions were posed to the experts in order to identify practices, challenges, and opportunities to overcome the challenges. The experts wrote their contributions in Post-it® notes that were grouped on a large panel on the wall. After that, the academics who facilitated the workshop carried out a discussion with the experts to get additional understanding of their answers. Last, experts presented their work and proposed topics to be explored in future collaborative initiatives among companies and universities.

Table 2: Workshop participant roles and companies

Expert	Role	Company Type
E1	Director General, PhD candidate	Volumetric modular construction manufacturer
E2	Co-founder and CEO	Software for offsite construction
E3	Principal	Global non-profit organization in sustainability
E4	Senior Associate	Global non-profit organization in sustainability
E5	Sr. Manager for Lean Project Development	General Contractor
E6	Director of Product Design	Global volumetric modular construction manufacturer, designer, and contractor
E7	Senior Technical Advisor, Researcher	Research and Policy Center for Housing Innovation
E8	Distinguished Professor of Engineering and Project Management	University
E9	PhD candidate	University

FINDINGS

EMPIRICAL STUDIES: A BRIEF SUMMARY

The practical problem noted in Empirical Studies 1 and 2 is that companies use an extensive catalog of single-family houses with low adoption of the MC strategy and related concepts, such as product platform, modularity, product families, and standardization. Other problems included: (a) a wide variety of products developed by using a traditional design approaches that do not adopt multidisciplinary work from the early design stages; (b) low levels of commonality, leading to rework and incompatibilities that tend to be identified late in the detailing design or construction stage; (c) engineering overload due to the need to detail many projects with low reuse of solutions; (d) uncompetitive prices; (e) very limited flexibility offered to the customers; (f) continuous improvement hindered by the low reuse of solutions. Most of these problems stem from the lack of understanding and proper communication of stakeholders' requirements from the early design stages onward.

Seeking a solution to these problems, in both studies companies have been working together on making some changes to reduce the size of catalogs, offering more flexibility and reaching economies of scope and scale through repetition. The changes include: (1) improving the capture, structure, analysis and communication of key customer information; (2) defining clearly the levels of customization to be offered for each market segment, based on data analysis; (3) exploring opportunities to implement IC key concepts and strategies; (4) understanding and communicating operations management constraints; and (5) improving communication and collaboration among stakeholders that represents different areas in order to iteratively develop solutions.

INSIGHTS FROM THE WORKSHOP

The most prominent issues raised by the experts during the workshop are discussed in this section. The insights were structured according nine questions posed to the experts, following a "Practices", "Opportunities", and "Challenges" sequence. The expert who suggested the issue is labelled by means of a code (e.g., E4 in Table 2).

How to reduce the gap between what customers want and what IC companies have offered? (Question 1.1)

One way to narrow the gap between wants and offers is to incorporate design practices that facilitate the reuse of solutions (E4). These practices would allow for changes or additions later on, suggesting a more flexible design that enables adjustments as customer needs evolve.

By contrast, a set of challenges were identified. First, the experts recognized that understanding customers and market needs remains underexplored in companies. "We don't know our customers" (E7) is a shared perception. Second, the customers of many IC companies are not the users (e.g., multifamily developers) (E7). Demand analysis is often carried out by developers based on their perception of the market, rarely on customer requirement data and structured analyses. Third, the dynamic nature of market preferences over time, influenced by factors such as tastes and macroeconomic cycles, further hinders efforts to align offerings with customer expectations (E3). Moreover, it is challenging to predict how family structure and living groups will change in the future (E4), requiring a forward-looking approach. Fourth, the siloing of design, engineering, manufacturing, and customers is identified as a crucial challenge (E9). Fifth and finally, the challenge of "sharing ideas and solutions across projects" (E9) may be associated with the lack of commonality between products and the reuse of solutions.

The experts recognized two opportunities to bridge this gap. First, solutions can be drawn from past and current projects (E9), leveraging lessons learned and successful strategies. Second, the prospect of establishing a nationwide industry coalition (E7) emerges as a strategic opportunity. Such a coalition could serve as a collaborative platform, fostering knowledge exchange, innovation, and the collective development of solutions to overcome challenges and reach economies of scope and scale.

How does a company define the level of product customization to be offered? Does it vary according to the business model or market segment? (Question 1.2)

Experts have highlighted a variety of practices employed by companies in determining the level of product customization. One is the informal and subjective case-by-case assessment (E1), suggesting that these decisions are often based on individual circumstances and unique project requirements. Another is based on business-to-business (B2B) customer catalogs (E1), by using predefined options from previous projects to guide customization levels. This definition is also based on the business goals, which means that companies with high product output tend to offer less flexibility in order to maximize efficiency and effectiveness (E6). Furthermore, a dynamic strategy involves initially paring down options based on specific requirements and subsequently increasing options as needed (E2). This strategy was adopted by Companies A and B from the Empirical Study 1 in order to gain understanding on the adopted concepts (e.g., modularity, product family, among others) from a more restricted product platform and then increase the level of customization according to the level of maturity of the company.

Maintaining focus and establishing a robust strategic definition is a challenge (E6). The lack of clarity about the level of flexibility to be offered in each market segment and the urge to ensure the sale leads companies to allow customers to make small adjustments, overloading the product development and engineering departments, and expanding the catalog.

Companies invest too little effort in customer data capture and processing, hindering the ability to fully understand market demands (E2). Additionally, shifts in market-segments, demanding adaptive strategies (E7) and continuous data capture and analysis. It is even more difficult to deal with this type of complexity due to the different perspectives brought by different stakeholders, and also by a limited understanding of manufacturing processes (E1). The lack of suitable performance metrics, which should be time-dependent, such as fabrication capacity and required slack, further complicates decisionmaking (E8).

The prospect of reducing fragmentation in decisionmaking (E7) and unlocking focus-goals related to manufacturing capabilities and planning (E6) stands out as another strategic opportunity. Research and Development (R&D) and prototyping emerge as promising avenues (E7) to explore innovative solutions, clarify questions about the construction system, help in the visualization of the product, and collect customer data. The development of a coherent product platform is also an opportunity (E1) to understand the boundaries of each market segment and its level of customization based on specific orientations, rules, and standards.

How to manage trade-offs between customization (generating value to customers) and operational efficiency and effectiveness (keeping costs low)? (Question 1.3)

Work in multidisciplinary teams was highlighted as essential to manage trade-offs, fostering collaborative, and iterative decisionmaking (E7). Another practice is to allow for customization options in simple areas and maintaining consistent interfaces in the same location between them (E6). This helps to isolate complexity in a specific function or subsystem, which means that exercising an option will not affect the whole system. A third practice emphasized by the experts was the importance of balancing intention with high customization expectations (E6), recognizing that achieving extensive modifications on a daily basis may not be realistic. This approach emphasizes balancing product flexibility and streamlined processes, ensuring that customization efforts align with operational efficiency and effectiveness.

One challenge involves identifying large segments of common opportunities (E3). This requires the understanding of customer needs and market trends to effectively tailor products or services without compromising operational capabilities. Another is providing the perception of flexibility and choice while keeping boundaries (E6), and the escalating redundancy and complexity associated with having more interfaces between modules (E2). Experts highlighted the difficulty of resisting revenue opportunities, particularly for early-stage businesses, even if the product may not align well with efficient manufacturing (E1). One challenge, but also an opportunity, is to secure a long-term pipeline of customer orders (E7). This includes proactively managing projects and establishing stable and reliable supply chains to secure long-term contracts, to support product platform standards, and to ensure a sustained workflow.

One strategic opportunity involves the development of trade-off models with virtual reality interfaces to explore various what-if scenarios (E8). These models, accompanied by associated cost and process models for both customers and producers (E8), offer a powerful tool for evaluating the impact of product development choices on both value generation and keeping costs low. These models could enable early visibility on production impact (E2).

What are the best data sources to understand what the market and customers want? (Question 2.1)

Experts suggested a diverse set of practices to understand the market and customers' needs, such as: large historical databases, permitting data at both local and regional scales, experience of homebuilders whether private or fragmented and market research (E3); past projects, surveys, interviews, and market trends (E9); sales data in the company (E6). Hiring skilled and innovative designers with a discerning aesthetic sensibility was mentioned as a good practice to support the understanding of the demand (E1).

Experts identified several challenges in finding the best sources of demand data. Some examples include: variability of data, both regionally and over time (E3); fragmentation and cost of data sources (E3); distortion of company data, introducing potential biases that require careful examination (E6). Additionally, some customer segments do not allow for choice, as in affordable housing, where limited options constrain data-driven decisionmaking (E7). The unavailability or proprietary nature of certain data sources adds an additional layer of complexity (E7). Fragmented and prescriptive building codes were highlighted as a challenge that affects the three questions regarding customer information to support product development (E7). Specific regulations for transportation and minimum dimensions differ across states, cities, and allotments. Structuring a database with these diverse regulations can assist companies in determining which parameters to adopt in order to accommodate various contexts.

Opportunities exist in terms of (1) understanding the focal points of the sales team, aligning product development efforts with areas of concentrated sales activity for optimal market responsiveness (E6); and (2) providing the development of solutions that address urgent, critical situations (E7). The National Association of Home Builders of the US (NAHB) was suggested as an opportunity to access market information and industry trends (E7).

How should this information be captured, analyzed, and communicated to the company and stakeholders? (Question 2.2)

Experts recommended registering, analyzing, and communicating information through workshops, trainings, customer-company meetings (E9), surveys, and analysis of sales data (E1). 'Dogfooding', which means experiencing the company's products or services first-hand, provide quantitative, qualitative, and experiential perspectives of customer information through the test of solutions in the market (E1). Another practice suggested was creating functional and features description without specific product details or brands, as done with Target-Value Design (E6). Presenting customer information as a cohesive story supported by visual aids can contribute to a clear and impactful communication strategy among stakeholders (E6).

Challenges include diverse workflows among companies, requiring different processes (E2) often for the same project, hindering standardization. "Skewed data can tell the wrong story" (E6). Informal and incoherent sales information poses hurdles in effectively translating insights back to the design phase (E1). Another challenge is privacy concerns that require handling or lack of access to sensitive customer information (E7).

Communicating the cost impact of the customization options offered to customers, particularly in the early stages of product development, presents a tangible opportunity (E2). Moreover, strategically positioning the product to align with current customer needs (E6) undermines companies' ability deliver value to customers and to compete effectively with more traditional design and construction processes.

How to use customer information to support decisionmaking regarding product development? (Question 2.3)

One approach involves leveraging customer data to define Minimum Viable Products (MVPs) for different product families (E6). This ensures that product development efforts are targeted, aligning with the most critical requirements. Another approach is assigning the responsibility for managing customer information and making it available to support decisionmaking (E7).

A major challenge is to have different stakeholders and customers represented in decisionmaking, especially in multi-family housing (E4), in which contact with customers is rare. By designating someone to present customer perspectives in the decisionmaking process, companies can foster a customer-centric culture that prioritizes and integrates customer insights into every stage of product development, enhancing overall responsiveness to customer expectations. However, who should do the customer analysis (E5) is still an open question. Customer preferences (stated preferences) may not always be associated with customers' choice (revealed preferences), i.e., people are not necessarily good at defining what is more important for them vs. their willingness-to-pay (E3).

A persistent challenge manifests in the lack of a steady project pipeline, complicating the consistent integration of customer demand into product development and among projects (E5). The pipeline and the development of a product platform from a collaboration effort among universities and companies were suggested as opportunities (E5).

How to manage trade-offs between stakeholders' interests (i.e. developers, manufacturers, GC, customers) in product development? (Question 3.1)

According to the experts, finances often dictate decisions (E1). Based on that idea, building close, long-term partnerships emerges as a key strategic practice (E7) to promote the mutual understanding among stakeholders, as well as fostering an open forum for transparent discussions about trade-offs, spanning from ideation to test sign-off (E6). Another important practice is to prioritize designs that are not necessarily easy to install but hard to install incorrectly, aiming to minimize issues related to GC and site crew errors (E3).

The challenges include fragmented and frequently conflicting interests across various stakeholder groups (E1, E2). Misalignments in interests require a moderator to control and guide the conversations, managing divergent priorities (E6). Moreover, a challenge emerges from the lack of performance metrics that are time-dependent (E8).

Overcoming these challenges implies the opportunity of fostering industry collaborations and coalitions (E2). This can create a better understanding of constraints across stakeholders, facilitating decisionmaking (E1). Another opportunity arises with organizations that encourage collaboration for collective change. One example is the Builders Lab, an initiative that supports developments from start to scale through the launch of tools for political decisionmaking or the modernization of construction methods (E7). Experts also mentioned the use of Lean Design tools to identify the best solutions among various options (E6). This approach enables a data-driven assessment of design alternatives, streamlining the decisionmaking process.

What are the best strategies adopted to support the design decisions in the IC context, considering operations' requirements from the early design stages? (Question 3.2)

Design Thinking (E6), Integrative Design, Interactive Effects, and Option Value (E7) were mentioned as practices adopted by the experts to support design decisions considering operational requirements from the early design stages. According to E7, Option Value considers the future evolution and potential trajectories of the project, assessing how current design decisions may either preclude or enable future developments.

Regarding challenges, the dynamic nature of design can result in a long design process, leading to low engagement levels among stakeholders (E6). Moreover, measuring the impact of design decisions can be hard, especially across projects (E7). Another challenge mentioned by the experts is the cost impact, as costs rapidly rise as Levels of Development (LOD) increase (E2). These challenges emphasize the need for approaches that address temporal, evaluative, and financial aspects of product development.

The prospect of platform integration of code requirements, potentially facilitated by artificial intelligence (AI), stands out as a promising opportunity (E4). Additionally, the development of product platforms offers an opportunity to structure design decisions through rules and guidelines that promote flexibility within a standardized set of solutions (E1). Cross-training initiatives among design and manufacturing representatives is another opportunity to foster a shared understanding of possible solutions in both domains (E9). Experts emphasized the importance of R&D and prototyping as strategies to support design decisions (E7).

How to fulfil demand for customization in product development while achieving operational efficiency in fabrication and assembly? (Question 3.3)

The experts reiterated previously-mentioned practices in answering this question, such as iterative improvement (E7), competent software(s) integration (E7), use of tools to continuously measure the impacts of customization on fabrication (E2), and establish robust product platform boundaries (E6) to ensure that both customer wants and operational demands are achieved.

By contrast, the first-time fabrication poses several unknowns (E2). Some of the opportunities raised to respond to these challenges were cost transparency (E7), designing and engineering with the understanding of what is a good operational performance and how to achieve it (E9), and utilizing projects to build platforms when possible (E1, E6). This suggests utilizing individual projects not only to fulfil immediate requirements of a specific context, but as opportunities to develop more consistent product platforms for use on subsequent projects.

DISCUSSION AND CONCLUSIONS

This paper discussed practices, challenges, and opportunities related to the development of single- and multi-family modular housing products and integration among stakeholders in the IC context. Results of this study can be summarized and categorized into five topics:

1. There is a need to align decisions and interests from different stakeholders at a strategic level. This includes defining someone in charge of managing conflicting interests and ensuring that customers and companies' requirements are considered and aligned with the level of customization and the defined business model goals;
2. Ensuring collaboration among stakeholders from the early design stages is imperative for improving product development and production system design. It is also necessary to use data on customer requirement and production capabilities, in order to foster a more competitive IC industry. This includes the implementation of initiatives for a better visualization and understanding of constraints, and the analysis of trade-offs;
3. Capturing, structuring, analyzing, integrating, and presenting information about customers' needs, companies' capabilities, and distinct code requirements within and among companies is crucial to support decisionmaking and for the IC industry to work together to overcome the challenges of competing with traditional construction;
4. Developing product platforms to define SSs can help IC companies to establish the boundaries of each market segment and its product families while reaching economies of scope and scale through repetition. The product platforms should be flexible to absorb changes over time and intuitive for the stakeholders to follow standards;
5. Promoting continuous improvement and learning through iterative development of products and reuse of solutions. This includes measuring performance across projects; prototyping and using MVP to shorten cycles or refinement; investing in data capture and analysis; understanding and communicating what good performance is and how to achieve it; and what is the response of the market to the offers.

The following steps of this investigation include the development of prescriptive knowledge that can be used to support the development of mass customized products for IC, and conducting a second round of interviews with experts to assess the utility and applicability of those prescriptions. Finally, suggestions for further research include to improve understanding on how to capture, structure, analyze, communicate and use design, engineering, manufacturing, and customers' requirements to support product development and production system design.

ACKNOWLEDGMENTS

We would like to thank Companies A, B, C, and D for the research collaboration and for their contributions to the development of the Empirical Studies. We also would like to thank the Coordination for Improvement of Higher Education Personnel (CAPES) for sponsoring this investigation. Finally, we extend a special thanks to the experts who took part in the workshop and shared their knowledge and experience. This study was supported by members of the Project Production Systems Laboratory (P2SL) at UC Berkeley. We gratefully acknowledge all support received. Any opinions, findings, and conclusions or recommendations expressed in this paper are those of the authors and do not necessarily reflect the views of members of P2SL.

PROCESS MODULARITY – A LEAN APPROACH TO DEVELOP INDUSTRIALISED BUILDING PLATFORMS

Mohaimeen Islam[1], Victor Bunster[2], Rachel Couper[3], Alireza Jalali Yazdi[4] and Duncan Maxwell[5]

ABSTRACT

The concept of modularity within product platforms and lean thinking has drawn attention in recent years, to achieve a balance between standardisation and customisation in industrialised building (IB). Modularity plays an important role in IB, where companies use standardised modules on common platforms for product development. Although the application of product modularity is widely discussed in the literature, the concept of modularity is not fully explored as a mechanism for process development, aiding to improve cost efficiency, quality and coordination across the IB value chain. Previous research within lean construction emphasises the importance of modularity in both product and process dimensions. However, a lack of clear understanding has impeded the full adoption of process modularity in IB platforms.

This paper examines the work processes of a Japanese case company to identify modular patterns in the technical systems for varied house production. By analysing qualitative data, the findings present potential advantages of modularity in the case company's lean approach to standardise the design, production, assembly and logistics processes. The study contributes in presenting a concept of process modularity to support developing process platforms in IB.

KEYWORDS

Process modularity, industrialised building, lean construction, platforms, technical system

INTRODUCTION

Industrialised building (IB) is seen as a means for streamlining building processes and promoting efficient and cost-effective activities to reduce resource waste (Björnfot & Stehn, 2004). IB comprises various constructs that require integration and continuous development to enhance productivity, product variety and quality through product and process predefinition (Lessing, 2006, 2015). This approach aligns with the concept of lean construction that defines a methodology for work structuring, aiming at streamlining the whole construction process across design, production and assembly (Ballard *et al.*, 2001a; Koskela *et al.*, 2002). Recent studies suggest that such efficiency has been achieved by a number of IB companies through

the adoption of a product platform approach (Jansson, 2013; Jensen *et al*., 2013; Johnsson, 2013; Thuesen & Hvam, 2011). Originating in manufacturing, a product platform is defined as “the collection of assets (i.e., components, processes, knowledge, people and relationships) that are shared by a set of products” (Robertson & Ulrich, 1998, p. 20).

Hvam *et al*. (2008) contributed to platform-related research by examining varying degrees of pre-engineering in four production strategies: Engineer-to-Order (ETO), Modify-to-Order (MTO), Configure-to-Order (CTO) and Select-Variant (SV) (Figure 1). At the lowest level – ETO strategy, traditional project-oriented norms and standards predominantly define pre-engineering. MTO involves increased use of standardised technical solutions. CTO employs predefined parts, components, and modules for building configuration, while SV involves the pre-definition of entire buildings with minimal project-specific solutions (Hvam *et al*., 2008). ETO and MTO strategies typically result in increased flexibility in traditional building production, with project-specific solutions. On a contrary, in CTO and SV strategies, limited flexibility in product offerings allows high levels of platform predefinition, where modularity plays an important role in product and process standardisation (Gosling & Naim, 2009; Johnsson, 2013; Lessing & Stehn, 2019). Extending this concept, Johnsson (2013) suggests that the dominant production strategy in construction is ETO, which allows different settings for the utilisation of platforms in house-building: design-to-order, adapt-to-order, and engineer-to-stock. By utilising an adapt-to-order structure – a subset of ETO, components of the design solution are pre-engineered, and the final product is achieved by assembling these pre-engineered parts. According to Johnsson (2013), such a strategy allows standardising and modularising processes along with the products.

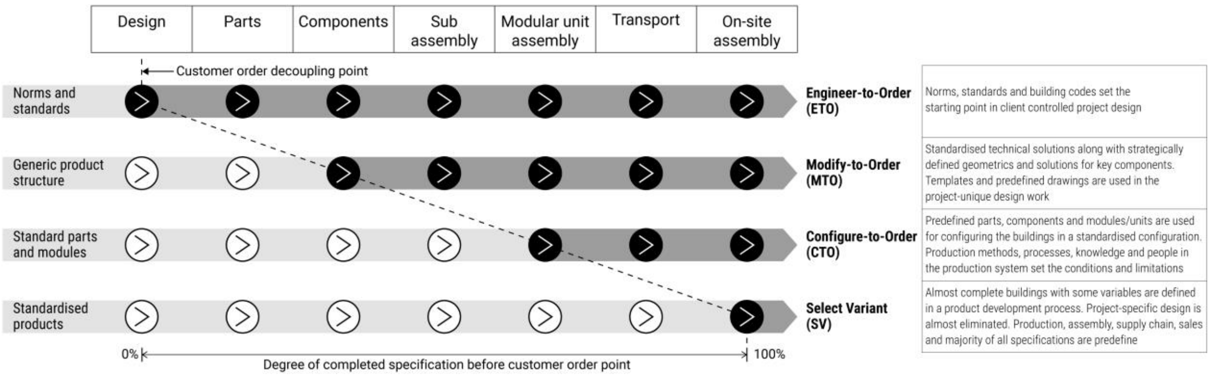

Figure 1: Four platform strategies in construction. Figure 1 adapted from Hvam *et al*. (2008)

Although modularity as a concept has received considerable interest among academics and practitioners, for product standardisation, there has been less research on the aspect of modularising IB work processes. Johnsson (2011) underscores the significance of standardising technical systems as strategic assets across the IB value chain. This involves structuring building activities, rules and decisions as process modules (Lessing, 2006; Lidelöw *et al*., 2015). The paper argues that these process modules have common attributes enabling their flexible rearrangement and interchangeability across multiple projects.

Reviewing the literature on modularity, lean thinking and technical systems as a basis, this study explores existing approaches to modularising work processes in IB. Empirical data are gathered from a Japanese case company and include live observation and document analysis, where the house design-to-production process and platform application were examined based on lean thinking. The aim is to analyse the technical systems across the IB value chain to evaluate the approach in modularisation, reuse and scalability of processes in varied projects. The analysis identified modular patterns within the case company’s technical systems across the design, production, assembly and logistics workflow, including relationships between actors, activities, and assets. From the evaluation of the findings this paper presents an understanding of the concept of process modularity from a lean perspective. Such an understanding of modular building processes is useful for developing IB process platforms and identifying opportunities for future research on this topic.

LITERATURE REVIEW

MODULARITY

Modularity has been an important topic within engineering literature and it refers to the structure of a product or process that comprises smaller subsystems (i.e. chunks or modules), and is managed independently, yet can perform together holistically (Baldwin & Clark, 1997; Ulrich, 1995). A module is perceived as a self-contained unit with its own functionality and standardised interfaces that interact based on the systems' definition. (Miller & Elgard, 1998). From a product design perspective, such independence of module development allows a company to standardise components and create product variety, with minimal impact on production. These concepts view modularity as a product development strategy, utilising a product platform approach (Simpson, 2004). In the construction context, modularity is frequently viewed through a product lens, referring to the utilisation of basic building blocks (Rampersad, 1996). Furthermore, research in construction on production systems and pre-engineering approaches (i.e. ETO, MTO, CTO, SV) have left modules with a rather narrow role as highly standardised volumetric units (Jonsson & Rudberg, 2014).

Nevertheless, modularity influences not just the architecture and structure of products but also the organisation and processes involved in their design and production (Baldwin & Clark, 1997; Fine, 1998). A modular process becomes significantly useful when a system becomes so large that interdependence between physical components for integrated design and production becomes difficult (Rocha & Koskela, 2020). Fine (1998) argues that the level of modularity present in the final product aligns directly with the level of modularity in the construction processes and supply chains. Fine's claim consequently presents three perspectives of modularity – product, process and supply chain modularity. In light of these insights, this paper aims to explore the concept of process modularity, shifting focus from mere product-driven considerations towards reshaping and streamlining organisational structures and supply chain dynamics to enhance adaptability and efficiency in IB.

PROCESS MODULARITY

The building process involves project-specific work activities that are often not pre-defined (Knotten *et al.*, 2015). These activities result in highly varied combinations of workflows for each project (Sibenik *et al*., 2022). Sibenik *et al*. (2022, p. 1) argue that single activities within the building workflows "are similar and constitute patterns that could allow for modularisation and eventual standardisation." According to Sibenik *et al*., identifying modular patterns becomes possible when building processes are divided into shorter processes or subprocesses as work activities. A modular process enables the use of shared production system, parallel assembly, along with standardised manufacturing, delivery, and assembly activities (Lennartsson & Björnfot, 2010; Peltokorpi *et al*., 2018). Lennartsson and Björnfot (2010) refer to this approach as process modularity, which is concerned with standardising building operations with shared interfaces. In IB, such standardised building operation means to utilise a set of technical solutions and processes for varied product developed, i.e design decisions, planning methods, component and interface configuration, workflows, supply chain logistics, production systems etc., across the entire building value chain (Lessing, 2006, 2015). Building on this, Peltokorpi *et al*. (2018) emphasise the process asset within the product platform definition. In their view, platform assets contributing to enhanced outcomes in IB are not necessarily standard components but rather standardised processes for manufacturing, preassembling, delivering, and assembling components on-site. These concepts relate to Bjornfot & Stehn's (2004) claim that process modularity effects in the IB value chain can be examined through the following criteria (Table 1):

Table 1: Effects of process modularity in IB. Table 1 adapted from Bjornfot & Stehn (2004)

Development of new modules	Its approach to the development of new modules with standardised processes
Allowing external variety	Its approach for minimising internal complexity and enhancing external variety
Production optimisation	Its strategy for designing and using standardised products and processes to achieve optimised production
Reusability and reconfigurability	Its approach to reuse standardised processes while recycling and reconfiguring modules to develop differentiated end products

In achieving these modularity effects, Bjornfot & Stehn suggest two strategies for viewing the construction process: top-down or bottom-up. The top-down view looks into streamlining processes by implementing lean thinking. It relates to the production system of new products that are volume-based, often caters for end customers' needs and allows the reusing of previous processes and technologies (Björnfot & Stehn, 2004). On the contrary, in the bottom-up view, the design of the product and the unique needs of end customers guide the production processes. This is more relevant to an ETO-based strategy in project-specific construction (Koskela, 2003). In lean terms, the top-down approach is suitable for CTO-based IB companies to achieve both product and process value, leveraging modularity and reusability of building processes.

Lean thinking

As previously discussed, modularity of processes can optimise the entire building workflow from design through production, assembly and delivery of the completed building. This relates to lean thinking, where the primary goal is the elimination of waste and the creation of value (Green, 1999). The term "lean" stems from the Japanese manufacturing industries as "Lean Manufacturing (LM)", where the aim is to optimise the value stream in mass production (Ballard *et al*., 2001b; Koskela, 1997; Womack & Jones, 1997). In the building industry, the concept is called "Lean Construction," aiming at improving site-level production, as well as increasing the value delivered to the customers (Ballard & Howell, 1994). Bjornfot & Stehn (2004, p. 6) define lean construction as "a process management discipline offering management during the whole construction process, aiming at streamlining production."

In lean construction, the organisation of production is referred as work structuring (Ballard *et al*., 2001a; Koskela *et al*., 2002). In this manner, applying modularity of processes leads to achieving lean construction principles, as it allows work structuring to reduce complexity and waste from design-to-completion stages in IB (Bertelsen, 2005). Bertelsen (2005) argues that modularisation allows an efficient construction process, asserting that such an approach is lean as it minimises customer influence on design while enhancing product quality and process flow. Lidelöw *et al*. (2015) further highlight that process modularity can support knowledge innovation and the breakdown of activities, helping to structure work processes through the interdependencies between them. Such work structuring relates to developing and reusing technical systems as a way to improve the IB platform strategy (Jansson *et al*., 2015).

Technical system

Within the concept of lean construction, the approach to streamlining the complex IB processes and modularising workflows entails standardising technical systems as strategic assets across the building value chain (Johnsson, 2011). Technical systems involve not only defining product configuration but also a set of rules, instructions and guidelines that govern the design, installation and operation of those building systems (Lidelöw *et al*., 2015). Standardising technical systems means analysing building activities and decisions to optimise all stages of the building processes with a focus on reusability across diverse projects. In analysing technical systems, information is partitioned into visible rules – comprising architecture, interfaces and standards. Architecture describes the modules that are part of the applied building system, whereas interfaces describe interactions between the modules, and standards govern how the modules are functioning in the system (Baldwin & Clark, 1997). In this relation, building systems relate to physical component configuration and are generally categorised into five types (Figure 2): site, structure, skin/enclosure, services, and space including furnishing and fixtures (Smith, 2010). According to Johnsson (2011), the choice of a building system defines not only what technical systems are required for standardisation, but also the organisation within the company, its market position and future growth.

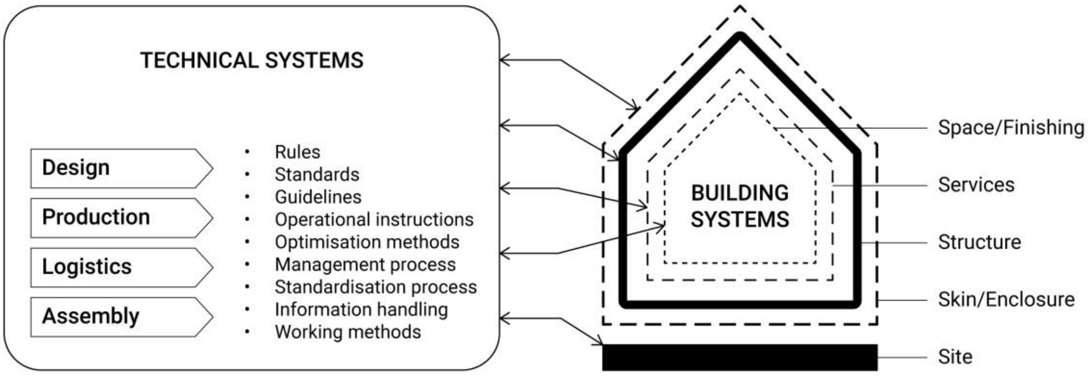

Figure 2: Relationship between technical systems and building systems in IB. Figure 2 adapted from Smith (2010)

Lessing (2006) includes a process model for IB that is supported by a technical and process platform. The process model emphasises the significance of technical systems in IB platform development. The technical systems include structural frames, installations, façade, roof systems etc., and are used for configuring complete buildings. According to Lessing, a technical platform configures technical solutions: establishing standards, and developing technical systems suitable for effective production, transportation, and assembly of building components; whereas the process platform involves a systematic collection of instructions and organisation of process modules concerning collaboration, design, planning, production and logistics methods, information handling systems etc. (Lessing, 2006, 2015). Lessing's (2006, 2015) concept of utilising technical systems, however, relates to the product side, concerning the configuration of building systems. However, building on the earlier literature, it can be argued that developing technical systems is not limited to standardising physical configurations of building systems and rather requires structuring associated work activities (i.e. workflows, collaborative decisions among different stakeholders, design, production and assembly methods etc.). In this manner, the modularisation of technical systems requires an efficient process platform to allow work structuring across the IB value chain. In Lennartsson and Elgh's (2018) view a properly developed process platform should facilitate structuring technical systems and enable lean practice both in design and production in IB. In this paper, the concept and implication of modularity are tested by analysing the building processes of a case company that enables a lean approach in their platform application.

RESEARCH AIM AND METHOD

This paper aims to understand the modular patterns, concerning work activities, actors, and assets, across the design-to-production phases, to evaluate the effects of process modularity

(Sibenik *et al*., 2022). To achieve this aim, a Japanese IB company (named in this paper as "H") was studied by mapping their technical systems as design and production interfaces. The company was chosen due to its extensive application of lean construction while meeting customers' requirements during house production. A visit to the factories of case company H was organised to observe the design, prefabrication, assembly and logistics processes of their varied modular house products. Through a Case Study Research (CSR) method, qualitative data concerning design and production processes, technical systems, supply chain management, working methods, knowledge resources, product and platform development strategies were captured and also through studying the supplied documents, i.e. drawings, reports etc. CSR is useful for studying a phenomenon in its natural context, as it enables the comparison of different theories and observations from empirical data (Miles & Huberman, 1984). In this method, a qualitative approach to collecting empirical data provides an opportunity to obtain a sufficient level of detailed information (Gummesson, 2000). While assessing the company's technical systems and platform strategy the research seeks to respond to the following questions:

1. Are there any recognisable modular patterns in the technical systems of the IB company?
2. How process modularisation strategies are currently utilised in the technical systems to support the development of a process platform?

Through the observations and documentation, and the analysis of the captured data, this study a) identifies modular patterns within the case company's technical systems across the design, production, and assembly processes, b) suggests a concept of process modularity that supports the development of an efficient process platform, and c) presents an opportunity for conducting future research on process modularity from a lean perspective.

CASE DESCRIPTION

The studied company has been a market leader in factory-built residential housing in Japan since the 1970s. The company manufactures volumetric houses across eight strategically located factories in Japan. These facilities utilise highly automated systems for the production of a variety of standardised components, aiming to attain greater economies of scale. The company applies a platform-based IB strategy for component production, with up to 80% - 85% of final production completed on the factory's automated assembly lines. The company utilises standardised building systems such as façade systems, building frames, wall and floor panels, and modular interfaces across a wide variety of project types to enable non-repetitive and unique product offerings. A lean modular approach has allowed the company to work towards optimising the entire building process, achieving an efficient flow of projects across multiple production lines. The building system is based on volumetric blocks, utilising both steel and timber-frame volumetric units. The system is defined as a Unit Method, where the functional spaces are produced as units and then several units are assembled on-site using standardised interfaces. The company is vertically integrated, incorporating sales, design, production, construction, after-sales, servicing and remodelling - all under the same organisation.

BUILDING PROCESS

This section presents an analysis of the collected qualitative data providing an overview of the product development process across the design-to-assembly stages for various house products. These findings are synthesised in the next section to discuss modular patterns that are identified.

The house product developed by the case company incorporates product families, building systems and previous house models. Most units, accounting for 80 per cent, are constructed with light gauge steels, while the remaining 20 per cent are built using light wood frames. In the factory, light gauge steel frame units, acting as "chassis", undergo customisation according to customer specifications, and serve as the primary structural support. The top factory floor fabricates the chassis while the bottom floor applies external & internal finishes, internal fit-outs, cables, pipes and indoor sub-components such as stairs, cabinetry and other equipment, with a just-in-time approach. The company has developed 6 basic house types, which can be customised using 70 types of units, including 40 standard cuboids available in 10 different lengths, 2 heights, and 2 weights, while the rest are uniquely shaped units, like trapezoids. Square steel tubes are used in different sizes for different applications, including: (i) 100 to 120mm tubes for posts, (ii) 200mm tubes for the beams, and (iii) 150mm non-flexible tubes for the floor beam. Typically, 10 to 15 of these steel-framed volumetric units, adjusted based on the house size and customer demands, are assembled to construct a two-storey family house with an approximate floor area of 130-150 sqm. For manufacturing efficiency, the units are designed for transportable dimensions, typically measuring 1.8 - 5.4m in length (nine standard lengths), 2.5m in height, and 2.4m in width. Moreover, the company provides units in half-sized dimensions for each measurement and also uses partitions at fixed 900mm intervals.

While configuring units for varied house types, the exterior and interior finish combinations vary (compound panels, composite panels with pre-attached veneers, aluminium plates, gypsum boards, etc.); so do roof styles (flat, sloping etc.), stairs, kitchen and bathroom fittings, plumbing fixtures, and light-switch locations. An average house contains approximately 30,000 distinct component types out of a vast selection of over 300,000 available options. The IB company also created an Open Engineering System (OES) that possesses the capacity for further development or transformation into new product models. For production efficiency the company employs a two-part order system, each unit divided into parts, prepared to basic standard specifications (concerning frames, floor, wall, and ceiling panel etc.) and standardised options (i.e. colour and finishes). Upon receiving a customer's order, the sales company drafts the floor plan and passes it on to the factory point with component specifications. A computer-controlled production management system handles received data necessary for diverse component assembly on the 400-meter production line. Constructing a house within the factory typically takes about three hours. It starts with cutting steel components for framing the units and progresses through the zinc coating process. This includes frame fabrication, including robotic automatic arc welding of ceiling and flooring elements to form a skeleton. After the welding process, the steel frame chassis progresses through the conveyor belts and receives finishing touches across more than 50 workstations. Workers proceed to install all essential panels, windows, doors, staircases, services, bathroom and kitchen units, and fittings according to work schedules. In this step, varied suppliers deliver materials, parts, components, and prefabricated sub-systems (such as bath and kitchen units) just-in-time and just-in-sequence through the gates placed on both sides of the assembly lines. Installation of external cladding, electro-mechanical services and plumbing are conducted in the next stage. At the final workstation, some units are stored and others are prepared for delivery. The on-site tasks encompass site preparation (2-3 weeks), assembling units, immediate weatherproofing, airtightness and connecting to utilities (1-3 days). After the initial assembly, additional work including minor interior and exterior finishing is completed within a month. To maintain quality and 100% error-free product handover, rigorous inspections occur post each production step. The stringent factory processes, supported by lean principles lead to decreased failure rates while improving the overall quality and long-term reliability of the building products. Figure 3 shows the streamlined design-to-assembly workflow for house production by the case company.

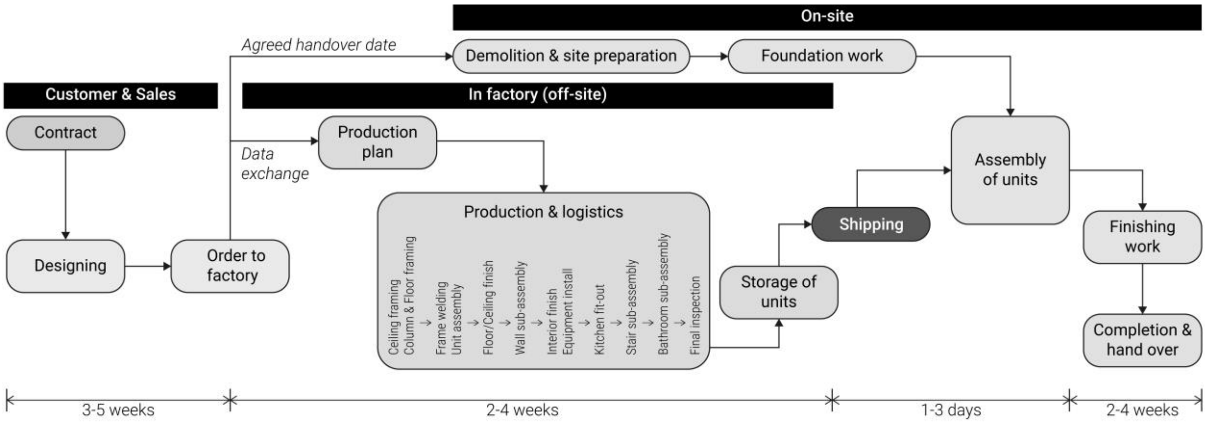

Figure 3: Standardised design-to-assembly work processes by the case company.

DISCUSSION

The case company presents a top-down view from a lean modular perspective to streamline processes (Björnfot & Stehn, 2004). This allows for reusing previous processes and technologies, achieving economies of scale. In this sense, the company adopts an adapt-to-order subset of ETO strategy as referred by Johnsson (2013) in developing its product platform with pre-engineered solutions. By applying such a strategy, the company responds to the individual demands for housing solutions while enabling modularised processes, product architectures, and supply chains. The platform assets (components, processes, knowledge, people, and relationships) described by Robertson & Ulrich (1998) are well-established in the case company through (1) a modular structure of the product - Unit Method, (2) a well-described technical system across design-to-production process, (3) technical know-how and reusability of knowledge, and (4) a well-managed supply chain and logistics system. Referring to Lessing's model, the interchangeability and reusability of the work processes (e.g. collaboration, design, planning, production and logistics methods, information handling systems) support the development of an efficient process platform by H. Building on Bjornfot & Stehn's (2004) concept, the analysis of the collected data identifies process modularity patterns as follows:

Development of new modules: The Open Engineering System (OES) developed by the company, based on parameters, enables the direct translation of customers' desired floor plans into production sequences, logistics, and work tasks. This reflects a lean approach to streamline the design-to-production processes. This innovative system has the potential to create new platforms and product variants using existing components and reconfigure building processes for new house production.

Allowing external variety: The houses made by H are assembled from several volumetric units. These room-sized units offer variety in the room layout, house shape, roof type, kitchen and bathroom pattern, materials, colours, finishing, fixtures, and fittings. By accommodating these varieties of standardised options, the units are customisable, allowing distinctiveness from each other. Moreover, the interfaces of the components and units are also standardised, reducing internal complexity while increasing external variety. Table 2 presents a synthesis of how standardised components are used to allow a certain level of customisation in the case company's varied house production.

Table 2: Standardised components by company H allowing customisation options

Standard components	Modular product architecture, allowing customisation	
Steel frames	n/a	100-120mm tube for posts, 150-200mm tube for beams
Room units	Dimensions	10 to 15 units: 1.8 - 5.4m in length (nine standard lengths), 2.5m in height, and 2.4m in width
Wall, Floor and Roof panels	Dimensions & finishes	900mm intervals and half-sized measurements
MEP work	n/a	
Fixtures, Fittings, Finishing	Choice	Approx. 30,000 component selections from 300,000 options
Paintwork	Colour Choice	
Joining interfaces	n/a	

Production optimisation: The production process follows a lean modular approach in terms of value flows across a sequence of 50 workstations, with a focus on process optimisation in each step. The standardised interfaces of the house parts allow interchangeability of the production process for six different house configurations across the six parallel production lines. The planning, production rate and transportation sequence for these components and units are predefined and support a repetitive process strategy. Table 3 presents the modular patterns that are observed across six parallel production lines for six basic house designs:

Table 3: Modular patterns observed in varied house production by company H

Common steps	Modular patterns in the work processes
1. Customer order and design	[3-5 weeks] The involvement of customers in the design process using a CAD system is modular and reusable across multiple house productions.
2. Data transfer for order entry	[1-2 hours] Modular patterns in design involve 80% predetermined parts and 20% custom parts, with a factory order system for component selection.
3. Conversion of design to objects	[1 day] The automated conversion of design data into objects and BOM, along with weekly batched production plans are modular and standard for all projects.
4. Unit production	[1-2 weeks] The production sequence on six assembly lines is modular, with predefined tasks, and standardised and interchangeable components.
5. Site preparation	[2-3 weeks] The procedure for site preparation (including demolition and recycling of old materials) follows a modular pattern across all projects
6. Delivery and assembly	[2-4 weeks] Modular activities on-site assemble units in 1-3 days, including weatherproofing and airtightness, optimizing completion timeline in 20-30 days.

For production optimisation, the company employs a parameter-based system that helps to modularise the entire workflow encompassing design, configuration, planning, order reception, logistics, fabrication, and delivery. Furthermore, modular work patterns are also evident in production checks by inspectors at different stages for quality assurance, using a system of green, yellow, and red demarcations of defect rates. Yellow suggests required corrective action; red means unacceptable defects. All processes follow the same modular pattern, however, depending on the house product type, the duration could differ for each of the steps.

Reusability and reconfigurability: The manufactured units developed by the company are not project-specific, and can be used interchangeably in a range of house products. This allows the reuse of a considerable proportion of technical systems, pertaining to the design, production, assembly, disassembly and recycling of the units for a completely new building. The technical systems work as a knowledge repository for process modularisation, allowing for the realisation of an efficient process platform. Moreover, the company relies on long-term relationships with numerous suppliers (approximately 200) for key product components, supported by a modular supply chain structure. In reference to Jansson's (2013) claim, in this case, experience feedback from the supply chain is utilised in the platform, a strategy that follows the principles of lean thinking, where long-term strategy and holistic view are the keys. From this perspective, process modularity is closely related to the degree of vertical integration.

To summarise, the IB company H has developed modular production processes, including a well-defined modular production facility and a modular supply chain structure. Standardised work activities and experience feedback support the development of an efficient process platform to optimise building processes across the entire value chain. The long-term benefits of defining, streamlining and refining activities by experience feedback follow the perspectives of Koskela *et al*. (2002), Bjornfot & Stehn (2004), and Bertelsen (2005) on lean thinking, as discussed in the literature review section.

CONCLUSION

This paper explores the concept of process modularity and its potential to drive lean construction in IB companies. The research comprises qualitative analysis on a Japanese case company, recognising their modular work patterns and how their application of a platform-based approach enables process modularity across different stages including design, production, and assembly. Previous studies have identified the concept of modularity in product, process and supply chain dimensions, however, a clear understanding and application of process modularity is missing in an IB context. This study argues that analysing IB work activities for repetitive patterns creates the base for process standardisation, ultimately leading to process modularisation, and in turn creating the conditions for increased lean construction.

In response to the research questions, this paper first conducted a literature review to establish an understanding of relevant concepts such as modularity, platforms, lean thinking and technical systems in an IB context. Then the effects of modularity on technical systems was examined, including work processes, actors and assets, through a qualitative analysis of the observations and extracted data from the building processes of the Japanese IB company H. Through evaluation of the case study analysis this research contributes by –

1. identifying a set of modular patterns in the IB value chain that supports the technical systems involved in the development of volumetric units;
2. mapping a flow of standardised activities that are common across house products; and
3. presenting a concept of process modularity that allows reusing technical systems, supporting lean principles, and enabling the realisation of an efficient process platform.

However, the findings from the case study suggest the applicability of modular processes in an adapt-to-order subset of ETO context, where the IB company is vertically integrated. The wider scope of modularising technical systems requires further examination in other platform contexts, i.e. ETO in general and MTO, to broaden the concept of process modularity in lean construction. Also, the dependency of the work activities and the amount of allowable deviation for interchangeability of process modules are not fully explored. Moreover, the boundaries of the level of modularity of work activities are not clearly defined, which presents future research opportunities in this area. Nevertheless, the evaluation of the case study may offer future guidelines for similar IB companies who intend to implement a platform strategy where modularity of process enables an efficient process platform. Owners, designers and developers may be benefitted from this case study findings to determine how work processes could be structured and modularised to develop their technical systems, and what kind of platform strategy would best support the modularisation effects to benefit from process modularity in IB.

NET-ZERO & DIGITALISATION IN OFF-SITE CONSTRUCTION

Nwakaego Onyenokporo[1], Patricia Tzortzopoulos[2], Sara Biscaya[3], Nick Collington[4] and Shellie O'Connor[5]

ABSTRACT

The UK Government set targets to achieve net-zero buildings by 2050. Consequently, there is a need for off-site construction companies to achieve net-zero over the coming years. However, small and medium-sized enterprises in off-site construction face challenges in implementing net-zero, as well as in implementing digitalisation, which can greatly support achieving net-zero targets. This paper reports on initial findings of a project focused on improving digitalisation and net-zero within an SME off-site construction company. Through process mapping and observations, implementation barriers to digitalisation and net-zero were identified, and a set of actions are suggested. The paper also discusses tools for optimising the lifecycle carbon impact of buildings. The recommendations include accurate carbon footprint measurement, creating a realistic reduction strategy, and adopting sustainable/low-carbon materials. Additionally, the paper recommends the use of smart technology to monitor as-built and compare it with the as-designed building.

KEYWORDS

Off-site construction; Net-zero; Lean construction; BIM.

INTRODUCTION

The construction industry is seen as a low-innovation industry, with a poor track record in schedule and budget compliance, and industrial accidents. Off-site construction has been posed as a means to help improve quality, productivity, reduce waste, and lower the carbon footprint of buildings (Generalova et al., 2016). Off-site is especially important now, given the current climate crisis, as the built environment has a crucial role to play in limiting global warming to 1.5°C and enabling the transition to net-zero by 2050 (UK Green Building Council, 2023).

To reduce overall emissions by 2050, it is recommended that the industry improve energy performance and reduce the carbon footprint of building materials through carbon emissions analysis and calculation models and by using sustainable materials (Sheikh, 2022; Chen et al, 2023). Furthermore, there is a need to multiply policy commitment alongside action and increase investment in energy efficiency (Sheikh, 2022). Figl, Ilg and Battisti (2019) explain that carbon neutrality must be considered at the early stages of building design and planning for the industry to meet the 2050 target.

It is known that Building Information Modelling (BIM) and Lean provide diverse opportunities for improvements. However, most companies are not yet exploiting this to its full potential. The implementation of BIM, Lean, and net-zero carbon is evolving and is a significant area where academic research can create solutions applicable in practice.

This research aims to support net-zero and digital transformation within one off-site construction company, implementing new processes and technologies to enhance productivity. It seeks to achieve BIM adoption, carbon footprint measurement and reduction, and the adoption of sustainable/low-carbon materials within the off-site construction process. The focus of this paper is to discuss the existing application of BIM and Lean towards the design of net-zero buildings in the company, to enable it to move forward in achieving the UK Green Building Council (UKGBC) net-zero targets by 2050.

LITERATURE REVIEW

DIGITALISATION AND BIM

Construction is one of the least digitalised industries (Veselka et al, 2019), even though there has been an increasing adoption of digital technologies, such as BIM (Gan et al, 2023). BIM encourages collaboration between project stakeholders fostering an integrated project delivery (Rowlinson, 2016; Gan et al, 2023). Furthermore, BIM allows for evaluating alternative designs, and hence design optimisation (Gan et al, 2023).

However, according to Holzer (2011) and Rowlinson (2016), drawbacks for BIM implementation include a focus on software rather than improving the design process, and ambiguity concerning BIM features which causes confusion across the industry. Interoperability issues also exist, and where team members use software programs from different distributors, a neutral transfer format is required for the different data to work on a common building model (Figl, Ilg and Battisti, 2019). Additionally, the use of BIM is still very monodisciplinary and profession-based, which does not encourage an integrated process (Rowlinson, 2016). There is therefore a continued need for supporting the implementation process before BIM benefits can be fully realised.

In the UK, the construction sector has the highest number of small and medium-sized enterprises (SMEs), approximately 882,770 (Clark, 2023). Zhang et al. (2016) highlight that the use of BIM provides great opportunity to improve the performance of off-site construction, however, there is still a lack of adoption within smaller construction companies. Figl, Ilg and Battisti (2019) also highlight that SMEs may not be able to invest in expensive software or training for BIM. According to Makabate et al. (2020) the adoption of digitalisation through BIM is a necessity for most of SMEs in the coming years.

CARBON NET-ZERO

Construction is one of the highest consumers of energy (Llatas et al, 2019). Globally, buildings and the construction industry account for 36% of final energy use and 39% of energy and process-related carbon emissions, of which 28% is operational carbon emissions and 11% is from the manufacture of building materials and products (International Energy Agency, IEA, 2019; World Green Building Council, 2019). Over the years, several strategies have been applied to tackle this, for instance, through the implementation of lean, adoption of renewable energy for operations, adaptive re-use of existing buildings, reuse and upcycle of waste by promoting a circular economy, use of digital technology, and use of environmental assessments and ratings. However, by 2035, a significant portion of the emissions from the built environment is predicted to be attributed to embodied carbon, due to the ongoing efforts to reduce operational carbon emissions from buildings (UK Green Building Council 2021a; 2023).

The World Green Building Council (2019) has therefore stipulated that by 2030, new buildings, infrastructure and renovations will have at least 40% less embodied carbon and net-zero operational carbon. By 2050, new buildings, infrastructure or renovations will have net-zero embodied carbon, and all buildings must be net-zero operational carbon. The industry needs to combine efforts and take decisive actions towards achieving these targets.

NET-ZERO DESIGN AND METHODS OF ASSESSMENT

According to the UK Green Building Council (2021b), net-zero carbon in building operations is achieved when the amount of carbon emissions associated with the building's operational energy on an annual basis is zero or negative. The World Green Building council, WGBC (2019) define a net-zero carbon building as one which is highly energy efficient and fully powered from on-site and/or off-site renewable energy sources, with any remaining carbon balance offset. Several assessments such as green building rating systems and sustainability certifications, have been developed over the years targeted at improving the environmental impacts of buildings (Llatas et al, 2019). Cole and Fedoruk (2014) explain that although green building performance and assessment methods have always aimed at achieving net-zero impact, net-zero energy buildings have now become a specific performance goal for attaining high recognition within the Leadership in Energy and Environmental Design (LEED) or Building Research Establishment Environmental Assessment Method (BREEAM) amongst others.

Furthermore, the focus has previously been on achieving net-zero in building operations. However, globally, embodied carbon related to materials manufacture accounts for a lower percentage of whole life carbon compared to operational carbon emissions (Gan et al, 2023). In the UK, buildings and infrastructure contribute to about 25% of greenhouse gas emissions and with the inclusion of transport emissions, this rises to 42% (UKGBC, 2023). 80% of this is associated with operational carbon from existing building stock and 20% from embodied carbon of new construction (London Energy Transformation Initiative, LETI, 2020). Although operational carbon is higher at present, embodied carbon emissions are expected to rise in the coming years. With increasing advances to improve the carbon emissions related to building operations, embodied carbon emissions will represent a larger portion of the carbon production of buildings and this figure could increase to 40-70% of new buildings in the UK (LETI, 2020).

According to the UK Green Building Council (2021b), a building can only achieve net-zero carbon "when the amount of carbon emissions associated with a building's product and construction stages up to practical completion is zero or negative, through the use of offsets." There is a potential to improve the performance of buildings at the design phase, by calculating the environmental, economic, and social impacts produced by the buildings during its life cycle. Therefore, obtaining an understanding of the lifecycle performance and incorporating quantitative assessments will improve building design and operation and foster a low-carbon built environment (Gan et al, 2023). It can also provide insights into possible economic gains and will also advance measures targeted towards achieving net-zero emissions in buildings.

The British Standard BS EN 15978:2011 sets out the overall principles of embodied and whole life carbon measurement in the built environment. The embodied carbon of a building refers to the emissions emitted producing building materials, their transport and installation to site as well as their disposal at the end of their life (LETI, 2020; BS EN 15978, 2011). Operational carbon, on the other hand, refers to emissions associated with the in-use operation of a building throughout its life (LETI, 2020). This includes emissions associated with heating, hot water, cooling, ventilation, lighting systems, cooking, equipment, and lifts. A visual representation of this is provided below in Figure 1.

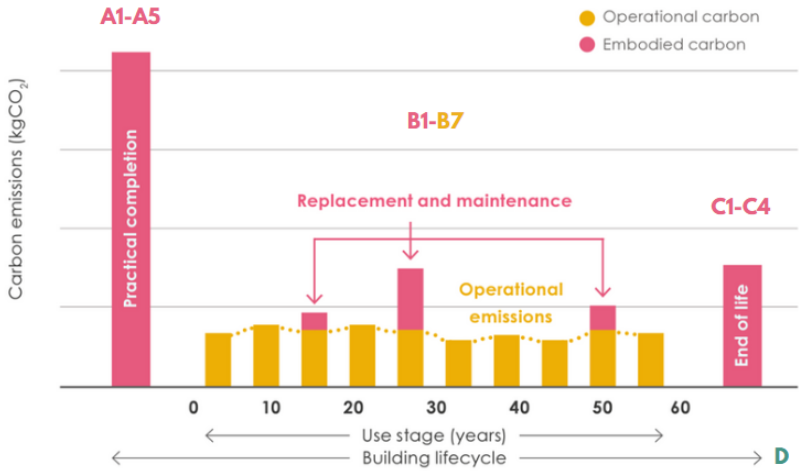

Figure 1: Carbon emissions breakdown over building's life cycle (Adapted from LETI Embodied Carbon primer 2020 and BS EN 15978:2011)

The potential to reduce carbon emissions reduces throughout the stages of a building project. According to Tsikos (2023), the lack of detailed data in early design makes it difficult to assess the impact of design decisions. Being able to quantify the embodied and operational carbon emission impact for a building project, that is the whole life carbon impact, would have a positive effect on construction and go a long way to achieving the net-zero carbon emissions. Furthermore, Collinge et al (2015) and Llatas et al (2019) explain that compared to other assessment methods developed over the years targeted at environmental aspects such as green building rating systems and sustainability certifications, the lifecycle assessment (LCA) is considered the most appropriate as it quantifies the buildings performance for sustainability through all life cycle stages. However, although LCA can be integrated in building design stages, one of its limitations is its time-consuming nature and vast amount of data required.

Gan et al (2023) explain that the use of BIM facilitates the calculation and mitigation of both embodied carbon and operational carbon emissions of buildings. BIM can be used to define construction material options and facilitate automatic derivation of material quantities for accurately determining embodied carbon (Hollberg, 2020; Roggeri et al, 2021). Furthermore, BIM has the capability to incorporate and manage a large amount of building information thus simplifying the Life Cycle Assessment (LCA) analysis by providing a visual representation of its impact (Llatas et al, 2019). Roggeri et al (2021) combined BIM with building energy modelling (BEM) to design a timber modular prototype and extract information to determine the energy impact in the building's lifecycle. To ensure net-zero design, the embodied energy/carbon, the environmental impact and the energy consumption were calculated. Similarly, Gan et al (2023) developed a BIM model to calculate upfront embodied carbon and aid energy simulation in determining operational carbon over the building's lifecycle whilst considering net-zero. They propose opportunities such as selection of low-carbon materials, operational efficiencies, modular integrated construction, and so on.

Nevertheless, although guidelines have been developed over the years by organisations such as the London Energy Transformation Initiative (LETI), UK Green Building Council (UKGBC), and the World Green Building Council (WGBC) since the announcement of the carbon net-zero targets by the WGBC and UKGBC, there is still a knowledge gap within construction industry regarding the implementation of net-zero.

BARRIERS TO THE IMPLEMENTATION OF NET-ZERO WITHIN CONSTRUCTION

According to Terblanche (2019), barriers to the implementation of net-zero buildings include high costs, limited resources and technology, client's perception of value, and lack of incentives from local authorities to promote net-zero buildings at the planning phase. There is also a lack of knowledge regarding net-zero buildings by construction professionals across the whole building design, operation and maintenance stages, leading to low implementation. Similarly, Aelenei et al (2023) mention the cost required to effectively integrate necessary technologies. Furthermore, there is not enough demand for low-carbon materials and technology and most companies just focus on low-cost products instead. Additionally, beneficiaries are not being fully aware of net-zero and its benefits for their projects (Aelenei et al, 2023). They do not have information on the materials, construction technologies and available funding opportunities. With more knowledge and understanding of the standards and guidelines by the beneficiaries and construction professionals, there will be an increase in the market demand thus encouraging construction professionals to develop themselves. This will also produce more reliable data on which policy makers can use to evaluate the success of these policies and measures.

Although several studies considered design towards net-zero and methods of assessment (Llatas et al 2019; Terblanche, 2019; Roggeri et al, 2021; Gan et al 2023), these studies have focused on quantitative data within their studies. However, the feasibility of using digitalisation and methods towards carbon net-zero design lies in its simplicity of use and effectiveness in verifying and quantifying its impacts (Llatas et al, 2019). With the transition from traditional construction to modularised and off-site construction, it is important that net-zero design and practice can be achieved within modular and off-site construction, especially as they consist of SMEs. This paper, therefore, seeks to add to the efforts of existing studies by providing qualitative data regarding the adoption of digitalisation and net-zero design in off-site.

METHOD

This study employs a qualitative methodology utilising Action Research (AR) which seeks to resolve practical problems. AR integrates research and action and involves collaborative participation from the case study participants to enhance the credibility and authenticity of the results (Argyris & Schön, 1991; Erro-Garcés & Alfaro-Tanco, 2020). For this paper, a literature review was first conducted to understand the efforts made so far regarding net-zero design and identify barriers limiting its practical adoption within off-site companies. The research also involved an in-depth understanding of a specific off-site construction company's operations, and the identification of barriers towards digitalisation and Net-zero in design, and the proposition of strategies for improvement. Data collection tools employed include process mapping, interviews with the operations manager, and observations of the company’s processes. Through the analysis of the design, off-site manufacture and on-site installation processes within the company, patterns were identified. Table 1 demonstrates the literature search applied in this study. It also highlights a lack of studies considering net-zero within off-site construction.

The selected case study – Company A - is an SME off-site volumetric construction company located in the North of the UK. The company specialises in the production of modular units, particularly in the healthcare sector, such as wards, theatres, endoscopy facilities, training facilities, etc. They also provide temporary buildings for site accommodations. These typically have a service life of less than two years and are either returned to the factory upon project completion or rented out to the next client. The company has a good client base as off-site construction is advantageous in the healthcare sector, because it causes the least disruption to the existing hospital environment and the construction is partially completed off-site, thereby reducing the total on-site construction time. The company was selected as there is an ongoing Knowledge Transfer Partnership project being developed between the company and the research team, funded by Innovate UK. The first stage of the project involved getting acquainted with the company and understanding their strategic objectives, key processes, products, and clients. It also involved getting an understanding of the volumetric modules’ workflow from design through to off-site production and on-site installation, including transport. This also involved understanding the typical design and construction of modular units off-site in the factory.

Table 1: Literature Search strategy (Data from UOH online library repository)

					No. of results	Scholarly and Peer reviewed	Engineering/ Architecture
Modular construction	AND	BIM			854	322	229

Off-site construction	AND	BIM	AND	Net-zero	1	1	1

RESULTS

PROCESS MAPPING

This section summarises the processes from planning and design to handover of the project to the clients (see Figure 2). The company’s projects are typically obtained via two routes. In the first route, they receive design briefs directly from clients for the full design of off-site structures. Here, they are the main contractors and provide all the drawings and details required for the project. In the second route, they receive the drawings from bigger construction firms and here they are sub-contractors to deliver modular buildings. RIBA Stage 3 or 4 architectural drawings are provided to Company A, and they create detailed modular designs to fit closely with the architectural drawings. They also have sub-contractors for structural, mechanical, electrical, and other required designs. Once all is agreed by the client, detailed drawings are prepared for the factory production of the modules off-site and the final installation on-site.

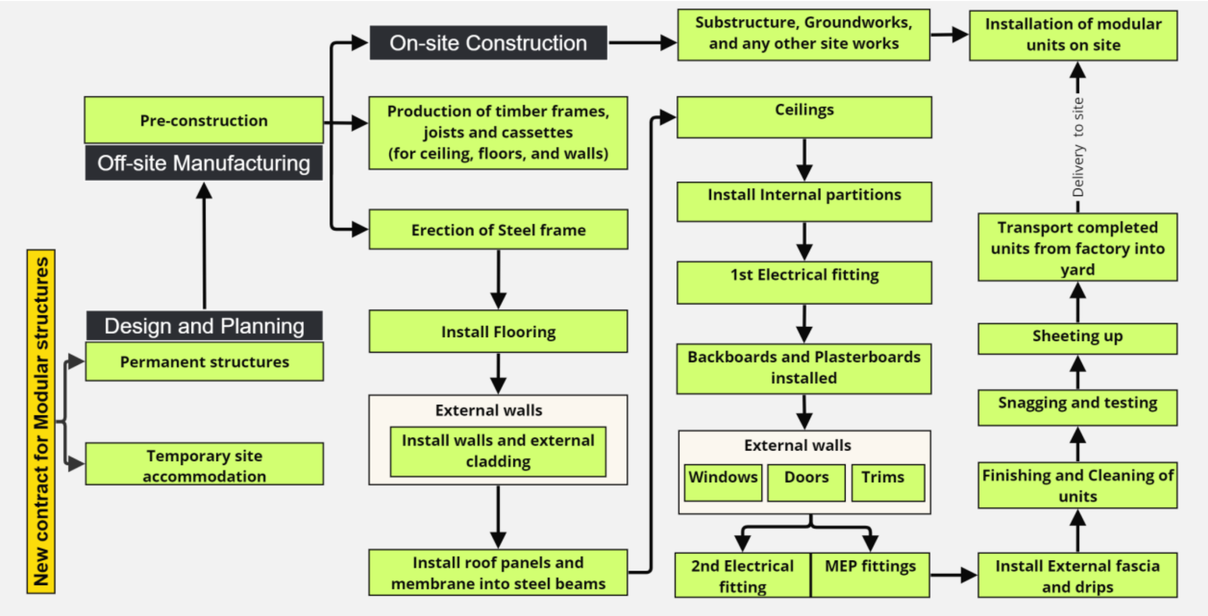

Figure 2: Summary of Production workflow at Company A

Through the production of the process map using flowcharts, the authors were able to identify areas for further improvement within the company.

KEY ISSUES IN DIGITALISATION AND NET-ZERO AT THE COMPANY

Current application of BIM

The use of BIM at Company A is currently limited to the big projects where it is mandated by clients or large construction companies. Although the company has architects sub-contracted to assist with BIM, they usually rely on 2D drawings and only started creating 3D models in-house using Autodesk Revit recently. It is worth noting that the company has not adopted all features of BIM such as 4D or 5D BIM. Autodesk Revit was initially introduced to enable them to view 3D models from the architects or incorporate modular design layout before sending off to steel fabricators for structural analysis.

Additionally, the team's design capabilities regarding BIM are still being developed, with only one design staff having the skillset to generate 3D models. Moreover, most of the factory and installation team still work off 2D paper drawings, which sometimes create issues with changes to drawings not being reflected, thus affecting the production process. In addition, the company produces material quantities and schedules for projects manually, especially for timber. Similarly, where clash detection is needed, this is currently done using 2D drawings. This has caused problems on-site, where the company needs to reconfigure designs to address clashes that were only identified during installation.

Current state of Net-Zero

In terms of the company's operations, one challenge is the lack of readily available data to quantify corporate carbon emissions, such as waste quantities. The waste generated from off-site manufacturing processes is not clearly quantified, except for paper waste. Additionally, data on the end-use of waste is not easily accessible from local waste management contractors. Moreover, manual material take-offs for materials like timber lead to high waste production, and sawdust is not quantified and often mixed with other dust waste from materials like plasterboard and plastic.

Despite these issues, the company has made significant strides in reducing their carbon footprint. For instance, they have included a biomass wood burner in their factory to aid with heating, and timber off-cuts are used as biomass fuel for the wood burner while the rest are sold.

They have also obtained electric vehicles for company use and converted most of their factory lights to dimmable LED lights.

Regarding net-zero building design, there is a lack of information regarding the embodied carbon of building materials used for the module envelope design. Life cycle assessments are not yet conducted for projects, and embodied carbon of materials is not considered during procurement. However, the company ensures that the timber they purchase is certified by either the Forest Stewardship Council UK (FSC) or Programme for the Endorsement of Forest Certification (PEFC) to ensure environmental sustainability. The main considerations for material selection are fire performance, thermal transmittance co-efficient (u-values), and cost.

To improve operational energy and carbon emissions, the company conducts BREEAM assessments and/or obtains Energy Performance Certificates (EPCs) for their big projects. Building energy modelling and analysis are currently outsourced and typically conducted after the technical design has been completed. Although Simplified Building Energy Modelling (SBEM) is conducted for many projects, dynamic thermal modelling to carry out full building performance analysis is done when requested by clients or when complex HVAC systems are used. To achieve carbon net-zero in all future projects, it is recommended that the whole life carbon analysis is conducted from the design stage through to final construction.

BARRIERS TO BIM AND NET-ZERO AT THE COMPANY

Regarding digitalisation, one of the barriers identified is that the construction process is very fast-paced, which stops the company using BIM more widely, due to the initial lack of productivity, which is common during the initial stages of BIM implementation. Similarly, many of the company's smaller jobs are still done in 2D as the clients do not require 3D models.

Another limitation is that many of their sub-contractors work in 2D, so it is not possible to do, for instance, automated clash detections. There are also interoperability issues with diverse file types used by different sub-contractors or the client and lack of coordination using BIM (except for big projects where BIM is mandated). Another limitation is the cost of training and software required, such as licenses for Autodesk AEC collection. The cost of training and software required to use advanced tools like energy modelling or whole-life carbon analysis is another current limitation.

PROPOSED BIM AND LEAN STRATEGIES TOWARDS NET-ZERO

Off-site construction aims to reduce project costs through standardisation, unification, and typification (Generalova et al, 2016). However, considering the net-zero targets, it is imperative to consider the whole life carbon impact of materials used. The implementation of Lean and digital strategies will facilitate better value generation and profitability through improved productivity, reduced waste, and the development of carbon efficient products. Lean principles are aligned with sustainability goals as they offer positive economic, environmental, and social impacts to a project. For instance, waste elimination and process streamlining enable efficient project completion and cost reductions, improve schedule adherence, improve predictability, and minimise uncertainties and delays. Additionally, projects can benefit from energy efficiency, use of sustainable materials, and safety on site for all workers. The identified areas for improvement were developed with the company's team and are summarised as follows:

Building Information Modelling (BIM)

The use of BIM will improve integration between planning, design and construction. This can lead to shorter design processes and better outputs, which meet industry targets. Additionally, increasing in-house design capabilities will help in reducing reliance on third parties. The design process will be better aligned with off-site processes, enabling more standardised physical production at the factory. According to Zhang et al (2016), data from the BIM model could provide relevant information to enable an integrated design, manufacture, and construction and in-use/maintenance process. It could also support the manufacturing process from procurement of materials to the end transport and installation on construction site. Errors can be identified during design rather than production through the implementation of BIM.

According to Gan et al (2023), building energy modelling allows the advanced calculation and analysis of building performance considering the location and geometry of the building, its construction and materiality, thermal zones, occupancy schedule, equipment, HVAC systems etc. Developing a digital model and simulating virtual construction environment will allow for building performance modelling and whole life carbon assessment during the design stage to final construction, aiding the evaluation of project carbon emissions. Furthermore, BIM adoption will make it possible to optimise the planning of works in the construction phase.

Carbon Footprint

In addition to the project carbon emissions, the authors further recommend strategies to improve the corporate carbon footprint in terms of business operations. This involves developing a carbon reduction plan and striving to achieve the carbon reduction targets, building on existing design and construction experience and utilising state-of-the-art and knowledge to refine construction methods. The corporate carbon emissions resulting from the company's operations and assets will also be calculated and avenues for further improvement will be highlighted. This involves calculating the annual scopes 1, 2 and 3 carbon emissions using tools and guidance set out by the UK government (2021) and the Greenhouse Gas Protocol (2022). Scope 1 emissions are incurred directly by the company, Scope 2 emissions are indirectly incurred by the business and Scope 3 emissions are indirectly incurred emissions from upstream and downstream activities within their value chain.

Material and Resources

There is also a need for the company to evaluate its resources and improve procurement processes for materials. This will involve an assessment of procured materials and wasted materials to look at cost savings and opportunities for reuse where possible. Also, considering new materials and incorporation of low carbon materials that have better capabilities for reuse, recycle or upcycle at the end of their life while still meeting regulations for fire performance, thermal performance, and considering cost. One common use of BIM is to obtain bill of material quantities (Soust-Verdaguer et al, 2017) which will be useful to Company A and save them from deriving this through manual calculations.

Building product information can assist in accurate measurements of embodied and whole life carbon emissions and can improve accuracy around carbon reporting. There is a need to consider third-party certification for construction products to show the reliability of the data; these could include responsible sourcing certification, Environmental Product Declaration (EPDs) and so on. EPDs are internationally recognised and communicate the environmental impact of a product. For construction products, life cycle assessment (LCA) is carried out to estimate the environmental impact at different stages of the lifecycle using EPDs, and there is an increasing demand for construction products to have EPDs.

Smart Building Technology

The use of smart building technologies, such as building management systems, can improve efficiency and monitor building performance, enabling also existing performance data to feed forward the improvement of new projects. The evaluation of energy performance is based on the estimated or measured amount of energy consumed annually for providing heating and cooling for comfort, as well as for meeting the domestic hot water requirements (Cole and Fedoruk 2014). According to Aelenei et al (2023), a gap exists between the energy performance of buildings as-designed and as-built which can be ascribed to various factors. Therefore, better monitoring of buildings using smart technologies can help fill this gap and improve the quality of simulations (Sturgis, 2017).

According to Zhang et al (2016), there is a need to further improve the performance of the industry, to better incorporate sustainability into building design and construction practises. Although this study has provided insights using one off-site construction company as case study, the outcome of this study could be adopted within similar off-site SMEs construction companies. The incorporation of these strategies throughout the project phases will enable them to evaluate the effect of their designs and building materials on a building's lifecycle carbon performance and follow opportunities for further optimisation.

CONCLUSIONS

This paper presents the initial steps towards achieving net-zero within an off-site construction company and the possibilities of adopting BIM and Lean principles to improve digitalisation, calculate whole-life carbon emissions and improve overall building performance. Future work will involve the implementation of these strategies and quantify their effectiveness. This will involve whole life carbon assessment of sample projects within the company. Additionally, the authors will implement a BIM execution plan within projects; and continuous and up-to-date carbon footprint calculation to develop a carbon reduction plan with achievable targets. A materials database for typical materials will be developed by the team considering not just fire performance and thermal performance but also embodied carbon and end of life of materials.

ACKNOWLEDGMENTS

The authors wish to acknowledge Innovate UK for funding this research study [Grant number 10065547]. They also wish to appreciate Company A for the opportunity provided for collaboration.

ROLE OF COLLABORATION IN PRODUCTION PLANNING AND CONTROL IN THE CONTEXT OF MODULAR CONSTRUCTION

Louise C. Amaro [1], Carlos T. Formoso[2], Iamara R. Bulhões [3] and Alexandre Soares[4]

ABSTRACT

Modular construction projects have complexity attributes that differ from conventional projects. To address this complexity, collaboration within production units and between different units is essential, as it contributes to resilient performance. The aim of the investigation is to understand the role of collaboration in the implementation of production planning and control (PP&C) in modular construction projects, considering complexity attributes. A case study was conducted at a Brazilian modular construction company. The unit of analysis was the PP&C system developed in this company for managing construction site installations, strongly based on the Last Planner System. As a result, a list of collaborative processes for planning and controlling modular construction projects was presented. Each process was thoroughly evaluated across six categories of collaboration factors: behavior, communication, team, management, technology, and contractual aspects. Collaborative processes related to meetings addressed the highest number of collaboration categories, suggesting that these are the most collaborative processes. In a high-complexity project, as it is typical of this modular construction company, addressing the highest number of collaboration factors contributes to alignment between sectors and achieving project objectives.

KEYWORDS

Lean construction, Production Planning and Control, Modular Construction, Collaboration.

INTRODUCTION

Modularity can be defined as the decomposition of a product into subsets and components, which facilitates standardization and increases the variety of products (Gershenson; Prasad; Zhang, 2003). Furthermore, it is considered that a modular product is composed of modules consisting of independent units with their own functionalities and standardized interfaces (Miller; Elgard, 1998; Gershenson; Prasad; Zhang, 2003). These units, according to Gibb (1999), can have a high degree of finishings installed in external environments (off-site), reducing the amount of activities carried out on-site, or they can also be limited to structural components, with the remaining activities completed on-site.

A new approach for industrialized construction has emerges from the application of the concept of modularity, named Modular integrated Construction (MiC). According to Pan and Hon (2018), MiC is a disruptive and innovative approach that transforms traditional fragmented construction with site-based installations into a value-oriented process with integrated manufacturing and assembly processes, providing greater quality, productivity, safety, and sustainability, when compared to traditional construction.

Due to the benefits provided by this new approach, such as increased speed, cost reduction, improved quality of construction, and reduced environmental impacts, it has grown substantially in many parts of the world, by replacing traditional construction methods (Molavi; Barral, 2016). Unlike traditional on-site construction, MiC usually involves a broad supply chain, with a complex network of stakeholders involved, in all construction stages, such as planning, design, legal approval, site preparation, modular manufacturing, transportation, storage, and on-site installation (Wuni; Shen, 2020). In this context, in order to get the full advantages of industrialization, proper planning for modular construction is necessary, especially in ensuring that manufacturing, transportation, storage, and installation occur in a timely and integrated form (Molavi; Barral, 2016).

The application of the modularity concept, from one hand, reduce the complexity of on- site construction operations, but, on the other hand, adds complexity by the need to coordinate several production units, e.g. design teams, manufacturing plants, construction sites. According to Saurin and Gonzalez (2013), complexity in socio-technical systems involves four attributes: (i) a large number of dynamic interactions among elements; (ii) a wide diversity of elements; (iii) unforeseen variability; and (iv) resilience to deal with an uncertain and dynamic environment. Considering these attributes, it can be stated that modular construction fits into a complex socio-technical system mainly due to the large number of manufacturing, transportation, and intensive assembly procedures, as well as the high degree of uncertainty and variability among processes. Additionally, other characteristics such as project and production fragmentation, coordination of activities in the factory and on-site, delivery process constraints due to large and heavy assembly and installation equipment, coordination to ensure that manufacturing, transportation, and assembly occur in the desired sequence and time, the need for highly skilled workers and specific construction techniques, also increase the system's complexity (Jensen; Bekdik; Thuesen, 2014; Molavi; Barral, 2016).

The complexity in modular construction systems is the combination of the intrinsic complexity of the modules and the composition of the system as a whole, which affects decision-making (Alkan; Bullock; Galvin, 2021). In this context, the management of these systems must be resilient, meaning that the managerial team should respond when undesirable events occur, monitor and anticipate developments, threats, and future opportunities, as well as learn from past experiences (HOLLNAGEL, 2018). Since it is not possible to completely eliminate variability, the production planning and control play a key role in coping with complexity in a modular construction system, and can make major contributions to resilient performance.

The Last Planner System (LPS) (Ballard, 2000) has a set of practices that have a positive impact on resilient performance, such as hierarchical planning and control, identification and removal of constraints, collaborative meetings, and a combination of delay and anticipation indicators (HAMERSKI Et Al., 2023). In fact, Pourrahimian et al. (2023) emphasize that a vital component for the success of LPS implementation is collaboration among all parties involved. Additionally, LPS promotes collaboration by bringing problems to the surface timely and enabling conversations that contribute to problem solving (Skinnarland, 2012). Those practices can also contribute to develop resilience potentials.

This research work is based on the premise that collaboration within production units and among different units is essential in Production Planning and Control (PP&C) of modular construction projects as it contributes to resilient performance.

Previous studies have explored several aspects related to production management and the implementation of the Lean philosophy in modular construction. Innella et al. (2019) discuss the implementation of lean techniques in the modular construction industry, covering all production stages, based on a systematic review. Olawumi et al. (2021) analysed digital tools and technologies in modular construction and how these impact production planning and control processes. Additionally, Khodabocus and Seyis (2024) investigated risk management in modular construction projects, providing insights into effective risk management approaches, which are strongly related to production planning and control.

Lerche et al. (2020) investigated the application of LPS in modular construction in the context of offshore wind farms. That study pointed out some benefits of applying the LPS in the specific context of modular construction, emphasizing collaboration as an essential element for effective production management. However, those authors have not deeply analysed the role of collaboration within this scenario.

The research question that guided this investigation was: How to improve the role of collaboration in planning and controlling modular construction projects? Therefore, the aim of this research work is to understand the role of collaboration in the implementation of production planning and control in modular construction projects, considering complexity attributes that differ those projects from the conventional ones. The collaboration considered in this study is related to the coordination among stakeholders involved in PP&C, both within each production unit, or between them. The expected practical contribution of this investigation is to devise a framework for assessing the degree of collaboration in the implementation of production planning and control systems, while the theoretical contribution is to understand the nature of collaborative processes, considering the context of modular construction.

COLLABORATION FACTORS

Collaboration is a process that requires the involvement and integration of different stakeholders, promoting a sense of involvement and ownership. In construction projects to collaboration plays a key role in improving reliability of project planning, leading to improvements in project performance (Elsayegh and El-adaway 2021a).

Elsayegh and El-Adaway (2021a) identified and defined collaboration factors impacting construction planning, based on an analysis of literature on collaborative planning in the construction industry over the past 30 years. In a subsequent study, Elsayegh and El-Adaway (2021b) divided the 50 proposed factors into six categories: behaviors, communication, team, management, technology, and contractual aspects. Table 1 presents the proposed collaboration categories by those authors and their definitions adapted according to the respective factors.

In this investigation, collaborative practices have been analyzed from the perspective of those six categories proposed in Elsayegh and El-Adaway's (2021a) initial study. The choice of this research as a reference for the concept of collaboration is justified as it is very recent study, based on an extensive literature review on construction planning and control.

Table 1 - Categories affecting collaboration in planning (adapted from Elsayegh and El-Adaway, 2021).

Categories	Description
Behaviors	Adaptive or resistant reactions to changes, dedicated commitment to the collaborative process, influence and dependency among parties, presence of leadership, building mutual trust and respect, and continuous effort to improve the collaborative process.
Communication	Formality and effectiveness of communication, frequency and type of meetings, sharing of lessons learned, early involvement of key project participants, timely reporting and updates, constructability feedback, and stakeholder contribution to schedule development.
Team	Relationship among project parties, skills, experience, and knowledge of those involved, vision and goal alignment, team members' ability to get along, engagement and active participation, motivation and incentives, guidance and workshops, training, and promotion of creativity.
Management	Stakeholder and management involvement, centralized workplace, management and sharing of risks/uncertainties, resource sharing, continuous focus on the customer, standardization of planning practices, joint problem-solving and decision-making, use of indicators, and identification and removal of constraints.
Technology	Efficient sharing of information and technology, BIM modeling for project understanding and implementation, and the use of tools and techniques, including visual signals, elimination of visual obstacles, and procedures to maintain a clean and organized workplace.
Contractual aspects	Definition and flexibility of scope/work packages, impact of project characteristics (type, size, and complexity), and effective conflict resolution.

RESEARCH METHOD

RESEARCH DESIGN

Case study was the research strategy adopted in this investigation, as it enables exploration of social-technical phenomena in real-world settings (Flyvbjerg, 2011). This study was carried out in a company involved in the delivery of modular construction projects, named Company A. The unit of analysis was the PP&C system developed in this company for managing site installation, which was strongly based on the Last Planner system. The research was divided into three phases: (i) understanding the problem and case study selection; (ii) collecting data on PP&C implementation; and (iii) cross analysis between PP&C practices and collaboration.

In the first stage, visits to the company and participant observation in planning meetings were conducted with the aim of understanding the context and complexity attributes of modular construction projects. At this stage, two projects (A and B) were chosen as case studies. The second stage consisted of collecting data on the development and implementation of a PP&C system for the selected projects. Initially, a production system design was carried out, followed by the development and implementation of the three planning and control levels, similar to the Last Planner System (LPS). Location-based planning was used at the long term planning level.

In stages 1 and 2, the sources of evidence used were: (i) participant observations of 58 medium-term meetings and 45 short-term meetings; (ii) direct observations at the construction sites, totalling 4 visits to the site of each project; (iii) semi-structured interviews with the project A and B engineer, planning coordinator, design manager, and manufacturing manager; (iv) workshops, comprising 2 Lean concepts training sessions and 5 Plan discussion workshops; and (v) document analysis such as Line of balance; Medium-term plans; and Short-term plans.

In phase 3, a list of PP&C practices was produced, including traditional LPS practices and also some additional ones that emerged along the implementation process, some of them necessary to deal with the complexity that exists in modular construction projects. Some of these practices were associated to different hierarchical levels, although some of them were related the PP&C as a whole. Each practice was then grouped into collaborative processes, such as meetings, technological tools for visualization and information exchange, as well as problem cause analysis processes. This organization of practices occurred because some of them do not directly involve collaboration but are integral parts of processes that promote collaboration. Thus, collaborative processes were analyzed in terms of categories of collaboration factors (Table 1), proposed by Elsayegh and El-Adaway (2021b). These categories were used to understand the role of collaboration in each process, enabling the evaluation of each based on the nature of collaboration. Data analysis was based on the subjective assessment of the degree to which the processes meet the collaboration factors of each category. Each collaborative process was assigned a weight corresponding to the degree to which it meets the factors, according to the following criteria:

- Weight 1.0: a process widely used in the company and strongly meets the category.
- Weight 0.5: a process is partially used in the company and partially meets the category.

For example, the process of analyzing the causes of non-compliance with work packages is a practice that the company implements; however, they analyze the causes superficially, without providing feedback or discussing action plan in meetings. Therefore, the process is carried out partially, involving only collaboration in identifying the cause, and not in the entire cycle of continuous improvement.

- Weight 0: a process that has no relation to any factor of the category. In this case, there is no evidence in the process that it is related to the analyzed category.

The result of the analysis stage consists of a table where the rows represent the PP&C practices and their respective collaborative processes, and the columns represent the categories of collaboration factors. By summing the weights assigned to each process, it was possible to analyze the practices with the highest degree of collaboration, as they address more categories, and also the categories most addressed by the implemented processes. With this tool, it was possible to analyze the relationship between the collaborative processes of PP&C and collaboration in modular construction projects, identifying opportunities for improvement. The authors assigned those weights based on their perceptions, using the data observed during the study to substantiate their decisions. The method proposed in this study can potentially be scaled to suit various projects, companies, and development stages within the modular construction industry. In phase 3, it is possible to select more practices according to the specific context of each project or company and group them in the same way in collaborative processes such as meetings, technological tools, information exchange and problem cause analysis. Those processes can then be evaluated according to categories of collaboration factors, previously established in the literature. The selection and evaluation of collaborative processes within different scenarios allows the method to be applicable to other contexts.

DESCRIPTION OF THE COMPANY AND PROJECTS

Company A has delivered modular construction projects since 2001. It has two main types of products: (i) heavy reinforce concrete modules used for penitentiaries; and (ii) steel chassis modules for other types of buildings, including schools and hospitals. The main reason for choosing this company is the fact that a Lean Production implementation program started in 2022, including all stages of project delivery: design, manufacturing, logistics and site installation. The two projects chosen for this investigation consisted of the construction of penitentiaries. The heavy modules used in this type of project is a patented solution, consisting of volumetric units arranged laterally to a central corridor, and above this, circulation through upper walkways for exclusive use by staff. The system involves two central elements: (i) cell-type module, and (ii) walkway-type module.

Project A involved the construction of a new prison complex (1650 vacancies), including prison areas (1884 vacancies), collective living spaces for inmates, administrative and technical areas, and infrastructure, summing up an area of 15,000 m². Different types of prefabricated components were used: 3 light modules, 240 heavy concrete modules, 120 walkway-type modules, and 566 W panels. The project duration was 12 months, starting in July 2022.

Project B consisted of a demolition of an existing penitentiary in two stages, and the construction of new cells, collective living spaces, administrative and technical areas, summing up 23,250 m². The construction stage started in July 2022. The main prefabricated elements were: 366 light modules, 220 heavy concrete modules, 110 walkway-type modules, and 798 W panels. During the first stage of the project B, part of the prison was in operation. Both projects had to be built in parallel, as the remaining prisoners from project B had to be transferred to Project A after it was concluded, This added some additional elements of complexity, the interdependence between the two projects, and the constraints for access of the construction site of Project B, due to the penitentiary in operation.

RESULTS

CHARACTERISTICS OF MODULAR CONSTRUCTION PROJECTS

Several complexity attributes of production systems in the company involved in the investigation:

(i) Large number of dynamic interactions between elements: This is mostly related to the interdependence between production units. The company has two manufacturing plants serving several construction projects. Individuals involved in factories, logistics operations, construction sites, design, and supplies are constantly interacting with each other. Additionally, these elements are strongly interconnected, meaning that the action of one sector directly impacts another due to the high degree of interdependence. Another important factor is that the company carries out design, fabrication, and assembly of various projects simultaneously, which become interdependent due to resources shared between them.

(ii) Wide diversity of elements: There were different hierarchical levels and disciplines involved, such as factory coordinators, project coordinators, architects, structural engineers, construction coordinators, engineers, workers, planning analysts, suppliers, logistics coordinators, etc.

(ii) Unforeseen variability: There was much uncertainty related to site conditions, fluctuations in demand, clients' requirements, and local regulations. The combination of variability and interdependences between production units tens to propagate variability.

(iv) Resilience: It refers to the system's ability to adjust its performance in the face of expected and unexpected conditions (Saurin; Gonzalez, 2013). This is a necessary attribute to be developed in the management system in order to cope with the existing complexity.

PP&C PRACTICES IMPLEMENTED

These are the main elements of the PP&C system: (i) Production System Design (PSD): it starts with the identification of requirements for the execution of this specific type of project (penitentiaries), which is based on the experience obtained by the company in previous projects, and also on the specific requirements of the projects A and B. Its scope involves the definition of a location system, layout, overall installation sequence, workflows, logistics flows, necessary capacity of the workforce and equipment, and 4D BIM simulation. Representatives from different sectors were involved in PSD: design, factory, construction site, material supply, logistics, planning, and contract management.

(ii) Long-term Planning: Based on the PSP, a location-based plan (line of balance) for the whole project, in which the main project milestones were defined. The final definition of the long-term plan was also developed in collaboration with different company sectors and made available online to all of them. Based on that plan a set of metrics based on the status of each location was defined, for controlling cycle time, work-in-progress, project progress, and batch completeness. The Production Status Matrix, which allows check-in and check-out in each location to be informed by each crew, plays a key role in the production of those metrics. This tool was only partially implemented, due to the lack of automated and user-friendly data collection tool.

(iii) Look-ahead Planning: Hybrid weekly meetings were carried out, considering a 6-week window, to allow the participation of representatives from different areas of the company. Both individuals in charge of identifying and removing constraints were involved. Those constraints were not limited to materials and labor, but also involved logistical and safety aspects. Responsibilities for eliminating these constraints were allocated among team members, each with a deadline for resolution. Due to the lack of effectiveness in removing constraints, an analysis of the causes for the non-removal of constraints was implemented. In this process, it was necessary to justify why constraints were not removed, and the group exchanged ideas on how to solve specific problems.

(iv) Short Term Planning*:* Weekly meetings were carried out on-site, in which work packages were assigned to each crew, specifying task content and location. Those meetings typically lasted for an hour, involving the site manager, engineering assistant, and crew leaders. An online spreadsheet was used to store and make available information to everyone. Site assembly activities were planned for a two-week horizon due to the need of the manufacturing plants planning process. Traditional LPS metrics were used, such as the Percent Plan Complete (PPC), and the causes for non-compliance.

(v) General PP&C practices*:* A set of additional practices related to the planning and control process as a whole was also implemented: digital dashboards with long, medium, and short-term metrics, weekly meetings for the joint analysis of medium and short-term indicators (involving top managers), and planning different types of slack at different planning levels. Additionally, there was a weekly planning alignment meeting, in which each sector (design, manufacturing and site installation) presented the existing plans, in order to align demands and identify the possibility of adding new projects or specific activities. Regarding Visual Management, besides the dashboards, and location-based plans, several visual devices were producing, including boards for displaying plans, constraints and metrics.

After multiple planning cycles, the need for load plans emerged, mainly to formalize the exchange of information between the sectors. Due to the existing uncertainty in the projects, issues on site installation were communicated to the manufacturing plant in order to confirm the capacity to meet project demands. This plan formalizes project needs, factory production, and logistics capacity, thus reducing the information conflict generated by informal communication, often conducted via WhatsApp. This tool was shared with the sectors involved, with the aim of increasing transparency and aligning everyone's demands.

ANALYSIS OF COLLABORATIVE PROCESS

In Table 2, the results of the analysis regarding the relationship of collaborative processes with the factors of collaboration categories are presented. Results in green correspond to processes that strongly adhere to the category, those in yellow represent processes that partially adhere, and those in white indicate processes in which none of the factors were observed.

Table 2 - Relationship between Collaborative Process and Collaboration Factor Categories

	PP&C practices	Collaborative Process	Collaboration categories: Behav	Commun	Team	Manag	Tech	Cont.	TOTAL
Production System Design	Identification of project requirements Definition of sequencing and batches Involvement of all sectors pre-project	Meetings at the beginning of the project	1	1	1	1	0	1	5
	4D BIM simulation	Technological tools	0	0	0	0	1	0	1
Long-term plan	Location-based plan Development of a visual long-term plan Indicators for assessing time deviation	Meeting at the beginning of the project, with different company sectors	1	1	1	1	0	1	5
	Production Status Matrix	Technological tools	0,5	0	0	0,5	0,5	0	1,5
Look-ahead Planning	Standardization (routine) Identification of constraints. Participatory decision-making	Meetings to identifying and removing constraints	1	1	1	1	0	0,5	4,5
	Non-removal of constraint	Analysis of the causes	1	0,5	0	0,5	0	0,5	2,5

Table 2 (continued) - Relationship between Collaborative Process and Collaboration Factor Categories

	PP&C practices	Collaborative Process	Collaboration categories: Behav	Commun	Team	Manag	Tech	Cont	TOTAL
General PP&C practices	Weekly alignment meetings of PP&Cs	Meetings in which each sector presented the existing plans	1	1	1	1	0	1	5
	Analysis of indicators with top management	Meetings for joint analysis of metrics.	1	1	1	1	0	1	5
	Set of interconnected dashboards for control	Technological tools	0	0	0	1	1	0	2
	Introduction of different types of slack	Information sharing between sectors and levels	0	0	0	0	0	1	1
	Load planning	Tool that allows information exchange	0	1	0	1	1	0	3
		TOTAL	8	9	6	9,5	5,5	7	

Collaborative processes related to meetings addressed the highest number of collaboration categories. This is because these practices are characterized by being formalized processes (management category) and involve several participants in the PP&C process. Members are expected to commit to plans (behaviour category), exchange information (communication category), align their objectives and goals, sharing risks and uncertainties (team category), and define procedures for conflict resolution (contractual aspects category). In a highly complex project, as it is typical of this modular construction system, addressing the highest number of collaboration factors contributes to improve to an effective coordination between sectors in order to achieve project objectives.

Processes linked to technological tools for visualization, information exchange, and shared understanding mostly addressed the technology category. The company invested in visual devices in planning to support project understanding and visualization of plans and metrics. These tools included planning spreadsheets, performance dashboards, and project activity warnings. All tools were made available online, and different stakeholders had access through the company server. Additionally, interactive screens and video calls were used to support planning routines. Therefore, the transfer and sharing of updated information among project stakeholders through involved different means, such as reports, spreadsheets, dashboards, and messages, with the aim of making everybody aware of the project process.

Another important factor concerns the complexity of the project. There was a formal process of using different types of slack in order to make project delivery more reliable, such as: (i) definition of alternative assembly flows (Project B), due to potential layout restrictions; (ii) possibility of producing some precast elements on-site, (iii) inventory of some standard small-size components at the manufacturing plants (e.g. furniture); (iv) spare formwork elements, among others. Slack planning was the result of information sharing between sectors and levels, either in formal meetings or informally, including brainstorm events to solve emerging situations, especially in the construction site. The most frequently used collaboration factor category in the collaborative processes was Management, justified by the operational nature of the practices included in this category, including participation in meetings, use of metrics that contributes to everyone's understanding. The least addressed category was related to Team, as these factors have a strong social character, such as team and stakeholders' skills, experiences, motivation, creativity, involvement and empathy. These competencies are related to each individual and the relationship among team members. These criteria are essential for collaboration, although not directly identified in processes. They must be present in the company and are not easy to develop in the short term. Therefore, a key topic for future research is to develop approaches for improving these competencies among stakeholders.

Two collaboration practices have been identified as only partially ineffective, and demand further attention: (i) the analysis of non-compliance problems with work packages, and (ii) the control of production status. In the former, although teams formally identified the causes of non-completion of work-packages, this process was done very superficially, and there was not enough effort to plan how to deal with the most frequent or severe problems. Regarding the latter, the company faced problems in implementing the production status matrix, such as poor definition of the location system, late updating of the matrix, and unreliable information. These two practices, besides promoting continuous improvement, also help understanding problems and monitoring the work-in-progress in other sectors of the company. These are necessary practices for collaboration and especially for integration among different sectors of the company.

CONCLUSIONS

This research presented a list of collaborative processes for planning and controlling modular construction projects. Each process was thoroughly evaluated across six categories of collaboration factors: behavior, communication, team, management, technology, and contractual aspects. It must be pointed out that some processes stand out for strongly promoting collaboration across multiple categories simultaneously, such as the use of PSP meetings, project kickoff meetings, look-ahead and short-term meetings, weekly PP&Cs alignment meetings among different sectors, and meetings for a joint analysis of metrics. Therefore, these processes need to be maintained and improved to promote collaboration.

However, evidence showed that although most practices address some collaboration factors, there are still areas that need to be improved to ensure more effective collaboration among stakeholders, especially the Team category. In this category, processes emphasizing motivation, engagement, and increasing team's sense of belonging need to be implemented.

This study is part of an ongoing doctoral thesis that will continue to delve into the analysis of collaboration factors in PP&C practices. One of the next steps in this investigation is to do and in-depth analysis of the 50 collaboration factors proposed by Elsayegh and El-Adaway (2021a), and understand the interactions between the categories. Regarding limitations of this investigation, it must be pointed out that this article has focused on formal collaboration practices implemented in a specific company. Further work is necessary to understand the role of informal practices that also contribute to foster collaboration. Additionally, the results reported are related to a single modular construction company. This study presents an analysis of collaborative processes in the early stages of implementation of a production planning and control model, based on LPS, and the results are limited to the specific context of that company. Therefore, the proposed recommendations are specific to this context, and cannot be generalized to the entire industry. Future studies must explore the context of other companies, considering other planning practices and collaborative processes.

A CASE FOR LEAN-BASED GUIDELINES FOR CONSTRUCTION AND DEMOLITION WASTE MINIMIZATION IN ZIMBABWE

Kurauwone Maponga[1] and Fidelis Emuze[2]

ABSTRACT

Construction and Demolition Waste (CDW) significantly costs Zimbabwe, as most waste is directed to landfills, riverbanks, and open spaces. This has made construction practitioners call for efficient strategies such as lean construction (LC). LC could help minimize construction waste in on-site operations. It could reduce land and water pollution and the blockage of watercourses caused by CDW. Minimizing CDW creates cost savings and value for the construction project clients. Although LC has addressed CDW minimization in varying countries, this is not the case in Zimbabwe, where a pressing need for resource efficiency is urgent. Thus, this paper proposes a conceptual framework for evolving LC-based guidelines for minimizing CDW in Zimbabwe. A critical review of relevant literature was conducted to observe how LC tools are utilized to minimize CDW. Given that such a framework could limit the pollution of land and open spaces with CDW, which affects people and the built environment in general, the next phase of the doctoral study would be to test and modify it through mixed methods research empirically.

Lean construction, Demolition, Lean, Waste, Pollution, Construction projects, Zimbabwe

INTRODUCTION

According to the Lean Construction Institute (LCI) (2012), Lean Construction (LC) is a manufacturing and production management system that focuses on the elimination of all forms of waste and the creation of value for the client. The focus on LC is on both physical and process waste. The paper concerns physical waste, which is a harmful dilemma because construction and demolition activities are considered the highest waste generators globally (Karaz et al., 2021). The development of lean strategies to minimize CDW is a priority for some countries in the European Union (EU) (Karaz et al., 2021). According to Gálvez-Martos and Istrate (2020), the proper management of CDW is usually associated with high costs due to logistics and the relatively low benefit from its recovery and recycling. The EU has released incentives such as Directive Number 2008 /63/EC to reduce CO2 emissions, encourage recycling, and urge contractors and other professionals in construction to minimize the overuse of materials and the disposal of CDW to open areas and landfill and challenges are being addressed on how to incentivize contractors who comply (Karaz et al., 2021). However, Zimbabwe is lagging in

CDW minimization techniques; hence, the guidelines provided by this study will act as an essential foundation for embracing lean construction.

According to Coşgun, Arslan, and Salgin (2012: 313), "the huge amount of construction waste streams in different countries has revealed the importance of local actions to manage, recycle and re-use the wastes generated through the lifecycle of buildings." Although the application of LC tools for the minimization of CDW has been investigated by several scholars who highlighted their potential (Gomez et al., 2018; Gutiérrez, 2020; Erazo-Rondinel & Huaman-Orosco, 2021; Orihuela et al., 2019; Erazo et al., 2020; Suarez et al., 2020; Ballard et al., 2009 and Ballard, Kim, Jang and Liu, 2007), in Zimbabwe such study is lacking. The construction sector worldwide faces severe challenges due to vast amounts of waste. Accordingly, the call for lean-based guidelines to minimize CDW cannot be overstated. The adoption of lean-based interventions has been shown to offer several benefits. According to Hamzeh and Albanna (2019: 179), "to reap the benefits of Lean Construction, construction companies should integrate, empower, and enable all personnel involved in the construction process whether on or off-site." Thus, in Peru, adopting lean-based guidelines achieved the following benefits: generating and adding value for the client, increasing productivity, reducing CDW, delivering the project on time, and improving communication (Erazo-Rondinel & Huaman-Orosco, 2021).

Despite the potential of lean-based interventions to minimize CDW, Zimbabwe still lags in embracing CDW minimization techniques. Accordingly, this study sought to develop guidelines to promote the adoption of lean-based interventions to improve construction and demolition waste minimization. The paper is part of a doctoral study that aims to develop guidelines for minimizing CDW in the Zimbabwean construction industry.

STATEMENT OF THE PROBLEM

CDW costs contractors and clients' money in Zimbabwe as most of the waste is directed to landfills, riverbanks, roads, and open spaces. In the country, 76% of the CDW produced is disposed of by open dumping, 7% is disposed of by burning, 10% is disposed of by a combination of open dumping and burning, 1% is disposed of by landfilling, and 5% is disposed of using other methods (Jerie, 2018). Limited or no recycling, reuse, or recovering techniques are employed to manage CDW. Figure 1 shows that CDW is often transported to landfills and dumped on roadsides, open spaces, and riverbanks. This leads to the pollution of watercourses and fertile lands. The lack of CDW minimization causes social, environmental, and economic problems. For instance, African countries are keen to overcome these challenges to meet their development and infrastructure needs for the 21st century. It is not news that Africa faces various problems in the construction industry that marginalize its ability to realize sustainable development goals (SDGs). Magadzire and Maseva (2006) suggest that Section 70(3) of the Environmental Management Act (2007) of Zimbabwe encourages the use of sustainable techniques for CDW management. The major hindrance is that the technology and knowledge needed to employ the techniques are unavailable. The Public Health Act (1996) of Zimbabwe stresses that the producers of waste should manage all forms of waste. The Act prohibits waste production and dumping on lands that the waste producers do not control. Waste producers are expected to transport and manage the waste; however, the Act is silent on the 3Rs: recycling, recovery and reuse, and lean construction techniques.

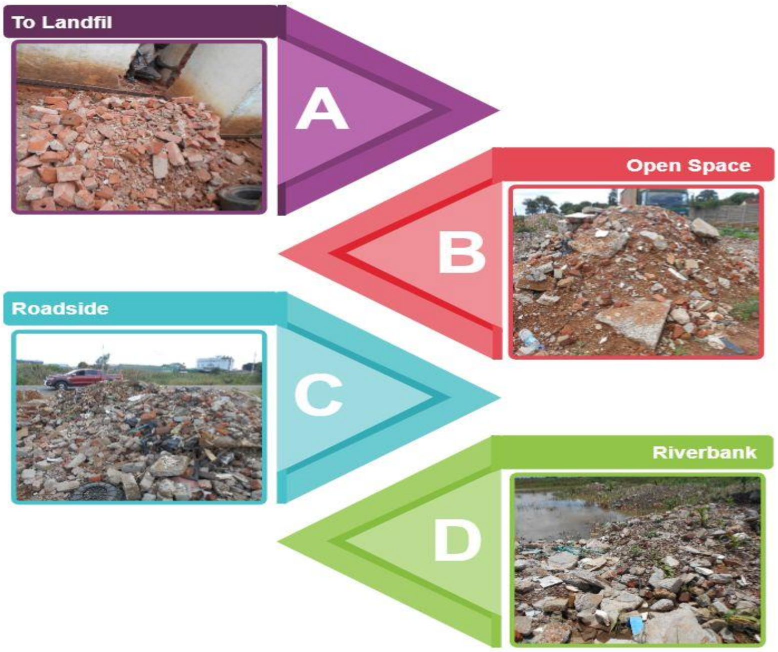

Figure 1: Disposal of construction and demolition wastes in Zimbabwe (Source: 2023 field survey of doctoral researcher)

According to the Environmental Management Act (2007) of Zimbabwe, a permit is supposed to be acquired for CDW disposal, fines are paid for illegal CDW disposal, and companies disposing hazardous waste into any waters or on the environment are made to remove their toxic waste and pay for environmental restoration. The Act also stipulated that a license should be acquired for transporting toxic waste, and construction sites generating CDW must minimize the CDW through treatment, reclamation, and recycling. Although some statutory instruments such as the Harare Waste Management by-law (SI 127 of 1981), Waste Management by-law (SI 477 of 1979) and (SI 185 of 1981) and other policies such as the Sustainable Strategy Policy and the Environmental Impact Policy exist, poor waste management of CDW in Zimbabwe persists because of lack of enforcement, lack of equipment and lack of expertise (Magadzire & Maseva, 2006).

The management of CDW in Zimbabwe can be improved by embracing several changes in design, communication, cost, scope, safety, and quality. Design aspects require changes to include more standardization, modularization, and modeling. The design must be done for CDW minimization to minimize offcuts, reworks, and defects. The design must include recyclable and reusable materials. Cost and scope aspects need to change to include more local and sustainable materials. The storage and transportation of CDW can cause cost aspects. Construction processes need to minimize the use of energy and environmental degradation. Safety and quality changes will help improve health and safety and reduce waste in materials, time, overproduction, delays, and unnecessary inventory. Legal and environmental constraints also come in, as CDW can cause pollution, and the Environmental Management Authority (EMA) can impose lawsuits. Communication and coordination will help minimize the time constraints for sorting and transporting CDW.

Tackling the poor handling and proliferation of CDW is one way to close this gap. The study thus sought responses to the following research questions:

- How will lean tools and techniques enhance CDW minimization practices in Zimbabwe?
- What lean-based guidelines would minimize the negative impacts of CDW in Zimbabwe?

Although exhaustive responses to these questions are beyond the scope of this conceptual paper, an attempt is made to present a framework that could aid the effort. The theoretical background of the framework is presented in the next section of the paper.

LEAN CONSTRUCTION AND CDW MINIMIZATION

According to Forbes and Ahmed (2020), LC is a technique used to design production and construction systems to minimize waste of time, materials, and effort to generate value for the client. Tommelein and Ballard (2016) define LC as applying lean thinking to the design and construction of construction projects. This means that effectively implementing LC tools and techniques will help minimize the materials used and save time. Salem et al. (2006) pointed out that the lean construction principles for the construction industry are transparency, process variability, continuous improvement, and flow variability.

Pedo et al. (2021) say that LC can enhance CDW minimization through early identification of requirements for process standardization and systematic waste analysis and offer accurate information regarding the materials and building systems, which allows stakeholders to decide on design early to provide reduced reworks, design iterations, and product visualization. Lean tools can help minimize CDW generation by allowing stakeholders to make critical decisions early, which helps minimize work variations, and reworks can be a source of CDW. According to Mawed et al. (2020), poor communication leads to project reworks, which generate CDW. Erazo-Rondinel and Huaman-Orosco (2021: 547), say "Even the construction industry in Peru is still working in silos, focusing objectively only on the project stage they oversee; however, client value mapping is still minimal." Employing lean-based CDW minimization techniques can help provide value for the client and reduce the amount of CDW produced on a construction site.

Najafpoor et al. (2014) stated that, in developed countries, 35 to 50% of the waste produced is CDW. Azmy and El-Gohry (2017) posit that one-third of domestic waste in Egypt is CDW. Elshaboury and Marzouk (2020) reported that CDW generated in the United States (US) amounts to 569 million tonnes, in Europe 330 million tonnes; in Germany 324.38 million tonnes; in Lebanon 9.6 million tonnes; and in Egypt 3.65 million tonnes. According to Huang et al. (2018), China produces an estimated CDW of 30-40% of the total waste. Ballard and Howell (2003) confirmed that 50% of construction waste goes to landfills, only 18% is recycled, and about 32% is reused. A case example will help to illustrate the CDW challenge in developing countries. In the example, Bajjou and Chafi (2018) note that poor project management and delivery in Egypt has caused CDW to proliferate, although there is a low level of use of LC in the sector. The use of LC would improve processes, project planning, inventory, time savings, health and safety, risk management, quality, and productivity, apart from customer value, improved decision-making, employee satisfaction, and better energy consumption (Shaqour, 2022). Reworks due to defects, material transportation, and overproduction caused a lot of CDW in the Egyptian construction industry, and the benefits of lean construction included reduced reworks and overproduction (Shaqour, 2022).

THEORY OF PLANNED BEHAVIOUR

The theory of planned behavior (TPB) was developed by social psychologists (Ajzen, 1991). The theory captures motivational factors influencing behavior. TPB expresses how hard people are willing to try to perform the behavior (Ajzen, 1991). In TPB, norms, attitudes, and perceived behavior control will have a physiological effect on workers' intended behavior in terms of the reuse, recovery, reduction, and recycling of materials (Ajzen, 2015 and 1991). The TPB postulates that project stakeholders' attitudes, CDW regulatory frameworks, CDW minimization techniques, and CDW project life cycle can lead to effective CDW management (Kabirifar et al., 2020). The most widely utilized CDW management technique encompasses reducing, reusing, and recycling strategies (Huang et al., 2018). CDW techniques involving reduce, reuse, and recycle strategies have been considered the most effective way to manage CDW (Kabirifar et al., 2020). Therefore, reducing, reusing, and recycling techniques will be a part of the Zimbabwean lean-based guidelines.

The application of lean-based CDW minimization is discussed based on best industrial practices from various countries. Kabirifar et al. (2020) developed a framework based on the TPB in Australia. The authors added that the regulatory frameworks involving rewards, incentive mechanisms, taxes on waste disposal and landfilling, and sustainable CDW management hierarchy are effective ways to manage CDW. According to Jahan et al. (2022), nearly 30% to 40% of total solid waste is generated globally, and in Australia, the amount of CDW increased by 61% from 2006 to 2017. They added that some Australian states achieved better CDW management from 2018–2019, where the State of Victoria and South Australia achieved 87% and 91.4% CDW recycling, respectively. Even with such efforts, 6.7 million tons of CDW went to landfills. Jahan et al. (2022) assert that prioritizing waste minimization and management are crucial to building a circular economy. The authors added that subjective attitudes and personal reluctance of designers and material suppliers to exercise waste mitigation techniques are crucial. Another effective CDW minimization strategy involves the designing out of the CDW; design for CDW minimization is also a practical approach to CDW minimization (Baldwin et al., 2009). The Australian government is emphasizing the use of BIM (Jahan et al., 2022). The industry lacks the utilization of BIM, CAD, and prefabrication because the effective utilization of prefabricated components could significantly minimize about 84.7% of construction waste (Jaillon et al., 2022).

RESEARCH METHODOLOGY

The paper is based on a literature review of LC principles. The conceptual framework was developed from working ideas in other countries. The literature was sourced from, Science Direct, LC textbooks, and the International Group of Lean Construction IGLC) conference papers. The keywords for the search included "lean construction", "lean-based CDW management", "lean tools", and "lean-based CDW case studies". An attempt was made to utilize the latest articles. Content analyses were utilized for conceptual framework development.

CONCEPTUAL FRAMEWORK

Figure 2 shows the proposed framework for the lean-based guidelines for minimizing CDW in Zimbabwe. The guidelines are hinged on CDW recycling, recovery and reuse, proper lean construction training, just-in-time deliveries, standardization of a worker rewards system, and proper regulatory frameworks. Achieving this helps come up with guidelines that can be utilized to minimize CDW on construction sites. The guidelines can aid in identifying further CDW issues as many huddle meetings, brainstorming, and planner systems will be used to gather feedback from workers; this can aid with continuous improvement.

The lean tools are implemented by the TPB stages of CDW stakeholders' attitude buy-in, CDW regulatory framework, utilized CDW tools, and CDW project life cycle standardization. The utilized CDW management lean tools will include the Last Planner System (LPS), Just-in-time (JIT), Continuous Improvement, 5S, and Flow Systems. The selected lean tools can be taught and adapted for utilization in developing countries. Stakeholders' buy-in and human resources training can be done through seminars, huddle meetings, and webinars. Stakeholders are essential because CDW minimization is a collective effort focused on reuse, reduce, and recycle techniques (Lu et al., 2015). CDW regulatory frameworks can be created by having rewards and incentives and lobbying for reduced taxes. The utilized on-site CDW minimization strategies will include reducing, recovering, reusing, and recycling. Last planner decisions on what to recycle will be used, the material will be delivered just in time (JIT), and there should be clear communication. The last stage of CDW project life cycle standardization will be standardizing a CDW process and rewarding practice. Lean CDW minimization should include all stakeholders because contractors and sub-contractors also affect the generation, recycling, reduction, and reuse of CDW through their attitudes (Saunders and Wynn, 2004).

The second column of the framework (Figure 2) shows the lean tools and activities utilized. The first stage of worker training uses seminars, huddle meetings, improved visualization, communication, and continuous improvement procedures. Training has benefits in column three, including improved communication, standardization, and reduced variability. The second stage of regulatory frameworks uses rewards, incentives, and lobbying for clear CDW policies on-site and in the country. Regulatory frameworks have the intended benefits of stakeholder buy-in, worker compliance, and waste stream identification. The utilized lean tools for CDW minimization in the next stage of the CDW minimization hierarchy include the LPS, which gives workers the autonomy to make decisions on CDW continual process improvements, reduced pollution, and reduced inventory. This helps minimize lawsuits caused by illegal CDW dumping. The last stage of the environmental life cycle will utilize 5S for site sorting, storage, and transfer of CDW. Information from the literature thus informed the proposed Lean CDW conceptual framework for Zimbabwe, as illustrated in Figure 2. Bajjou et al. (2018) stated that developing a lean-based conceptual framework helps show good practice and procedure. Figure 2 involves three main strands: TPB components, lean tools and activities, and client focus and benefits.

Theory of Planned Behaviour Components	LEAN TOOLS AND ACTIVITIES		CLIENT FOCUS AND BENEFITS
Norms and Worker Attitudes Stakeholder Engagement and buy-in 1	- Training	-Persuade management -Seminars, Improve CDW awareness -Webinars	• No variability • No miscommunication • Simplify CDW process • Simplify the training • Compress cycle times • Change acceptance
	- Improved communication	-Involve employees and open communication flow	
	- Huddle meetings - Weekly kaizen meetings	-Worker feedback -Educate all subcontractors	
Sustainability Frameworks Circular Economy 2	- JIT deliveries	-Procurement plan	• No inventories • Stakeholder buy-in • CDW quantification • Supplies done on time • Identification of CDW-producing streams
	- Value Stream Mapping	-Identify, understand current waste minimisation strategy	
	- Define-Measure-Analyse-Improve-Control (DMAIC)	-Define, Measure, Analyse, Improve and Control noting CDW problems	
CDW Hierarchy and Techniques Circular Economy 3	- Continuous improvement	-Brainstorm and refine procedures	• Last planner decisions by workers • Regulatory frameworks • Design for waste management
	- LPS	-Involve all workers	
	- BIM	-Build from BIM models	
	- 4Rs	-Recycle, Reduce, Reuse and Recover	
CDW Environmental Impact Life Cycle Assessment 4	- Standardisation of procedure	-Select on site CDW storage area -Select team, CDW sorting. Transfer. -CDW collection and transport -Rewards, incentives, taxes on waste disposal -Create continuous flow of work, refine procedure	• Increase customer value • Results analysis of recorded processes • Knowledge consolidation • Rewards and appraisals of workers who did well

DISCUSSION

The guidelines target construction companies registered with the Construction Industry Federation of Zimbabwe. The construction project manager will spearhead implementing and managing the guides on the construction site. The skilled and semi-skilled workers will then implement the guidelines practically. Thus, an essential user guide is proposed to ensure effective implementation of the developed conceptual framework.

STEP 1: CONDITIONING OF WORKER NORMS AND BEHAVIOUR BY TRAINING

In step 1, training, huddle meetings, and improved communication will be utilized. Training employees in the organization and hiring new workers ensures the availability of the skills and expertise needed in the lean implementation phase (Watfa, and Sawalha, 2021). The project operation phase provides data and analysis, which creates a valuable database, which enhances learning capability (Moradi and Sormunen 2022). It is essential to document Lean guidelines, which specify the plan and scope of implementation (Watfa, and Sawalha, 2021). The conceptual framework provides a construction project lifecycle-based application of LC tools and techniques, which makes it easy to understand for project practitioners (Moradi and Sormunen 2022).

STEP 2: SUSTAINABILITY AND REGULATORY FRAMEWORKS

In step 2, the lean tools JIT, VSM, and DMAIC will be used to define and understand CDW generating streams. The second stage of regulatory frameworks uses rewards, incentives, and lobbying for clear CDW policies on-site and in the country. Regulatory frameworks have the intended benefits of stakeholder buy-in, worker compliance, and waste stream identification. A conceptual framework with sustainability frameworks has the advantage of mixing sustainability and LC for client value and delivery (Moradi and Sormunen 2022).

STEP 3: CDW MINIMIZATION HIERARCHY, TECHNIQUES

In step 3, CI, LPS, BIM, and 4Rs will be utilized as these tools can help with brainstorming, involving workers, modeling, and recycling of CDW. Engagement of all employees is a key element that supports and encourages management of resistance to change (Watfa, and Sawalha, 2021). Individual application of LC tools has fewer benefits and is more effective when integrated and used together (Moradi and Sormunen 2022). Karaz et al. (2021) defined LPS as collaboratively planning and controlling work processes. Supervisors and operatives are the last planners, as they are also involved in CDW minimization.

STEP 4: CDW ENVIRONMENTAL IMPACT LIFE CYCLE MANAGEMENT

Step 4 will involve mainly concretizing and standardizing perfect procedure. JIT is producing and delivering the right items at the right time in the right amounts and is used to reduce variation and waste (Ballard, 1995). Continuous Improvement (CI) is a procedure done by clearly documenting and constantly checking back to look for causes of CDW and find solutions (Marzouk et al., 2019). CI is an incremental, ongoing procedure to improve products, processes, and services (Imai, 1986). It is practically impossible to utilize all the discussed LC tools in this study as the resources required to do so may not be accessible. Table 1 gives the important lean implementation steps.

Studies by Bansal and Sing (2013), Akhtar and Ahmar (2018), Jin et al. (2019), Xing and Hao (2019), Shooshtarian et al. (2019), and Ghosh et al. (2020) have shown that standardization of 3D visualization and the 3Rs are the most common lean tools in CDW minimization cases. The cases given by the authors showed that LPS, GPS, GIS, BIM, CAD, daily huddle meetings, in-time inspections, incentives, and penalties utilized lean CDW minimization strategies. Clear policies, research, action cards, 5S system, clear communication, and pull planning were the third most effective techniques for CDW minimization. The last techniques that can be utilized are constraint analysis, prefabrication, clash detection, field software, and 5 WHYS.

Table 1: Application of the lean tools in the proposed framework

Lean Tools Applied	Important Implementation Steps	Source	Targeted Challenges
Value stream mapping (VSM)	Uses flow charts to depict every work process. Identify and monitor CDW-generating work areas.	Hamzeh and Albanna (2019)	Quality, Site organization, environmental and legal
Just-In-Time (JIT)	Procurement plan. Producing and delivering the right items at the right time in the right amounts	Karaz et al., (2021)	Reduced inventory
Six Sigma	Split smaller work processes and reduce the changeover of tasks.	Al-Aomar (2012)	Cost, legal, and environmental
Kanban	Card systems devised by the automotive industry produce or procure only parts needed at a particular time.	Marzouk et al., (2019)	Time and quality
Last Planner System, clear visualization, and 5S	Planning work collaboratively. Rules for workplace housekeeping. Include (Sort), (Set in order), (Shine), (Standardize), and (Sustain).	Enshassi and Zaiter (2014)	Clear communication, environmental sustainability
Continuous Improvement	Documenting and always checking back work for improvement.	Marzouk et al., (2019)	Communication, Time, and cost
BIM	Digital representation of the building. Models could be utilized.	Steel et al. (2012);Marte et al. (2012)	Scope design for CDW minimization.
Daily huddle meetings	Short everyday meetings focus on CDW-specific issues.	Memon et al. (2018).	Feedback meetings

CONCLUSION

The minimization of CDW in Zimbabwe has been an issue, as most of them are dumped on roadsides, watercourses, open spaces, and landfills. Some of the CDW is used for filing road potholes and as low-cost building hard cores, just improvisations of materials not intended for them. By applying lean-based CDW minimization guidelines, the contractors can minimize the environmental and health impacts of CDW, which are dumped everywhere. The guidelines can help minimize project reworks and work variability and increase customer value. In addition, Zimbabwean contractors can find the causes of CDW and develop more effective waste minimization techniques. The study, therefore, is just a preliminary step of a doctoral thesis; the study will provide further guidelines and recommendations from practicing construction industry professionals as more and more professionals will be consulted.

ABSTRACT

From a lean construction perspective, the role of a Public Roads Administration is to identify the value from the client's point of view and define the processes able to develop the value stream. In the long-run strategy, the public role is to be sustainable and apply the sustainability principle in the management of the portfolio of projects under the administration's control. This implies the development of a performance measurement system for sustainability. The case of the Norwegian Public Roads Administration is presented and analysed in the paper, as an example of an actor working on performance measurement for sustainability. The purpose is to evaluate the state of the art and use document study and literature to propose improvements. The research questions addressed in the paper are how sustainability is measured today for the construction portfolio in the Norwegian Public Road Administration and what are the pros and cons of the actual method (for measuring sustainability today). The proposal for improvements is made by comparing the state of the art with performance measurement theory.

KEYWORDS

Lean construction, sustainability, action research, performance measurement, and infrastructure projects.

INTRODUCTION

Among the roles of the project owner, understanding the value connected with a project is the first step to defining a committed process for managing the project with a clear vision (Fisher et al., 2017). From a public ownership perspective, the value must be identified from a societal point of view, as society is the direct client of the infrastructure work, in a lean construction perspective (Kalsaas 2017). Looking at the long-term perspective, sustainability is identified as a strategic goal for society (Samset, 2010) and it is towards this goal that the project and

portfolio management must be evaluated. Evaluating sustainability has different implications, depending on the level of application of the requirement: a sustainable company must have a sustainable portfolio of projects, but a company with a sustainable portfolio is not necessarily a sustainable company. The focus of the paper is measuring sustainability at the project and portfolio levels. This is because having a single sustainable project could bring a not-sustainable portfolio: the investment, necessary to reach the goal at the single project level, could, for example, bring a lack of finance for other projects, already evaluated as necessary, with a consequent negative effect on society as a result for the whole portfolio. Before developing a performance measurement system for portfolio sustainability, it is necessary to understand how sustainability is measured for a single project.
The research questions addressed in the paper are

- how is sustainability measured today for the construction portfolio in the Norwegian Public Road Administration?
- what are the pros and cons of the actual method (for measuring sustainability today)?

The paper focuses on the case of the Norwegian Public Roads Administration (NPRA), as an example of a project owner with a large portfolio of projects dealing with the sustainability goal. The sustainability evaluation system used to define the construction portfolio for NPRA is compared with the chosen literature in terms of the choice of sustainability criteria. Pros and cons of the actual method are described and evaluated and a proposal for improvement is done using performance measurement theory, with a focus on sustainability performance measurement for the project portfolio.

LITERATURE REVIEW

The literature used for the article has three main branches. The first is dealing with the available literature on sustainability for infrastructure projects. In particular, the authors were investigating what the existing literature means with sustainability for infrastructure projects. The concept of sustainability is intended as a strategic measurement (Samset, 2010) for the long-term effect (Samset et al, 2022). But sustainability is also intended as the group of goals defined by the United Nations in the adoption of the Sustainable Development Goals (2015) built on the principles stated in the resolution "The Future We Want" (A/RES/66/288, 2012). These goals focus on the three pillars of economy, environment and society.

There are numerous scientific papers and publications on the sustainability topic (among 1'500'000 just in Google Scholar, searching for sustainability and infrastructures; over 2'300'000 searching for sustainability and roads), but few of them are focused on sustainability as set of criteria defined for a long-term goal. The sustainability criteria presented in the literature include economic criteria, environmental criteria, social criteria and a set of governance criteria, as for example time, innovation and seriousness of actors (Akomea-Frimpong 2022). Among the selected articles, some adopt the definition of the three pillars of sustainability (Faiz et al., 2012; Scope et al., 2021), while others investigate the sustainability topic in the infrastructure sector in a more holistic perspective (Corriere et al, 2012; Montgomery et al., 2015). Part of the investigated literature, nevertheless, especially if related to material development, limits the concept of sustainability to the environmental or climate topic (Hu et al., 2019). Like other actors operating in the infrastructure field, NPRA has adopted the broader definition, recognizing sustainability as a long-term value and building the strategy for the agency on 5 main goals that deal with the three sustainable pillars.

The second branch of the investigated literature deals with performance measurement and in particular with guidelines for performance measurement (Andersen et al., 2021). The available literature on performance measurement with a focus on sustainability is often an inherent production field (Qorri et al., 2018) and is almost always focused on the measurement of performance at the company level, even when related to public agencies (Adams et al., 2014). Interesting considerations can be made from the study of literature on performance measurement focused on sustainability applied in different fields from infrastructures (Warhurst, A., 2002), especially on the definition of the indicators and on the importance of stakeholders in the strategic focus of the company (Silva, 2019). The application of performance measurement guidelines to the sustainability measurement of the projects and portfolio of projects for a company is a necessary step towards the measurement of the sustainability of that company: to be a company focused on sustainability, the management of the portfolios and projects needs to be focused on sustainability (while the reverse is not automatic, as a company deals with additional activities outside the portfolios of projects). Developing a performance measurement for sustainability for the projects and the projects portfolios of a company is therefore a necessary step for a sustainable organization and the analysis of NPRA's methodology for performance measurement of projects and portfolio's sustainability will be the focus of the present paper.

Chosen literature on performance measurement theory (Andersen et al., 2021) and application (Andersen et al., 2021; Koho,2015) has been used to analyse the existing performance measurement method in NPRA and to suggest improvements.

Finally, the third branch of literature is related to sustainability and Lean. The connection between lean theory and sustainability performance is not new in the literature (Garza-Reyes, 2015; Martínez León, 2017), also in the engineering and construction field (Khodeir and Othman, 2018), but especially in the production field (Carvalho et al., 2011; Kofi et al, 2023; Mollenkopf et al, 2010). Since lean theory and the green concept have similar goals, the application of lean principles generally improves sustainability performance (Bhattacharya et al., 2019; Duarte and Cruz-Machado, 2015). The vice-versa effect is also supported in literature, since the explicit consideration of environmental sustainability, as the capacity to sustain the positive environmental effect gained in the long term (Samset, 2010), is seen as so effective from the lean perspective that sustainability is proposed by some literature (Fliedner, 2008) as an additional lean principle. Several aspects of sustainability are considered in lean literature, from the environmental to the social one (Duarte and Cruz-Machado, 2015). Nevertheless, there is no agreement in the literature on how sustainability is measured.

METHODOLOGY AND RESEARCH LIMITATIONS

The paper has two areas of the research design: the first is the case study analysis, with documents and programs study; the second is the document study of chosen literature.

The case study chosen is the Norwegian public roads administration, as a relevant example of actors dealing with sustainability in several phases of infrastructure projects. NPRA has published 5-top-goals for the strategy of the agency, together with the sustainability strategic areas (Figure 1). The status of portfolio management focusing on sustainability has been investigated (Minoretti et al, 2023) and specific documents and program studies have been performed. The documents analyzed have been suggested in information-gathering meetings with key informants from NPRA. Among the analyzed tools, the program used for suggesting the prioritization of the projects in the construction portfolio, called Effekt, has been studied. The program is used in the early-stage design and is evaluating each project's performance among societal, economic and environmental goals.

The system used today to measure sustainability in NPRA, for the specific application of the Effect program, is compared with chosen literature (Haavaldsenet al., 2012) and the pros and cons are investigated, in terms of indicators and in terms of process, using relevant literature on performance measurement (Andersen et al., 2001).

For the choice of the literature used in the study, a scoping literature review has been done on the topic of sustainability and infrastructures and on the topic of performance measurement systems. Google Scholar, Scopus and Research Rabbit are the chosen database. Using the keywords “sustainability”, “indicators”, “portfolio”, “selection”, “roads” and “projects”, no results are found in Scopus research database. The same combination allows us to find 20’900 results in Google Scholar. A systematic screening of the documents shows the scarce relevance of the literature for the research topic. Therefore, a partial combination of keywords is used and selected articles are inserted in Research Rabbit to increase the number of documents that could be interesting for the study. Finally, chosen relevant literature on the sustainability topic and on the performance measurement theory is selected from the search findings and used for the discussion.

The findings from the case study on NPRA, applying the results from the literature search, can be used to propose improvements in the performance measurement system for sustainability, both in terms of indicators and in terms of the process for evaluation. The study is used to understand the challenges in sustainability performance measurement for projects and portfolios of infrastructures, with a particular focus on the sustainability indicators used and on the process of measuring sustainability.

RESULTS

The present chapter describes how sustainability is measured today in NPRA and in the chosen literature, in terms of selected criteria and in terms of performance measurement, at the project and portfolio level. The strategic criteria for the organization are presented and a detailed description is done on the measurement and indicators used for the early phase of the investment (construction) portfolio. In particular, the tool ‘Effekt’ is taken into the analysis, since it is the only tool used by the agency to take care of the economy, environment and society in the sustainability measurement. The tool is used only in the early phase of the projects. The indicators are compared with the chosen literature and the general performance measurement system is described.

THE CHOSEN INDICATORS FOR SUSTAINABILITY

For each one of the three sustainability pillars, the specific department dealing with the concept phase for the project has defined a list of indicators that are used in a specific program called ‘EFFEKT’. The program, previously used for the analysis of the societal and economic impact, has been recently implemented to take care also of the environmental criteria.

As for the societal and economic indicators, for which the program allows to perform specific calculations and derive a defined measurable value, the climate impact has been implemented as one of the measurable indicators for the environmental impact analysis. On the contrary, other environmental indicators, for example, related to the evaluation of the impact on landscape, outdoor life, natural diversity and resources and cultural heritage, are considered separately in the evaluation and listed as non-numerical parameters. For them, an evaluation based on a level choice for the impact has been the chosen output and nine levels of consequence have been defined, from very negative to very positive.

For the priced themes (measured in money), the principles used in the evaluation are:

- utility about the benefits of a measure
- cost (or negative benefit) of disadvantages of a measure
- net benefit/net present value about the difference between benefit and costs
- socio-economic profitability (or positive net benefit/net present value) of measures where the benefits are calculated to be greater than the costs.

For the non-priced consequences (evaluated in a qualitative method), the principles used in the evaluation are positive consequences of the benefits of a measure or negative consequences of the disadvantages of a measure.

While the non-measurable indicators are listed, with the related evaluation, in a separate file, all the measurable indicators are returned in a monetary equivalent global evaluation. The evaluation is done for every proposed project and the program is used to compare the projects and to compile a list of suggested projects for prioritization. The indicators chosen in the Effekt program are listed in the following table (Table 1) and tentatively divided into the three sustainability pillars, showing the holistic perspective of the early-phase analysis that NPRA is performing.

In literature, considering the publications with a uniform concept of sustainability as based on the three pillars concept, it is possible to find a similar indicator list. The list stated in chosen literature is therefore selected (Haavaldsenet al., 2012), as specifically defined for investment projects and divided into the three sustainability pillars (Table 1). The indicators are listed in the table grouping them considering the similarity with the correspondent indicators defined by NPRA.

SUSTAINABILITY PERFORMANCE MEASUREMENT IN NPRA

NPRA is one of the actors dealing with different phases of a project, from the concept phase to the design, to the construction phase, until the use and maintenance of the infrastructure. The mentioned phases imply the involvement of different portfolios of projects internal to the organization. The concept phase may need a pre-involvement of the Research and Design portfolio of projects (not all the projects include necessarily an R&D phase). From the concept phase, the investment portfolio of projects flows to the design phase, then to the construction phase (after the necessary governmental approvals), and finally into the Maintenance portfolio.

The Public Road Administration has defined 5 strategic goals that are derived from the three sustainability pillars of economy, environment and society. The goals are: more value for money, efficient use of new technologies, contribution to Norway's fulfillment of its climate and environmental goals, vision zero -no fatalities or serious injuries-, and easier everyday mobility and increased competitiveness for business and industry. The Agency is supposed to measure its performance toward these goals, both at a company and at a portfolio level. For this purpose, a specific set of sustainability criteria has been defined by NPRA, especially tailored for the investment (construction) portfolio and the maintenance portfolio of the public administration (Figure 1).

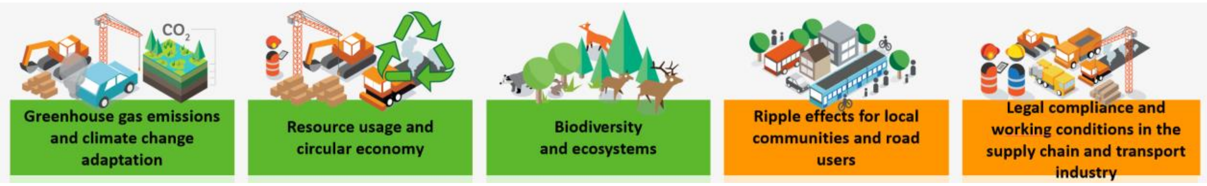

Figure 1: the five sustainable strategic goals in NPRA, Statens vegvesen (Statens vegvesen sin virksomhetsstrategi | Statens vegvesen, 2024)

Focusing on the sustainability measurement at the portfolio level of the organization, the study has investigated, through informal information gathering meetings and documental study, the way sustainability is measured along the project process and along the different portfolios, focusing on the investments (construction) portfolio. The construction portfolio is composed by project selected by the Government that are previously analysed and prioritized by the Agency on the base of sustainability criteria and indicators. This evaluation is done in the early stage of the project, considering the three dimensions of sustainability: economy, environment and society. The department taking care of this phase is using the specific tool Effekt, previously mentioned. After the government's choice of the projects to finance, other departments are taking care of the projects and, at the present moment, the work to define specific indicators or tools for the sustainability measurement is ongoing.

Table 1: Comparison of indicators used in NPRA (Effekt program) and in chosen literature (Haavaldsen et al., 2012); the NPRA's indicators are also specified if or not priced

Criteria	Priced/ Not Priced	Indicators from Effekt program (Handbook V712, NPRA)	Indicators from chosen literature (Haavaldsen et al., 2012)
ECONOMY	P	Operator benefit	
	P	Budget consequence for the public sector	Infrastructure costs
	P	Residual value	
	P	Tax cost	Consumer costs
	P	Road user and transport users benefit	Mobility barriers
	P	Traffic accidents	Damage by accidents
			Non-renewable resources
			Accessibility
			Traffic congestion
ENVIRONMENT	P	Noise and air pollution	Noise and noise control Air pollution
	P	Greenhouse gas emissions	Climate change
	NP	Natural diversity	
	NP	Natural resources	Non-renewable resources Water pollution Effects of water resources
			Housing and households
			Deterioration
SOCIETY	NP	Outdoor life/city and rural life	Living standard of the local society Effects on health Consequence for handicapped
	NP	Landscape picture	Aestetic
	NP	Cultural heritage	
			Equality Coexistence and discrimination
			Less expensive consumer products and services

The sustainability performance measurement method presented now has been evaluated in the next chapter using relevant chosen literature on guidelines for performance measurement (Andersen et al., 2021). The concepts described in the guideline to develop a performance measurement method toward a specific goal can be applied to the case of the sustainability performance measurement for the investment/construction portfolio of NPRA.

DISCUSSION

Using the principles described in performance measurement theory (Andersen et al., 2021), the NPRA's methodology for sustainability performance measurement in the early stage of the investment portfolio is analysed. In particular, the concepts of validity, reliability, completeness and coherence are discussed. The results are discussed in terms of pros and cons for both the indicators chosen and the process used to measure sustainability. Further work and improvements are proposed.

PROS AND CONS OF THE CHOSEN INDICATORS

The comparison between the indicators chosen by NPRA and the list of indicators shown in literature (Table 1), shows a discrepancy within each of the sustainability pillars. Even if both the methods shown are used within the same topic, that is infrastructures, there is no agreement on a unique set of indicators to measure the impact on each of the three criteria of economy, environment and society. This is clear also considering other literature sources from the same application field (Suprayoga,et al., 2020, Ugwu, et al., 2005).

From the perspective of measurement of performance, avoiding detailed evaluation of the specific measurement methodologies for every specific indicator and applying the general guideline considerations (Andersen et al., 2021), several considerations can be made.

The mentioned discrepancy in the indicators' list is somehow justified by the need of the actor to choose *valid* indicators. The validity of an indicator is connected to the ability of an indicator to "*correctly measure what it is supposed to measure"* (Andersen et al., 2021). Due to the different roles of the actors involved in a process and the possibility for them to gather and measure specific data, it is reasonable for them to choose indicators that they have the real possibility to control. In addition, it must be considered that the meaning of an indicator is specific for each company and specifically related to the company's activities. An example can be done also using an indicator whose use is very diffused and whose meaning has been generally agreed upon by the actors operating in the field, such as the indicator on *Emissions.* Depending on the specific role of the actor and on the data handled by the company, the same indicators could refer to different things, such as direct emissions, for example, produced by machinery, or indirect emissions, for example, related to the production of the material used, or third parties' emissions, dependent on the activities of third parties involved in the actor's activities.

The need for a specific choice for the indicators for each department has also been confirmed during the informal gathering meetings in NPRA and is traceable in the documents and tools used in the different phases of the projects. Furthermore, the literature review conducted shows that, in several fields of application, the preferred choice is to define a tailored list of sustainability indicators, especially to take into consideration the stakeholders' interest and to better support the company's approach towards sustainability (Warhurst, 2002).

This opens another consideration connected with the *reliability* of the chosen indicators, intended as "*the ability of an indicator to produce the correct value consistently over time*" (Andersen et al., 2021).

The specific departments need to define the specific indicators in the performance measurement, since these departments are connected, for example, with different phases of development of the same project, which means that, without a specific handling in the transition phases, it is not possible to check the same measurement in the next phase, characterized in practice by other defined indicators.

These specific departments' needs show a risk of compromising the reliability of the measurement along the process from the conceptual to the final stage of every single project. The possibility to transfer the measurement done on each specific indicator as an equivalent level for the related criteria in the phase stage could represent a solution for transferring the information on the expected performance (at the criteria level) in the transition phase stage. Looking at the strategic criteria defined for the Public Administration, the sustainability criteria specified and the list of indicators used in the early-stage analysis for the investment portfolio (Effekt tool), it is clear that a specific definition of the interdependencies among the different levels of criteria and with the specific indicators is a necessary further step for NPRA to guarantee not only the reliability of the performance measurement, considering the project process from evaluation to design, construction and maintenance, but also to perform control on coherence and alignment of the projects with the governance.

A process where the performance of every phase is measured in terms of the same criteria, but with specific-phase indicators, could represent a way to guarantee both the validity and the reliability of the performance measurement system along the project process.

Finally, the *completeness* of the indicators could be discussed, in terms of the presence of the three main pillars of sustainability (economy, environment and society) in performance evaluation. The investigated literature shows, for example, a lack of focus on societal indicators (Sierra Varela, 2017). Applied practice (NPRA), shows a not coherent development of the topic along the portfolio development: while in the early phase of the portfolio (analysis of projects for prioritizing, using the tool 'Effekt'), the three pillars are clearly all present in the indicators' list, at a later stage (construction, maintenance), sustainability is confined to specific areas of interest that are not clearly covering the whole spectrum of criteria. For this purpose, it has to be specified that the 'sustainability strategy' for NPRA is under development, so further specifications are expected. In addition, the topic of sustainability in the construction phase (after the approval of the financing) for the investment portfolio is additional to the previous main control criteria method, based on time, cost and quality. If we combine the set of main goals defined by the public Agency with the sustainability strategic goals (Figure 1) recently presented by NPRA, we see that the chosen global set of criteria is within the four areas of sustainable criteria defined in some literature for performance measurement of Public-Private Partnership (PPP) Projects (Akomea-Frimpong, 2022).

PROS AND CONS OF THE ACTUAL PROCESS: THE PORTFOLIO PERSPECTIVE

The process of developing a project in NPRA (Figure 2) includes several stages from the expression of the public need to the design phase, construction phase and it concludes with the realization of the effect (object) on the society. This includes the collaboration of Private and Public actors and a transversal coherent definition and control, along the process, for the chosen criteria. This is the actual challenge for NPRA.

In the development and implementation of ongoing processes, the application of standardized approaches, like for example the DMAIC (Define, Measure, Analyse, Improve, Control) approach, often used in performance improvement programs (Koho, 2015), could be helpful for the public Agency. The goal, from a strategic long-term perspective, would be to apply the approach at the portfolio level, following the whole process for the projects. An additional consideration could be done on the separate visualization of the priced and not-priced indicators, and this could be useful also to develop the potential of the measurement system in a portfolio perspective. The validity of a measurement system itself is also dependent on the ability of the system as a whole to perform the intended measurement. While the two groups of indicators could provide information on the single measurement and globally on the countable and not-countable groups of indicators, the measurement system remains incomplete in terms of providing a single evaluation for the measurement applied for example to two different projects in the portfolio. For this reason, a system to visualize globally the measurement of all the indicators is suggested. Applying a weighing system among the single indicators and among the criteria, to reflect the relative importance in the strategic perspective, it would be possible to use a spider diagram (Haavaldsen et al. 2012, Fischer et al., 2017) to show countable and non-countable indicators on the same graph.

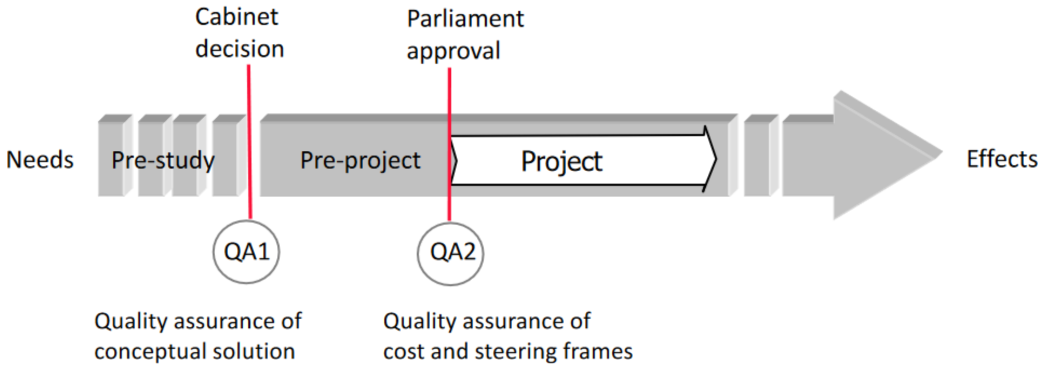

Figure 2: The Norwegian Quality Assurance regime for major public projects. Source: Norwegian Ministry of Finance. Samset and Volden (2016).

From a portfolio perspective, there is actually no consideration in the described tool of the eventual influences of a project on another. This means that there is no actual portfolio perspective, and it is therefore not possible to visualize eventual synergies for the global performance measurement in considering several projects together. Eventual synergies among different projects could give the possibility to enhance the performance of the whole portfolio for some specific criteria, always checking the effect on the global set of chosen performance criteria. A very practical example could be, for example, the possibility of treating the soil quantities in a project as a +/- requirement in a portfolio perspective: for a project that produces mass to disposal (from excavation, for example), another project could need soil for landfilling. The two parameters, that would score with a negative performance in a project perspective, would 'compensate' each other (in a simplified description of the topic) and not have a negative performance scoring for the environmental criteria in a portfolio perspective. The same example could be done on the possible positive consequence of different indicators if the portfolio perspective is used actively: a group of projects that could be realized with the same material would give the possibility, if managed in the same contract, to allow the market to offer a better economical offer for the same 'quality' (for example related to the CO2 reduction-goals connected with material production) of the material, thanks to the possibility to buy larger material quantities. A negative score on the economic criteria for a single project could therefore turn into a positive performance score if the same project is handled in a portfolio perspective.

The need of improvement for portfolio management should be highlighted also in a multiple portfolios perspective: the actual system of sustainability performance measurement is also not consider the possible influences of the choices done on a specific portfolio on the other portfolios of the agency. For example, the possible impact of the choices made for the investment/construction portfolio on the sustainability performance of the maintenance portfolio. Another example could be the consequences of the choices made for the R&D portfolio, in terms of projects financed, for example in the future alternatives for new materials available for the infrastructures, both for the construction and for the maintenance portfolios

The performance measurement system is part of a management system (Andersen et al., 2021) and it is necessary to follow it in the various management modes, such as the strategic level, the day-to-day management and the improvements that are emerging along the management practice. As the criteria and the indicators are usually connected to different levels of management, it is fundamental to draw the connections between the different criteria and the single indicators with the specific criteria they belong to and follow the dependencies in a coherent way along the process, especially in the transition phases where different departments or actors are involved. This is necessary also considering the timeline of a project development, to "*follow up in the whole process for the temporality of performance evaluation"* (Dalcher, 2012).

CONCLUSIONS AND FURTHER WORK

The paper is bounded on the case of NPRA as an organization focused on sustainability as strategic goal in the long-term-run. The chosen case study is one of the biggest actors in Norway, dealing with infrastructure management, involving different phases of the project development and from the concept to the design, construction and maintenance phase. Due to the long-term nature of the sustainable strategic goal, the importance of having an actor dealing with the whole project process and with an additional portfolio perspective, results in the possibility to investigate a perspective wide enough to generalize some of the conclusions. Nevertheless, additional data from similar organizations could give the opportunity to understand and share best practices, also in an international perspective.

The paper describes the sustainability performance measurement system, in terms of indicators and in terms of process, for the Norwegian Public Roads Administration, within the investment portfolio of projects, as an example of actor committed to develop the value stream in the long-term perspective. The performance measurement method applied for the construction projects and portfolio is therefore described and analyzed with respective to pros and cons, using relevant literature and performance measurement theory. The study shows that, at the present moment, the sustainability topic, as a combination of environmental, economic and social goal, is evaluated just in some phases for the project and just in a project perspective, missing possible synergies only possible in a portfolio level.

The study also highlights a lack of agreement in literature on the definition of sustainability in performance measurement. Specific focus on some of the sustainability pillars is underlined in part of the literature, while other publications adopt a more holistic perspective.

Using the findings from the performance measurement theory, applied to project and portfolio performance measurement focused on sustainability, further work is proposed for the improvement of the actual performance measurement system in NPRA. The actual choice of indicators in NPRA could be valid, reliable, and complete to measure sustainability, but the sustainability measurement is, by now, based on measurement done just in the early phase of a project and not followed up in a coherent way along the project development and construction. In addition, there is no portfolio perspective, so that all the possible synergies among the projects to enhance sustainability are lost. A general guideline could be helpful for the development of a specific performance measurement system for the infrastructure sector focused on sustainability. A dedicated tool could be designed and tested in the specific field applications, not only for the sustainability measurement of a single project but also to evaluate possible strategies in the portfolio management focused on optimizing the sustainability performance.

The challenges for the proposed improvements deserve a specific effort, especially in the general organization of the agency. To develop sustainable goals, it is necessary to implement the performance measurement system in a transversal way along the project process and in terms of portfolio management. Literature shows that the organizational structure has a great influence on the success in implementing the strategies in the portfolio (Petro, 2015). In addition, the perception of the organizational factors, in terms of transparency and performance measurement coherence and strategic alignment, is so important that can affect the performance of the agency's practitioners itself (Pellegrinelli et al., 2006), and therefore requires a dedicated endeavor.

A COMPARATIVE ANALYSIS OF LEED AND GREEN GLOBES: A CASE STUDY APPROACH TO ENVIRONMENTAL PERFORMANCE ASSESSMENT OF AN EDUCATIONAL CAMPUS FACILITY

Tran Duong Nguyen[1], Pardis Pishdad[2] and Ebenezer O. Fanijo[3]

ABSTRACT

The construction industry faces significant challenges in reducing energy consumption and achieving sustainability goals. Green building rating systems (GBRS) have been created to assess and confirm the effectiveness of sustainable construction practices. As buildings strive to reduce energy consumption, a holistic approach to building design, construction, and operation is necessary. The study aims to explore sustainable construction practices and their sustainability in high-performance green buildings (HPGB). The Georgia Tech Life Science Building (GTLSB), designed to serve the life science community in Metro Atlanta, is the chosen case study. Our research will involve (1) examining guidelines and standards for a sustainable building, (2) understanding the use of sustainable criteria, and (3) demonstrating technical expertise. Initially, we conducted a literature review of the current state of the GBRS and analyzed project information as a case study. Our analysis showcases an in-depth understanding of the technologies, methods, and resources required to produce and operate an HPGB. Our findings contribute to the knowledge of sustainable building and provide insights into the utilization of GBRS, focusing on two widely adopted systems, LEED and Green Globes (GG). The study's findings will help promote sustainable construction practices for professionals, policymakers, educators, and researchers and help achieve a more sustainable built environment.

KEYWORDS

Green building rating systems, LEED, Green Globes, Sustainable construction practices, High-Performance Green Building.

INTRODUCTION

The construction industry is one of the world's largest industrial sectors, accounting for about 10% of global GDP (Statista, 2024). However, it is responsible for approximately 40% of global

energy consumption and carbon dioxide emissions. (*McKinsey,* 2023). As the world faces the effects of climate change, the construction industry has become an increasingly important focus for creating more sustainable and energy-efficient built environments. Green Building Rating Systems (GBRS) is a solution to promote sustainable building techniques by utilizing energy-efficient building materials (Doan et al., 2017), renewable energy sources, and sustainable construction practices, thus reducing the environmental impact of buildings in keeping with lean principles of efficient resource use (e.g., Antonio et al., 2019; Carniero et al., 2012, Holloway and Parrish, 2013; Parrish, 2012). GBRS accelerates the adoption of building practices that result in resource-efficient, healthier, and environmentally sustainable buildings (Matisoff & Noonan, 2022). These systems provide more affordable and realistic measurements than other sustainable building rating systems, which justifies a discussion to replace the term 'green' with 'sustainability.' (Berardi, 2013)

The benefits and challenges of sustainable building practices are essential for the construction industry to achieve a more sustainable built environment. For instance, according to a report Global Data (2022), the US green building market grew 8% between 2017 and 2021. However, the initial cost of constructing green buildings is increasing (Li et al., 2020) due to the changing nature of the construction industry with respect to the environment. Developers usually cover the design costs, which can be over 30%, and use the equity in the early stages of the project (Leskinen et al., 2020). Sustainable building developers also face longer construction times. This is because some eco-friendly materials used in construction have longer lead times than their conventional counterparts (Hayles & Kooloos, 2008). As a result, delays may occur, leading to a longer wait for positive cash flow (Jermak, 2023). A further obstacle to adopting sustainable practices is the need for more knowledge among construction professionals in designing and constructing. Also, building owners, architects, and contractors need more practical guidance on these practices. For instance, obtaining LEED certification can be expensive and time-consuming, which makes it challenging for smaller projects to achieve certification (Carneiro et al., 2012). On the other hand, GG offers a more affordable and practical measurement system than LEED, but it does not have the same level of recognition and market demand (Reed et al., 2009).

The industry increasingly focuses on sustainable and energy-efficient building design and operation, particularly Lean construction practices. To achieve these goals, current research evaluates and compares the assessment methods of GBRS. The objective is to improve our understanding of how LEED and GG systems can be utilized to promote environmentally responsible and energy-efficient practices. This research will be valuable to construction stakeholders seeking to implement sustainable building practices. Our paper proposes a method for analysing different GBRSs and acting as a green building consultant for the GTLSB project. We aim to evaluate the suitability of two assessment methods, LEED and GG, and suggest improvements to enhance the building's environmental performance. This study intends to answer the following research questions (RQs): RS1: What are the key differences between the LEED and GG certification systems, including their unique strengths and weaknesses? RS2: What are the specific sustainable criteria used in the project? RS3: Which rating system is more appropriate for the project? RS4: What are the potential credit points and strategies to improve the built environment and operational efficiency of the project?

The paper is organized into different sections. The first section introduces GBRS within the context of building construction. The second section is a literature review that describes two assessment methods, LEED and GG. It identifies the most suitable systems for application based on assessment criteria, potential credit points, and strategies to improve the built environment and operational efficiency. Section 3 defines the methodology used for the study. The following section presents data analysis and explores the case study of the GTLSB project.

The results and discussions suggest ways to improve the building's environmental performance. The paper concludes with the final sections: the conclusions and references.

BACKGROUND

COMPARATIVE ANALYSIS OF THE TWO GREEN BUILDING RATING SYSTEMS

The construction industry's sustainable practices have gained significant attention in recent years due to the increasing awareness of the environmental impact of buildings. As a result, two of the most widely recognized rating systems, namely LEED and GG, have emerged to assess a building's environmental performance. The Leadership in Energy and Environmental Design or LEED system, introduced by the United States, has become a widely adopted means of assessing the environmental impact of buildings. LEED is widely recognized and has a larger market share in the green building industry (Kibert, 2016), making it easier to find professionals familiar with the system (Peng et al., 2010). Other countries have created their systems based on LEED or adopted the approach. GG is a Green Building Initiative (GBI) certification program that improves a building's environmental performance. It offers a user-friendly and cost-effective alternative to other green building certification systems, focusing on practicality and flexibility. Recently, GG has evolved to include the latest sustainable building practices. According to Kibert's 2016 research, LEED and GG have strengths and limitations. Both systems share similar categories for evaluation, such as energy efficiency, water conservation, and indoor air quality. Despite their differences in certification approaches, the two approaches aim to promote sustainable and environmentally responsible practices. They provide frameworks for designing, constructing, and operating HPGB and have raised awareness about the importance of the environment in the industry.

To help those who use these rating systems better understand which system would work best for their project quickly, this research proposes a decision framework with ten criteria for comparative analysis. This framework expands upon the framework proposed by Reeder (2010). The selection criteria filter project characteristics, allowing researchers to analyse unique project features and decide which ones to include. These criteria, including Eligible Building Types, Brand Recognition, Rating Building Performance, Third-Party Verification, Ease of Use, Costs of Compliance, Professional Designation, Certification Process, Program Points, and Adaptability, will serve as attributes in a decision support framework that assists stakeholders in identifying the most relevant GBRS in construction projects. They need first to understand the fundamental differences between the two rating systems.

Firstly, both LEED and GG are voluntary certification programs developed by the U.S. Green Building Council (USGBC) and the Green Building Initiative, respectively, to assess the sustainability of High-Performance Green Buildings (HPGB). Both systems employ a point-based evaluation approach, covering categories such as sustainable sites, water efficiency, energy and atmosphere, materials and resources, indoor environmental quality, and innovation (*Green Building Initiative*, 2023). These systems offer various project types, like commercial, residential, etc., and online tools for project progress tracking. LEED's online certification platform encompasses new construction, major renovations, and continuous improvement of existing buildings, including commercial and multifamily residential projects. GG applies to similar project types, emphasizing an online self-assessment tool that allows users to evaluate projects based on available points, earning certification with a rating from 1 to 4 globes (*Green Building Initiative*, 2023; Reeder, 2010).

From another perspective, brand recognition is crucial for developers to highlight sustainability claims, attract tenants, and gain media attention. LEED, the older and more established system with over 150,000 certified projects worldwide, enjoys higher brand recognition than GG (*USGBC*, 2023; *Landscape Management*, 2015). Comparing their comprehensive performance targets, LEED and GG share similar sustainability goals but differ in their approaches. GG introduces the Project Management aspect, focusing on effective project team management. At the same time, LEED incorporates categories like Innovation in Design and Regional Priority to incentivize exceptional credit requirements and address regional priorities. In addition, GG provides a free Life cycle assessment (LCA) calculator tool, while LEED has a task force working on incorporating LCA into its system. Differences also exist in mandatory measures for certification: GG has none, while LEED has specific prerequisites (*Green Building Initiative*, 2023). Similarly, GG offers four paths for energy performance points and five certified wood options, while LEED provides two paths for energy performance points and only considers FSC-certified wood products. Third-party verification is also essential for green building certification. LEED includes design and construction phase reviews, and GG requires mandatory verification at the end of the design phase, followed by a site visit and additional documentation review.

Additionally, ease of use is a consideration when choosing a rating system. The LEED rating system provides several advantages over GG. For instance, LEED has a more detailed scoring system with certification levels ranging from Certified to Platinum *(Landscape Management*, 2015). However, GG is often considered more user-friendly and suitable for “do-it-yourselves” types due to its online application and self-assessment nature. Cost is another critical factor, and LEED costs are determined by project size and complexity. Implementation costs may vary based on the credits pursued, requiring staff time for learning, or hiring a consultant (*Green Building Initiative*, 2023). In contrast, GG is perceived as more cost-effective due to lower consultation fees and a fixed certification fee. Other aspects, such as professional designations like LEED Accredited Professional (LEED AP) and Green Globes Professional (GGP), demonstrate an individual's expertise in green building. Requirements for these designations include a minimum of years of experience and continuing education (*Green Building Initiative*, 2023; *USGBC*, 2023). The certification process involves project teams registering on online platforms (LEED Online for LEED, self-evaluation for GG), submitting documentation, and undergoing third-party verification.

Moreover, from a different standpoint, regarding program points, GG employs a 1,000-point scale compared to LEED's 110 points, with both systems prioritizing categories such as Energy, Water, Materials and Resources, and Indoor Environment. GG emphasizes project management by allocating a substantial percentage of points to progress meetings, coordination, benchmarking, commissioning, and documentation (Wu & Low, 2010). Predesign construction to post-construction stages are evaluated, and points are allocated for assessment (Peng et al., 2010). LEED and GG offer value when evaluating and certifying the sustainability of buildings. While LEED has distinct features and benefits, GG also boasts unique advantages. Ultimately, the decision to choose between the two depends on the specific goals and priorities of the project.

Table 1: Comparative Analysis of two green building rating systems

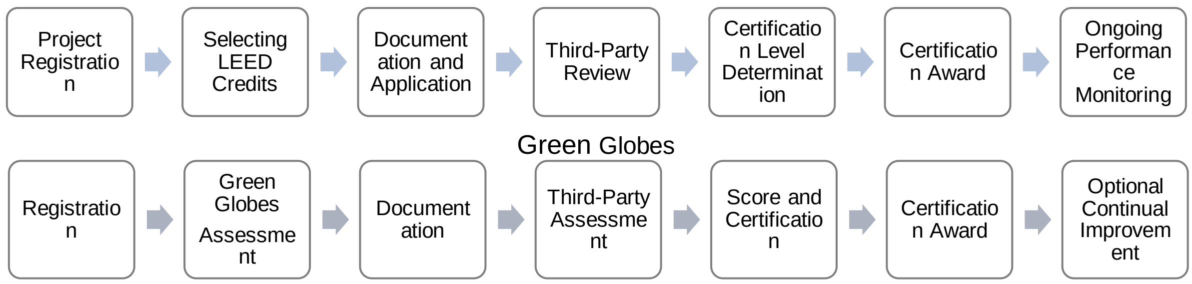
Criteria	LEED	Green Globes
Project Types Eligible for Certification		
Eligible Building Types	Commercial over 1,000 SF or over 250 SF for LEED-CI	Commercial & Multifamily Residential (4+ stories)
Prerequisites	Yes	No
New Construction/ Renovations	✓	✓
Existing Buildings	✓	✓
Market Penetration		
Year Launched	1998	2004
Number of Buildings Certified	105,000	3,223
Number of square feet Certified	12 billion square feet	600 million square feet
Category Types Considered in Rating Building Performance		
Site Selection & Development	✓	✓
Energy Efficiency	Two paths	Four paths
Water Conservation	✓	✓
Material & Resource Efficiency	✓	✓
Indoor Environmental Quality	✓	✓
Additional Categories	Innovation, Regional Priority	Project management
Forestry Certification	FSC Only	Five options
Point Systems		
Level of Certification	4	4
Total points available	110	1,000
Certification points minimum	Req. 40 pts + prerequisites	Project points: 35%.
Point Minimum or Partial Credit	No	Yes
The accessor visits a project.	Yes	No
Certified Levels	Certified 40 – 49 pts	1-globe 36 – 55%
	Silver 50 – 59 pts	2-globe 56 – 70%
	Gold 60 – 79 pts	3-globe 71 – 85%
	Platinum 80 – 110 pts	4-globe 86 – 100%

**Note*: Data and rates are from Feb. 2023 from the Green Building Initiative (2023) and USGBC (2023).*

Table 1 (continued): Comparative Analysis of two green building rating systems

Criteria	LEED	Green Globes
Registration and Certification Fees		
Registration Fee for each project	$1,200	$1,500
Assessment and Certification	New Construction: $2,500-$22,000 Existing Buildings: $1,750-$15,000 Consultant Fee: $10,000-$30,000 Testing & Verification: $1,000-$10,000	Pre-Design Review (NC): $3,000 - $12,500 Design Review (NC): $4,635 - $15,500 Final Certification: $4,120 - $15,500
Certification Process		

LEED



Program points

Rating systems	Categories	Points	Weight (%)
LEED BD+C	Integrated Process	1	0.91%
	Location & Transportation	16	14.55%
	Sustainable Sites	10	9.09%
	Water Efficiency	11	10%
	Energy & Atmosphere	33	30%
	Materials & Resources	13	11.82%
	Indoor Environment Quality	16	14.55%
	Innovation	6	5.45%
	Regional Priority	5	3.64%
	Total	*110*	*100 %*
Green Globes	Project Management	100	5 %
	Site	150	12 %
	Energy	260	39.5 %
	Water	190	11 %
	Materials & Resources	150	12.5 %
	Indoor Environment	150	15 %
	Total	*1,000*	*100 %*

**Note: Data and rates are from Feb. 2023 from the Green Building Initiative (2023) and USGBC (2023).*

Over the years, GBRS, including LEED and GG, have faced criticism and debates as they attempt to address sustainability in buildings. One of the reviews was the insufficient integration of LCA, which will be included in future rating system versions. Another criticism was that certification could be granted to buildings that were not necessarily energy-efficient, although this flaw was addressed in later LEED versions. To address the issue of energy efficiency further, LEED v4 now requires projects to provide actual energy and water usage performance data to the USGBC for at least the first five years of occupancy. This will allow the USGBC to compare actual building performance to a modeled performance, provide feedback about operations to owners, and potentially offer helpful feedback to design teams (Reeder, 2010). On the other hand, some judges claim that GG lacks transparency, while others argue that LEED is too prescriptive and inflexible. Also, there have been discussions about the minimum percentage of points required for each environmental assessment area that may not fully address all aspects of sustainability (Reeder, 2010). Apparently, the choice between LEED and other rating systems like GG depends on the specific needs and priorities of the building owner or developer, considering factors such as transparency, flexibility, and the level of detail desired in the certification process.

METHODOLOGY

The research project has begun with a literature review of the current state of Green Building Rating Systems (GBRS). This section involved examining the two assessment methods, LEED and GG. Google Scholar database was used to conduct literature research as it showcases a wide range of scholarly literature. Initially, the research used keywords in the 'Article title, Abstract, Keywords' field. The search was limited to articles and review papers, and the keywords used in the research field were "LEED," "Green Globes," "Green building rating systems," and "High-Performance green buildings." A total of 146 documents matching the keywords were obtained. Next, the 146 papers were thoroughly reviewed by evaluating the title and abstract to find relevant papers focusing on GBRS in building construction. The search included 94 publications containing critical terms in titles, author keywords, and abstracts. The full papers of the remaining 94 publications were carefully analysed in the last stage to fully comprehend the relevance of completing the research aim. As a result, 15 papers were identified as relevant for a detailed literature review.

In the Case Study analysis, a set of criteria for comparative analysis will be developed through a literature review to identify suitable systems for application. The chosen systems will be evaluated based on assessment criteria, potential credit points, and strategies to improve the built environment and operational efficiency. Research practices should be used to ensure the accuracy and reliability of findings to make informed decisions. The next step will use a case study research design focusing on three main aspects. Firstly, explore the sustainable criteria used in the Georgia Tech Science Square project and their contributions to sustainability. Secondly, it provides fragments of an in-depth understanding of the technologies, methods, and means required to produce and operate high-performance green buildings (HPGB) in the project. Lastly, we suggest improvements to enhance the building's environmental performance in the recommendation section. The study will utilize evidence from a literature review and a case study to address research questions and provide recommendations for utilizing GBRS and promoting sustainable construction practices.

CASE STUDY

To compare the effectiveness of different GBRS, we conducted a case study with the Life science building project. In this project, the authors intended to investigate the sustainability aspects of the building design and construction practices during the preconstruction and construction stages. The choice of a GBRS for a project depends on its specific needs and the stakeholders' preferences. This study uses the later Proposed Criteria (Table 3) to evaluate which systems are most suitable for project certification. The findings of this study will be helpful for construction professionals, policymakers, and researchers interested in promoting sustainable construction practices and achieving a more sustainable built environment.

PROJECT DESCRIPTION

Georgia Institute of Technology has announced its plans to apply for green building assessment and certification for the Science Square Building on North Avenue near Northside Drive. The building is part of a new development complex called Science Square at 387 Technology Circle NW, Atlanta, GA 30313. This 18-acre complex will comprise a mixed-use residential and commercial community. The community already has a few existing buildings, including the Biotech Innovation Lab and an office building constructed in the early 2000s. The development is a five-phase project expected to cost over a billion dollars. Phase 1A, the life science project, includes an office building, residential components, and a parking lot. The Science Square Building has a total square footage of 750,000, which includes 285 residential apartments and a six-floor, 1,000-spot parking deck. This combines the two buildings and provides parking for the district. The construction comprises all the MEPs, structure, skin, lobby, and core restrooms. The tenants occupying the space have design input on the interiors, and the owners will lend them a hand. This is known as the Core & Shell portion. The construction began in April 2022 and is expected to be completed by Fall 2024.

SPECIFIC SUSTAINABLE CRITERIA AND UNIQUE FEATURES USED IN THE PROJECT

Table 2: Comparison Table of Scorecard between LEED and Green Globes

Categories/ Sustainable Criteria	Life Science Building project - Unique Features	LEED	GG
	Project Management	1	98
Integrative Process	Contract type: Cost-plus		
	Collaboration with Perkins & Will for Green Certification		
	Accountability for Design and Construction elements		
	Location & Transportation	15	N/A
Location	Convenient location near Belt Line, Midtown, and Stations		
Transportation	Bicycle facilities, EV parking deck, charging stations		
	Sustainable Sites	4	86
Pollution Prevention	Maintain the record forms during construction.		
Habitat Protection	Consideration of preserved open space & rainwater Mngt.		
Bioretention Areas	Handling stormwater and preventing city line overload		
Existing Water Detention Vault	Reaching max capacity, requiring extra bioretention areas		
Rainwater Management	New construction requiring a new detention vault		

Table 2 (continued): Comparison Table of Scorecard between LEED and Green Globes

Categories/ Sustainable Criteria	Life Science Building project - Unique Features	LEED	GG
	Water Efficiency	4	113
Indoor Water Reuse	Lab Office building with three cooling towers		
HVAC System	Convective system for water recycling		
Plumbing Fixtures	Low-flow mechanisms, sustainable materials		
Hot Water System	Four boilers on the top meet specified criteria.		
	Energy and Atmosphere	20	124
Energy Metering System	Monitoring individual-level energy consumption		
Electrochromic Glazing	5,000 panels of smart glass for UV light control		
LEED Certification	Two-for-one deal with Electrochromic glazing		
Glass Control System	QR codes, low-voltage wires, EMS system control		
	Materials and Resources	5	56
Recycled Material	82% recycled content for LEED certification		
Construction Waste Mngt.	Professional handling of recycled materials		
Raw Material Sourcing	Meeting EPD standards, concrete mix design		
Raw Material Availability	Easy availability in Metro Atlanta's local market		
Carbon Emissions	Concrete usage remains despite LEED incompatibility.		
	Indoor Environmental Quality	7	84
Indoor Air Quality Mngt.	Blue cellophane wraps over ducts, post-installation cleaning.		
Daylight Improvement	Electrochromic glazing for better daylight		
Quality Views	Strategic placement of labs and offices		
Low-emitting Materials	Use of materials with low emissions		
Cleanable Surfaces	Polished concrete and cleanable walls instead of carpet		
	Innovation in Design	6	N/A
Innovative Features	Electrochromic glazing, convective mechanical system		
Certification	Pursuing LEED gold certification with a score of 64		
	Regional Priority	2	N/A
	Total	*64*	*561*

**Notes: Sustainable Criteria above are based on LEED and GG certification categories. The project achieved LEED Gold certification with 64 out of 110 points (58%), compared to achieving 2-Globe certification with 561 out of 1000 points (56%) for Green Globes.*

CRITERIA PROPOSAL

Each building has different characteristics that could influence the stakeholders' selection of different GBRSs. Based on a literature review of published studies, this research suggests ten criteria for comparative analysis (Table 3). Selection criteria were included to filter the project's attributes and help improve data analysis. The decision support framework uses these criteria to enable stakeholders to make transparent decisions when selecting Green Building Rating systems for construction projects. When evaluating green building assessment systems, there are several factors to consider. For example, eligible building types refer to buildings certified under a specific green building assessment system (Reeder, 2010). In addition, significant factors like market penetration, brand recognition, reputation, and credibility refer to people's awareness and familiarity with a particular brand or organization (Reeder, 2010; *Landscape Management*, 2015). Rating building performance involves evaluating its energy efficiency, water efficiency, indoor environmental quality, and other sustainability-related factors (Manoj Katiyar et al., 2020). Moreover, third-party verification is necessary for all green building rating systems to ensure that the certification process is objective and credible (Reeder, 2010). Ease of use, compliance costs, professional designation, certification process, program points, and adaptability are essential factors when selecting a green building assessment system. The research used the proposed criteria to compare two examples of GBRS, LEED and GG. A decision support framework was used to apply these criteria as a filter, which helps stakeholders select the most suitable green building assessment system for their project.

PROJECT CERTIFICATION SYSTEMS EVALUATION & RESULTS

Choosing the appropriate assessment system is a crucial first step in the green building assessment process. The choice should be based on the unique needs and objectives of the project, as well as the preferences of the building owner and design team. The choice of a green building assessment system for a project depends on its specific needs and the stakeholders' preferences. This study uses the Proposed Criteria to evaluate which systems are most suitable for project certification. Factors such as eligible building types, brand reputation, rating building performance, third-party verification, ease of use, compliance costs, professional designation, certification process, program points, and adaptability are considered when evaluating suitable systems for project certification. The project team will use the Proposed Criteria to make their evaluation correctly.

Table 3: Evaluate the suitable systems for project certification using Proposed Criteria

#	Criteria Analysis	LEED	Green Globes	Justifications (based on the GTLSB project)
1	Eligible Building Types	✓	✓	All building types.
2	Brand Recognition	✓		Widely used, with over 105,000 compared with 3,223 certified projects worldwide.
3	Rating Building Performance	✓	✓	LEED has a prescriptive approach, with specific requirements for each credit. GG offers flexibility and can choose strategies that best fit the project's goals.
4	Third-Party Verification	✓	✓	Both Required. GG: Site visit
5	Ease of Use		✓	LEED: This can be complex and time-consuming. GG: Easier to use and less time-consuming.
6	Costs of Compliance	✓		LEED: Structured based on project size and more complexity in cost.GG: More cost-effective in a less complex process.
7	Professional Designation	✓	✓	LEED Accredited Professional (LEED AP) Green Globes Professional (GGP)
8	Certification Process	✓	✓	LEED can take several months. GG can be completed in a shorter timeframe. GT is familiar with the LEED process.
9	Program Points	✓		Based on Scorecard, LEED gold compared with 2-Globe certified
10	Adaptability	✓	✓	LEED: Global, adaptable framework for sustainability. GG: Adaptable, user-friendly sustainability assessment.
	Total	*9*	*7*	

**Note: The number of remarks for each criterion shows how important they are for the proposed study. A higher number of remarks means that the chosen system is a better fit. The table shows LEED scored 9/10 points, while GG only scored 7/10 points.*

RESULTS, DISCUSSIONS, AND RECOMMENDATIONS

RESULTS ON SELECTING THE SUITABLE GREEN BUILDING RATING SYSTEMS

After analysing the criteria presented in Table 3, it was concluded that LEED is the most suitable choice for the project. This decision was made based on several key factors. LEED and GG were deemed eligible for all building types, but LEED stood out due to its widespread recognition, with over 150,000 certified projects worldwide compared to GG. Additionally, LEED's prescriptive approach with specific requirements for each credit aligned well with the project's goals and expectations. Both systems meet third-party verification requirements, but GG includes a site visit as part of its verification process, providing an additional layer of assurance. GG is considered more straightforward and less time-consuming than LEED, which may be crucial for a streamlined and user-friendly certification process. However, LEED's structured costs based on project size and complexity may impact the decision based on budget constraints. LEED outperforms GG in terms of program points, achieving a higher level of recognition with LEED Gold compared to 2-Globe certified for GG. The difference in recognition between the two rating systems can impact the decision-making process for building owners and developers. LEED's higher level of recognition might be a decisive factor in favor of selecting it over GG, especially if achieving a prestigious certification level is a priority. When considering these factors collectively, the overall recommendation for LEED is well-supported by its brand recognition, alignment with project goals, and professional designation, among other important considerations.

RECOMMENDATIONS FOR IMPROVING ENVIRONMENTAL PERFORMANCE

The project evaluated in Table 1 showed that several areas of environmental performance need improvement. The Sustainable Sites and Water Efficiency categories scored the lowest percentage from the total points available, receiving a 4/11 score (36%) each. The lack of on-site rainwater management, failure to protect or restore habitats, and limited heat island reduction measures were some of the most significant issues of environmental performance observed in the category. These issues resulted in zero on-site rainwater management and habitat protection points, while only one out of two points was awarded for heat island reduction measures. Additionally, no points were awarded for light pollution reduction.

To improve the project's environmental performance from a site perspective, incorporating a robust green roof could address almost all the issues in the Sustainable Sites category. Water-absorbent plants across the building's footprint can significantly reduce stormwater runoff. Creating habitats for animals such as bee hives, birdhouses, and bat boxes requires thorough planning, installation, and maintenance to ensure that they help to preserve biodiversity without causing any harm or inconvenience. If done correctly, these habitats can be integrated into green roofs, improving ecological performance and earning credits. A green roof can also contribute to reducing the heat island effect. However, practical concerns such as cooling towers, mechanical ventilation, and specialized exhaust systems must be integrated into the overall design to ensure they do not interfere with the green roof's functionality or harm the local ecosystem. The construction phase must consider weight loads by reinforcing the structure, but it is a viable option with a suitable investment. The only aspect of Sustainable Sites that a green roof would not overcome is light pollution reduction, which is caused by exterior lighting systems and affects wildlife and health (Kibert, 2016). However, one solution is to limit the opacity of electrochromic glazing after sunset or install light-reducing window coatings and shades to reduce night glow. Reducing light pollution in such an urban environment is less practical (given current technology and safety standards) than other options listed in this section.

The project receives partial credit in many areas in the LEED category of Water Efficiency. The project must reduce indoor and outdoor water usage to obtain high scores. Half of the points can be earned through reduced water use, while the other half is earned by optimizing water use processes. As such, the project can expand the planned greywater-recycling cooling towers and recycle water for additional cycles before using it to rinse green spaces and roofs. Low-flow water fixtures are installed; future tenants must agree to use similar fixtures to earn credits.

The project had un-awarded points in Energy and Atmosphere (E&A), 61% of the total points, and Materials and Resources, 36%. Some credits were partially awarded from the E&A category, but Advanced Energy Metering received no points. To address this issue, the owner can install more energy metering devices on the large lab equipment, fulfilling metering requirements and allowing more manageable maintenance and energy optimization. Additionally, windmills could be installed to complement the solar array on the roof, reducing the necessary space for solar panels and enhancing the ecological performance of the project.

The largest area of lost points in Materials and Resources was related to reducing the impact of the life cycle. While the proposals above could have partially focused on this issue, a more comprehensive LCA of all materials used in the project, especially the Sourcing Raw Materials, would have been necessary earlier in the construction phase. These points may be lost now, but undertaking these areas for future phases of Science Square is essential.

DISCUSSIONS

The research findings presented offer valuable insights into evaluating GBRS, explicitly focusing on comparing LEED and GG within HPGB. The study's project analysis provides a practical application of sustainable construction principles. It highlights the importance of integrating sustainable criteria, innovative technologies, and continuous improvement strategies in building design and operation. One key finding of the research is identifying areas for improvement in environmental performance within the project. By pinpointing inefficiencies, the study reveals that the Sustainable Sites and Water Efficiency categories scored the lowest percentage points, indicating opportunities to enhance on-site rainwater management, habitat protection, and heat island reduction measures.

Moreover, the research emphasizes the significance of practical considerations, such as cooling towers, mechanical ventilation, and structural reinforcement, in effectively implementing green roof systems. Addressing these technical challenges and ensuring compatibility with building systems and local ecosystems is crucial to optimizing environmental performance in HPGB projects. This finding underscores the need for a multidisciplinary approach to sustainable construction practices, requiring collaboration among architects, engineers, and environmental specialists.

Furthermore, Lean Construction principles focus on maximizing value and minimizing waste throughout the construction (Alarcón et al., 2013). This study contributes to Lean Construction by providing a comparative analysis of LEED and GG within the context of environmental performance assessment for an educational campus facility. This study emphasizes efficiency, sustainability, and continuous improvement in construction, aligning with Lean principles of optimizing resource utilization and enhancing project outcomes. The research suggests a sustainable framework integrating guidelines, standards, and technical expertise to achieve green building. Analyzing GG and LEED within environmental performance assessment allows construction stakeholders to select the most suitable GBRS that best aligns with project goals, sustainability objectives, and performance criteria.

CONCLUSIONS

The construction industry is transitioning towards sustainable building practices and reduced energy consumption. This shift is driven by various factors, including environmental concerns and the demand for more energy-efficient and environmentally friendly buildings. As the demand for sustainable buildings grows, sustainable building practices and rating systems like LEED and GG will become more important in promoting a sustainable environment for future generations. Our research contributes to the body of knowledge by providing an in-depth understanding of developing sustainable construction practices and the long-term sustainability of HPGB. Our study suggests that using GBRS and a comprehensive approach to building design, construction, and operation can help solve significant challenges the construction industry faces, such as energy consumption reduction and achieving sustainability goals. These approaches can promote a more sustainable built environment for future generations, benefiting both people and the planet. Our study proposes a sustainable decision framework that integrates guidelines and standards, sustainable criteria, and technical expertise, advancing prior works. The Georgia Tech Life Science Building is an excellent example of sustainable building practices, with its energy-efficient systems, natural light and ventilation, eco-friendly materials, and responsible waste management practices. Our study benefits professionals and academics by providing a valuable resource for comparative analysis and promoting the implementation of GBRS. Although there are some limitations, our findings are helpful to construction professionals, policymakers, and researchers interested in enhancing sustainable construction practices and achieving a more sustainable built environment.

JET GROUTING: APPLYING LEAN PRINCIPLES IN GEOTECHNICAL ENGINEERING TO REDUCE WASTE

Björn Bernhard Vauk[1] and Dennis Dalchau[2]

ABSTRACT

Jet grouting is a widely used method for ground improvement and for sealing measures in geotechnical engineering. Due to the nature of the process, the material consumption of water-binder suspension is high. The objective of this research is to enable a more efficient use of resources by evaluating and reducing the waste of the resources used in the jet grouting process, taking lean principles into account.

The objective of this paper is to develop a production flow model for the jet grouting process. This is to enable a continuous improvement of the production processes and a reduction of the associated material consumption through recycling.

A production flow model is proposed to determine the amount of binder suspension required for production as a function of production time. The model presented will be used to control and continuously improve the production process and associated use of resources in future research. This will be done in accordance with the lean principles of customer value, value stream identification, flow, pull and striving for perfection.

KEYWORDS

Lean and Green, Sustainability, Waste, Production Pull

INTRODUCTION

The construction industry is currently facing the challenge of simultaneously achieving greater sustainability and enhancing efficiency. Sustainability and lean construction are increasingly becoming key topics in the german construction industry, with ecological responsibility and efficiency through the optimal use of resources taking centre stage. The objective of sustainability is to achieve long-term ecological, social and economic stability in order to meet the needs of the present without compromising the opportunities of future generations (Schlacke, 2023). This principle is also enshrined in Article 20a of the German Basic Law.

The objective of lean construction is to focus on effectiveness through customer orientation and to continuously improve efficiency by reducing waste. Waste can be classified into construction-specific categories (Koskela et al., 2013), which facilitates its identification. The five key principles of the Womack & Jones (2003) model must be considered in their entirety for the successful implementation of lean construction. Firstly, the principle of value specification defines the value of a service from the customer's perspective, which forms the basis for all subsequent steps. Subsequently, value stream identification leads to the analysis and optimisation of all necessary activities in the value chain. This involves the identification

and elimination of cost-increasing activities (Muda Typ 2) and the reduction of (un)necessary activities that do not increase value (Muda Typ 1). The objective of the flow principle is to design all activities in a manner that ensures a continuous and uninterrupted process, with the aim of minimising cycle times. The pull principle means that production is controlled by actual demand, which enables agile and demand-oriented value creation. Finally, the principle of striving for perfection promotes a culture of continuous improvement by making incremental changes to get closer to an ideal state.

The jet grouting process is used in geotechnical engineering for the construction of auxiliary structures such as underpinning of buildings, horizontal sealing of excavations and ground improvement. Once the binder suspension mixed with the subsoil has hardened, a structurally stable and sealing earth mortar body is created.

The sequence of production processes in jet grouting can be identified using the value stream analysis method (Rother & Shook, 2003) and described quantitatively using a model to be developed. The erosion process begins after the borehole is drilled with the use of a high-energy hydraulic cutting jet, which consists of a binder suspension (1- and 2-phase system), to erode the existing soil structure and mix it with the binder suspension. The binder suspension, which has been mixed with the eroded soil structure, is returned via the borehole annulus as backflow suspension in accordance with the law of continuity and is then disposed of. In consideration of the lean principles, ideas are presented on how the backflow suspension from the production processes can be reused. In particular, the objective of this work is to contribute to the creation of a foundation for reducing the waste of finite resources through the production flow model presented and to promote the circular economy in geotechnical engineering. This will facilitate the transition towards more sustainable and efficient construction practices.

METHODOLOGY

The methodology describes the systematic methods used in the research to collect, analyse and interpret data. It includes both the theoretical foundation of the selected research approaches and the practical implementation of the study.

A comprehensive analysis of the process steps was carried out for the development of the production flow model of the jet grouting process. The key process steps were recorded directly on the construction site before and during production using value stream analysis and multi-moment recordings. These process steps were coordinated with the construction and project management teams to ensure precise documentation of the individual processes and their duration. The processing times of the rig were extracted from the machine data, which served as the basis for setting up the process model. Furthermore, the separation technology, consisting of screening systems and hydrocyclones, was carefully dimensioned. The adaptation was based on the expected geological conditions of the case studies, which were derived from the soil reports. The separation performance of the plant was determined in a systematic manner based on the density of the suspension and the remaining sand content of the backflow suspension.

A comprehensive literature review on the subjects of lean construction and jet grouting initially yielded no direct hits under the search terms used. This indicated a need to deepen the research and further elaborate the concepts of lean principles in the field of geotechnical engineering, in particular regarding the jet grouting method.

The investigation of the rheological properties of the suspension and the contents of water, cement and soil in the suspension is based on previous research by the authors. These previous studies form the basis for the current methodological orientation and future research activities based on them, which were also carried out by third parties (Thienert et al., 2017) on the basis of earlier investigations by the authors (Vauk, 2011).

JET GROUTING

SUSTAINABILITY CHALLENGES

Approximately 30 million tonnes of cement are consumed in Germany each year, resulting in an annual CO_2 equivalent of approximately 17 million tonnes (Verein Deutscher Zementwerke e.V., 2022, 2023). In the context of geotechnical engineering, the jet grouting process results in the disposal of approximately 50% of the approximately 220 to 350 thousand tonnes of cement used (Thienert et al., 2017).

"On average, 2,787 MJ of fuel energy and 113.1 kWh of electrical energy were used to produce one tonne of cement in Germany in 2022." (BVSE, 2022) The total energy consumption is thus approximately 887 kWh per tonne (0.2778 kWh/MJ). The operation of a separation plant as used in the case studies requires approximately 33 kWh of energy. This energy is used by two 2.3 kW screening plants and a hydrocyclone with a feed pump, which has an estimated energy consumption of around 25 kW, depending on the pump characteristic curve. The water requirement for the additional cleaning of the separation plant and the energy consumption of the separation process have already been amortised in terms of a positive ecological balance when processing 1 m³ of water-cement suspension (750 l/m³ water; 750 kg cement at w/c=1.0).

The DGNB certificate from Germany (DGNB, n.d.) or comparable certificates such as the LEED certificate from the USA (U.S. Green Building Council, n.d.) adopt a holistic approach to the sustainability of buildings, basing their assessments on defined criteria catalogues and usage profiles (Carneiro et al., 2012). The LC method value stream mapping enables the analysis of production processes from a sustainability perspective, identifying waste in the use of resources (Rosenbaum et al., 2012).

In the production process of the jet grouting method, the water-binder suspension required for the drilling and erosion processes is mixed and stored in the agitator regardless of the actual time-dependent demand (push). It is possible that the maximum processing time of the binder may be exceeded, resulting in the disposal of the fresh suspension unused, particularly in the event of high outside temperatures and production disruptions. If disposal is not carried out after the maximum possible processing time has been exceeded (hydratation), it is no longer possible to achieve the required final material strengths with certainty, which may result in defects (waste).

In the event that a mixed water-binder suspension is utilised during the maximum processing time, the suspension is utilised on a single occasion for the drilling and erosion processes. The water-binder suspension, which has been mixed with the eroded soil structure during the drilling and jet grouting processes, is returned via the borehole annulus as backflow suspension in accordance with the law of continuity (ratio 1:1 of water-binder suspension to backflow suspension). Subsequent to this, the volume of approximately 100% of the introduced suspension is disposed of, containing approximately 50 % of the introduced binder (waste).

USE OF EXCESS BACKFLOW SUSPENSION: FLOW CHART AND PULL CONTROL

Instead of disposal, the excess backflow suspension is to be treated and reused in order to prevent the waste of binder and water.

In instances where the actual demand for water-binder suspension can be determined by a production flow model based on time (depending on the process steps of moving the rig, setting up, drilling and erosion process), it can be mixed on demand (pull). Furthermore, the work content of the workers can be more evenly distributed according to the duration of the individual process steps, thereby increasing labour productivity.

Figure 1 shows the flow diagram of the suspension in the production process and the separation plant to be proposed. The requisite binder suspension, comprising water and cement, is combined in the mixer and previously stored in the agitator for delivery to the drilling rig. The drilling rig is supplied with the binder suspension via the high-pressure pump, and after the drilling and erosion process, it is pumped into disposal troughs or earth basins as backflow suspension via the return pump (1). After solidification, the backflow suspension is previously disposed of.

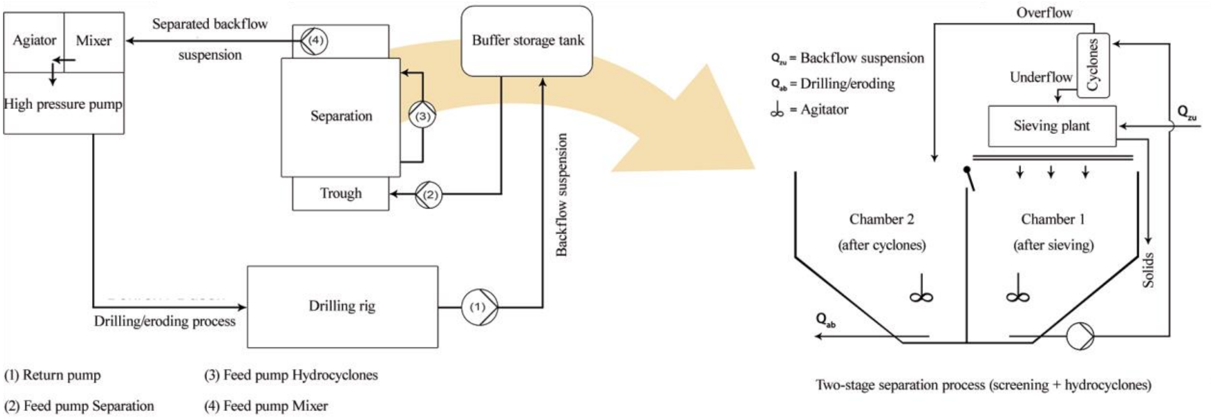

Figure 1: Flow diagram of the suspension and separation plant (Vauk, 2011)

The treatment of backflow suspension by separation is proposed. The use of a separation plant (two-stage separation consisting of screening and hydrocyclones) allows the backflow suspension to be treated for reuse. (Vauk, 2011) The separated backflow suspension is pumped to the mixing plant via the feed pump of the mixing plant (4), treated by the addition of binder and fed back into the production process.

In order to determine the time-dependent quantity of binder suspension required for the drilling and erosion process in accordance with demand, a production flow model is proposed. This model enables the time-dependent demand for binder suspension to be determined in advance, and the flow diagram to be designed in accordance with the lean principle of pull. The binder suspension required for the production process is drawn into production by the drilling rig from the high-pressure pump (pull). The separation plant is responsible for preparing the requisite quantity of binder suspension for production, with no excess. This is done according to demand. The proposed production flow model based on the pull principle ensures that the required quantity of binder suspension is known at all times. This allows the separation plant to be continuously improved in terms of its capacity (flow rate) and required separation performance (separation cut, screen area, mesh size of the screens, number of hydrocyclones, pressure of feed pump for hydrocyclones, etc.). This, in turn, enables the binder suspension to be recovered more economically.

In order to optimise the utilisation of the cement contained in the separated backflow suspension and thus reduce the need to add fresh cement, it is necessary to empirically test the effects of this reduction on the compressive strength of the elements produced from the suspension in the sense of a suitability test. In the authors' opinion, the addition of fresh cement should be gradually reduced, for example to 90 %, 80 % or 70 %. It is recommended that this test be conducted prior to any reduction in the addition of cement to the separated backflow suspension. Furthermore, it is essential to ensure that the cement already present in the suspension is processed before solidification commences.

PRODUCTION FLOW MODELLING FOR PULL CONTROL

In order to reuse the backflow suspension in the erosion process, it is necessary to determine the binder content that remains in the separated backflow suspension. In order to ensure that the static compressive strength of the jet grout body produced meets the required specifications, the missing binder content, which results from the water-binder value (target value) minus the remaining binder content, should be added.

Verification of the binder content after separation is not possible using electrometric, thermal and kaliometric methods (Vauk, 2011). As the solids properties change over time depending on the eroded subsoil (homogeneous areas), the time-dependent formation of the backflow suspension is to be described by the following production flow model.

The time required for the erosion process of a jet grouting element is dependent on the erosion performance of the subsoil in homogeneous areas:

$$t_j = \left(\frac{E}{\pi \cdot \left(\frac{d^2}{4} \right)} \right)^{-1}$$

with

t_j	Erosion time per metre [min/m]
E	Erosion rate (depending on the subsoil) [m³/min]
π	Constant
d	Diameter of the jet grouting element [m]

The suspension volume required for the erosion process for each homogeneous area is obtained from the erosion time t_j and the distance to be eroded l_j at a constant binder suspension flow rate of $Q_{j,min}$ per minute:

$$Q_j = Q_{j,\min} \times t_j \times l_j$$

with

Q_j	Suspension volume per homogeneous area (erosion process) [m³]
$Q_{j,min}$	Suspension volume per minute (erosion process) [m³/min]
t_j	Erosion time per metre [min/m]
l_j	Erosion distance per homogeneous area [m]

The suspension volume required for the drilling process for each homogeneous area is calculated from the drilling time t_d and the drilling distance l_d at a constant binder suspension flow rate of $Q_{d,min}$ per minute:

$$Q_d = Q_{d,\min} \times t_d \times l_d$$

with

Q_d	Suspension volume per homogeneous area (Drilling process) [m³]
$Q_{d,min}$	Suspension volume per minute (Drilling process) [m³/min]
t_d	Drilling time per metre [min/m]
l_d	Drilling distance per homogeneous area [m]

Depending on the geotechnical terrain model, a binder suspension requirement Q_E per jet grouting element results for n homogeneous areas:

$$Q_E = \sum_{i=1}^{n} (Q_{d,i} + Q_{j,i})$$

with

Q_E	Binder suspension requirement per jet grouting element [m³]
$Q_{d,i}$	Binder suspension requirement (drilling process) [m³]
$Q_{j,i}$	Binder suspension requirement (erosion process) [m³]
n	Number of homogeneous areas [-]

The production time t_E, in which the binder suspension Q_E is required, is calculated from the drilling time $t_{d,i}$ and the erosion time $t_{j,i}$ for n homogeneous areas:

$$t_E = \sum_{i=1}^{n} (t_{d,i} + t_{j,i})$$

with

t_E	Processing time (drilling process and erosion process) [min]
$t_{d,i}$	Drilling time [min]
$t_{j,i}$	Erosion time [min]
n	Number of homogeneous areas [-]

Taking into account the set-up time (moving and setting up the rig), the binder suspension requirement Q_E over time is calculated using the cycle time t_c per jet grouting element:

$$t_c = t_R + t_E$$

with

t_c	Cycle time (set-up time, processing time) [min]
t_R	Set-up time (moving and setting up the rig) [min]
t_E	Processing time (drilling process and erosion process) [min]

This results in the requisite binder suspension volume Q_E over the cycle time t_c, which is also produced as backflow suspension due to the volume balance (binder suspension to backflow suspension ratio of 1:1). The dilution of the backflow suspension (rinsing water) results in a dilution factor of 1.30 for cohesive homogeneous areas and 1.15 for rolling homogeneous areas. This indicates that 15 to 30% more backflow suspension is produced than the fresh suspension used (Vauk, 2011).

The time-dependent calculable binder suspension requirement Q_E over the cycle time t_c and the resulting backflow suspension quantity allows for the determination of the time-variable solids content of the suspension from the individual homogeneous areas with greater precision. The separation plant is to be dimensioned on the basis of the proposed production flow model, with regard to the required capacity according to the pull principle, and the achievable separation performance is to be continuously improved.

LEAN AND GREEN: ENVIRONMENTAL AND ECONOMIC BENEFITS

Taking In consideration of the principles of flow and pull as outlined in the LC methodology, the throughput time for the production of a jet grouting body comprising n jet grouting elements and the associated distribution of material consumption over the throughput time can be determined on the basis of the proposed production flow model. The throughput time is calculated as follows, taking into account the cycle time per jet grouting element:

$$TPT = \sum_{i=1}^{n} t_{c,i}$$

with

TPT	Throughput time for the production of the jet grouting body [min]
$t_{c,i}$	Cycle time per jet grouting element [min]
n	Number of jet grouting elements per jet grouting body [-]

The value stream analysis will facilitate a further reduction in throughput time by means of an analysis and optimisation of the processing and cycle times in accordance with the flow principle.

The implementation of the production flow model in the machine control of the jet grouting plant (drilling unit, high-pressure pump and peripherals) will also result in a continuous improvement of the production process in terms of labour productivity through automation. While manual operation of the mixing plant and the high-pressure pump currently utilises personnel capacity, the binder suspension required for production is to be automatically determined, mixed and drawn into the drilling and erosion process by the drilling rig according to the pull principle.

The solids properties of the backflow suspension should be able to be determined more precisely on the basis of the production flow model and the separation technology should be adjusted to this more efficiently. This would enhance the efficiency of the separation process, thereby increasing the recovery rate of the backflow suspension.

The required construction time should be estimated during construction based on the production flow model and the actual set-up times from the available machine data. Continuous construction time forecasting during construction would enable transport to be planned with greater precision in advance and transport costs to be reduced in a multi-project approach by sequentially linking construction sites.

The reduction of material stocks is to be achieved through the implementation of material requirement forecasts and needs-based material orders. In addition to the potential economic benefits, there is considerable ecological potential through the reduction of binder consumption as a result of a higher recovery rate of the binder suspension used and a resulting significant reduction in the amount of waste produced.

In light of the ecological objectives resulting from the ESG criteria (Environmental, Social, and Governance) and the obligation for companies to report on sustainability in accordance with the CSRD (Corporate Sustainability Reporting Directive) in the European Union, the necessity for improvement in production from a sustainability perspective is becoming increasingly important, regardless of economic interests (European Union, 2022).

CASE STUDIES: REPROCESSING OF EXCESS BACKFLOW SUSPENSION

The separation technology has already been successfully implemented on two construction sites in Germany (Figure 2). By separating the backflow suspension, the solids content could be largely separated from the water content of the backflow suspension and returned to the production process.

Figure 2: Schematic representation of the separation plant for processing the backflow suspension (Keller, n.d.a, n.d.b)

The savings at a construction site in Heidelberg, Germany, amount to 30% of the otherwise incurred disposal volume of the backflow suspension (Keller, n.d. a). The backflow suspension that was not disposed of could be reused for necessary drilling processes after separation.

The savings at a construction site in Dortmund, Germany, amount to 10% of the otherwise incurred disposal volume of the backflow suspension and 35% of the binder used. This is because the suspension at this construction site could also be partially processed for the erosion process (Keller, n.d. b).

CONCLUSIONS

The proposed production flow model enables the precise determination of the required amount of binder suspension and its time-dependent control in accordance with the lean principles of flow and pull. The parameterisation of the separation technology, adapted to the geological and process engineering conditions in accordance with the production flow model, can facilitate efficient reprocessing, taking into account relevant homogeneous areas. Potential secondary effects include increased labour productivity and reduced transport costs, as production times become more predictable and sites can be effectively sequenced.

The precise determination of the binder content in the separated return suspension represents a challenge that requires further research. The precise determination of the binder content is crucial for the further development of the sustainability and efficiency of the process, as it enables a more precise remixing of the required amount of binder.

Another field of research is the development of an advanced machine control system. A control system based on the pull principle has the potential to enhance labour productivity through automation and to improve the recovery rate of the backflow suspension by enabling the separation of the backflow suspension as required.

LEAN CONSTRUCTION SUPPLY CHAIN: A TRANSPORT PERSPECTIVE

Kamal Dhawan[1], John E. Tookey[2] and Mani Poshdar[3]

ABSTRACT

The extensive and interdisciplinary construction supply chain is susceptible to inefficiencies at the interfaces of organisations. These inefficiencies are exacerbated by intricate logistics systems that operate among numerous stakeholders and actors, involving concurrent activities, processes, and on- and off-site systems. Transportation stands out as the most significant element within construction logistics. The fragmentation of the transport function stems from its intrinsic nature to every business, typically involving externalised asset ownership and deployment. Inefficiencies infiltrate the system due to isolated planning across different segments, gradually accumulating into macro-level visibility.

To optimise logistics, particularly the transport function, identified strategies involve reconfiguring activities, combining resources, and repositioning actors. This paper delves into the impact of vertically integrating distribution, implementing integrated planning for transport operations, and incorporating reverse logistics into operations on the transport function within a supply chain for manufactured construction products. The study evaluates sustainability impacts using transport efficiency metrics and domestically determined parameters to benchmark the 'leaning and greening' of the specific supply chain under consideration.

KEYWORDS

Construction transport, Construction logistics, Optimised transport, Lean construction supply chain.

INTRODUCTION

The construction sector, as a norm, makes up around 13% of the global Gross Domestic Product (GDP) (UNEP, 2020). This industry holds a crucial position in fostering job opportunities, advancing infrastructure, and supporting businesses, thereby contributing significantly to socio-economic progress. Despite its beneficial influence, construction is a noteworthy consumer of resources and a substantial emitter of carbon. Worldwide, it is responsible for about 36% of energy consumption and 39% of emissions (UNEP, 2020).

A typical construction project involves the amalgamation of numerous resources and materials sourced from various suppliers, resulting in a complex and distinctive end-product (Guerlain et al., 2019; Tetik et al., 2021). Logistics, encompassing transportation, warehousing, and inventory management, represents a crucial interdisciplinary aspect of construction supply chains (CSC). It exerts a significant impact on project management and costs (Ying & Tookey, 2014). In a fragmented supply chain (SC), inefficiencies in coordination and integration become

apparent at organizational and operational boundaries (Alashwal & Fong, 2015). The subsequent increase in logistics process overheads gives rise to sustainability concerns.

Construction logistics undertake two primary roles: overseeing on-site logistics activities and facilitating the transportation of resources to and from construction sites (Ghanem et al., 2018). Approximately 60-80% of the total work conducted on a construction site revolves around the acquisition of materials and services (Sezer & Fredriksson, 2021). The intricacy of construction logistics arises from the adoption of customised procurement methodologies by the relevant stakeholders, coupled with the fragmented nature of the SC (Tetik et al., 2021).

Transportation constitutes the most substantial element of logistics, as most other logistics processes, other than warehousing, are categorised as business processes rather than physical ones (Szymonik, 2012). The characteristic of construction materials being of low value but high volume (Balm & van Amstel, 2018) can result in significant transportation needs, even for relatively modest projects. Consequently, transportation holds considerable importance in the realm of construction logistics.

Apart from energy consumption, emissions, and financial costs, transport comes with inherent externalities. These externalities may manifest directly, such as noise, air pollution, and congestion, or indirectly, e.g., disruptions in ecosystems, health impacts, and reduced quality of life (Chatziioannou et al., 2020). Issues related to transport in construction arise both within the construction site and beyond it, influenced by factors such as (Fredriksson et al., 2020):

- SC inefficiency, where lack of information and coordination leads to low delivery performance.
- Inefficiency of on-site logistics, leading to avoidable loss of resources, and therefore, higher inputs for maintaining delivery performance.
- Disjointed management of the construction site and the associated SC, with a distinct boundary between the two.

Given the projection that transport is expected to account for approximately 60% of global emissions by 2050 (Edenhofer, 2015), the diverse array of resulting impacts suggests the potential for enhanced sustainability outcomes through optimisation. In the construction industry, in particular, the primary rationale for pursuing optimisation is the improvement of workflow reliability (Perez et al., 2015; Tetik et al., 2021).

Every business inherently involves transportation, with asset ownership and deployment typically being outsourced. Consequently, from an SC standpoint, both strategic instruments and operational mechanisms serve as effective tools for optimising transport (Dhawan et al., 2022). However, the ability to make evidence-based decisions in the freight/logistics domain is hindered by a lack of pertinent data, as the available data usually pertains to individual journeys and lacks a comprehensive SC perspective (McKinnon, 2015).

In the context of New Zealand (NZ), approximately 93% of freight transportation relies on roads, with construction accounting for over 30% of this activity (Ministry of Transport New Zealand Government, 2020). The average truck's Gross Vehicle Mass (GVM) stands at around 22,500 kg (Wang et al., 2019), yet the average payload carried is only about 9.64 tonnes (Ernst & Young, 2021). These industry-wide figures, relevant to construction transport as well, underscore the immediate need and potential for optimising transportation, leading to improved sustainability.

The identified research gap pertains to using logistics planning as a means to achieve optimisation of transport at the strategic as well as operational levels. This study delves into the effectiveness of vertically integrated distribution, integrated transportation planning, and the integration of forward and reverse logistics as strategies to enhance efficiency and sustainability within a specific segment of the NZ CSC. The findings of this study indicate the potential applicability of these strategies across the broader spectrum of the CSC.

ANALYSIS BASELINES

The analysis baseline for this paper evolves along four directions: -

1. The problem of construction logistics.
2. A review of the construction materials SC.
3. Metrics for evaluating freight transport efficiency.
4. The resulting research questions.

THE CONSTRUCTION LOGISTICS PROBLEM

Construction logistics coordinate, control, and manage material flow from processing of raw material to final use in the construction process. Additionally, they include waste removal and disposal along the reverse route (Ying & Tookey, 2014). Stakeholders participate in various on- and off-site activities, which may be in the domains of planning/organising, transport, and activities related to construction on site (Janné, 2020). Key concerns include planning, designated spaces for loading/unloading, materials handling, storage, and linking actors and channels of the logistics system through transport (Janné & Fredriksson, 2019; Lange & Schilling, 2015).

The conventional perspective on construction logistics primarily centers around the main contractor's viewpoint, aiming to enhance on-site production efficiencies (Fredriksson et al., 2022). The management of suppliers and on-site deliveries is guided by the primary constraint of storage space (Lundesjö, 2015). The main contractor can effectively tackle both horizontal fragmentation issues (involving disaggregated skill sets/expertise) and vertical fragmentation issues (related to well-defined phases) due to the project-centric nature of construction delivery. However, concerns related to longitudinal fragmentation are overlooked, as suppliers and transporters operate independently and only collaborate for site-specific deliveries. The following major reasons for the differences between freight transport and construction transport (optimisation) are, therefore, inferred: -

- The distinctive characteristics of the CSC, marked by bespoke operations and a fragmented composition (Alashwal & Fong, 2015; Guerlain et al., 2019).
- Patterns of transport usage driven by project-centric delivery requirements (Sezer & Fredriksson, 2021).
- The widespread use of industry-specific equipment (Guerlain et al., 2019).
- Unlike city logistics, where responsibility lies with city managers, the construction industry bears the responsibility for construction logistics management (Janné & Fredriksson, 2021).

From the suppliers' standpoint, the fragmented logistics perspective undergoes a reversal. Deliveries managed by suppliers become effectively consolidated, showcasing greater efficiencies in comparison to the typical business-as-usual (BAU) approach (Dhawan, 2023).

THE CONSTRUCTION MATERIALS SUPPLY CHAIN

The construction materials SC is composed of three primary actors. The bulk suppliers and the construction site represent the two ends. The Builders' Merchants (BMs) and retailers are interposed between the two. The interposed actors provide interim storage and consolidation. The typical methodologies adopted for construction materials supply are illustrated in Table 1 (Commerce Commission New Zealand, 2022).

In the CSC, BMs play a crucial role as the primary economic stabilisers. They extend lines of credit to contractors and absorb market fluctuations by holding 'safety' stocks. BMs' inventory carrying costs can reach up to a fifth of the overall inventory costs (Vidalakis et al., 2011).

Table 1: Construction materials supply models (Commerce Commission New Zealand, 2022)

Model	Description	Typical supplies
Freight into Store (FIS)	Routing of bulk or retail quantities of materials through BMs, where bulk suppliers cannot manage retail quantities.	Aggregate, bricks, cement, fittings, plumbing, fixtures, heating supplies, tools
Specialist stockist sales	Marketing by manufacturers through their own subsidiaries.	Proprietary items
Direct to Site (DTS)	Material supplied directly at the construction site by the bulk supplier, where intermediaries are not required.	Steel framing

BMs operate nationally, regionally, and locally. Customer interaction invariably takes place through area specific depots, whose transport is driven by customer delivery demands. A small vehicle fleet caters to local customers. Delivery planning relies on staff knowledge of the local area layout (Dhawan, 2023).

Regional and national merchants centrally oversee their vehicle fleets, typically under the management of a transport professional. However, in the case of local BMs, the depot manager, who may lack transport expertise, is responsible for fleet management, prioritising customer service over transport efficiency. The order cycle is typically 24 hours, catering to the next day's tasks (Commerce Commission New Zealand, 2022). Inefficiencies are concealed within the seamless quantity take-off, representing 'hidden costs' of construction material (Balm & Ploos van Amstel, 2018; Verlinde, 2015; Ying & Tookey, 2014).

FREIGHT TRANSPORT EFFICIENCY METRICS

Freight transport system efficiency is a strategic measure of goods handling, whereas vehicle efficiency is operational/tactical (Pahlén & Börjesson, 2012). Vehicle efficiency revolves around 'filling rate,' - the ratio of actual loads transported to the maximum achievable with vehicles consistently loaded to their rated capacity (McKinnon, 1999). For trucks, vehicle efficiency - the ratio of utilised and available capacities - is expressed by five individual measures (McKinnon, 2010; Pahlén & Börjesson, 2012):

- **Level of empty running** Percentage of the distance travelled empty.
- **Weight-based loading factor** Ratio of the actual weight carried to the rated payload capacity.
- **Tonne-km loading factor** Ratio of the actual tonne-km (product of weight and distance) to the rated payload capacity-based tonne-km.
- **Volumetric loading factor** Percentage of the total vehicle cubic capacity occupied by the load.
- **Deck-area coverage** Percentage of the floor area of the vehicle covered by a load.

Measuring vehicle efficiency includes both onward and return trips. The construction sector faces difficulties in securing loads for return transport, turning what was once deemed empty running waste (Bølviken et al., 2014) into consideration through the sustainability lens (Kohn & Brodin, 2008). As a result, both policy and business perspectives prioritise minimising empty running in the pursuit of sustainable distribution strategies (McKinnon & Ge, 2006).

PROBLEM DESCRIPTION, DATA, AND RESEARCH QUESTIONS

The absence of pertinent data hampers evidence-based decision-making in the field of construction freight and logistics. The currently accessible data tends to focus on individual freight journeys without providing a comprehensive SC perspective (McKinnon, 2015). This poses a challenge when attempting to quantify efficiency improvements and analyse the potential for further enhancement resulting from implemented SC models and operational philosophies.

PROBLEM DESCRIPTION

The focus of the investigation is plasterboard supply in Auckland, NZ. The BAU scenario uses the FIS model for distribution through a disaggregated network having three key nodes: the manufacturing facility warehouse, BM establishments, and construction sites. Two links connect these nodes for both information and material flow (Bulk supplier – BM and BM – Construction Site), each emphasising storage as a primary function. This model aligns with the theoretical ‘Distributor storage with carrier delivery' logistics model (Chopra et al., 2013).

The modified (DTS) model integrates distribution and manufacturing vertically, outsourcing transport through second-party logistics (2PL). In contrast to the FIS model, this configuration includes three nodes and three links. Two of these are information links for invoicing and delivery (Contractor – BM, BM – Bulk Supplier), while the third (Bulk Supplier – Site) manages physical delivery. The manufacturer directly delivers materials invoiced by the BM to the site, exemplifying the 'Manufacturer storage with direct shipping' logistics model (Chopra et al., 2013).

DATA AVAILABILITY

This study examines three months’ truck movements data (October 2020 to December 2020) related to plasterboard delivery using the DTS model in Auckland, NZ. The data was obtained from the logistics department of NZ’s largest plasterboard manufacturer and supplier, who maintain a log of daily truck movements for plasterboard delivery. The dataset was obtained in two parts. The first part provided the details of trucks used for plasterboard delivery (i.e., manufacturer, model, rated payload, and Gross Vehicle Mass - GVM). The second part provided details of trips undertaken by these trucks daily for plasterboard delivery (i.e., truck ID, departure time, quantities of items in accounting units and weights, and delivery destinations for various consignments). The data pertained to 2762 trips across 58 days. Travel distances and drop sequences were, however, not available in the dataset. The following operational characteristics emerged from the dataset: -

- 26 trips with different rated payload undertaking 42 trips transporting an average of 330 tonnes of plasterboard daily.
- One to six drops associated with each truck trip.
- More than three drops were seen in less than 1% of the trips, hence ignored, being insignificant for analysis.
- Almost 75% of the trips were single-drop trips.
- Transport was procured on a per-tonne basis irrespective of distances involved.
- Diesel-powered flat-bed trucks comprising the fleet.

RESEARCH GAP AND QUESTIONS

The DTS solution appears to have provided greater service efficiency and customer satisfaction vis-à-vis the FIS model. However, improved transport efficiency has not been quantified. In the Lean philosophy context, this research gap prompted the following research questions: -

- **RQ1.** What is the improvement in transport efficiency in DTS deliveries compared to FIS deliveries.
- **RQ2.** What is the potential for further transport efficiency improvement and the potential means to achieve it?
- **RQ3.** What are the means available to integrate reverse logistics and what are the likely impacts of this integration on transporting efficiency?
- **RQ4.** How does the supply chain become Leaner as a result of the above?

TRANSPORT EFFICIENCY ANALYSIS

MEASURES SELECTED

The analysis focused on weight-based and tonne-km-based efficiencies, termed 'loading efficiency' and 'capacity utilisation,' respectively. Loading efficiency (static), is measured at dispatch, and does not consider transportation distance. Capacity utilisation (dynamic) factors both loads and distances. To introduce distances and drop sequences, 370 trips were selected as a statistically significant sample representative of the dataset (2762 trips), using random (probability) sampling (Krejcie & Morgan, 1970).

QUANTIFYING EFFICIENCY IMPROVEMENT OF DTS OVER FIS MODEL

Through vertical integration, the DTS model reduces one node and one link in the distribution transport network (Figure 2).

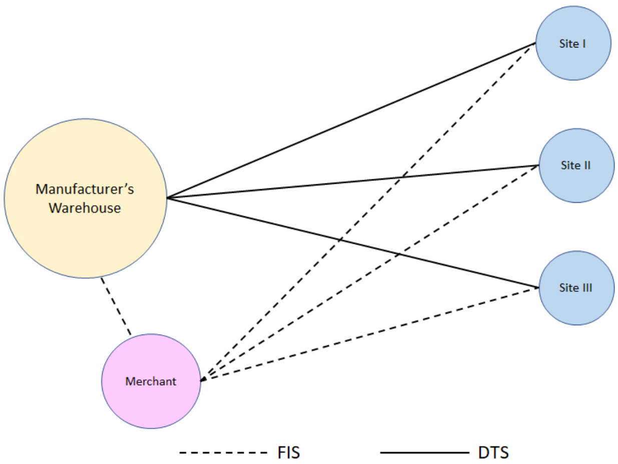

Figure 1: Transport network configurations for the DTS and FIS distribution models

Given that the three nodes connected by links form a triangle, any one link would always be shorter than the sum of the other two, unless all three are collinear – highly improbable in an urban setting. To estimate efficiency improvement through DTS rather than FIS deliveries each BM-destination pairing, the reduction in travelled distances served as a straightforward assessment parameter. A majority of the truck trips being single-drop (circa 75%) permitted considering individual BM-destination distances for the analysis. Inter-node distances were obtained from Google Maps. The analysis revealed a 30% reduction in distances travelled, equivalent to 11.1 km per trip, between the DTS and FIS models.

POTENTIAL FOR FURTHER EFFICIENCY IMPROVEMENT

The drop sequence was incorporated into the data sample (370 trips) from the 'Eroad' database (a NZ IT company providing GPS-enabled tracking services). Utilising inter-node distances, sequence of drops, loading efficiency, and individual destination loads, the analysis focused on tonne-km based capacity utilisation (Table 2).

The findings revealed a daily underutilisation of approximately 252 tonnes of truck payload, leading to non-utilisation of 72% tonne-km available. This highlights the necessity for enhanced planning strategies to decrease the number of daily truck trips while maintaining delivery output.

Table 2: Loading efficiency and capacity utilisation of trucks (DTS)

Drops	Trips	Loading Efficiency			Capacity Utilisation		
		Maximum	*Minimum*	*Average*	*Maximum*	*Minimum*	*Average*
1	261	99.21	4.31	55.89	49.61	2.16	27.99
2	81	99.77	6.45	57.08	55.79	3.33	27.84
3	28	90.33	14.99	60.53	42.11	4.93	24.82
Weighted Average (Fleetwide)				56.36			27.61

APPLICATION OF OPERATIONS RESEARCH

Transportation Problem

Logistics incorporates strategies and tools from various fields (Hrablik et al., 2015). In this case, the Transportation Model from operations research was explored as an optimisation tool. It typically involves a network with nodes representing sources and destinations connected by arcs representing routes, material quantities, and per unit shipping costs, with the objective of minimising costs while meeting destination requirements within the origins' supply capacity (Taha, 2013). The problem could not be transformed into a classical transportation problem due to a single origin and uniform channel costs. It was, therefore, reformulated as follows: -

- The sample dataset was disaggregated into daily operations' sub-datasets.
- The rated payload of each truck was considered an individual source (supply).
- Each delivery was considered an individual consumer (demand).
- The channel cost, being fixed, was considered unity.

The transportation problem was solved using MSExcel, which presented an upper limit of 200 objective co-efficients in the problem matrix. Being 'proof-of-concept' exercise, a truncated daily trip dataset while maintaining trip integrity, was used. The solution (decision variables - allocation of loads to trucks) are in Table 3.

Table 3: Transport optimisation (improved efficiency) using LP

Parameter	Manual truck allocation	LP based truck allocation	Improvement (%)	
			Absolute	*Over manual baseline*
Average loading efficiency	56.36%	92.89%	36.49%	64.81%
Daily truck trips	11	7	-	36.36%
Capacity utilisation (tonne-km)	27.61%	49.38%	21.77%	78.84%

The application of Linear Programming (LP) optimised the initial (truncated) 11 trips to 7. Extrapolating this to the actual baseline of 42 trips results in a daily reduction of 16 trips, without impacting delivery.

The Need for Integrated Planning

The application of LP highlighted the necessity for integrated planning between the transport contractor (supplier) and the bulk supplier/manufacturer of plasterboard (consumer). Currently, the manufacturer's priority is the daily transportation of ordered plasterboard quantities. The quantity of trucks employed, or the distances covered is not a consideration, given the 'per-tonne' pricing model. The transport contractor has the discretion of resource allocation. No resource-use analysis was considered essential as long as the daily tonnages are delivered.

Optimising transport becomes a necessity in two scenarios: when payments are distance-based (per-km) and when sustainability is integrated into the operational philosophy. The result is integrated planning, involving the manufacturer, even if only to monitor transport utilisation.

INTEGRATION OF REVERSE LOGISTICS

Truck capacity utilisation for a single-drop trip reaches a maximum of 50% (if fully loaded at the origin), and less than 50% for trips with more than one drop (Vrijhoef, 2015). Consecutive unloading at different drop points along the route creates capacity for backloads. This offers a potential opportunity to integrate reverse logistics with forward delivery, utilising waste backhauls on material delivery transport (Shakantu & Emuze, 2012). Considering estimates by Jacques (1999) and Nelson et al. (2022), approximately 20% plasterboard waste generation per site is considered a fair estimate.

Incorporating reverse logistics for removing plasterboard waste from construction sites relies on a comprehensive trip model, which includes the number of trips per truck site, load per trip segment, and the waste generated per site per truck. It considers average distances and loads from the sampled dataset, along with estimated plasterboard waste based on material delivery. Figure 2 illustrates the generalised trip model.

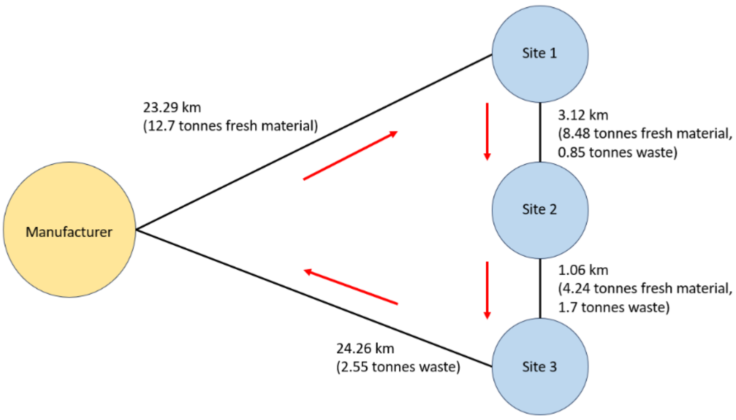

Figure 2: Generalised trip model

The incremental efficiency improvement utilises 326 tonne-km after LP application and 393 tonne-km with waste plasterboard backhauls, out of an available approximately 672 tonne-km per trip. This results in enhanced efficiencies of 49.38% and 58.04%, respectively, compared to the baseline of 27.61% (DTS).

LEANING THE SUPPLY CHAIN

THE LEAN PERSPECTIVE

The Lean perspective is discussed based on the three fundamental Lean construction principles, i.e., Respect for People, Continuous Improvement, and Maximising Value while Minimising Waste (Doan, 2022).

Philosophy 1: Respect for people

Respect for people extends to the environment. Thinking about the long-term environment, sustainability, and the impact of current actions on the planet and future generations (hidden stakeholders) forms an inseparable part of this philosophy (Doan, 2022). Table 3 brings out the reduction in vehicle-km and diesel consumption.

Table 3: Annual reduction in vehicle-km and fuel consumption

S. No.	Reason for improved transport efficiency	Impact parameters		Conversion based on
		Vehicle-km	*Fuel (litres)*	
1.	Adoption of DTS model over the FIS model	126,100	-	BAU truck GVM
2.	LP-based reduction in truck trips	207,600	-	
3.	LP-based improved capacity utilisation	-	35,500	Reduced truck GVM
4.	Integration of reverse logistics	-	19,674	

The impacts of these are reduction in emissions, pollution, carbon embodiment per-unit weight of plasterboard, noise, traffic congestion, disruption of ecosystems, negative health impacts from reduction of emissions due to optimised transport, and reduction in disposal to landfill and embodiment of resources due to re-cycling of waste plasterboard as raw material.

Philosophy 2: Continuous Improvement

Continuous improvement is illustrated by progressive application of tools and methodologies to scaffold improvements achieved. In the instant case, vertical integration, followed sequentially by application of operations research and integration of reverse logistics form the 'improvement staircase'. The progressive transport efficiency improvement is shown in Figure 3.

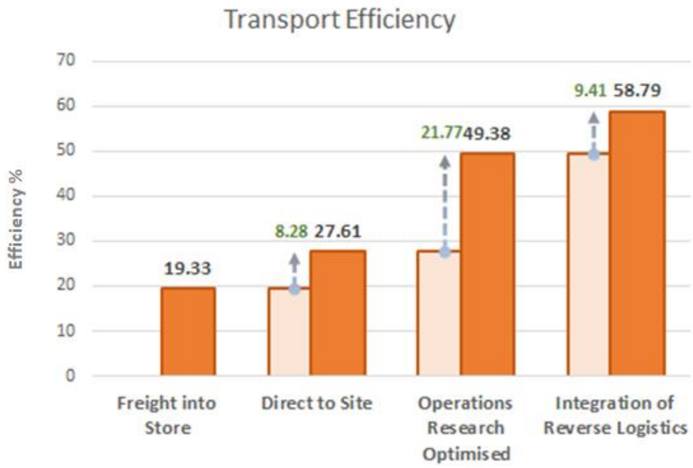

Figure 3: Progressive transport efficiency improvement

Philosophy 3: Maximising Value while Minimising Waste

Waste minimisation is achieved through i) Improved transport efficiency (reducing resource wastage); and ii) Utilisation of waste plasterboard as raw material for manufacture (Erbs et al., 2021) to the extent of approximately 10% to maintain quality, diverting it from landfill.

CONCLUSIONS

Logistics is multidisciplinary and does not have its 'own' tools and methodologies, adopting these from various domains. In answering the research questions, the initial analysis pertained to the quantification of transportation efficiencies achieved as a result of vertically integrating (Lidelöw & Simu, 2015) distribution with manufacture, from the Supply Chain Management domain. Next application of LP from the operations research/management domain was discussed as a tool for further optimisation. Integrated reverse logistics further improved transport efficiencies. The question of Leaning the SC was addressed by viewing the progressive improvement through the lens of fundamental Lean construction principles, i.e., Respect for People, Continuous Improvement, and Maximising Value while Minimising Waste.

The simple analysis leads to life cycle improvements in the SC, in addition to direct ones. It also points to further research directions such as quantification of reduced embodied resources, economic/cost implications of improved efficiency both within the CSC and economy-wide, issues of fleet management for improved operational sustainability, and the means for integrated planning.

SMART HOMES AND WASTE REDUCTION

Samira Awwal[1], Patricia Tzortzopoulos[2], Mohammad Ruhail Gulzar[3], Rakesh Mishra[4], Leigh Fleming[5] and Scott Conor[6]

ABSTRACT

The concept of smart homes includes smart technologies, systems, and devices to facilitate efficiency, security, comfort, and overall management of the home environment. This paper presents the concept of smart homes and discusses how it relates to waste reduction, especially energy waste. As waste reduction is one of the key lean principles, the notion of a "smart home" and " waste reduction" can be connected to optimising efficiency and increasing the functionality of the home. An experiment was carried out in the Huddersfield smart house research facility for the optimisation of energy usage through smart home technologies and efficient appliances, resulting in lifecycle waste reduction. The investigation highlights the connection between Smart Home' and 'Lean Waste Principles' indicating how energy use in the building lifecycle is hidden in lean waste. This suggests a need for future empirical research to better understand how to reduce waste using smart home technology and provide solutions to resolve energy waste on a wider scale.

KEYWORDS

Smart Home, energy efficiency, waste reduction, comfort, lean waste

INTRODUCTION

In today's world, the rapid development of 'The Internet of Things' has led to the gradual integration of the concept of a 'Smart Home' into people's daily lives. Meanwhile, there is a worldwide increase in energy demand, resulting in negative environmental impacts. Buildings are one of the major contributors to rising energy consumption (Chenari et al., 2016). There are 29 million homes in the UK which use 14% of the UK's energy consumption (Pérez-Lombard et al., 2008) and the UK government aims to reduce 60% of these emissions by 2050 (Zala et al., 2017). This highlights the critical need for more effective strategies to manage energy consumption (Hakawati et al., 2024).

Efficient waste elimination is crucial to address the stated problem (Nižetić et al., 2019). One of the key Lean principles is waste reduction (Koskela et al., 2013). Seven types of waste are found in lean literature i.e. transport, inventory, motion, waiting, overprocessing, overproduction, and defects, and the eighth waste, making-do (Koskela et al., 2013). This paper will focus on waste in use, as opposed to production waste, i.e. wasted energy due to the

inefficiency of buildings; and defects- appliance inefficiency in the home during a building's lifecycle, emphasising energy-efficient living environments. In a lifecycle analysis, five stages are typically recognised in the life cycle of infrastructure: material manufacturing, construction, maintenance, operation, and end-of-life (Liljenström et al., 2022). This study focuses on the operation stage of the building lifecycle.

Andrade et al., (2022) highlights that the integration of smart technologies expedited by the Internet of Things (IoT) has a pivotal role in reducing energy usage and enhancing user comfort. Monitoring energy consumption and improving efficiency through computational solutions can be achieved through smart homes, equipped with technologies for customised services.

The notion of Smart home technology and energy usage in the built environment is not novel. However, fewer evidence is found on waste reduction through energy efficiency from a lean construction lens. This paper discusses the concept of a 'Smart Home' and waste reduction from a lean construction perspective, for instance, energy optimisation using energy management systems, appliance efficiency, home automation, scheduling thermostats to reduce energy usage, and renewable energy integration. The main aim of the paper is to link smart homes to Lean from the context of lifecycle waste reduction. An experiment in the smart house research facility (Huddersfield Smart House Research Facility-HSHRF; see link here: Smart House - University of Huddersfield) is presented to support the findings.

RESEARCH METHOD

The research method included three steps; (i) a bibliometric analysis of Scopus-indexed papers; (ii) a review of relevant topics, and (iii) an experimental case study in the Smart House research facility at the University of Huddersfield.

The bibliographic analysis was conducted to understand the connection among Smart homes/ intelligent buildings, energy utilisation, and waste reduction. The following keywords are used: {smart AND home AND waste AND management AND energy AND efficiency} (See Figure 1). 36 Scopus-indexed journals were used as a database to generate the co-occurrence of topics and create a network of visualisation.

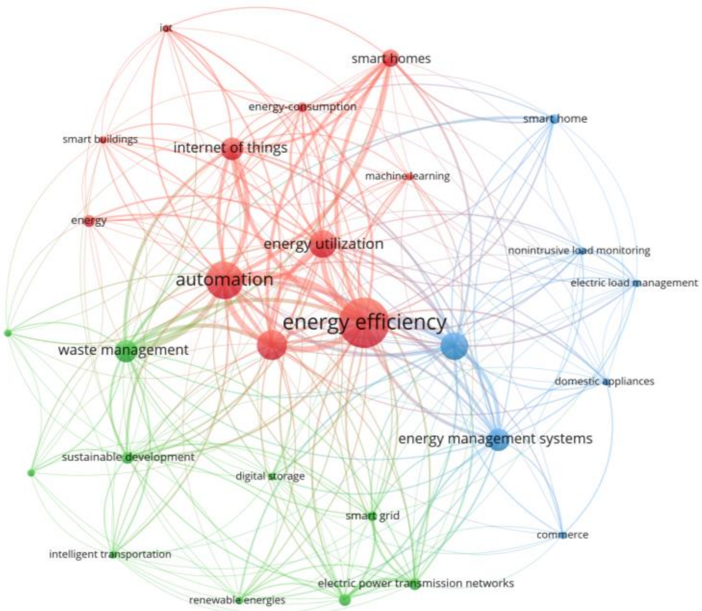

Figure 1 Bibliographic Analysis- Network visualisation of papers' keywords

It is observed in Figure 1 that effective energy efficiency is intrinsically connected to certain keywords, such as energy management, waste reduction, smart home, IoT, renewable energies, and energy consumption. After identifying keywords from the co-occurrence network, a related relevant topic is selected for the review of the literature.

A case study experiment conducted at Huddersfield Smart House Research Facility (HSHRF) is presented to support the findings. The HSHRF is a house built within a building, which has a number of sensors, as well as a digital twin, and it's used for testing is used for various physical testing purposes. The experiment explored a smart radiator in the HSHRF to observe the energy usage through a period of 24 hours and evaluate optimisation of energy in smart home environments.

LITERATURE REVIEW

CONCEPT OF SMART HOME

A smart home is supplied with a high-tech network connecting sensors and home devices, which can be remotely accessed, monitored or controlled (Wu et al., 2023). The 'original' concept of a smart home is an integrated home with various services interconnected by a single communication system (Lutolf, 1992; Aldrich, 2003). In a regular home environment (i.e., not smart), residents operate home appliances and devices individually and separately. Appliances and lighting are individually controlled by occupants rather than a centralised control system. However, network devices have proliferated in the environment of ubiquitous computer technology. As a result, in the last decade, the "smart home" concept has received considerable attention in the built environment (Yang et al., 2017). There are various definitions of a Smart Home in the literature, as shown in Table 1.

Table 1 Definition of Smart Home

Author	Year	Description of Smart Home
American Association of House Builders	1984	In the early 1960s, the concept of smart homes was called 'Wired Homes', built by hobbyists.
(Lutolf, 1992)	1992	A Smart Home is known as a network of home electronic devices and attributes linked to the internet.
(Aldrich, 2003)	2003	A "smart home" is a residence installed with computing and information technology that senses and reacts to the needs of the residents, aiming to enhance comfort, security, and entertainment through technology management.
(Lertlakkhanakul et al., 2008)	2008	smart home can be regarded as a 'smarter' version of home automation with integrated technological systems
(Albany et al., 2022)	2022	A smart home is a group of connected IoT devices that can be controlled remotely using a smartphone or computer.
(Munirathinam, 2020)	2020	Smart home technology, is defined as home automation, providing homeowners security, comfort, convenience, and energy efficiency by allowing them to control smart devices.
(Basarir-Ozel et al., 2023)	2023	A smart home represents smart devices and sensors, integrated into an intelligent home network, offering control, monitoring, and support services to satisfy user needs.

Smart home technology can be used primarily in two ways: (i) to ensure the occupants safety, health and comfort and (ii) to facilitate household operations, especially reduce energy costs (Schieweck et al., 2018). A smart home is connected with cutting-edge technologies for automation of functionalities, household appliances, and electronics for communication and entertainment (Lertlakkhanakul et al., 2008; Schieweck et al., 2018; Albany et al., 2022). In summary, the concept of the 'Smart Home' has been proposed to increase the building's efficiency and performance, enabled through the rapid development of artificial intelligence (Zhang et al., 2023); and integrated smart systems play a role through IoT technology (Huang et al., 2018).

CONCEPT OF WASTE IN LEAN

A core principle of Lean is to eliminate waste with the aim to increase performance (Aisyah et al., 2023) and as a driver for improvement (Tzortzopoulos et al., 2020). Seven lean waste types are:1. Transport: redundant and unproductive flow of information or materials; 2. Inventory: information or materials waiting to be processed; 3. Motion: Employee performed activities associated in the workflow; 4. Waiting: waiting for information or inputs; 5. Overprocessing: Associated with the processor (conversion) operation, which can possibly be prevented; 6. Overproduction: Producing more than is needed for immediate use; 7. Defects: accusation, untrustworthy or miscoded data, documentation and transcription errors, unauthorised procedures (Koskela et al., 2013; Owais et al., 2023; Sutherland & Bennett, 2007). Energy usage reduction is often concealed in lean wastes. EPA, (2007) highlight energy impacts associated with wastes targeted by lean. Table 2 provides an overview of lean waste types, lean waste in production, and energy use hidden in lean waste by (EPA, 2007; Owais et al., 2023; Sutherland & Bennett, 2007).

Table 2 Lean Waste in production and energy use hidden in lean wastes

Waste Type	Lean Waste in production	Energy Usage
Overproduction	Connected to a larger volume of production than requested or desired	Unnecessary energy used in operating equipment
Inventory	Pertaining to material waste caused by overstocks or unused stockpiles	Additional energy required to heat, cool, and light inventory storage and warehouse
Transport	Avoidable movement of products, materials, or information.	Additional energy used for transport
Defects	It occurs when the result fails to fulfil the quality standards.	Energy consumed in making defective products-, increasing lighting, heating, and cooling demand and energy consumption
Motion	Unnecessary movement of people, such as walking, reaching and stretching	Deals with activities performed by users
Over-processing	Associated with the processor (conversion) operation, which can possibly be prevented	More energy consumed in operating equipment due to unnecessary processing
Waiting/Delays	Any delay between the end of one process and the start of the next activity	Wasted energy during production downtime from heating, cooling, and lighting

In addition to the above wastes, the eighth category of waste is conceptualised by (Koskela, 2004). Making-do occurs where a task is initiated without all standard inputs, especially in production where there are multiple uncertain inflows to the tasks. The inputs can be materials, machinery, tools, personnel, external conditions, instructions, etc. Waste by making do can occur in different ways, for example, efficiency syndrome- the urge to maximise resource utilisation; pressure for an immediate response- situation of incomplete inputs and unreliable inflows of the production system (Koskela, 2004).

Buildings contribute significantly to the depletion of natural resources and emissions to the environment during its lifecycle. Buildings generate manufacturing waste, transportation of materials waste, construction waste, operation/use waste, and deconstruction/end-of-life waste. As the building industry is shifting its focus to sustainable development, the consideration of these waste factors is crucial to ensure waste reduction (Hossain & Thomas, 2019). The following section discusses the notion of smart home technology in waste reduction from the building use/operation point, especially in energy waste.

WASTE REDUCTION THROUGH SMART HOME

The evolution of smart home is transitioning from the initial emphasis on occupants' comfort to the development of innovative solutions aimed at effective and efficient control of the infrastructure (Murty & Kumar, 2020). A smart home can significantly influence waste reduction through the integration of multiple technologies and smart systems, resulting in reducing environmental pollution, and thus increasing the degree of environmental health (Škulj et al., 2019). The deployment of smart meters and controls, and the emergence of smart appliances and their inclusion in home networks allow energy consumers to benefit from a more comfortable, and healthier living environment, while consuming less energy thus reducing waste (European Commission et al., 2017).

There are multiple aspects connecting the smart home with energy waste reduction among which the paper reviews the following topics: (i) Energy monitoring and optimisation; (ii) Smart appliance efficiency; (iii) Home automation; and (iv) Renewable energy integration and smart home energy storage.

Energy Monitoring and optimisation

Smart monitoring systems can play a crucial role in integrating energy management and monitoring control systems through IoT technology (Huang et al., 2018). 'Smart Sensors' can be defined as sensors using semiconductor technology to join output power devices with control circuitry (Naidu, 1998). The smart home comprises of sensors that are wirelessly connected and dedicated to measuring physical quantities, such as various environmental characteristics- temperature, sound, light intensity, humidity, force, and pressure (Chakraborty et al., 2023; Chauhan et al., 2022). Additionally, smart home wireless sensors can detect smoke, gas, and temperature and alarm early fire in a smart home environment.

Optimisation of energy can be achieved through a smart energy management system for residential buildings (Essa, 2019). The energy management system prioritises energy conservation, expenditure reduction, safety improvement, and easy maintenance (Li et al., 2020). Efficient energy management systems reduce energy consumption, waste, and costs, help conserve fossil fuel resources, and increase occupant comfort. For instance, if Matsui, (2018)'s home energy management systems (HEMS) are installed in smart homes, they can predict the indoor comfort level, reduce 5.15% electricity consumption, and increase the comfort level by 16.4% for occupants. Another example is IoT-based smart sensors through energy-applied load monitoring (ALM) systems can be explored to predict energy consumption through smart data collection. Users are then informed by the total energy usage from several sensors connected to home devices; and take corrective actions to optimise consumption (Oudat et al., 2019).

Appliance Efficiency

Smart home appliances constitute multiple devices and applications such as smart washing machines, smart kettles, smart dishwashers, stoves, and smart refrigerators among others. Smart appliances can be remotely accessed, controlled, and monitored by the occupants (Balta-Ozkan et al., 2013). In a smart home environment, various devices can be remotely controlled through mobile terminals such as smartphones (Ma et al., 2023). One of the essential benefits of smart home appliances is the potential for energy reduction by both smart appliances themselves and (in)direct feedback options to the user (Du et al., 2023). For instance, smart lighting integration contributes to energy efficiency when combined the required lighting with natural lighting. User requirements are calculated and the lighting system can be adjusted using automation or task/user-based lighting to reduce the waste of energy (Vijayan et al., 2020).On the other hand Paul et al., (2022) argue, that the older version of the same appliance consumes more energy, than the newer ones. It is better to determine the economic and energetic replacement time of the appliances for the customer thus impacting the overall economic impact. In summary, smart appliances when appropriately installed and replaced in a timely manner, can optimise resources more efficiently, improving equipment utilisation and reducing waste.

Home Automation

Automation is defined as the capacity of technology to carry out functions in an autonomous mode with the least possible human interaction (Wong et al., 2017). An automation system is at the core of the concept of a Smart home, consisting of multiple systems in a home, for instance, control of HVAC systems, lighting control, energy management, security systems, and entertainment in home environments (Asadullah & Raza, 2016), designed for user comfort and energy efficiency. Automation allows better utilisation of advanced technologies and conservation of energy to be prioritised through smart homes that are inbuilt with communicative and innovative technologies (Vijayan et al., 2020). The development of automation can act as a key factor in resolving the issues of energy poverty (Niu et al., 2024). Specifically, automated processes improve to streamline operations, minimise energy wastage, and optimise resource utilisation, resulting in energy supply increase (Farzaneh et al., 2021)

Renewable Energy Integration and Storage

To support a cleaner environment, there is a shift toward the integration of smart meters, renewable energy resources (RERs), smart sensors, and energy storage systems (Nie et al., 2023). Renewable systems are equipped with a fully automated energy system, photovoltaic panels, and battery-electric storage systems (Nakıp et al., 2023). For instance, Nezhad et al., (2022)'s paper discusses the smart home with solar power generation through a rooftop PV panel. The solar power generation is forecasted and scheduling can be organised to minimising the operational cost, for example using the energy for a home appliance load. Essa (2019) presents a home energy management strategy that adjusts electricity generation and consumption based on the operating parameters of photovoltaic battery systems and thermostatically controlled loads. Battery energy storage and renewable generation in Smart homes will therefore optimise energy and further contribute to emission waste reduction.

DISCUSSION

Building components consisting of individual autonomous behaviours, to be controlled by a level of central control is considered smart and lean (Chien, 2013). From the theoretical point, there is not enough existing empirical evidence to consider smart house waste reduction from a lean point of view, especially, how the energy use in the building lifecycle hidden in lean waste relates to lean waste principles. From a practical point of view, it is observed that there is a gap in the interoperability of smart home technologies within the lean construction framework. Albeit both concepts prioritise efficiency and optimisation, integrating smart home systems without standard protocol requires careful consideration. The data exchange poses a threat to safeguarding information resulting in resistance to smart home technology installation (Yang et al., 2017). Furthermore, there is a gap in knowledge and expertise within the construction industry (Pavlou et al., 2007) to implement smart home technologies which will require a collaborative approach among construction firms, technology providers, and regulatory bodies to overcome these challenges.

CASE STUDY EXPERIMENT

EXPERIMENT DESIGN AT THE HUDDERSFIELD SMART HOUSE

An experiment was carried out in the Huddersfield Smart House research facility (HSHRF), which is a physical house providing a collaborative hub to accelerate research and development for energy efficiency in the built environment.

The HSHRF is a fully monitored physical smart house with real-time data over 48 wireless sensors to analyse temperature, humidity, CO2, and particulate matter. All the sensors are connected to a cloud-based system, called ‘iMonnit’. iMonnit refers to a cloud-based mobile internet platform and a central hub to manage iMonnit and ALTA products. All data is secured on dedicated servers operating Microsoft SQL Server (See Figure 3). The sensors installed in the smart house are constantly collecting real-time data, and they can be analysed and optimised through a digital simulation of the building.

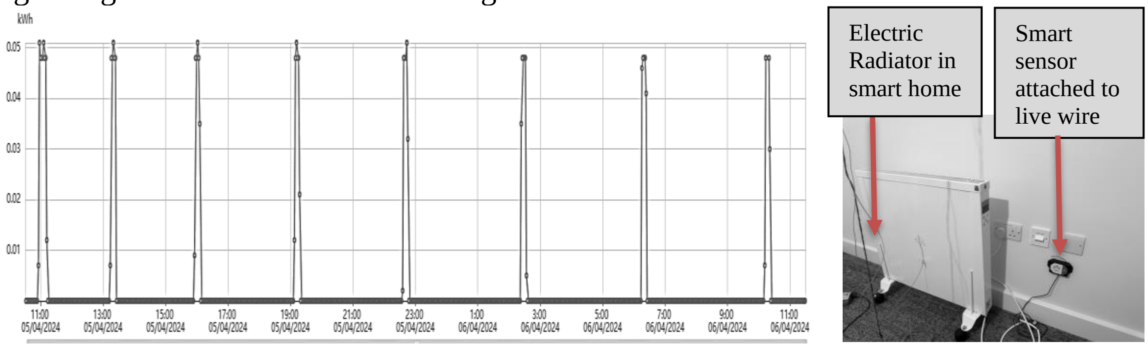

Figure 2 Experiment of Optimisation in Energy Consumption; Left: The usage of energy; Right: The experiment set up in HSHRF

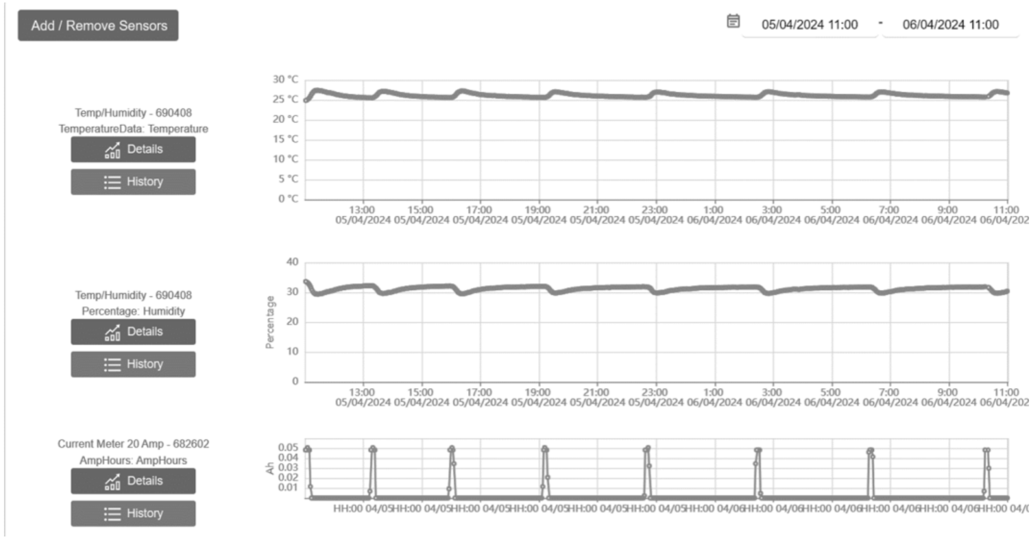

Figure 3 iMonnit chart- Monitors in Huddersfield Smart House research facility

The experiment was set up to validate energy optimisation through smart appliances, and smart sensors in a smart home environment (See Figure 2). The experiment was conducted to evaluate energy optimisation through a smart sensor and an electric radiator and generate an optimal temperature and humidity for the users. Electric radiators are becoming popular due to the government's green schemes for new-build housing (Zala et al., 2017). The data collection sensor is attached to the live wire, sending real-time data through the iMonnit cloud-based database system. The smart radiator was used to observe the energy usage over a period of 24 hours and evaluate optimisation. It should be noted the Smart house has installed external insulation properties such as external cavity walls and triple-glazed windows and acts as an energy-efficient experimental testbed.

RESULTS

The American society of Heating, Refrigerating, and Air-Conditioning Engineers (ASHRAE) has established guidelines for thermal comfort, recommending a range of 20 °C to 23.88 °C for temperature and 30-60 % for relative humidity. At the start of the experiment, the base temperature for the experiment room was 24°C. The smart house is built within a building and not exposed to outdoor environmental parameters, which is a limitation. However, this provides accurate data due to the repeatability of the testbed; results are consistent.

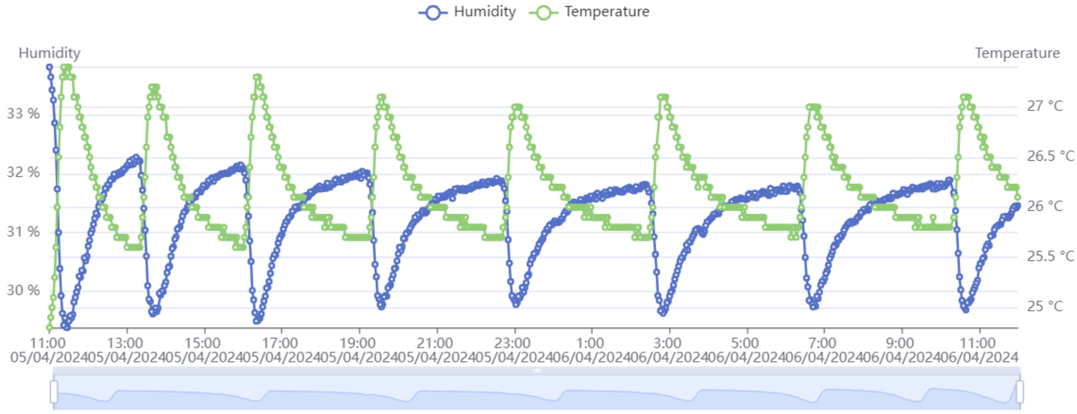

Figure 4 iMonnit chart- Temperature and Humidity graph

It is observed that this electric radiator consumed 1.90 kWh during a 24-hour test period (See Figure 3). After achieving the desired temperature, the radiator remained switched on for 1 hour and 20 minutes out of 24 hours, accounting for 8.3 % of the total time, indicating its ability to maintain room temperature effectively without constant energy consumption. This indicates that the appliance can maintain the optimal room temperature and minimise energy usage in an insulated smart home (See Figure 3). It effectively raised the room temperature from 24 °C to 27 °C during the 24 hours, with humidity levels ranging from 33% to 30%, indicating its ability to control humidity and create a comfortable living environment for occupants (See Figure 3). Figure 4 illustrates that when the temperature is high, the humidity is low, and vice versa, illustrating the temperature-humidity interrelationship in the living environment. As mentioned above, the experimental temperature is at a high range due to the limitations of the testbed. Nevertheless, as the Smart House is well insulated, the smart appliance successfully optimises energy usage and uses negligible energy when reaches the desired optimum temperature in a smart environment. This can be observed in Figure 3 through the smart charts derived from the collected real-time data.

CLOSING REMARKS

Smart home technologies are essential for improved energy energy, resulting in reducing carbon footprints. The household conditions can significantly improve with the deployment of smart technologies (Ehsanifar et al., 2023), and health and well-being can be improved through better management of internal environments, safety, and security. From the experiment, it is shown that the use of efficient appliances in a sensor-controlled energy-efficient smart home environment creates a comfortable living environment for the occupants with low energy consumption. The energy-efficient testbed successfully optimised the energy usage when reached the desired optimum temperature according to AHSRAE guidelines. The use of smart sensors contributes to real-time data and allows continuous improvement in smart product development. Furszyfer Del Rio et al. (2021) describe the potential sustainability benefits of smart home technologies that can support cost benefits and contribute to social and environmental impacts.

The waste reduction through smart homes can be directly connected to lean in the context of energy efficiency, energy waste reduction, data-driven decision-making, and improving user functionality. The review shows that Smart homes relate to increased capacity, better tracking, improvements in equipment utilisation, streamlined operations, and lower emissions.

Smart homes allow waste reduction through increasing efficiency, appraising user control in a home environment, and inducing continuous improvement. A summary of how the notion of smart home addresses lean principles is presented in Table 3. The findings presented in Table 3 are consistent with some synergies identified in Table 2, adapted from Awwal et al. (2023).

Table 3 Lean principles and Smart Home in waste reduction

Lean Waste	**Energy Usage (EPA, 2007)**	**Synergies with Smart Home**
Overproduction & Over processing	Additional energy consumed in operating equipment and more energy consumed due to unnecessary processing	A smart home allows energy efficiency through smart appliances, smart monitors and controls, and the integration of renewable technologies
Defects	Energy consumed in making defective products-, increasing lighting, heating, and cooling demand and energy consumption	A smart home allows the monitoring of real-time data and enables determining when there is a need for product replacement (e.g. Building materials and appliances) during the lifecycle of the building
Waiting/Delays	Streamlining operations	-Automation in smart homes allows streamlining daily operations and reduce waste

Table 3 depicts that the adoption of smart home technologies allows waste reduction/elimination during a building's lifecycle. The contributions were categorised into three groups: Overproduction and overprocessing-where smart home can minimise energy usage through better tracking and optimisation; Defects- Smart home allows real-time data collection; it can offer information on building deterioration over time, for example, if the humidity level is continuously high, measures can be taken to improve the condition, or if the appliances are older and consuming more energy, a replacement can be considered through smart data observation and waiting/delays- automation in a smart home can streamline operations which can result into increasing energy efficiency, especially in a well-insulated smart home which can retail heat for a longer time.

It should be noted that Table 2 is limited to the conceptual analysis presented in the paper. which needs further empirical data. The paper is limiting the study to a specific element of the smart system (e.g. radiator) and a case study in terms of building envelop (HSHRF). The smart house as an experimental testbed has some limitation, for instance, the building does not have a direct connection with the outdoor environment, which impacts independent variables such as temperature, precipitation, humidity etc. The experiment applied in this research is small, and not applied in a larger case study; further research is needed to assess the applicability.

Despite the limitations, this paper points out that Smart Home' connects to a 'Lean' perspective from an efficiency and operations point of view. It is evident that energy-efficient devices and systems, such as smart thermostats, lighting controls, and energy monitoring systems, contribute to reducing overall energy consumption in a smart house. Thus, smart homes could be explored further as an improved approach to promote energy efficiency and a better lifestyle for the building occupants and contribute to sustainability development goals. Energy consumption is a pressing concern worldwide. Smart home through lean construction allows optimisation, streamline workflows, and maximise efficiency which supports several SDGs for instance SDG-7 Affordable and Clean Energy; SDG-11- Sustainable Cities and Communities; SDG-12 Responsible Consumption and Production and SDG 13- Climate Action. In conclusion, the deployment of smart home technologies from a lean construction point of view offers valuable insights into energy waste on a larger scale and provides guidance for future research on informed regulatory decisions toward a more sustainable built environment.

ACKNOWLEDGMENTS

The paper reports on the findings from the smart house initiative at the University of Huddersfield. The authors would also like to thank Trust Electric Heating Ltd for their support.

AN INTEGRATED FRAMEWORK FOR PRODUCTION AND ENVIRONMENTAL WASTE MANAGEMENT IN CONSTRUCTION

Saleh Alazmi[1], Mohammed Abdelmegid[2], Saad Sarhan[3], Mani Poshdar[4] and Vicente Gonzalez[5]

ABSTRACT

Lean construction has successfully developed and utilised several tools to minimise production waste generation in construction projects. In addition, sustainability research has contributed to improving the environmental performance of the construction industry by managing the impact of construction waste on the environment. Research on construction sustainability has been utilising some of the capabilities of lean construction tools to address environmental-related issues that are difficult to tackle using conventional approaches. Even though research in the Lean-Sustainability area has progressed over the last two decades, knowledge of Lean-Sustainability applications is still limited amongst industrial practitioners. A potential reason is the lack of an integrated approach combining lean principles and sustainability for construction applications. To address this limitation, this paper proposes a management framework that deals with both production and environmental wastes concurrently. The framework is developed by combining a lean process improvement method with an environmental management system approach. The framework is validated through interviews with experts in lean construction and sustainability to establish its theoretical contribution and practical applicability. Through this integrated waste management framework, this study contributes to the efforts of managing production and environmental wastes to deliver more efficient and environmentally friendly projects in the construction industry.

KEYWORDS

Sustainability, Lean Construction, Value Stream, Production waste, Environmental waste

INTRODUCTION

There have been growing concerns about the adverse environmental impact of the construction industry over recent decades (Li et al., 2022). Extensive research efforts have been dedicated to investigating the environmental issues associated with construction activities, including greenhouse gas emissions and the depletion of natural resources (Dräger

& Letmathe, 2022; Farias et al., 2019; Kosasih et al., 2023). Many studies have been conducted to propose concepts and practices to enhance the environmental performance of construction projects, but there remains to be a gap in translating existing research recommendations into practical implementation. A potential explanation for this shortage in knowledge lies in the current industry focus on managing waste based on its consequences rather than addressing its root causes (Farias et al., 2019; Kosasih et al., 2023; Poshdar et al., 2022). Furthermore, prevailing sustainability practices tend to concentrate primarily on the design phase of construction projects, often neglecting process wastes and the interrelationship between design and construction (Rosenbaum et al., 2014).

To bridge these gaps, lean construction research has sought to address these limitations by emphasising the interrelationship between production and environmental waste in construction. This shift in focus can potentially overcome the constraints of managing production and environmental wastes separately (Arroyo & Gonzalez, 2016). Therefore, integrating lean and sustainability principles presents an opportunity to tackle different types of waste at different production levels (Khodeir & Othman, 2018).

In response to the existing gaps in construction waste management, this paper introduces a novel management framework that integrates lean and sustainability concepts. Adopting a constructive research methodology, this study identifies a practical problem within the existing body of knowledge and introduces a new construct to address it. By combining elements from lean and sustainability approaches and considering all production planning levels (strategic, tactical, and operational), the proposed framework ensures the visibility of all waste types, effectively addressing the challenge of invisible waste, as highlighted by Koskela (2004).

BACKGROUND

The environmental repercussions of construction activities rank among the key concerns within the industry (Araujo et al., 2020). The magnitude of construction-related waste generation remains alarmingly high in both developed and developing countries. For instance, in 2018, the United States produced over 600 million tons of construction-related waste, surpassing the municipal solid waste generated in the country (US Environmental Protection Agency, 2020). Similarly, the Gulf Cooperation Countries (GCC) produces a staggering 120 million tons of construction and demolition waste annually (Ouda et al., 2018). This surge in construction waste has substantial consequences, impacting production costs (Formoso et al., 2020) and depleting natural resources (Pradhan et al., 2017). Consequently, global awareness regarding the magnitude of construction waste and its environmental impact has grown, leading to an increased focus on waste minimisation in the construction domain (Ajayi et al., 2017).

Waste has been a central theme in the field of lean construction. From a lean perspective, production waste arises from non-value-adding (NVA) activities, which represent processes that consume resources without contributing value to the final product or end-user. Examples of NVA activities include over-production, waiting, and unnecessary motion (Ohno, 1988). Ohno initially defined seven categories of NVA within the manufacturing industry, a classification subsequently adopted by lean construction, which expanded to include additional categories (see Table 1).

Research has established that NVA activities can exert adverse effects on the environment (Banawi & Bilec, 2014; Belayutham et al., 2016). Therefore, the elimination or minimisation of waste, particularly NVA activities, has been proposed as a mechanism to enhance both process flow and the environmental performance of construction projects (Formoso et al., 2020; Sarhan et al., 2019). Despite the growing interest in advancing sustainability in construction through waste minimisation approaches, current waste management practices often lack practical applicability in the industry (Ajayi et al., 2017; Sarhan and Pretlove, 2021). This limited adoption of current practices can be attributed to their reactive nature, as they tend to address wasteful processes and their root causes after they have occurred. Additionally, these practices frequently treat production and environmental waste as separate entities (Kabirifar et al., 2020), indicating a lack of recognition of their interconnectedness within construction projects. Interested readers on the interrelated connections and trade-offs between Lean and Sustainability are referred to the systematic review by Sarhan et al., (2019).

Table 1: Construction Waste Categories

Waste Categories	Definition	Reference
Motion	Equipment or people moving more than necessary	(Ohno, 1988)
Waiting	Time lost in between steps in production	
Transportation	Moving products that do not need to be moved	
Inventory	Work and finished work not being processed	
Over-Processing	Poor use of tools and in the production of the goods that the customers do not need	
Overproduction	Production moves ahead of demand	
Defects	Extra effort involved in fixing problems	
Making- do	It refers to a situation where a task is started without all its standard inputs, or the execution of a task is continued although the availability of at least one standard input has ceased.	(Koskela, 2004)
Work in progress	Working on relatively small tasks left from the previous plan	(Hopp & Spearman, 2011)
Unfinished work	It includes rework and small finishing tasks that are left over after a crew leaves a workstation.	(Fireman & Formoso, 2013)
Waste of human potential	For example, not speaking and not listening. It also includes late or lack of involvement of contractors and specialist subcontractors in design and planning stages	(Macomber and Howell, 2004)
Institutional waste	Systems, norms, and routines, which are taken for granted and impede efficiency and improvement efforts in construction	Sarhan et al (2014)

RESEARCH METHODOLOGY

This research is conducted over five phases following the constructive research approach, which is centred around developing innovative solutions to practical problems that have research potential (Kasanen et al., 1993). The first phase included an examination of the body of knowledge to identify the gap related to the lack of a practical framework for the integrated management of production and environmental waste in construction. Subsequently, the second phase focused on obtaining a comprehensive understanding of the identified problem through a thorough literature review on the topics of lean construction and environmental waste management. In the third phase, a solution is proposed by integrating lean process improvement techniques with an environmental management system to develop a conceptual framework. The framework was validated in the fourth phase through expert interviews (refer to Table 4 for further details). Also, a case example is presented to demonstrate the framework's applicability in actual construction piling operations. Finally, insights for the successful implementation of the framework are presented based on the lessons learned from the validation exercise and the case-example demonstration. The final stage aims to establish the theoretical and practical contribution of the proposed solution as per the requirements of the constructive research approach.

PRODUCTION AND ENVIRONMENTAL WASTES IN CONSTRUCTION: A MANAGEMENT FRAMEWORK

DEVELOPMENT OF THE FRAMEWORK

Traditional practices for waste management in construction usually tackle production and environmental waste separately. This paper suggests a way to combine the two by integrating principles from lean and sustainability research. The proposed framework combines a lean-six Sigma improvement model and an environmental management system by integrating the DMAIC (Define, Measure, Analyse, Improve, and Control) with the Aspect and Impact Analysis (AIA).

DMAIC is a data-driven model that guides the process of gathering information and optimising production processes (Banawi & Bilec, 2014). In this context, DMAIC is employed in the framework to define and measure wastes, analyse and manage their root causes, and enhance overall process performance. It also helps control the proposed actions and establish procedures for future improvements. On the other hand, AIA is an environmental management system that focuses on improving environmental performance (International Organization for Standardization, 2015). In the scope of this research, AIA is utilised to identify NVA activities contributing to environmental waste, find their root causes, prioritise them based on impact level, and suggest suitable actions to address these causes and impacts. The integrated framework is structured into six stages as illustrated in Figure 1.

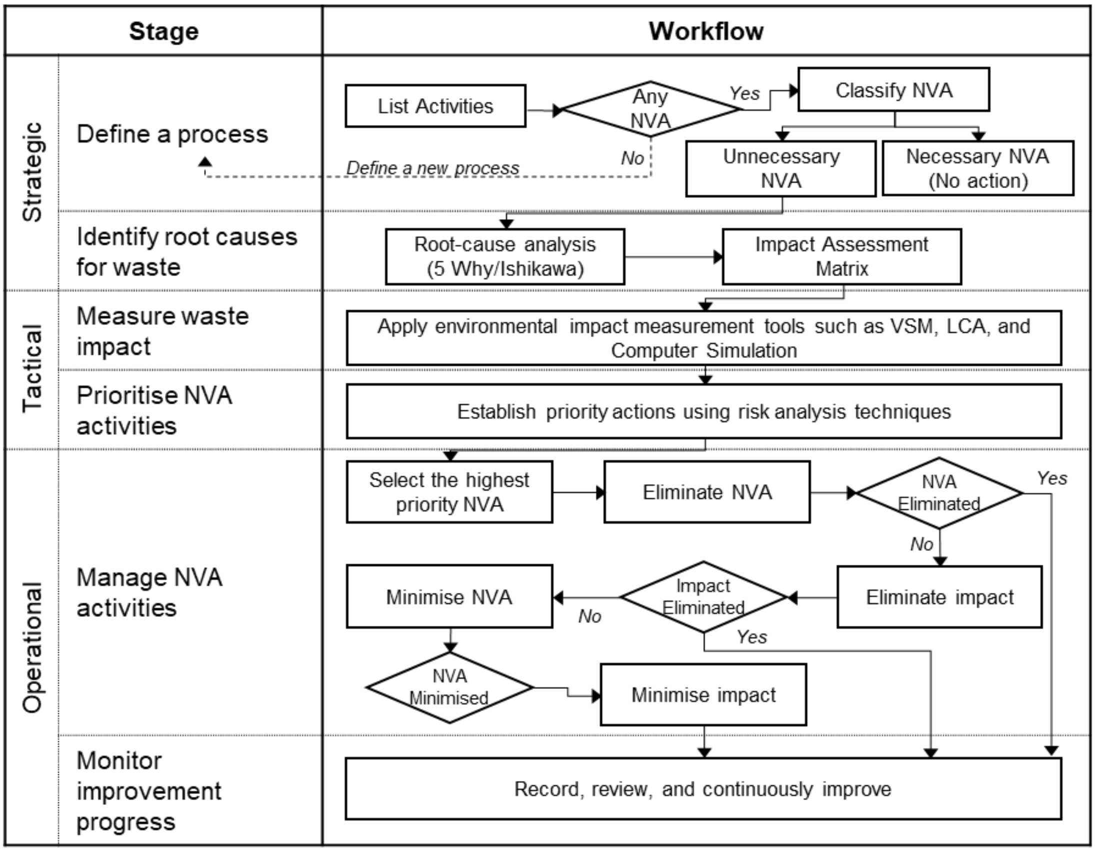

Figure 1: The Proposed Framework Stages and Workflow

The framework flow is designed in a straightforward approach to provide clear guidance to industry practitioners on production and environmental waste management in construction projects. The main aim of the framework is to capture NVA activities and recognise their impact across three production levels: strategic, tactical, and operational. However, it is essential to realise that some NVA activities are unavoidable in construction and that aiming to eliminate them completely is unrealistic. Therefore, the aim should be focused on minimising their existence or mitigating their impact as much as possible. The framework should be implemented iteratively to ensure that all NVA activities are identified and dealt with.

CASE EXAMPLE

To illustrate the application of the framework, a case example of the construction of cast-in-place reinforced concrete piles will be utilised. Piles are crucial structural elements in various construction projects. Piling operations are chosen for this example due to their complexity as they involve interrelated activities that require different materials and machinery. In addition, external factors, such as groundwater level, space constraints, and soil profile, can all contribute to the complexity of operations. This aligns with the findings of Banawi and Bilec (2014), who demonstrated the use of a Lean, Green, and Six Sigma (LG6) model on pile cap operations. Their study found that lean implementation in the construction of piling caps can reduce costs by 1% and environmental waste by 9%.

The case example is a retrospective study based on the construction project of an educational building in Auckland, New Zealand. The project faced several challenges as it was in a busy area with proximity to a hospital and residential buildings. Therefore, constraints on machinery types and numbers necessitated careful planning to ensure undisrupted production. The piling process involved seven main activities: site preparation, land survey, pile drilling, dewatering, steel cage insertion, concrete pour, and excavated soil removal. Additionally, two activities were required for the constant supply of steel cages and fresh concrete. The following subsections provide a detailed overview of each stage of the framework, followed by a demonstration of how these stages can be implemented in the case example.

STAGE 1: DEFINE A PROCESS

This stage of the framework aims to identify wastes generated during the construction phase, where their root causes will be investigated in the following stages. It begins by selecting a production process or sub-process in a construction operation to explore the reasons behind waste generation within the process. In this step, it is essential to assess the current state of the chosen process by identifying all activities and categorising them into Value-Adding (VA) or NVA. NVA activities should then be categorised into necessary and unnecessary. Necessary NVAs are unavoidable and integral to the production process, while unnecessary ones consume resources without directly contributing value to the final product. The primary focus of the framework is on addressing unnecessary NVA (i.e. waste). It is essential to indicate that activities like necessary NVA and VA can have environmental impacts. However, addressing them requires separate methods and falls outside the scope of the proposed framework.

Table 2 illustrates the analysis of the seven activities for the case example of piling operations. As can be seen, three activities are classified as VA, three as necessary NVA, and one as unnecessary NVA. It is important to highlight that this analysis depends on the project requirements, complexity, and circumstances. Thus, these activities can be classified differently in other contexts.

Table 2: VA and NVA activities for the construction of cast-in-place concrete piles

Piling activities	VA	Necessary NVA	Unnecessary NVA	Explanation
Site preparation		✓		Although this process does not directly contribute to pile production, it is necessary to allow piling machinery to operate within the pile location.
Land survey	✓			Land survey is classified as VA as any mistakes in pile locations might diminish the operational value of the pile to support the building structure.
Drilling	✓			Piles can not be constructed without displacing the soil in the pile location to allow for the steel and concrete to be inserted.
Dewatering		✓		Dewatering is a necessary NVA due to the negative effect of water on the quality of the pile materials. It is not VA as the pile can still be produced underwater using special tools and materials if necessary.
Steel cage insertion	✓			Steel is a critical structural component of reinforced concrete piles, so it has to be inserted into the piling location.
Concrete pouring	✓			Concrete is a critical structural component of reinforced concrete piles, so it has to be poured into the piling location.
Excavated soil removal			✓	The process of drilling produces soil from the pile location. The removal of this soil does not add value to the production of piles. This soil type was found to be suitable for recycling in any future construction operations and thus was unnecessary to be removed from the site.

STAGE 2: IDENTIFY ROOT CAUSES FOR WASTE

To address waste at its origin, it is essential to identify its root causes. Accordingly, this stage aims to identify the root causes of NVA activities and their impacts. It is proposed to utilise the 5-Whys technique developed by Sakichi Toyoda (Ohno, 1988) and Ishikawa diagram, also known as the fishbone diagram (Ishikawa, 1982). The 5-Whys technique is helpful in uncovering the origins of waste in the process. On the other hand, the Ishikawa diagram is effective in illustrating the cause-and-effect relationships among different causes of waste and their impacts. The outcome of this stage can be presented in a matrix that shows the connections between identified root causes and their potential impacts. The role of this stage is to ensure that the root causes and impacts of each identified NVA activity are transparent to facilitate actionable waste management strategies in the following stages.

For the case example, the Ishikawa diagram method was utilised to identify the following root causes for the soil removal activity:

- Excessive drilling leading to excavated soil surplus
- Incorrect geotechnical information leading to unnecessary excavation
- Poor maintenance of machinery leading to contaminated soil
- Lack of expertise in investigating soil types for recycling purposes

Table 3 illustrates the relationship and impact that the identified NVA for the case example could have on production and environmental waste generation during the construction process.

Soil removal may generate production and environmental waste due to the use of transportation within the construction site and outside to the dumping site. The removal of soil requires excessive movement of excavators to move the soil to a stocking area. In addition, it involves haul trucks to transport the soil from the construction site to the dumping station. These machines consume energy, generate pollutants, and create dust. Moreover, the use of heavy machinery increases the risk of hazardous material leakage and soil pollution.

Table 3: Impacts of NVA

NVA	Production waste											Environmental waste								
												Excessive Consumption				Excessive Emission				
	Transportation	Inventory	Motion	Waiting	Over-processing	Overproduction	Defect	Making – do	Rework	Work in progress	Unfinished work	Material	Energy	Water	Land	Air pollution	Solid Waste	Hazardous Materials	Water	Soil
Soil removal	✓	✓	✓	✓	✓							✓	✓		✓	✓	✓	✓		✓

STAGE 3: MEASURE WASTE IMPACT

This stage is designed to explore the environmental impact of NVA activities. Traditional lean practices primarily focus on enhancing productivity, time, and cost performance with less focus on the environmental impact (Teixeira et al., 2021). However, studies suggest that lean principles can be extended to include environmental measures (Arroyo and Gonzalez, 2016; Kosasih et al., 2023). To strengthen the environmental aspect of lean, the framework recommends employing process analysis techniques, such as Value Stream Mapping (VSM) (Weinheimer et al. 2017), Life Cycle Assessment (LCA) (Farias et al., 2019), and Simulation modelling (Golzarpoor et al., 2017), to measure the environmental impact of targeted NVA. The selection of analysis techniques can vary depending on the types of waste and the available information and are within the discretion of the framework user. As the case example was a retrospective study, waste impact of soil removal activities was not measured. However, we envisage that the use of a simulation model can be very effective in facilitating impact measurement.

STAGE 4: PRIORITISE NVA ACTIVITIES

This stage operates at the tactical level of the framework. The identified NVA activities should be assessed using a risk assessment rating system (e.g., probability and impact matrix). Then, the risk matrix can be utilised to determine which NVA has a low, medium, or high risk in terms of both production and environmental waste. This prioritisation process helps to focus attention and resources on addressing the riskiest NVA activities to aid the following stages of defining a strategic and efficient approach to waste management.

For the case example, as illustrated in Table 2, three NVA activities were identified. Soil removal is the only unnecessary NVA, so it is the highest priority for management intervention. As illustrated in the next stage, other NVA activities should also be dealt with. Although site preparation and dewatering are assessed as necessary for the process, they should be further analysed to reduce the need for such NVA or minimise their impact on production and environmental wastes.

Stage 5: Manage NVA activities

This stage provides a series of tools and procedures to address NVA activities and their environmental impact. It begins by selecting the top prioritised NVA activities and proposing actions for their management. The ideal goal is to eliminate NVA activities to prevent the generation of environmental waste. If elimination is not feasible, alternative measures are taken to reduce the impact on the production and environmental waste of the process. To manage NVA activities and their impacts, the framework suggests using the following steps in the designated order to ensure a strategic and efficient approach to managing NVA and minimising their impact.

- Eliminating NVA activities in the currently selected process to address the problem at its root cause.
- Eliminating impact by focusing on immediate measures to prevent waste generation in the process.
- Minimising NVA activities by redesigning production operations to avoid unnecessary NVA activities.
- Minimising impact by utilising approaches to control waste generation in the process.

In the case example, it was found that soil removal can be partially eliminated as some of the excavated soil was unsuitable for other construction operations. A mitigation strategy was to re-examine the geotechnical report and update it based on the accurate information from the site, to avoid future errors. Also, the additional soil can be used as a temporary protective layer under heavy machinery and be removed by the foundation contractor as part of their site excavation activities to avoid the production and environmental wastes associated with the removal of the small amount of soil only excavated from piling operations.

Stage 6: Monitor improvement progress

In the last stage, the framework focuses on tracking the performance of the framework. Also, it aims to capture any new wastes that might emerge from the strategies implemented in the previous stage. To ensure continuous improvement, it is essential to maintain a record of current challenges and the decisions or solutions applied. These records can be used as lessons learned to facilitate knowledge retention and transfer to enhance the effectiveness of the proposed framework over time.

FRAMEWORK VALIDATION

Expert validation

The proposed framework was validated through input from academic and industry experts in the field of lean construction and sustainability. Expert validation is an exploratory qualitative method, which is a common practice for validating conceptual models and frameworks (Hancock et al., 2001). In this study, a sample of 10 participants was initially formed based on their extensive academic and/or industry experience in both lean construction and sustainability. Six experts from both academic and industry backgrounds agreed to participate. The demographic details of the participants are outlined in Table 4.

Table 4. Demographic details of participant

Interview Reference	Title of Interviewee	Education	Country	Years of experience in lean and/or sustainability	Experience
VAL01	Researcher/ Academic	Doctoral	USA	Over 15 years	Academic+ Practical
VAL02	Researcher/ Academic	Doctoral	Chile	Over 15 years	Academic + Practical
VAL03	Researcher/ Academic	Doctoral	Turkey	Over 15 years	Academic + Practical
VAL04	Researcher/ Academic	Doctoral	Malaysia	five to ten years	Academic + Practical
VAL05	Project Manager	Master	Saudi Arabia	five to ten years	Practical
VAL06	Construction Manager	Bachelor	New Zealand	Five years	Practical

Semi-structured interviews were conducted via Zoom with a focus on how to ensure the framework's alignment with advanced research outcomes and industrial best practices. The interview covered four key themes, and content analysis was performed to extract insights on these themes from the participants' responses. The following subsections cover the results of the expert validation process. Based on the outcomes of these interviews, the developed framework underwent refinement to incorporate feedback and recommended modifications.

GENERAL OVERVIEW OF THE FRAMEWORK

The initial part of the interview focused on obtaining the overall impressions of participants about the framework. The aim was to ensure the clarity, ease of understanding, and its effectiveness. Prior to the interview, the framework was shared with the participants for review. All six experts confirmed that the framework was well-structured, easy to follow, and has the potential to enhance waste management in construction projects. The following statements from experts affirmed this sentiment:

"It looks well organised. It looks relatively, going to be easy to follow…The flow of the framework is clear, easy to follow." (AVL02)

"I found your framework very useful, and it's a good idea to combine lean and sustainable concepts every time, in my opinion." (AVL03)

"The framework looks well-structured to me. It is good to have a framework that can manage waste and assist us to achieve sustainability at the same time." (AVL05)

The second question in the validation process investigated the framework's efficiency, with responses provided below:

"It can eliminate the non-value adding activities...It has the potential to reduce schedule for sure, environmental impact in terms of emission from the construction phase." (AVL01)

"The framework consists of strategic, tactical, and operational levels...This will help in LEED accreditation...I notice that in your framework." (AVL02)

"This framework could definitely improve the efficiency of construction, provided the users could properly conduct and understand the impact measurement well." (AVL04)

APPLICABILITY OF THE FRAMEWORK

The next question aimed to explore the practical application of the framework to identify potential issues or limitations that could impede its implementation in real construction projects. Participants expressed confidence in the applicability in actual construction projects. They highlighted the ease of practical implementation and reported no significant impediments. Examples of participants' responses include:

> *"Yes, in my opinion, you can apply it to a real construction project." (VAL03)*

> *"Absolutely yes...I would apply it straight away as we are suffering from a lack of attention in waste management." (VAL05)*

BENEFITS AND DRAWBACKS OF IMPLEMENTING THE FRAMEWORK

To assess the practicality of the framework, the next question examined both the benefits and drawbacks associated with its implementation. The reported drawbacks were generally around the time and costs associated with implementing such a management intervention. Additionally, Expert VAL01 noted that *"Measuring NVA can be hard but depends on NVA types."* On the positive side, the participants found potential benefits for the framework in construction projects. These include a reduction in both production and environmental waste. Also, the framework can enhance productivity and improve time and cost performance. Moreover, the experts indicated that the framework can foster increased awareness about environmental waste and improve understanding of the relationship between lean and sustainability concepts.

CHALLENGES OF IMPLEMENTATION

While there was a consensus about the applicability of the framework, the experts raised awareness of potential challenges during implementation. Resistance to change was reported as a critical barrier. Another identified barrier was the lack of knowledge about lean and sustainability concepts among construction practitioners. Differences in regulations across countries also posed a challenge. Furthermore, the scope of implementation was considered, with a suggestion to apply the framework initially in smaller pilot projects before addressing entire projects. The experts highlighted the need for well-designed guidelines and clear demonstrations of the framework's benefits to overcome these challenges.

CONCLUSION

This study underscores the critical interplay between production and environmental waste in construction projects, emphasising the urgent need for a comprehensive waste management approach. The developed framework uniquely integrates lean and sustainability principles by addressing waste at strategic, tactical, and operational levels. Unlike previous studies that primarily focused on specific site operations, this framework systematically tracks waste's root causes and potential impacts across various production stages.

The application of lean concepts in construction offers a promising avenue for the simultaneous reduction of production and environmental waste. The framework equips construction organisations with the means to enhance operational efficiency while adopting environmentally friendly strategies. Practitioners can leverage this tool to identify and rectify inefficiencies in construction processes to enhance the overall performance of the industry in terms of cost, time, and environmental sustainability.

This paper has the following limitations. First, the proposed framework is limited to addressing unnecessary NVA. However, it is important to recognise that necessary NVA as well as VA can be sources for waste in construction operations. Addressing such activities requires redefining engineering methods to embed sustainability into the design of construction operations (and potentially the asset itself) to avoid any waste generation during the construction and operation of the asset. Another limitation is the use of a simple case example to illustrate the application of the framework, which might not represent the overall picture of real-life implementation. To address these limitations, further refinement of the framework will be conducted in future research. These refinements include the development of a holistic framework covering all lifecycle phases of construction projects and investigating the incorporation of cause-effect relationships between different waste types. The evaluation of the applicability of the framework and its impact in a real construction project is also recommended to validate its effectiveness in practical settings. Through these initiatives, ongoing advancements can be made to revolutionise waste management practices in the construction industry.

EVALUATING THE AWARENESS OF DESIGNING OUT WASTE IN CONSTRUCTION: A LEAN–GREEN SYNERGY

Sena Assaf[1], Farah Ezzedine[2], Amal Nahle[3], Hala Zahr[4] and Farook Hamzeh[5]

ABSTRACT

The construction industry generates millions of tons of material waste annually throughout a project's life cycle. In Lebanon, one million tons of Construction and Demolition Waste were generated during the years 2009 and 2010. To support organizations in enhancing their environmental efficiency, the Green paradigm has emerged. Such a paradigm can be complemented with the Lean management approach paving the way for a Lean-Green synergy. This synergy is based on the alignment of the two approaches on the need to minimize waste, in its different forms, as well as maximize stakeholder value; the client, and the environment. As such, this paper introduces the concept of the Design out Waste (DoW) approach. This approach aims to improve the sustainability aspect of a project, throughout its lifecycle and starting from the early design phase, supported by Lean tools and principles. Specifically, the aim of this paper is to investigate the current state and examine the level of awareness of implementing DoW principles in the Lebanese construction industry through conducting surveys. The survey results showed a low level of awareness of the DoW approach among practitioners in Lebanon with little attention given to waste minimization when making decisions.

KEYWORDS

Lean construction, Green construction, sustainability, Lean-Green synergy, waste minimization

INTRODUCTION

Each year, the construction industry generates millions of tons of material waste across the different stages of a project's life cycle (Wang et al., 2014). Estimates also show that 30% of the materials brought to a typical construction site go to waste (Osmani, 2011). More specifically, the construction industry in Lebanon has generated one million tons of Construction and Demolition Waste (CDW) during the years 2009 and 2010 as per the latest available studies (Tamraz et al., 2012). With the absence of a proper regulatory framework to

manage solid wastes in Lebanon, including CDW, the waste issue has become more critical to handle (Tamraz et al., 2012).

With the increasing cost overruns, clients are requesting a further reduction of waste in the projects (Akintoye, 1995). This can be due to the high proportion of materials cost that amounts to 50%-60% of the project's cost (Polat & Ballard, 2004) . Therefore, any reduction in material waste can lead to substantial cost savings (Polat & Ballard, 2004). Additionally, research shows that failing to apply waste reduction measures in the design phase of a construction project could result in an estimated 33% of the total waste generated on-site (EPA, 2015).

Given the environmental and economic concerns with the large amounts of CDW waste generated each year (Wang et al., 2014) and the clients' need to reduce waste on their projects (Akintoye, 1995)., it is essential to consider sustainable construction (Polat & Ballard, 2004). The Green paradigm has emerged as an approach to support organizations in enhancing their environmental efficiency (Garza-Reyes, 2015). To support the implementation of Green initiatives in construction projects and to maximize value to the client and the environment, Green approaches can leverage the use of tools and principles developed by the Lean community (Huovila & Koskela, 1998).

Lean has initially emerged as a management approach to designing production systems with the aim of maximizing customer value and minimizing waste in its different forms (Koskela et al., 2007). It is governed by a set of 14 principles adopted from the Toyota Production System (TPS) that cover 4 aspects: 1) "Philosophy" which focuses on long-term thinking as opposed to short-term wins, 2) "Process" which focuses on leveraging lean tools and techniques to eliminate any form of waste in the production process, 3) "People and Partners" that focuses on respecting and challenging the people in the organization as well as other stakeholders, such as suppliers, to understand the organization's philosophy and to help them improve and finally 4) "Problem-solving" which aims to solve problems by identifying the root cause in the pursuit of continuous improvement (Liker, 2004). Additionally, Taichi Ohno identified 7 categories of waste that need to be eliminated from any production process. These include (Polat & Ballard, 2004):

1. Product defects
2. Overproduction
3. Inventory
4. Unnecessary processing
5. Unnecessary movement
6. Unnecessary transportation
7. Workers waiting on work

LITERATURE REVIEW

Although the foundation of the Lean philosophy is rooted in the manufacturing industry, the construction industry has been witnessing a successful implementation of the Lean management approach (Singh & Kumar, 2020). Specifically, Lean in construction emphasizes the need to reduce different types of waste that are present throughout the different phases of a project's lifecycle (Horman et al., 2004). Among the common tools and techniques used in construction are the 5S, visual management, standardization, big room, and continuous improvement along with many others (Liker, 2004). The successful implementation has been reflected in terms of customer satisfaction, waste reduction, cost reduction, and timely project delivery (Singh & Kumar, 2020).

The success of Lean implementation has also been witnessed in the Lebanese construction industry in particular. To start with, Kallasy and Hamzeh (2021) developed a "Lean Culture

Index" to assess the readiness of construction companies in Lebanon to apply Lean tools and principles. The developed index covered all the aspects of the 4Ps: philosophy, process, people and partners, and problem-solving. The authors also proposed practical recommendations to guide practitioners in Lebanon on Lean implementation. Moreover, Hamzeh et al. (2016) analyzed a large-scale construction project case study regarding its first intensive implementation of Lean tools and the Last Planner System (LPS) in Lebanon. The project team witnessed improvements upon implementation including improved performance visualization, better communication among engineers and the foremen, and better linkage of the main project metrics on time, cost, and quality to the principles of the TPS. In another study, Awada et. Al (2016) evaluated the potential of adopting Lean tools and concepts to reduce safety-related incidents in the Lebanese construction industry. The study showed that practitioners understand the benefits associated with such Lean tools to enhance safety management in construction.

Lean and Green approaches align well with the idea of waste elimination, in its different forms, and with the idea of maximizing stakeholder value; the customer stakeholder and the environment stakeholder. As such, a Lean–Green synergy can be considered where the two approaches complement one another. This synergy has become practically possible in construction given that the Lean construction community has shown the potential of considering the environment as a customer (Huovila & Koskela, 1998).

The aforementioned synergy allows for a smooth implementation of Lean tools and principles to achieve - on top of customer satisfaction - environmental benefits in the construction industry. For example, Vieira and Cachadinha (2011) showed that the use of the 5S Lean tool helped maintain a clean and organized site by placing waste containers in the immediate vicinity of the generated material waste as well as sending material waste to their identified locations. The case study presented by Valente et al. (2013) utilized the Gemba Lean practice on a monthly basis to monitor and document the requirements needed to apply for LEED certification. Moreover, just-in-time (JIT) material delivery and Kanban systems were utilized to improve the flow of material on-site (Rosenbaum et al., 2012). In another study, Abou Dargham et al. (Abou Dargham et al., 2019) showed that adopting a pull material delivery system ensured a more efficient use of the material delivery trucks.

Although the integration of Lean and Green approaches has been successful, previous studies mostly address the construction phase of the project as opposed to the different stages of the lifecycle. To spread awareness of the benefits of Lean to improve projects' sustainability aspect during their lifecycle, the Designing out Waste (DoW) paradigm is introduced.

The guidelines of DoW were developed in the year 2000 by the Waste and Resource Action Programme (WRAP) to promote sustainable waste management (WRAP, n.d.-a). It is a methodology implemented from the design phase to control, monitor, and eliminate waste in construction projects. It consists of identifying key waste reduction opportunities, investigating the promising ones further, and implementing the most practical option (WRAP, n.d.-b). The DoW process has presented five key principles described below (WRAP, n.d.-b):

1. *Design for waste efficient procurement:* requires an agreement between the suppliers and project teams to provide only the needed quantity of material at the right time as opposed to batch delivery. The aim is to avoid the storage of excess material on site. Accordingly, this will also reduce potential material damage and thus the need to order new batches (WRAP, n.d.-b). The Lean concepts of the JIT delivery system and the pull approach can be utilized to support a waste-efficient procurement (Abou Dargham et al., 2019) thus reducing excess inventory and potential defects (Polat & Ballard, 2004). As such, this principle aligns well with the following Lean principles of the TPS: "Use pull systems to avoid overproduction" and "Respect your extended network of partners and suppliers by challenging them and helping them improve" (Liker, 2004).

2. *Design for off-site construction:* is based on fabricating construction elements in a controlled factory environment and then shipping them to the site for assembly (WRAP, n.d.-b). It is a method well accepted by the Lean community to efficiently reduce construction waste (Polat & Ballard, 2006). Being in a factory setting, off-site construction entails a production line approach similar to that adopted in the manufacturing industry. In this case, the tasks performed at each workstation are standardized to a certain extent. This must be accompanied by levelling the workload among the different stations to reduce waste in the process. Waste here covers a variety of aspects including inventory, work waiting on workers, and workers waiting on work. Moreover, value stream mapping acts as an effective Lean tool to help identify different types of waste in the production process and thus propose opportunities for improvement (kaizen) (El Sakka et al., 2016). So, this principle aligns with the following principles from TPS: "Standardized tasks are the foundation for continuous improvement and employee empowerment" and "Level out the workload" (Liker, 2004).
3. *Design for materials optimization:* tackles design approaches that consider efficient use of resources without affecting the quality or the design (WRAP, n.d.-b). This can be achieved by minimizing the amount of materials incorporated in the design through value engineering to reduce waste production in the construction phase (WRAP, nd). It can also be achieved by standardizing the materials and components used as much as possible (WRAP, n.d.-b). This principle aligns with Lean thinking by eliminating Muda; waste in its different forms, and using only what is required of the resources (Polat & Ballard, 2004). Additionally, standardizing the materials and components used allows for a smoother standardization of the construction processes which is a core Lean concept as well (Liker, 2004). As such, this principle aligns well with the following principles from the TPS: "Standardized tasks are the foundation for continuous improvement and employee empowerment" (Liker, 2004).
4. *Design for reuse and recovery:* considers the entire life of the materials used on site. Material reuse allows the reduction of the consumption of new raw resources by exploiting materials and the facilities present originally on-site to their fullest capacity before considering new resources (WRAP, n.d.-b). From a Lean perspective, designing projects in a way that allows material reuse requires pulling information from the client in the early design stages (Elmaraghy et al., 2018). Additionally, implementing this principle supports the elimination of Muda by reusing existing materials as opposed to transforming them to waste and using new materials (Polat & Ballard, 2004). In order to effectively design for material reuse and recovery, the project stakeholders need to focus on longer-term goals as opposed to short-term gains. In other words, it might require more effort and some additional costs to reuse and recover existing materials as opposed to ordering new materials. However, in the long run, this will reduce the overall waste generated and will add value to the customer and the environment. So, the principle is rooted in the following Lean principle of the TPS: "Base your management decisions on a long-term philosophy" (Liker, 2004).
5. *Design for deconstruction and flexibility:* considers the recovery and the deconstruction stages of materials by incorporating methods that facilitate their maintenance and reprocessing (WRAP, n.d.-b). Lean principles can be applied to plan for deconstruction by pulling information from the clients to meet their needs and expectations thus increasing client value (Elmaraghy et al., 2018). Developing a deconstruction plan requires the project stakeholders, including the client, to think about the long term as opposed to focusing on short-term gains. Although this requires additional planning, effort, and potential cost at the early stages of the project design, however, on the long term this is expected to reduce the total waste generated and will add value to the customer and the environment. As such, this principle is rooted in the following Lean principle of the TPS: "Base your management decisions on a long-term philosophy" (Liker, 2004).

Implementing each principle requires effective coordination between the teams of the project: clients, designers, contractors, and subcontractors, from the preliminary design phase (WRAP, n.d.-b). Therefore, following an integrated approach to enhance effective communication starting from the design phase could help avoid several construction problems (Emmitt et al., 2004). From a Lean perspective, following such an approach can practically be achieved by adopting an Integrated Project Delivery (IPD) method (Ballard et al., 2011).

The literature shows the benefits of the DoW approach accompanied by integrated practices in minimizing the waste generated during a construction project's lifecycle which then saves on cost and time and increases stakeholders' value (the client and the environment). Additionally, the urging needs to handle the CDW in Lebanon calls for leveraging the described Lean-Green synergy whereby Lean tools and principles smoothly support the implementation of Green initiatives. As such, this paper aims to study the current state and examine the level of awareness of implementing DoW through integrated practices in the Lebanese construction industry. The specific research questions that this study aims to answer are as follows: 1) What is the level of awareness of the construction industry in Beirut, Lebanon regarding each of the DoW principles? 2) What is the level of integration between the client, designer, and contractor in the early stages of the construction project? and 3) What is the relative importance of time, cost, and waste aspects in construction projects? The study outcomes will act as a baseline for construction practitioners and researchers to identify opportunities for improvement related to implementing Green initiatives backed up by Lean thinking.

METHODOLOGY

To examine the current practices and the level of awareness of implementing DoW methods through an integrated approach in the construction industry in the city of Beirut in Lebanon, a qualitative approach using questionnaire surveys was followed in this study. Survey-based research can help researchers collect information from a certain group of individuals based on the responses they provide to a pre-defined set of questions (Ponto, 2015). Generally, the researchers start by formulating a set of questions that can help them understand certain preferences or behaviours of the population (Ponto, 2015). Specifically, the Likert scale can be used to measure the attitudes of the individual to identify the degree to which they agree or disagree with a certain statement (Likert, 1932). As it is not possible to collect data from an entire population, a sample of the population is often selected to estimate how the responses of the population (Ponto, 2015). As such, researchers would try as much as possible to select a sample of individuals that have characteristics similar to the population (Ponto, 2015).

The developed questionnaire was based on key findings from the literature regarding the five principles of DoW and integrated practices in construction as well as the synergy with Lean practices. It was divided into two main sections: section one tackled the DoW principles, while section two focused on the integrated approach.

In the first section of the survey, when addressing the first principle, design for waste-efficient procurement, the survey tackled the concept of JIT ordering, supplier cooperation in delivering the needed quantities, the extent of buffers allowed when ordering materials, and the flexibility in the choice of material. The second principle, design for off-site construction, was approached by investigating the reason behind using off-site construction methods and whether the contractor was involved in making such a decision in the design phase. The third principle, design for materials optimization, tested if the designer involves the contractor in the design phase to find solutions for constructability issues and whether the contractor raises such concerns to the designer during construction. In addition, this principle addressed the purpose behind minimizing material cut-offs. The fourth principle, design for reuse and recovery, was studied by examining the use of recyclable and reusable materials in construction projects. The fifth principle, design for deconstruction and flexibility, was addressed by checking if the design accounts for potential future changes and for developing a deconstruction plan.

The second section of the survey targeted the implementation of DoW from the design phase through an integrated approach. The questions addressed the extent to which regular follow-up meetings take place between designers, clients, and contractors and the contractor's involvement in the design phase regarding the construction methods and constructability issues.

Two formats of the survey questions were produced; one for the designers and one for the contractors. Both surveys had the same content. However, the formulation of the questions was slightly modified so that each respondent could better relate to it given their background. The surveys were filled by professionals in the construction field through interactive interviews ensuring the reliability of the collected data.

To measure the different degrees of attitudes and opinions of the respondents, the five-point Likert scale was used (Likert, 1932). An answer of "1" stands for "strongly disagree", an answer of "3" indicates a "neutral" opinion, whereas an answer of "5" means "strongly agree". The awareness level was then measured from the mean score (MS) of each topic under study. In other words, an MS of less than 3 indicates a low level of awareness, whereas an MS of more than 3 indicates a high level of awareness. Questions were formulated in both positive and negative senses to ensure unbiased feedback thus increasing the trustworthiness of the results. Throughout all the survey questions, the relative importance of time, cost, and waste in the project delivery process was measured.

A total of 33 valid surveys were completed upon interviewing professionals in the Lebanese construction industry, specifically in the city of Beirut. The sample of respondents included architects, engineers from different disciplines, contractors, and consultants with an experience range of one to thirty years in the Lebanese construction industry. Specifically, 20 of the surveys were completed by professionals on the designers' teams with experience ranging between 1 and 30 years and an average of 10 years of experience. As for the remaining 13 surveys, they were completed by professionals on the contractors' teams with experience ranging also between 1 and 30 years with an average of 9 years of experience. The responses were collected from a total of 7 organizations; 4 engineering companies and 3 contracting companies.

The collected data were sorted and analyzed using descriptive statistics and a one-sample T-test. Then, recommendations for implementing DoW in Lebanon, with the support of Lean tools and principles, are suggested.

RESULTS AND ANALYSIS

Table 1 shows the level of awareness of the survey respondents along with the mean and standard deviation on the following items: each of the DoW principles, the integrated approach, and the overall DoW approach. Moreover, Figure 1 shows the corresponding box plots. The results obtained are then analyzed to understand the current construction practices.

Table 1: Level of awareness summary

Section	< 3	= 3	> 3	Mean	Standard Deviation
Principle 1	51.92%	21.15%	26.92%	2.8	0.7
Principle 2	53.54%	19.19%	27.27%	2.6	0.6
Principle 3	55.70%	17.72%	26.58%	2.8	0.5
Principle 4	68.18%	21.21%	10.61%	2.2	0.3
Principle 5	57.50%	15.00%	27.50%	2.7	0.65
Integrated approach	58.18%	19.39%	22.42%	2.6	0.7
DoW	57.50%	18.95%	23.55%	2.5	0.6

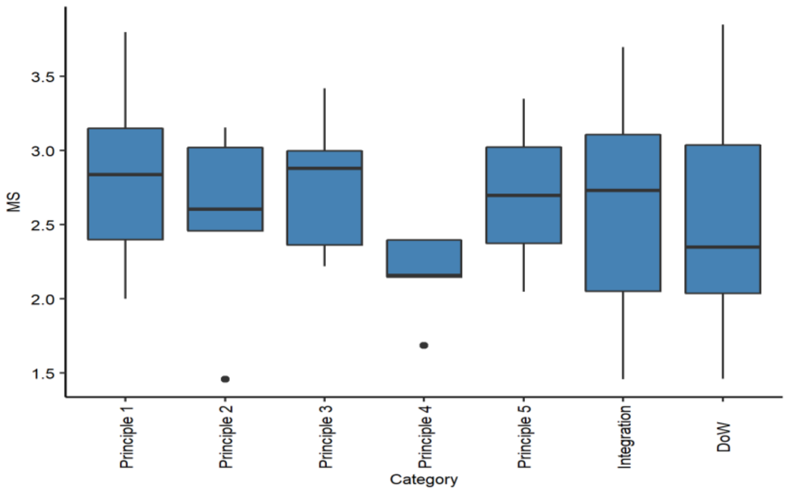

Figure 1: Level of awareness box plots

PRINCIPLE 1: DESIGN FOR WASTE-EFFICIENT PROCUREMENT

Table 1 shows the relative frequency of the respondents who answered less than 3 (52%), 3 (21%), and greater than 3 (27%) on the questions related to the 1st principle. The box plot in Figure 1 confirms the results by having more than half of the data scoring below 3. The MS of the data turned out to be 2.8 with a standard deviation of 0.7 reflecting a low level of awareness on this principle.

Most of the interviewed contractors order materials in batches and store them on-site as opposed to adopting JIT procurement methods. Their point of view was that ordering in batches helps them save on transportation costs and get better deals from suppliers. Moreover, based on the professionals' answers, the suppliers showed little cooperation in delivering materials in small quantities when needed because it would cost them more. In addition, excess material buffers were often used to account for variability that takes place on-site including material damage, loss, or delayed delivery. Moreover, little flexibility was shown in changing the materials being used to ones that generate less waste.

PRINCIPLE 2: DESIGN FOR OFF-SITE CONSTRUCTION

Table 1 shows the relative frequency of the respondents who answered less than 3 (54 %), 3 (19%), and greater than 3 (27%) on the questions related to the 2nd principle. The MS of the data turned out to be 2.6 with a standard deviation of 0.6. The box plot in Figure 1 shows that the median is below 3, which means more than half of the scores are below 3. This can be explained by the current practices that follow traditional contractual relations prohibiting the early engagement of the contractor. Hence, the results indicate a low awareness regarding designing for off-site construction.

The results confirm that off-site construction methods were used for the sake of reducing the construction time and getting better quality instead of the purpose of reducing waste in its different forms. In addition, the decision to use such methods was mostly taken in the early design phase without the involvement of the builders, thus increasing the chances of conflicts during construction. As such, current practices have not prioritized maximizing value to both the client and the environmental stakeholders.

PRINCIPLE 3: DESIGN FOR MATERIALS OPTIMIZATION

Table 1 shows the relative frequency of the respondents who answered less than 3 (56%), 3 (18%), and greater than 3 (26%) on the questions that tested the 3rd principle. The box plot in Figure 1 shows that the median is slightly below 3, which means more than half of the scores are below 3. The MS of the data turned out to be 2.8 with a standard deviation of 0.5, reflecting a low level of awareness regarding designing for material optimization.

The results indicate that most of the targeted practitioners do not consider standardizing the design to reduce the material cut-off generated during construction. In addition, contractors seemed to be hesitant about raising related constructability issues with the designers since they believe that they are two independent entities. On the other hand, designers do not consider addressing contractors about the feasibility of constructing the generated design for the same purpose.

PRINCIPLE 4: DESIGN FOR REUSE AND RECOVERY

Table 1 shows the relative frequency of the respondents who answered less than 3 (68 %), 3 (21%), and greater than 3 (11%) on the questions related to the 4th principle. The MS of the data turned out to be 2.2 with a standard deviation of 0.3. Similarly, the box plot in Figure 1 shows that the median is below 3 which also confirms that more than half of the data is below 3. Hence, this indicates a low awareness regarding designing for reuse and recovery.

It can be inferred from the results that most of the respondents do not incorporate materials that have a percentage of recyclable content throughout the projects. The clients' perspective on this matter was sought based on the information shared by the respondents. Clients are not aware that they could save on the cost of dumping the materials in landfills by recycling them, which could increase their profit. Additionally, clients might not have a thorough background on the associated environmental value of material reuse and recovery. In addition, choosing materials that can be reused later for a purpose it is suited for, whether on the same project or a new one, is not taken into consideration either. In this case, the old material will be considered unnecessary waste (Muda). Moreover, the project stakeholders might not find it financially feasible to recover and re-use existing material as this would require a certain up-front cost regardless of the long-term benefits. Stakeholders also find it challenging to re-use and recover material between different projects as each project is likely to be handled by a different team. As such, more planning is required between the teams to support a smooth transition of material reuse and recovery.

PRINCIPLE 5: DESIGN FOR DECONSTRUCTION AND FLEXIBILITY

Table 1 shows the relative frequency of the respondents who answered less than 3 (55 %), 3 (16%), and greater than 3 (29%) on the questions related to the 5th principle. The box plot in Figure 1 shows that the median is below 3 which also confirms that more than half of the data is below 3. The MS of the data turned out to be 2.7 with a standard deviation of 0.65. This indicates a low awareness of designing for deconstruction and flexibility.

The results reveal that most designers do not account for potential future changes in the project during design. Also, most of the contractors do not consider developing a deconstruction plan in the design phase to deal with the CDW generated. This can be explained by their lack of awareness about the cost savings, environmental benefits, and added client value upon reusing and recycling materials as stated in the previous principle.

INTEGRATED APPROACH

Table 1 shows the relative frequency of the respondents who answered less than 3 (56%), 3 (19%), and greater than 3 (22%) on the questions related to following an integrated approach. The box plot in Figure 1 shows that the median is below 3 which also confirms that more than half of the data is below 3. The MS of the data turned out to be 2.7 with a standard deviation of 0.7.

It could be concluded that there is minimal integration between the client, designer, and contractor altogether in the early design phase to develop strategies to design out waste. Results show that meetings do take place between clients and designers or between clients and contractors. However, these meetings are held further into the project construction phase as opposed to the early stages of design. These meetings often address general updates on the progress of the project, issues faced -if any -, time delays, and cost overruns.

LEVEL OF AWARENESS OF DESIGN OUT WASTE

Table 1 shows the relative frequency of the respondents who answered less than 3 (59%), 3 (18%), and greater than 3 (23%) on the questions related to DoW: the five principles and the integrated approach. The box plot in Figure 1 shows that the median is below 3, which means more than half of the scores are below 3. The MS of the data turned out to be 2.5 with a standard deviation of 0.6. Hence, this indicates a low awareness of DoW through integrated approaches in the construction industry in Beirut, Lebanon.

The normality of the collected data was confirmed using the Shapiro test with a confidence level of 95%. The PDF of the data is plotted in Figure 2 showing a symmetric distribution. The graph shows that there is a probability of 78.9% of having a low level of awareness (less than 3).

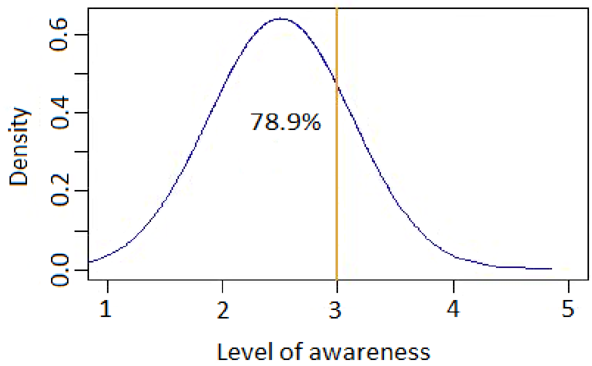

Figure 2: PDF of Level of Awareness of DoW

It was possible to conduct a one-sample T-test since the data was normal to check whether the MS of the survey questions addressing DoW through integrated practices (2.5) is statistically significant from the neutral MS (3). The null hypothesis states that the data is not statistically different from 3 and the alternative hypothesis states that the data is statistically different from 3. The resulting p-value was equal to 0.0002343 which is less than 0.05. Thus, the null hypothesis can be rejected meaning that the data is statistically significant with a 95% confidence level.

IMPORTANCE LEVEL OF DIFFERENT FACTORS

The survey questionnaire included certain questions that reflect how important the factors of time, cost, and waste are important to the respondent. The results revealed that the most important factors that practitioners take into consideration when delivering a construction project are time followed by cost as Figure 3 shows. The time factor had an MS of 4.1 while the cost factor with an MS equivalent to 3.8. However, the importance of considering waste showed an MS lower than both of the latter (2.5). This shows that professionals focus on time and cost while making decisions. However, they are not aware that the waste factor indirectly affects the other two; investing more in adopting methods that generate less waste will save time and cost in the long run. Additionally, it would increase value to both the client and the environment which is the ultimate goal of the DoW approaches.

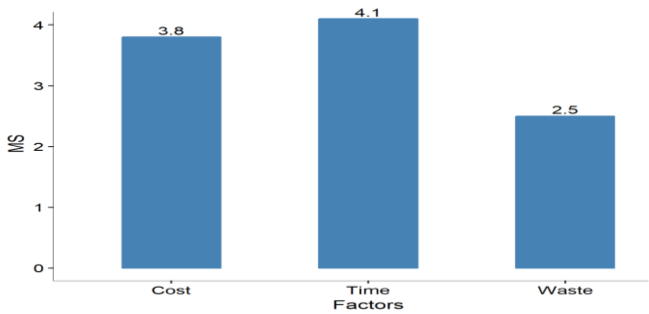

Figure 3: Results for the importance level of the different factors in project delivery

CONCLUSIONS AND RECOMMENDATIONS

DoW is a strategy that aims at minimizing waste by following five main principles: design for waste-efficient procurement, design for off-site construction, design for materials optimization, design for reuse and recovery, and design for deconstruction and flexibility. It requires the integration between the project stakeholders from the beginning of the project. Lean tools and principles, on the other hand, help support the implementation of the DoW principles in construction projects. As such, the Lean–Green synergy in construction was introduced in this paper. This study also showed how the DoW principles and Lean TPS principles go hand-in-hand with a focus on the 4Ps model: philosophy, process, people and partners, and problem-solving. A questionnaire conducted among professionals in the construction industry in Beirut, Lebanon, given the high numbers related to CDW waste in the country, revealed a low level of awareness regarding DoW. Also, results showed that professionals' focus in project delivery is the direct time and cost savings disregarding the benefits of minimizing waste to ultimately add value to the client and the environment.

Given the study outcomes, the Lebanese construction industry can benefit from a set of recommendations to support the implementation of DoW accompanied by the corresponding Lean tools and principles. To start with, construction companies need to thrive to build a Lean culture in the organization which would act as the foundation for continuous improvement in the different aspects. Second, construction companies should invest in training employees on the benefits of implementing the different Lean tools and principles to reduce waste and maximize value. Third, the companies should carry on training on the benefits of leveraging these Lean tools in implementing DoW principles to further maximize value to the environment. Fourth, companies also need to guide owners on how they can better define their value while maximizing value to the environment. Finally, it is recommended to implement the DoW along with the necessary Lean tools and TPS principles on a pilot project in an attempt to showcase the potential benefits of minimizing waste, and maximizing the client and environmental value.

Future research should further examine the level of awareness of clients regarding DoW approaches supported by Lean tools and techniques to obtain an overall awareness. Another direction for future research is to investigate, based on a case study analysis, the benefits of implementing DoW principles supported with Lean tools and principles. Finally, the authors will be working on expanding the study by increasing the sample size of the respondents to get a better representation of the current state in Beirut, Lebanon. Additionally, a larger geographical context in Lebanon will be considered. This would help ensure a better representation of the population in the Lebanese construction industry.

EVALUATION OF THE LITERATURE SYNTHESES ON LEAN CONSTRUCTION CONTRIBUTIONS TO SUSTAINABILITY

Müge Tetik[1], Lauri Koskela[2], Ergo Pikas[3] and Kädi-Riin Vendel[4]

ABSTRACT

In the last ten years, the interest in the question on how lean construction could contribute to sustainability has considerably increased. This is reflected in the rapidly growing number of publications addressing this question. Especially systematic literature reviews have been popular. In this explorative paper, such reviews are critically evaluated. A synthesis of findings about the conceptual framework of the relation between lean and sustainability is provided. Based on the findings, we determine the missing topics in the available literature reviews. For example, target value design and takt production have not been gaining attention on reviews focusing on lean and sustainability relationship compared to other lean methods. We present suggestions for future research as well as a conceptual framework for contributions of lean construction on sustainability.

KEYWORDS

Lean construction, sustainability, critical evaluation, target value design.

INTRODUCTION

Sustainable development initiatives have been significantly impacting the building lifecycle phases already for the last three decades (Kibert, 2022). In the same period, another initiative for improving construction, namely lean construction, has been evolving. In the community of sustainable construction, there has not been much interest in lean construction. For example, the thorough book by Kibert (2022) mentions lean construction only twice and does not go into much detail. In the community of lean construction, there has been more interest in sustainability, but still that topic has been somewhat in the periphery.

Sustainability is defined as a long-term strategy where economic growth, social coherence and environmental protection are closely associated and are jointly supporting (European Comission, 2024). Lean contributes to sustainability, for example, through reduced waste and resource consumption, and improved safety (Solaimani & Sedighi, 2020). The idea of a relation between lean construction and sustainability has been raised already in 1998 by Huovila and Koskela. After that, the interest into this topic has increased dramatically (Fig. 1). Examples of current studies exploring the connection between lean construction and sustainabilityare provided by Moradi & Sormunen (2023) and, Le & Nguyen (2024). Thus, the topic is

contemporary and continues to attract attention. The wider topic of the relation between lean and sustainability has experienced a similar pattern of increased popularity (Fig. 1s).

What can we learn from this considerable literature about the possible contribution of lean construction to sustainability? Because this question triggered the publication of many literature reviews (many are systematic), we choose to critically evaluate them. A specific topic is to make a synthesis of findings regarding the conceptual framework of the relation between lean and sustainability. Our method to achieve this is the critical evaluation of systematic literature reviews.

The underlying research has been done in two stages. First, a number of the most cited papers looking at the contributions of lean construction to sustainability were analyzed. Based on findings, a few topics for critical evaluation were determined. In the critical evaluation, when relevant, more papers were taken to be scrutinized. After critically evaluating the available literature, missing topics in the reviews have been determined. Then we discuss the conceptual relationship between lean and sustainability, ways to scale up its sustainability benefits and the methodological limitations of literature reviews.

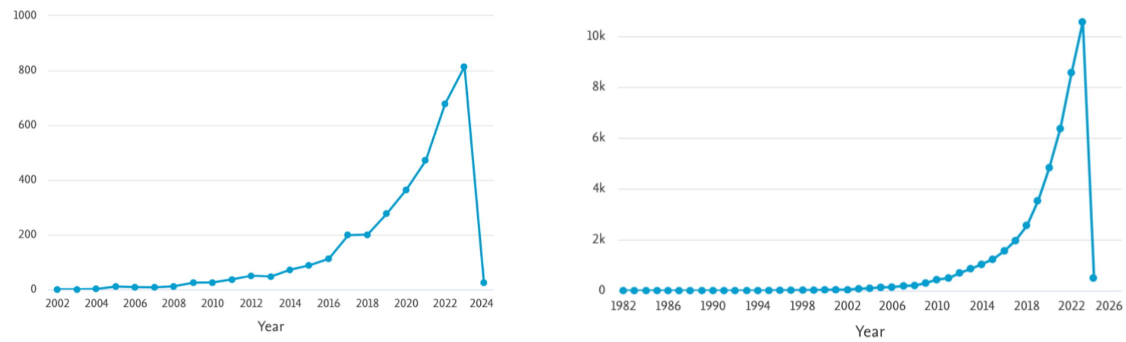

Figure 1. Number of documents found in Scopus database illustrated by year for "lean construction AND sustainability", and the number of documents found in Scopus database illustrated by year for "lean AND sustainability" (taken from scopus.com).

RESULTS OF THE PRELIMINARY STUDY

Among the 20 most cited papers which match the "lean construction AND sustainability" query in Scopus database, a classification of the nature of papers was done. The existing literature mostly consists of literature reviews, and conceptual frameworks to integrate sustainability and lean construction. Examining and trying to use the proposed frameworks, especially with utilizing case studies, as well as implementing more real-life cases would crystallize the findings obtained from the current studies. Among the most-cited 20 papers, the systematic literature reviews (SLR) were selected and more SLRs were added when found relevant. Table 1 summarizes the contents of the selected articles.

Table 1. Synthesis table of the selected articles

Paper	Scope, sample	Key findings
Rosenbaum et al., (2014)	Structural concrete work phase, medical center project in Chile	Reports a value stream mapping (VSM) application case study as a lean approach in a hospital project to improve its environmental and production performance
de Carvalho et al., (2017)	Building sector, 46 papers	The literature review determines synergies between lean thinking and sustainability and provides a conceptual framework depicting their integration
Erdil et al., (2018)	4 cases from healthcare, manufacturing, construction	Proposes a framework to integrate sustainability into improvement initiatives with a DMAIC process
Khodeir & Othman (2018)	Design and construction management, 16 company reports in 11 countries	Provides guidelines for firms through a correlation matrix for applying integrated lean and sustainability principles on design and construction management
Carvajal-Arango et al., (2019)	Construction phase, 117 papers	Reveals that prefabrication, VSM and Kaizen lead to the most sustainability benefits. The social aspect of sustainability is the least addressed by researchers
Solaimani & Sedighi, (2020)	Different construction phases, 118 papers	The current literature focuses more on the economic values than social and environmental aspects, provides a holistic, multi-dimensional framework toward sustainability
Mellado & Lou (2020)	Building lifecycle, 215 papers	Suggests an integrated framework based on theoretical elements. The analysis reveals that the focus is on waste reduction regarding the interactions between BIM and lean
Li et al., (2020)	Structural construction, MEP installation in 6 high-rise projects in China	A conceptual framework of the on-site industrialization method developed; it is suggested to be a cleaner and more sustainable industrial construction method
Dehdasht et al., (2020)	Survey of 23 construction professionals, case study in Malaysia	The empirical study determines the key drivers for successful and sustainable lean construction implementations

A few preliminary observations can be made based on the analysis conducted on the selected 9 papers. The case studies focus only on a specific phase of construction projects such as Rosenbaum et al., (2014) and Li et al., (2020), lacking the whole lifecycle perspective while literature reviews try to have a more comprehensive and holistic perspective such as in De Carvalho et al., (2017), Soleimani and Sedighi (2020), Mellado and Lou (2020) and Khodeir and Othman (2018). While most papers try to focus on all three aspects of sustainability, the social side was found to be under emphasized such as in Erdil et al., (2018) and Carvajal-Arango et al., (2019) and limited to only intra-company interactions in especially case studies such as in Mellado and Lou (2020).

However, when engaging with this small sample of papers, a number of such observations were made which indicate that another tack than systematic literature review as such had to be taken in our research. One such observation was that the share of systematic literature reviews was surprisingly high; what is the reason for this? Another finding was that it is difficult to compare the papers as the results were presented in different ways, i.e., some proposing theoretical frameworks and some listing mere findings. Furthermore, it was spotted that there are three times as many papers on lean and sustainability in comparison to lean construction and sustainability. Probably many conclusions from this more general literature are valid or interesting for construction, too. How to take this wider literature on board? Thus, it was decided to continue towards a critical evaluation of the literature syntheses on lean construction contributions to sustainability.

CRITICAL EVALUATION OF THE METHODOLOGY IN PRIOR REVIEWS

SYSTEMATIC LITERATURE REVIEWS: CRITIQUE

The problems of systematic literature reviews may be visible in many papers. First, a general term, such as lean, does not necessarily catch all activity which could be termed lean but is not. An important example is provided by value engineering/management/methodology (Musa, Pasquire & Hurst, 2016), which exists as an independent method but is also used, at least informally, in lean efforts (especially Target Value Design). Terminology problems exist also on the sustainability side, for example, the terms green and sustainability are used interchangeably. Thus, Garza-Reyes (2015) is using the term green as a synonym for sustainability, more or less.

Second, it might be also argued that SLRs have been partially misunderstood; having a well-documented and disciplined way of finding literature is not always that important; especially when the intention is to have as comprehensive a picture on the phenomenon as possible.

Third, the SLRs have been mostly conducted with a focus on the quantitative aspects such as lists of cited works, classification of papers based on the publisher, or number of hits in databases, rather than considering the qualitative aspects in depth.

Fourth, contextual and historical awareness would be needed. The method of Integrated Project Delivery, now a common lean method, was originally developed in Canada in the framework of sustainability efforts (Kibert, 2022). This is rarely mentioned in the literature reviews.

ABUNDANCE OF LITERATURE REVIEWS

The somewhat strange abundance of literature reviews on lean and sustainability deserves a comment. Taşdemir and Gazo (2018) are among the few authors (of literature reviews on lean/lean construction and sustainability) who have analysed past literature reviews on this topic.They found 35 of them. Consequently, the authors present thinly veiled criticism on this situation:

> *Researchers are expending substantial effort to discover the path to "true sustainability" by re-visiting findings and proposals of their colleagues who approached the situation from various perspectives.*

Aligned with this, these authors proposed that the research must focus on new actionable methods for promoting sustainability:

> *Researchers and professionals should channel their concentration on the development of new methodologies, frameworks, and tools that could help with the achievement of truly sustainable organizations and supply chains compliant with the proposed ultimate objective concept.*

One can ask what the reasons for this inflated interest towards literature reviews on lean and sustainability are. One basic reason of course is that there **is** an ample stock of recent papers to review. Another might be that both topics, lean and sustainability seem extensive and amorphous, and thus a literature review seems a good way to create some basic order and understanding and to start research in this area. Often, when reading a literature review, one gets the impression that the authors have scarce familiarity with either lean or sustainability.

CRITICAL EVALUATION OF SUBSTANTIAL FINDINGS IN PRIOR REVIEWS

SYNTHESES OF FINDINGS

Most review papers present a synthesis of the findings as a conceptual framework. In fact, a considerable variety of conceptual frameworks are presented in the papers:

- Simple diagram showing that lean-green and sustainability tools are contributing to economic growth, environmental integrity and social accountability (Carvajal-Arango et al., 2019)
- Overlap of Lean and Green presented as a Venn diagram (Mellado & Lou, 2020)
- A pie chart for Lean principles and practices for sustainable construction (Solaimani & Sedighi, 2020)
- Conceptual map: Common features of lean and green, moderated by contingencies, lead to triple bottom line results (de Carvalho et al., 2017)
- Causal-loop diagram (Forrester-style) of Lean management in sustainable construction (Solaimani & Sedighi, 2020)
- Concept map of the lean and green literature review showing the different research streams identified (Garza-Reyes, 2015)
- Sustainability additions to DMAIC (Erdil et al., 2018)
- *Affects* and *Effects* between lean and sustainability from the environmental perspective (León & Calvo-Amodio, 2017)

It is evident that the conceptual frameworks presented are largely incommensurable, and this makes it difficult, but not impossible, to compare the results of different papers. Especially, in this case, this problem is alleviated by the fact that the findings are relatively straightforward (as discussed below).

Besides conceptual frameworks, review findings are usefully presented in the form of

- Types of related literature (Garza-Reyes, 2015)
- Questions for future research (Garza-Reyes, 2015)
- Propositions (León & Calvo-Amodio, 2017)

The distinctions between different types of papers will not necessarily surface in conventional systematic literature review, however, these may throw illuminating light on the research activities. Questions for future studies reveal gaps in current knowledge. In turn, propositions contain broad, preliminary conclusions which attract validation in future research.

RELEVANCE OF LEAN AND ITS PRINCIPLES TO SUSTAINABILITY

Lean and lean construction are overwhelmingly found to produce benefits, rather than disbenefits, from the sustainability viewpoint. Thus, Solaimani and Sedighi (2020) write:

> *[…] that almost all the Lean principles and techniques seem to have a positive impact (or a 'reinforcing' effect) on triple bottom line across the construction process.*

Further:

> *…the Lean principles and practices are useful in largely all the facets of construction process, across various phases and stakeholders.*

Carvajal-Arango et al., (2017) similarly claim:

> *Implementation of lean construction practices during the construction project generates positive effects on the three dimensions of sustainability, namely, economic, social, and environmental, in the construction phase."*

It is noteworthy that if (almost) all the Lean principles and techniques contribute to sustainability, one of the central justifications for literature reviews drops out, namely responding to the question whether such a contribution exist. Koskela (2020) has claimed that lean construction is the best available (although constantly evolving), theory-based method to manage construction towards the goals set by the client. If we accept this, then, of course, lean construction should be used in sustainability efforts. Then, it is not an optional or niche approach, and the focus should be turned away from whether it can contribute, and which are the impacts, etc., to how it can best contribute.

ARE THE FINDINGS RELEVANT?

The typical result of a literature review has the following form: Lean method X, when applied in construction project phase Y, brings benefits to environmental (or social or economic) sustainability. The number of lean methods covered is typically large, 50 – 100. As stated above, most lean methods are found to contribute to sustainability. It can be asked whether these results are relevant?

Those results can be considered relevant in a situation where the relation between lean and sustainability is not well known. Such a situation indeed prevailed 5 – 10 years ago. However, today, such results lack academic novelty and industrial relevance.

What, then, would be industrially relevant knowledge? While determining industrial knowledge needs is a fertile research topic as such, we posit that there are two obvious directions for relevant research, both geared towards narrowing the gap between lean and sustainability. First, it is probably worthwhile to augment lean methods so that sustainability aspects are taken into consideration. There are already excellent examples on this, such as sus-VSM, and takt production. The purpose is to extend the lean construction toolbox to be fully able to promote sustainability targets. Second, the current methodologies for sustainable construction could be looked at and the opportunities for added efficiency through lean methods could be suggested.

MISSING TOPICS IN PRIOR REVIEWS

The literature mostly focuses on lean construction and sustainability integration (de Carvalho et al., 2017) as well as lean practices applications such as VSM (Carvajal-Arango et al., 2019; Rosenbaum et al., 2014). Takt production, TVD and value engineering have high potential for sustainability aspects. Based on our review of the previous synthesis literature, the relation and interaction of TVD, value engineering and takt production with sustainability have not gained much attention. Thus, it is deserved to outline possible sustainability connections regarding these three approaches.

TARGET VALUE DESIGN/DELIVERY

Target Value Design (TVD) is an important lean methodology for sustainability because it is possible to achieve all three aspects of sustainability through TVD (Olender & Rosen, 2023; Russel-Smith et al., (2015). Decreasing the environmental impacts of buildings is possible by establishing sustainability targets in the design stage of the building projects. Sustainability values are required to be clearly communicated to obtain a shared view (Novak, 2014). Silveira and Alves (2018) mention that TVD inspired practices such as involving the users and owners in the process, pull design, transparency, and creating a clear vision leads to environmentally friendly buildings. Iteratively utilizing sustainable design targets during the design phase is proven to decrease the environmental impact of buildings throughout the life cycle, especially reducing the energy consumption during the use phase of the buildings (Russel-Smith et al., 2015). Thus, taking sustainability aspects earlier into account in building projects enhances sustainability performance.

TAKT PRODUCTION

Takt production in relation to sustainability aspects has gained limited attention. An exception is provided by Slosharek et al. (2021) who develop a conceptual framework to evaluate environmental performance using the takt production method. Both qualitative and quantitative environmental impacts were examined. Takt production has considerable potential for sustainability. It decreases process waste and shortens lead times (Frandson et al., 2013; Heinonen & Seppänen, 2016), improves control and flow of the construction processes (Lehtovaara, 2023), increases transparency (Kujansuu et al., 2020) and enforces the production schedule (Tetik et al., 2019). Increased transparency and control enable workers to focus on the tasks without losing time due to uncertainty over processes. Takt production also decreases material waste (Chauhan et al., 2021), thus contributing to the environmental performance of construction projects. Moreover, improving the flow of the production reduces the energy consumption on site (Maraqa et al., 2023). However, more case studies are needed to concretize the impacts of takt production in sustainability on construction industry.

VALUE ENGINEERING/MANAGEMENT/METHOD

Value engineering/management has the potential to benefit sustainability in construction by addressing environmental concerns in the early project stages. Yet, its focus has often been predominantly on cost reduction (Zainul Abidin & Pasquire, 2005). Integrating sustainability into the VE/VM job plan is significantly influenced by clients' priorities, often conflicting with sustainability objectives, especially in terms of first cost (Wao et al., 2016). To encourage the consideration of sustainability in proposals, VE/VM facilitators must establish connections between sustainability and other value drivers, align these goals with ongoing activities, and showcase potential monetary benefits to create real incentive (Abidin & Pasquire, 2007). A paradigm shift is necessary from the traditional approach of VE, which assesses cost-worth primarily in terms of initial expenses, towards a performance-worth VE that seeks optimal value for the lowest economic investment throughout the entire building life cycle (Wao et al., 2016). Still, further research is needed to validate proposed methods and explore additional approaches to adapt the VE/VM practice to sustainability.

DISCUSSION

HOW IS LEAN CONCEPTUALLY RELATED TO SUSTAINABILITY?

That lean can contribute to sustainability is thus widely agreed in the literature examined, however this conceptual linkage is variably presented. We contend that little new has been forwarded in comparison to the scheme presented already in 1998 by Huovila and Koskela. Basically:

- Lean and sustainability are aligned by their purpose; specifically, the lean purpose of waste reduction/elimination aligns with the general sustainability purpose of reduction of the use of material resources. In this angle, the contribution of lean to sustainability is broad and diffuse.
- Lean, through its methods for increasing value, is instrumental in achieving sustainability purposes and the contributions of lean to sustainability are related to specific sustainability purposes.

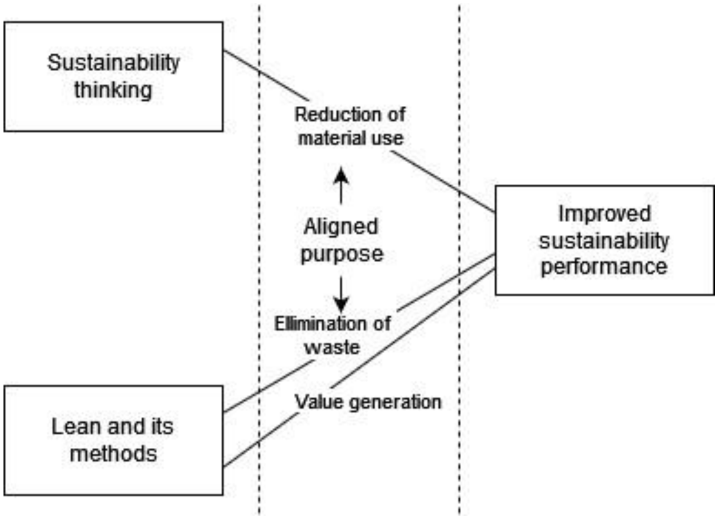

Figure 3. Conceptual relationship between lean and sustainability

SCALING LEAN UP

Lean construction has been thus far utilized in individual projects and mega-projects (Leth et al., 2019; Evans et al., 2021). Scaling lean application beyond single projects to neighbourhoods can scale up the sustainability contributions especially for the social and environmental aspect of sustainability. Moreover, since almost all lean practices seem to contribute to sustainability in construction industry, there is value in incorporating lean principles into policy making to reap more benefits for all sustainability aspects. For instance, it was suggested that efforts for trainings and spreading knowledge in collaboration with policy makers would improve the practical impact of using lean construction practices on regional level through the industry, specifically for small and medium sized enterprises (Tezel et al., 2019). Involving policy makers for adopting lean practices due to their contribution to sustainability would enhance the contribution to sustainability to a larger scale.

To determine the highest sustainability performance and low-cost solutions, algorithmic optimization methods have been developed for urban scale (Kämpf & Robinson, 2009). Several methods exist utilizing design automation, such as computational design for assessing sustainability of design solutions (Shahi et al., 2021). Simulations can be run to assess and determine the design options with higher sustainability performance (Østergård, Jensen & Maagaard, 2022). Utilization of these solutions are limited to specific instances and application in larger scale is needed.

METHODOLOGICAL PROBLEMS

The systematic literature reviews seem to suffer from two specific methodological problems: lack of criticality regarding systematic literature reviews and loose definition of the notion of conceptual framework. Both problems may have been inherited from the weaknesses of more general management literature.

Systematic literature review (SLR), as a methodology, originates in medicine and healthcare, representing settled disciplines with stable terminology. Later, SLR has started to be used in many other disciples, such as management and information technology. However, this methodology has also attracted critical views. For example, Boell and Cecez-Kecmanovic (2014) argue that SLR as a general approach to conducting literature reviews is highly questionable, concealing significant perils and caution that SLR could undermine critical engagement with literature. In the case of lean contributions to sustainability, the risk that seems to have been unnoticed or underestimated by authors is related to the still evolving terminology and scope of both areas, namely lean and sustainability.

Thus, when trying to create a literature overview on a selected topic, it is clearly advisable to critically approach the available methodological choices. Especially, an integrative literature review (Torraco, 2016) offers itself as a methodological alternative where active engagement of the researcher with the literature is supported. As discussed above, there is considerable looseness regarding the notion of conceptual frameworks. Van de Veldt (2020) states that there is evidently no clear-cut definition and application model for conceptual frameworks. This lack of unity has clearly created the impractical manifold of different understandings of conceptual frameworks in the SLR papers reviewed. It would be advisable to consult some of the few guidebooks covering how to define and prepare a conceptual framework (for instance, Ravitch & Riggany, 2016).

CONCLUSIONS

The interest into lean/sustainability topic has grown exponentially. The many literature reviews have been instrumental in showing that the general question whether lean can contribute to sustainability has already been solved: it definitely can. It must be concluded now that research efforts should be directed elsewhere. Now, it is time to focus on relevant topics and target actionable outcomes. We propose especially the following for further research:

- Critical case studies on implementation of lean/sustainability programmes in companies and projects.
- Augmenting existing lean methods with sustainability add-ons.
- Using value generation methods for sustainability purposes (especially Target value Design and Value engineering).
- Developing lean support for methods aligned with sustainability but usually not covered from the lean viewpoint, especially Circular design and production.
- Possible contributions of lean towards developing renovation policies at national and urban level must be explored.
- Identifying how lean can best contribute to sustainability.

The limitation of this study is that the analysis covered only some of the most cited “sustainability and lean construction” related papers.

ACKNOWLEDGMENTS

The authors would like to thank Professor XXXX for reviewing and commenting on the intermediate paper version. COUPLING DEMAND RESPONSE AND PDCA TO LEAN BUILDING OPERATIONS: A PROOF-OF-CONCEPT

Abdulmhseen Shaibh[1] and Kristen Parrish[2]

ABSTRACT

The Plan-Do-Check-Act (PDCA) approach allows stakeholders to identify potential changes and measure their impacts on a small scale prior to making a larger investment in such a change. One change that could be evaluated through PDCA is the installation or implementation of energy efficiency measures (EEMs). Building owners may be reticent to implement energy efficiency measures (EEMs) without fully understanding their costs and benefits. A PDCA approach coupled with demand response (DR) – whereby building owners reduce electricity consumption during periods of peak electricity demand in exchange for incentive payments – allows owners to assess EEM performance in a pilot study prior to making a larger investment in the EEM. Various EEMs can help building owners and operators shift their energy consumption to off-peak hours to earn DR incentives, e.g., reducing lighting power via controls, precooling a building prior to the peak hours. This paper documents how one building owner, Arizona State University, leveraged PDCA to identify DR strategies for a campus building and then used results from the DR event to identify permanent EEMs for the building. This case study serves as a proof of concept that indicates that a PDCA approach that leverages DR implementation supports identification of EEMs for permanent installation.

KEYWORDS

PDCA, energy management, lean operations.

INTRODUCTION

This paper crosswalks the lean concept of PDCA with energy management. This paper explores, through case study, how participation in a Demand Response (DR) program can serve as a first run study and inform future energy management efforts in a building.

PLAN DO CHECK ACT (PDCA)

Shewhart (1939) and Deming (1986; 2000) discuss the plan-do-check-act (PDCA) cycle that supports continuous process improvement. In the buildings industry, this cycle can be implemented in support of lean design, construction, and operations processes. Implementation of PDCA for improving the building design and construction process is well-documented (e.g., (Hassan 2006; Sobek II and Smalley 2008; Parrish et al. 2009; Zhichun and Yuejun 2011). In the operations phase, research documents how PDCA can be used to improve work processes, not necessarily to improve energy performance (Smith and Hawkins 2004; Ishikawa et al. 2012). Literature also documents how PDCA can be used to reduce building energy consumption (ISO

[1] Graduate Student, School of Sustainable Engineering and the Built Environment, Arizona State University, ashaibh@asu.edu

[2] Associate Professor, School of Sustainable Engineering and the Built Environment, Arizona State University, Kristen.Parrish@asu.edu

2011; Parrish et al. 2012; Parrish and Whelton 2013). In this paper, we explore how participation in DR programs serves as a first run of PDCA for energy management, through the application of PDCA on a case study project.

DEMAND RESPONSE

Demand Response (DR) is generally defined as a measure to decrease energy demand in a building to alleviate the strain on the grid during peak hours (FERC 2019). DR programs involve a contractual commitment for demand reduction and agree to an incentive payment for said reduction (Motegi et al. 2007). Utility providers often activate their DR programs, or call a DR event, to manage demand based on forecasted energy prices and weather (Henríquez et al. 2018; Abapour et al. 2020; Gerke et al. 2020; Liu et al. 2022). DR supports reliability in that it can reduce demand, in turn reducing the need for brownouts or blackouts within the utility service territory. Weather forecasting allows for reasonable prediction of the demand and also allows utilities to determine the value of demand reduction (i.e., if DR incentive payments [$/kWh avoided] to customers are the most cost-effective means of reducing demand on a given day). Customers opt in or out of a DR event and then reduce their demand in accordance with the commitments outlined in the agreement with the utility. In some cases, customers implement DR strategies in house, while in other cases, an outside contractor will implement building controls to achieve load reduction during an event. For example, a building owner precool a building to reduce the need for air conditioning, and therefore, reduce energy demand, during a DR event. To do so, an owern may set their thermostats to temperatures below comfort levels prior to the period of peak demand, and then allow the temperature to “float” to a temperature at the high end of the comfortable range during the DR event (e.g., (Yin et al. 2010; Sun et al. 2012; Arababadi and Parrish 2016; Arababadi et al. 2017; Arababadi and Parrish 2017). According to Gerke et al., approximately 9% of commercial buildings in the United States participated in DR programs as of 2018 (2020).

RESEARCH OBJECTIVE

The authors’ objective is to develop a PDCA process that leverages DR to support assessment of DR strategies for permanent EEM installation. This is paper documents such a process and presents results from an implementation at Arizona State University (ASU).

LITERATURE REVIEW

Literature (Assimakopoulos et al. 2020; Moran et al. 2020; Qu et al. 2020; Rau et al. 2020; Uidhir et al. 2020; Coyne and Denny 2021; Li et al. 2021) supports that addressing energy management holistically, e.g., through implementation of a certified energy management system (ISO 2011; Parrish and Whelton 2013), is a best practice. Indeed, Moran et al. (2020) discuss the benefits of coupling building envelope retrofits with heating system retrofits. This allows building owners to reduce their heating demand (through increasing insulation in the envelope) and install a smaller heating system when they replace their original heating system with a heat pump. Similarly, Li et al. (2021) discuss the ability to reduce the air conditioning load in a school building when daylighting is used in lieu of artificial lighting – the need for air conditioning decreases due to the fact that the daylighting does not generate as much heat as the artificial light. Finally, Qu et al. (2020) discuss the energy and carbon reduction benefits of coupling passive and active energy efficiency measures with renewable energy production in Norwegian apartment buildings; their work illustrates that a holistic approach yields 66% more savings than an approach that only installs passive efficiency measures.

While a holistic approach that leverages the synergies between building systems is effective, this approach may represent too significant of an investment for many building owners or operators, who may not be able to justify the capital expense of EEM implementation without knowing how the EEM(s) will perform in their particular building and in their particular climate. PDCA allows building owners and operators to first test EEM performance prior to investing in the EEM installation throughout the building, using the DR event as the "Do" phase of the PDCA cycle and evaluating EEM performance through the "Check" phase prior to implementing the EEM in the building in the "Act" phase. Given that DR participation involves an incentive payment, leveraging PDCA to identify DR (and subsequent EEM) strategies and their performance represents a lower-cost opportunity for owners to reduce energy consumption.

METHODS

This research began by documenting how the PDCA process could be used to identify DR strategies, as well as for evaluating their implementation. To assess whether this proposed process would be feasible, the authors conducted an interview with the energy manager responsible for implementing DR at Arizona State University to determine whether a PDCA approach could be used to identify and evaluate DR opportunities on campus. Finally, the authors present energy data from DR implementation to serve as a proof of concept and illustrate the efficacy of using PDCA to identify DR strategies and evaluate whether these strategies show promise for EEM implementation throughout the building(s).

DEVELOPMENT OF PDCA APPROACH THAT LEVERAGES DR

The authors began with the PDCA process and added DR implementation to it as a proposed process for identifying EEMs, where DR implementation serves as a first run study.

INTERVIEW PROTOCOL

The authors developed the interview protocol (Table 1) to assess the feasibility of implementing the proposed PDCA process at ASU. As such, the questions focus on whether or not, and how, ASU currently completes PDCA to identify DR strategies (questions 1 and 2). The authors also sought to understand how ASU's DR participation impacted the selection of EEMs for campus buildings (questions 3 and 4). The authors conducted the interview in November 2022 with the energy manager responsible for DR implementation on ASU's Polytechnic campus; he has over 20 years of experience in facilities and energy management in higher education. Given that this paper documents a proof-of-concept for a single building owner, the authors interviewed the one energy manager that makes decisions about DR and EEM implementation on the campus. The authors did not code the interview responses, as three of the four questions had straightforward responses. Question 2 asked the energy manager to share a process, this was documented by the authors as the interviewee described it.

Table 1: Interview Protocol

Question	Response Options
How much load do you commit to DR?	kW committed
How do you currently determine strategies to implement to achieve load shift or shed during a DR event?	Process for selecting DR strategies
Do results of DR implementation help to identify potential investments in long-term energy efficiency measures?	Yes or No
Do you consider permanently implementing the successful DR strategies for sustained energy savings?	Yes or No

RESULTS

PROPOSED PDCA APPROACH FOR SELECTING EEMS BASED ON DR RESULTS

Figure 1 documents the proposed PDCA approach for selecting EEMs based on DR implementation.

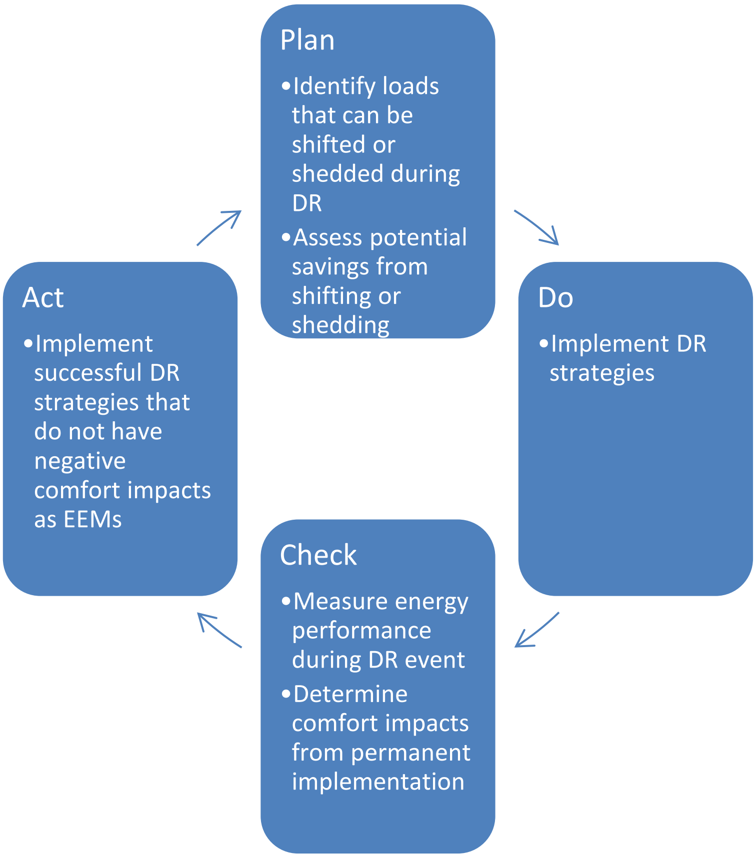

Figure 1: Proposed PDCA Approach for Selecting EEMs based on DR Implementation

The Plan phase requires that energy managers consider the energy consumption and demand of their building(s) and identify loads that may be able to be shifted, e.g., through precooling a facility (Yin et al. 2010) or shed, e.g., turning lights off, during a DR event. The Plan phase also requires that the energy manager estimate the potential reduction in demand to ensure that the DR strategies being considered provide sufficient demand reduction to secure the incentive payment associated with the DR program. During this phase, the energy manager(s) may generate several alternative DR strategies that satisfy the demand reduction commitment; if this is the case, the authors suggest using Choosing by Advantages, or CBA (Suhr 1999; Parrish and Tommelein 2009; Arroyo et al. 2015), to select the most advantageous set of DR measures to implement during a DR event.

The Do phase is when energy managers implement DR strategies, either via building controls or through manually adjusting building operations.

The Check phase requires energy managers review the impact of the DR strategies on demand reduction and energy consumption. At this stage, energy managers also need to evaluate whether DR strategies led to increased complaints from building occupants about thermal or visual comfort. For example, did occupants complain that the building was too hot or too cold during the DR event?

Finally, the Act phase requires energy managers determine which DR strategies have most promise for permanent implementation as EEMs. Research documents several examples where building owners and operators have implemented DR strategies on a permanent basis to realize those energy savings consistently (Mathieu et al. 2013; Arababadi et al. 2017).

INTERVIEW RESULTS

Following the implementation of DR strategies in the summer of 2022, the authors interviewed the energy manager at ASU to determine whether the proposed process (Figure 1) would be a viable approach for ASU to identify EEMs. The energy manager indicated that a formalized process for permanently implementing successful DR strategies would be helpful. Further, they indicated that, to date, the review of DR implementation was generally done to determine what DR strategies would be repeated in the future without considering which DR strategies may be strong candidates for permanent installation as EEMs.

PROOF OF CONCEPT: ASU ENERGY DATA REVIEW

Plan

In 2020, ASU participated in a DR program for the first time. To prepare, the campus energy manager reviewed energy consumption across campus in the campus' energy information system (Figure 2) and took the following approach during the "Plan" phase:

1. Review the metered electrical usage data for campus buildings and identify anything with at least one 15-minute demand interval larger than 500kW, i.e., the campus' largest loads.
2. Look for buildings that had at least one 15-minute demand interval larger than 150kW, i.e., medium-sized loads.
3. Examine the total kW and kWh of the buildings with "large" demand (those from Step 1) or "medium" demand (those from Step 2) over the course of the previous fiscal year to create a list of candidates based on the percentage of demand intervals that were over the targets listed above.
4. Work with the campus Facilities Management team to discuss recommendations and refine the list based on "boots on the ground" knowledge.
5. Finalize the list of buildings for participation in the DR program.

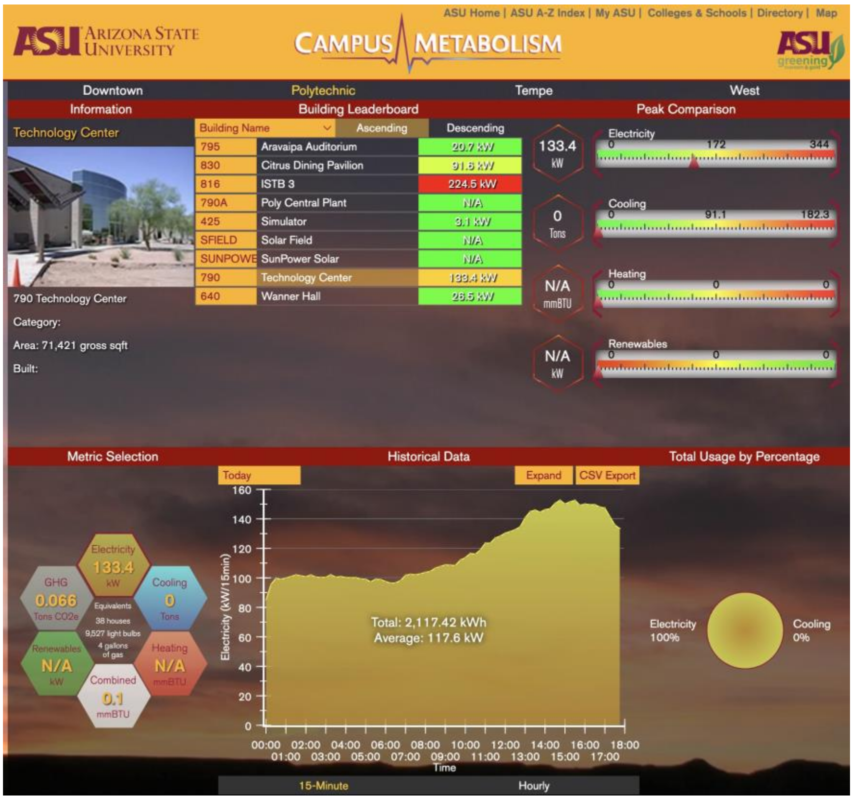

Figure 2: ASU's Energy Information System, Campus Metabolism, helps to identify buildings that may be good candidates for DR (screenshot from K. Parrish on 17 April 2024)

Once the list of buildings was finalized, the campus energy management team worked to identify specific measures to take in each of the facilities to reduce demand. They considered "typical" DR strategies like dimming lights and changing temperature setpoints (Gerke et al. 2020). Unfortunately, due to the operating requirements for classrooms and offices on campus (ASU 2024), these 'traditional' DR strategies were not feasible for ASU. Thus, the Facilities Management and Energy Management teams worked to identify customized DR strategies, including changing fan operations, increasing the temperature in the book storage facility, and dimming the lights at the Fitness Centre. The variables considered when evaluating potential DR strategies were demand reduction, in kW, where more reduction was preferred, and human comfort, where more comfort was also preferred. The energy management team avoided any DR strategies that violated ASU's operating requirements for classrooms and offices on campus, which limited their number of feasible DR strategies such that leveraging multi-criteria decision-making was not required. In fact, the energy management team initially struggled to develop feasible DR strategies that would yield the demand reductions necessary to earn the incentive payments.

Do

During the summer of 2020, ASU implemented the strategies outlined above in fifteen (15) buildings measured in eleven (11) meters and saved ~620kW per DR event.

Check

Following the implementation in the summer of 2020, the campus energy and facilities teams reviewed their success in the DR program to determine how they could increase their DR commitment in the summer of 2021, thereby increasing their incentive payment. They determined that several DR strategies implemented negatively impacted occupant comfort. For example, when classroom temperatures were set to 25.5C (the high end of the allowable operating temperature range in classrooms) during the summer at 15:00 (the start of the DR event), the classrooms quickly became uncomfortable as students released sensible and latent heat when they entered the classroom warm from an outdoor walk (outdoor temperatures in Arizona are approximately 40C during DR events). Thus, strategies that increased classroom temperatures were determined unfit for future DR seasons.

The energy and facilities teams also identified DR strategies that showed promise for future implementation, including shutting down the air handler to the book storage facility, which had sufficient thermal mass to maintain safe temperatures throughout the three-hour DR event, even when the air conditioning to the facility was shut off. Similarly, the light dimming in unoccupied areas of the Student Fitness Centre showed promise for future implementation.

Act

In 2020, this phase consisted of documenting the DR strategies that could be implemented in future DR events, in 2021 and thereafter. Indeed, reflecting on the successes and challenges associated with DR implementation provided valuable insights for future DR enrolment. By 2023, ASU had increased its DR commitment to over 1MW, and was able to secure increasing incentive payments each year.

In 2022, the authors presented the Energy Manager with the proposed PDCA approach for selecting EEMs. At this point, the conversation following DR implementation expanded to include an agenda item for identifying DR strategies that could be permanently implemented, i.e., those strategies that could serve as EEMs rather than simply DR strategies. The energy and facilities teams highlighted that the automated light dimming in unoccupied areas of the gym was a strategy they would like to implement year-round. The teams also identified other DR strategies they would consider as EEMs, like precooling classrooms and automated light dimming across campus. Importantly, the teams also highlighted those DR strategies that could not be permanently implemented, like shutting down the air handler that served the book storage facility.

DISCUSSION AND RECOMMENDATIONS

The authors discuss herein how the PDCA approach described above can support identification of potential EEMs, thereby reducing the investment cost and minimizing the risk that the EEM does not yield the expected energy savings.

EVALUATING ALTERNATIVE DR STRATEGIES IN THE "PLAN" PHASE

At ASU, the set of feasible DR strategies was limited due to the campus' strict operating guidelines for classrooms and offices. The operating guidelines made light dimming and temperature setpoint adjustments greater than 2.25C infeasible. However, other commercial building owners and operators may find that they have a large set of feasible DR strategies that they can evaluate during the "Plan" phase. When owners and operators are faced with large sets of feasible alternatives, the authors suggest using CBA to select from among alternatives. As at ASU, the factors to consider when evaluating potential DR strategies would be demand reduction, in kW, where more reduction is preferred, and human comfort, where more comfort is also preferred. Building owners and operators will also need to explicitly state 'must' criteria for CBA, e.g., "The building must provide light and conditioned air that supports productive work throughout the DR event" that ensure that DR strategies do not render the building uncomfortable or impossible to work in.

LEVERAGING THE ACT PHASE TO IDENTIFY EEMS

While ASU did not refer to their DR commitment process as a PDCA effort, their process was essentially a PDCA process, even prior to the authors' engagement with the energy management and facilities management teams. Indeed, the teams had a standardized process for planning, doing, and checking. The teams used that knowledge to act on future DR commitments. The authors' engagement in this process added a new dimension to the "Act" phase, whereby the teams identified DR strategies that could be implemented permanently alongside those that showed promise for future years' DR events. While this change was relatively small for ASU, the entire process (Figure 1) may be unfamiliar to other building owners or operators. Thus, the authors recommend that all building owners and operators consider implementing PDCA to identify DR strategies and then explicitly identify the subset of DR strategies that show promise as EEMs during the Act phase.

CONTINUOUSLY IMPROVE THE "CHECK" PHASE TO SUPPORT EEM SELECTION

EEMs perform differently in different environments. For example, at ASU, light dimming yielded savings in the Fitness Centre, but not in the classrooms due to differing occupancy patterns. The "check" phase of the proposed PDCA process offers an opportunity to align evaluation criteria to evolving goals. For instance, building owners and operators may want to add criteria about consistency of energy savings during DR events to their reviews; this way, prior to investing in a permanent installation, owners and operators can be assured they will achieve the savings they expect. (Typically, energy savings for EEMs are determined via spreadsheet calculation for technology changes like ballast replacements or via energy modelling for, e.g., new building control sequences.)

Building owners and operators may consider a set-based design approach (e.g., (Ward et al. 1995; Sobek et al. 1999; Rekuc 2005; Parrish et al. 2007; Parrish et al. 2008a; Parrish et al. 2008b; Parrish 2009) when selecting potential EEMs based on DR implementation. Set-based design allows project teams to consider multiple design options longer than would be typical in a point-based design scenario. For EEMs selection from the proposed PDCA process, set-based design may involve considering certain DR strategies for multiple years before deciding to implement those strategies as EEMs. This allows project teams to consider various DR strategies and explore their fitness for the building at hand and ensure that these EEMs make financial sense for the building owner and operator, given that EEMs cannot be used for collecting DR incentives once they are part of daily operations. (This is because once installed, EEMs will reduce the baseline energy demand, and DR requires reductions from **actual** demand, rather than from a baseline demand in a prior year.) Once DR strategies that could transition into EEMs are understood, project teams can make data-driven decisions about which to install permanently using Choosing By Advantages (e.g., (Suhr 1999; Parrish and Tommelein 2009; Arroyo et al. 2015). Energy demand reductions can be expressed as a 'must' or a 'want' criterion for either DR implementation or EEM installation at the owner's discretion.

BROADER CONTEXT: EXISTING BUILDING RETROFITS

This paper explores the transition from DR strategy to EEM, and how a PDCA approach could support this transition. As decarbonization and energy efficiency policies begin to be implemented (e.g., (State of California 2018; New York City 2019), building owners may need to retrofit their facilities. A PDCA approach is demonstrated to support building energy retrofits (ISO 2011; Parrish and Whelton 2013), and this paper builds on these existing processes by highlighting how DR can be used to earn money while testing potential EEMs in actual facilities.

CONCLUSIONS

This paper explored, though case study, how a PDCA approach can be implemented alongside participation in a DR program to support selection of EEMs for building energy retrofits. The authors proposed a PDCA approach and illustrated its potential via a proof-of-concept at Arizona State University. This proposed process allows building owners and operators to understand how potential EEMs will perform in their building(s) prior to investing in EEM installation. The authors discuss how PDCA, and lean tools like set-based design and Choosing By Advantages, can help building owners and operators reduce energy demand and consumption, in turn supporting decarbonization of the building sector.

The authors note that the sample size for this work is small, so this paper only illustrates a possible process for transitioning DR strategies into EEMs. Future work may present the proposed process to other higher education institutions, and other DR program participants, to evaluate the feasibility and efficacy of the proposed process in a new context. Such efforts would be welcome in future research by the IGLC community.

INSIGHTS ON SUSTAINABILITY IN INDUSTRIALIZED CONSTRUCTION IN EUROPE AND THE UNITED STATES

Giulia Scagliotti[1], Jerker Lessing[2] and Martin Fischer[3]

ABSTRACT

Embracing lean philosophy, which emphasizes waste reduction and resource efficiency, is a pre-condition to improving the environmental impact of a building but is not sufficient to produce a sustainable building. To increase the environmental sustainability of their products, industrialized construction (IC) companies need to understand the constraints of the location where they operate, and best practices applied by leading IC companies. To delve into constraints and best practices, we interviewed sustainability leaders of six IC companies at the forefront of sustainability practices in Europe and the United States. The purpose of each interview was to highlight the challenges and opportunities caused by external factors that companies are experiencing, and the advancements that other companies could replicate. Based on comparative analysis, our results show stricter sustainability regulations and a collaborative stakeholders' network with similar sustainability goals in Europe compared to the US. These factors seem to favor 1) a careful evaluation of tradeoffs when considering technical solutions; 2) the adoption of disassembly, adaptability, and circularity principles; 3) the development of new business models; and 4) companies developing new rating systems to capture their advanced product sustainability. Our results can inform lagging IC companies to adopt the most advanced sustainability practices.

Lean Construction, Lean and Green, Sustainability, Industrialized Construction, Off-site Construction

INTRODUCTION

Improving the efficiency of construction processes and minimizing waste, as embraced by lean philosophy, has been widely recognized for its economic benefits (Poppendieck, 2011). Beyond the economic advantages of reducing waste, some studies highlight the positive relationship between lean philosophy and environmental sustainability (Solaimani & Sedighi, 2020; Johnsen & Drevland, 2016; Galeazzo et al., 2014; Carneiro et al., 2012). Specifically, the lean philosophy holds promise in reducing the environmental impact of construction (Degani & Cardoso, 2002; Ghosh et al., 2014). In addition to following lean philosophy, the application of industrialized construction (IC) methods generates several environmental benefits over the entire building life cycle if compared to conventional construction methods (Kedir & Hall, 2021;

[3] Professor, Civil and Environmental Engineering Department, Stanford University, Stanford, USA, fischer@stanford.edu.

Sotorrío Ortega et al., 2023). Companies that adopt industrialized construction methods design their buildings using a product-oriented approach based on predefined solutions structured in platforms, which are used project after project and are essential for continuous improvement and systematic management of knowledge. IC companies can be more efficient in material estimation and acquisition (Banawi & Bilec, 2014), can control the source of energy to power their factories and their means of transportation (Quale et al., 2012), and achieve sophisticated buildings with consistent quality that support energy-efficient solutions (Podder et al., 2020).

However, achieving the environmental sustainability of a building involves multifaceted considerations beyond applying lean principles and industrialized construction methods (Tasdemir & Gazo, 2018). These additional considerations depend on the location in which each company operates and include, for example, the possibility of innovating product design, regulatory compliance, and stakeholders' engagement to create a more environmentally sustainable building product. With new IC companies emerging in different countries around the world (Pullen et al., 2019; Wuni et al., 2022; Malmgren, 2014) and the increasing pressure to create sustainable products (Dutil et al., 2011), it becomes critical to identify how external factors differ depending on the country and what their impacts are on the sustainability of a product. The goal is to raise awareness among companies and policymakers about regulations and stakeholder's engagement that foster sustainability in different countries and highlight the best sustainability practices adopted by leading IC companies.

This work shows initial findings of the external factors relevant to the advancements of sustainability practices and the impact they have on final building products and the structure of IC companies. We hope this work enables emerging or lagging IC companies to replicate the identified sustainability approaches and new policies that will favor sustainability practices.

METHODOLOGY

In this work, we chose a multiple case study method to enable a broad understanding of the sustainability approaches taken by six different industrialized construction companies in the US and Europe. Over four months in 2023, we researched all six companies and interviewed them to collect information and data. Our data collection followed the same pattern and included the following three steps:

- Analyze the company's public stance on sustainability as expressed on the company's website.
- Conduct a 1-hour semi-structured video interview with the sustainability manager or CEO of each company.
- Review additional documents shared directly by the company (e.g., pilot study results and projects in collaboration with universities).

COMPANY SELECTION

We chose six companies based on the following four primary criteria:

- Categorized as working with industrialized construction methods according to Lessing's framework for industrialized construction (Lessing, 2015).
- Produce wood based modular residential buildings.
- Companies are based in different countries, including Europe and the US, and at different maturity stages, including well-established and recently started companies.
- Companies are at the forefront of sustainability practices in their country.

We selected six IC companies: four in Europe, specifically two in Sweden, one based both in Denmark and the Netherlands, one in Switzerland, and two in the US, one in Pennsylvania and one in California. Among the companies selected in Europe, two were newly established startups (Group A), and the other two were well-established Swedish IC companies (Group B). The two companies selected in the US (Group C) were established about ten years ago. Each company is briefly described in the following section, and all companies' names have been anonymized.

Group A: European IC Startups

Company A1 is a non-traditional real estate startup established in 2021 with operations in Denmark and the Netherlands and a team of about 25 people. Their main goal is developing urban communities that are inclusive, livable, and sustainable. They recently partnered with a construction company to build their first residential project, which has a minimal carbon footprint. They are using modular timber construction, have developed material passports, and are applying circular economy principles.

Company A2 is a Swiss startup established in 2021 that designs and develops reusable and re-adaptable buildings for real estate owners and investors and has a team of about 10 people. The company aims to help cities become more dynamic and fulfill changing users' needs through their future-proof circular building products. Their products are manufactured as a standardized modular kit of components and designed to maintain value over multiple life cycles since they can be quickly readapted or relocated to minimize their environmental impact.

Group B: Swedish Family-owned IC Companies

Company B1 is a well-established family-owned Swedish wood company with over 2,000 employees. They act as suppliers of wood materials and components but also as manufacturers and developers of wood volumetric modular multifamily houses. Environmental consciousness is one of their core values. They source raw materials from forests and replace the trees removed with new trees. They build climate-smart and energy-efficient homes with the goal of creating sustainable communities.

Company B2 is a well-established family-owned Swedish company with about 150 employees that builds wood volumetric modular multi-story dwellings. About 70% of their production is offered to external customers, whereas the remaining 30% is used by their own real estate company. They consider sustainability from an ecological, social, and economic perspective, looking at the entire life cycle, and have the goal of developing long-lasting communities.

Group C: United States IC Companies

Company C1 is a vertically integrated wood volumetric modular construction company established nearly ten years ago with factories in Pennsylvania and California and about 300 employees. It is focused on providing multifamily affordable housing that is resilient and environmentally friendly and invests in sustainability on many fronts, from using clean energy to power factories to reusing and recycling materials.

Company C2 is a California-based company that produces wood panelized components that can be assembled into volumetric modules. Launched in 2016, the company has about 100 employees. Their goal is addressing the housing shortage in California while supporting people and the planet. They have had carbon-neutral operations since 2020 and are working to further reduce emissions throughout their value chain, reducing waste, and selecting sustainable materials.

Data Collection and Execution

We developed interview questions about sustainability to better understand the company's motivation, technical advancements, challenges, future vision and whether they use Whole Building Life Cycle Assessment (WBLCA) on their products, track their direct and indirect environmental impact, and collaborate with their stakeholders to improve the product sustainability. We also asked additional questions about circularity, e.g., whether they apply circular principles in their product development or plan to include them in the future. The interviews were 1-hour long, semi-structured, and via video with the sustainability manager or CEO of each company. They were conducted by the same interviewer who asked open-ended questions that encouraged a conversation. Once the information was collected, our analysis followed a qualitative approach using qualitative coding to systematically categorize the excerpts to find themes and patterns and qualitative synthesis to pool data and draw conclusions. The study revealed similarities and differences between the six companies, which are reported in the next section.

RESULTS AND DISCUSSION

All the IC companies in this study see lean principles and industrialized construction methods as advantageous to achieving a more sustainable building product. In this section, we show how, in the last decade, the IC companies interviewed similarly developed buildings that can support energy-efficient solutions and are now shifting towards lowering the embodied carbon emissions of their building products. We also illustrate that finding sustainable technical solutions is not their main challenge. Conversely, cost, industry resistance to change, and regulation play a greater role in hindering their ability to make their final product more sustainable. These factors are common in both Europe and US based companies though in some countries in Europe, the establishment of a network of stakeholders interested in improving sustainability and stricter building regulations that promote sustainability seem to have accelerated the continuous improvement of more sustainable products. Indeed, only the European companies interviewed evaluate tradeoffs between operational and embodied carbon impact; consider products' disassembly, adaptability, and circularity while developing their technical solutions; and look beyond typically adopted business models and rating systems.

SUSTAINABLE TECHNICAL SYSTEMS

All companies interviewed have focused on achieving energy efficiency for both their factories and the final products they offer. All companies' factories are partially or totally powered by solar energy, reducing the environmental impact of the production and assembly phases of the building life cycle. In the last decade, all the companies put substantial effort into reducing operational carbon and developing an energy-efficient building product. They offer buildings powered by electricity generated by solar energy or geothermal energy, heat pumps, and wastewater recycling systems to treat and reuse water. These options are available to customers and could be easily implemented in the final building product. After focusing on energy efficiency and achieving products that generate low operational carbon during their lives, all the IC companies interviewed are now switching their interests towards reducing the embodied carbon of their products. These companies are now experimenting and testing new bio-based materials to substitute materials commonly used in construction and lower the initial carbon footprint of their building product. For example, company B1 is trying to replace mineral wool with cellulose to insulate buildings and company C1 is testing bamboo as a replacement for lumber. Given the high embodied carbon of traditional concrete foundations, companies are exploring alternatives such as using cross laminated timber (CLT) or steel for the foundations and bedframes of their buildings. This work of lowering embodied carbon emissions is quite challenging since the companies must triangulate their sustainability goals with financial constraints and current regulations.

BARRIERS AND CHALLENGES TO IMPROVING SUSTAINABILITY

Although innovating technical systems can present challenges, none of the interviewed companies explicitly mentioned technical issues among the main barriers and challenges they face while improving the sustainability of their products. Conversely, all the interviewed companies identified financial issues, their industry's resistance to change, and regulation and compliance requirements among the challenges preventing the wide adoption of the most sustainable solutions, as summarized below.

High Initial Cost

The IC companies interviewed shared that the most sustainable option, on average, is not yet cost effective and that bio-based choices on the market are more expensive. This represents a barrier for them to improving the sustainability of the baseline product. Although they see a growing interest in sustainability, only a few customers choose the most sustainable option available since they need to pay a premium for it. In addition, progress in building sustainability requires increasing investment by IC companies. However, it is hard for them to prioritize sustainability when the building sector is struggling, and they find it challenging to be profitable and guarantee fast product delivery.

Resistance to Change

The IC companies interviewed note a general resistance to change from their stakeholders. For example, suppliers would need to change how they produce materials and use cleaner energy instead, customers would need to change their approach and consider the entire building life cycle and opt for the most sustainable option. The adoption of sustainable options is still quite limited and to expand it, we need a change of mindset that prioritizes sustainability as a factor that matters when evaluating a final product.

Regulation

The IC companies interviewed believe regulatory infrastructure is quite fixed and difficult to change. It is often challenging for them to bring new sustainable products into the market because of compliance issues. It is difficult to meet fire, acoustic, and structural requirements with new sustainable products. Doing so would require them to do more testing and larger investments of money and time in mockups. In the US, building codes are fragmented because it is a large country with different needs (seismic, hurricane, etc.). Therefore, it is difficult to broadly adopt certain technologies and methodologies.

DIFFERENCES: EUROPE VS UNITED STATES

All European and American IC companies face similar challenges and barriers to achieving a more sustainable product. However, different regulations and business norms create differences in how European and American companies address these challenges and barriers. In this section, we will present two external factors that favor sustainability advancements in Europe: the presence of stricter regulation and a stronger network of stakeholders to collaborate with. We highlight factors that are indicative of the progress of the European IC companies interviewed that can be taken as models of how to achieve further sustainability: evaluating tradeoffs between operational and embodied carbon emissions when choosing a technical solution; considering disassembly, adaptability, and circularity of the final product; and developing new business models and sustainability rating systems.

Regulations and Life Cycle Assessment Requirements

External factors that exist in Europe and not in the United States yet are regulations that mandate reporting the environmental impact of a company (Directive 2022/2464) and a maximum carbon footprint for projects (One Click LCA, 2022). In the European Union (EU), in addition to reporting Scope 1 emissions, which are direct emissions that occur from sources controlled or owned by a company, and Scope 2 emissions, which are indirect emissions from the generation of purchased electricity consumed by the company, companies must report Scope 3 emissions, which are indirect emissions from upstream and downstream activities in the value chain (Bhatia & Ranganathan, 2004). As of 2024, large companies are reporting Scope 1, 2, and 3 emissions, whereas small and medium-sized companies will start in 2026 (Directive 2022/2464). This also means that IC companies in the EU will soon need to report the environmental impact of purchased materials; upstream and downstream transportation and distribution; waste generated; processing, use, and end-of-life treatment of their sold products (in this case buildings); employee commuting and business travels; etc. In the US, only public companies need to disclose greenhouse gas emissions. Starting in 2026 (Scope 1 and 2) and 2027 (Scope 3), the State of California (S.B. 253, 2023) will mandate disclosure of GHG emissions to public and private companies, but only if operating with over 1$ billion in revenue.

Besides the mandated reporting of companies' environmental impact, in recent years, several North European countries such as Denmark, Finland, France, Netherlands, and Sweden, put in place mandatory regulations for Life Cycle Assessments (LCA) of all newly constructed buildings including residential, whereas in the UK, Germany, and Switzerland, similar requirements exist for public buildings only (One Click LCA, 2022). Regulations setting limit values for the carbon footprint of buildings will be further revised in the upcoming years to progressively reduce the environmental impact of new buildings. The European IC companies interviewed are in the countries with the most advanced mandatory legislation to lower the carbon footprint of new buildings. The life cycle stages and building components and systems required to be included in the calculation of the LCA differ depending on the regulations in each country, and details are reported in Table 1 (One Click LCA, 2022). In the United States, no requirements around the carbon footprint of buildings are yet enforced, although there are programs to support green buildings and initial work to require embodied carbon considerations in new construction and major renovation projects. With CALGreen, starting in July 2024, the State of California will require LCA calculation for certain projects, but this does not apply to residential buildings (California Building Standards Commission, 2010).

Table 1: Mandatory regulations for the LCA of newly constructed buildings in each of the country where the companies interviewed are based (One Click LCA, 2022).

Country	Buildings	Year	Limit value	Future plan	Stage LCA	Components required for LCA
Denmark	All new buildings >1000m^2	2023	Yes	All new buildings in 2025	A1 to A5, B4, B6, C3, C4, D	All except for MEP, furniture, and appliances.
Netherlands	Offices >100m^2 and residential	2018	Yes	To be determined	All except for B6 and B7	All except for external work, furniture, and appliances.
Sweden	All new buildings >100m^2	2022	Not yet	Mandatory limit value in 2025	A1 to A5	All except for floor and wall finishes, external work, MEP, furniture, and appliances.
United States (California)	Office and schools	2024	Not yet	To be determined	To be determined	To be determined

Although limit values enforced today are not yet strict, the European IC companies interviewed envision their path ahead and the need to become more sustainable year after year to comply with more stringent rules in the future. They have already started the journey to lower the carbon footprint of their final product. On the other side, the American IC companies interviewed are still in an experimental phase, since their initiatives to lower the carbon footprint of their product are taken on a voluntary basis and not because of pressing regulations or the belief that rules will be stricter in the years to come. They have assessed the building life cycle environmental impact only on specific projects or when the client asks for it, whereas the European IC companies interviewed do it routinely because of regulations that enforce it.

Network of Stakeholders with Similar Sustainability Goals

Besides the presence of a different regulatory infrastructure, we found that the network around IC companies in Europe is more supportive of and interested in sustainability than the network present in the United States. Swedish IC companies collaborate with stakeholders on sustainability throughout the entire product value chain (Fig. 1). Customers, municipalities, architects and engineers, facility managers, construction companies, suppliers, subcontractors, and waste management companies share their perspectives and tackle sustainability from different angles, enriching the discussion and proposing solutions to technical and commercial issues. In addition, academia is involved in the discussions within this large network of stakeholders and acts as an independent and impartial entity. Even financial institutions and insurance companies are part of this large network. The former offers advantageous loans to customers that invest in a more sustainable project, creating a virtuous loop; the latter is working to provide insurance for buildings made of reused materials, increasing the expansion opportunities of this nascent market.

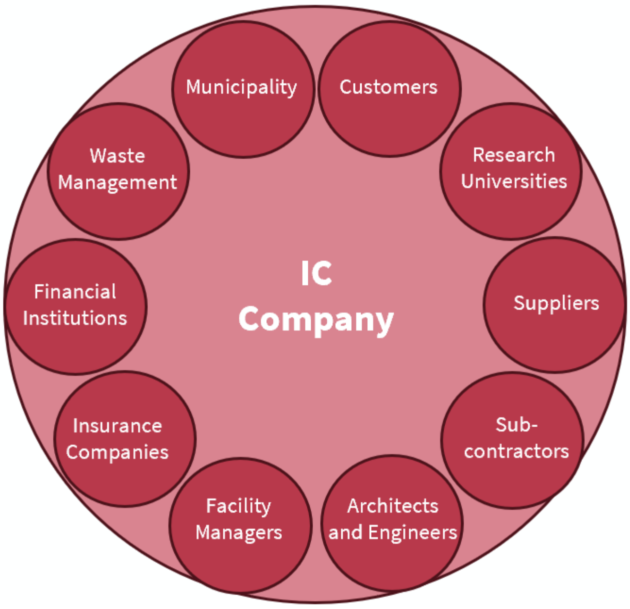

Figure 1: Network of stakeholders in Europe supporting sustainability efforts throughout the product value chain.

Like Swedish companies, company A1 based in the Netherlands and Denmark has created an online platform to engage the entire industry in the sustainability and circularity journey. This platform offers a place to connect many stakeholders but also serves educational purposes. European IC companies interviewed have a collaborative approach and work on advanced topics related to the sustainability of their product even with direct competitors, understanding that the journey towards achieving sustainability cannot be undertaken alone.

Although willing to cooperate with stakeholders, the companies interviewed in the US find challenges on the supplier and developer sides. For example, company C1 aspires to have a consortium of all stakeholders in the market with a third party, whether academia or government, to get more attention from all the players in the construction market on sustainability topics and foster the circularity of their final product. Unfortunately, such a consortium has not yet been established, and today it is rare for individual suppliers to be willing to address IC companies' concerns around embodied carbon emissions and modify or adapt their production to satisfy the request of only one IC company. Startups offering more sustainable materials are emerging, but often can't satisfy the large demands required to complete a building project. For example, company C2 identified a potential supplier of an innovative sustainable material that could be used in buildings. However, the supplier did not have the capacity to supply enough material for their entire building project. In addition, developers typically flip the project after a short period of time, which results, with rare exceptions, in no investment in durable materials and no consideration of the usage and end-of-life stages of the project. Moreover, customers generally don't choose the most sustainable option among the many available on the market because of the high initial cost of the most sustainable option and the lack of financial incentives.

Evaluation of Tradeoffs of Technical Solutions

From the interviews conducted, a factor that is indicative of the advancements in European IC companies is the evaluation of tradeoffs when opting for one technical solution or another, including variables such as embodied carbon, operational carbon, the source of energy for building operations, cost, and estimated building life in the decision-making process. Our analysis indicates that two practices enable evaluation tradeoffs: the habit of analyzing the entire life cycle of a building, partially due to the new regulations in force, and the developer's interest in keeping the building in their portfolio for a long time instead of flipping the project soon after construction. We report some examples that companies shared with us below.

1. **Wall Thickness**

   About 15 years ago, Swedish company B1 developed a new wall system that was much thicker than the typical one with the belief that it could be a more sustainable solution in the future and reduce operational carbon emissions. However, this solution was expensive and could not reduce the energy consumption enough to balance the high cost and higher carbon footprint generated by the extra layers. Therefore, the company did not adopt the thicker wall and concluded that increasing the thickness of the wall to achieve better performance during building use does not always represent the best sustainable option when we also account for the embodied carbon and the life cycle costs.

2. **Envelope Material**

   Swedish company B1 offers multi-story residential buildings with wood-cladding façades. This type of façade needs to be repainted every 12-15 years for maintenance. Company B1's clients prefer a brick or glass façade to reduce maintenance costs and time. However, a brick or glass façade would cost much more than a wood façade and have a higher carbon footprint. Repainting the wood façade every 12-15 years is cheaper and results in a lower carbon footprint for the envelope. Although offering the option of a brick or glass façade, company B1 recommends clients to choose a wood-cladding façade if sustainability is among their priorities.

3. **Triple Glazing**

   Company A1 explored to what extent they need to insulate a building. The building code forced them to use triple glazing to have a better insulated building and decrease the operational energy use. However, after carrying out an analysis, the company discovered that the production of the glass for the extra panel would require more energy than the energy saved by having triple glazing in the building. Therefore, the savings in operational carbon would not balance the higher embodied carbon of the extra glass panel and the company recognized triple glazing is counterproductive in the project examined.

These examples reveal that a company needs to make decisions looking beyond the initial cost, and considering the entire building life cycle with a clear understanding of all the factors that play a role in the decision. The most sustainable option sometimes is not the most obvious or the one desired by other stakeholders.

Consideration of Disassembly, Adaptability, and Circularity

Another difference that emerges when comparing companies, not only between Europe and the United States but also considering their maturity stage, is the attention to disassembly, adaptability, and circularity.

European IC startups (Group A) are placing these future-proof concepts at the core of their business. For example, company A1 offers adaptable buildings with large apartment units that can be subdivided into smaller units in the future, if necessary, as the trend indicates that families are decreasing in size on average. They also design their buildings for disassembly and embed circularity into the product from the beginning with the idea of reusing their buildings at the highest possible value once they reach their end of life. Similarly, company A2 designs its products to be reusable, embedding specific technical characteristics that make the building circular, enabling disassembly and re-assembly an infinite number of times. Their buildings are also adaptable and flexible: the floor area or number of floors can be increased, and elevator shafts can be added.

Although companies B1 and B2 are well established and much more mature than companies A1 and A2, they are considering future-proof concepts as well, evaluating how to modify their products step by step to increase the disassembly, adaptability, and circularity potential. In collaboration with a Swedish university, company B2 performed a WBLCA on one of their projects to understand whether and how a more flexible and adaptable product could reduce their life cycle environmental impact. During a workshop organized by the same university, Group B companies developed their disassembly instruction manuals as a first step towards increasing the disassembly potential of their buildings. They recognize the challenges of disassembly in practice, as the guidelines would only apply if the assembly was carried out following precise instructions, i.e., without adding additional nails or not-tracked elements to the product during construction. The wood volumetric modules can be disassembled because each module is attached to another through dry connections only. Conversely, disassembling the module itself would be challenging, especially because the mechanical, electrical, and plumping (MEP) system is not designed to be easily disassembled and glue and adhesive are used within each module. Moreover, the market value of an assembled module would be higher than the total value of each detached single component within the module. For now, companies B1 and B2 have difficulties imagining how to solve the commercial aspects of disassembly and reuse, but both foresee the importance of circularity in the future.

Group C companies do not have disassembly, adaptability, and circularity on their roadmap or among their priorities. However, company C1 considers product sustainability during design, using a scorecard system to assess the end-of-life treatment of the materials chosen: whether they are reusable, recyclable, intended for landfill, or hazardous. Company C2 is focused on increasing the quality of assembly to be able to easily replace components in the future.

Beyond Commonly Used Business Models

IC companies have different business models than traditional construction companies (Lessing & Brege, 2018). These business models are structured based on continuity and are more suitable to improving the sustainability of their product and achieving full product circularity (Berglund-Brown et al., 2022). Startups that design their business models based on industrialized construction principles have beneficial conditions to fully embrace circularity principles and translate them into practice. For instance, company A1 invested a lot of time in developing its business model. As developers, they intend to keep each building in their portfolio throughout their life to maximize the benefits of including disassembly, adaptability, and circularity. They have developed material passports since they see their buildings as a temporary deposit of materials. In this way, materials will have a retained value and investing in the sustainability and circularity of the product becomes much more attractive from an economic standpoint. Although a company changing their business model requires much effort and risk taking, especially by well-established companies, mature companies in Europe are starting to think about new business models to enable circularity. For example, company B2 envisions keeping material ownership of their buildings during their lives as a good opportunity to better control the end-of-life phase of the building and reuse its components and materials.

Beyond Commonly Used Sustainability Rating Systems

In recent years, many rating systems to assess the environmental impact of buildings have been established (Bernardi et al., 2017). Commonly available rating systems, such as the Deutsche Gesellschaft für Nachhaltiges Bauen (DGNB) and the Leadership in Energy and Environmental Design (LEED), provide a framework with precise criteria for assessing different categories of a building's environmental impact, such as materials, water efficiency, and indoor environmental quality. The IC companies interviewed use these systems to benchmark their products and gain certification, which they use to market their products to customers. However, the different companies had different opinions of the commonly used sustainability rating systems and how useful they are, mostly depending on the level of maturity of the company. Group A startups criticized the commonly available rating systems because they find them too limited to capture the entire value of their innovative product. Company A1 shared that companies using these systems can achieve very good ratings with traditional approaches and materials without necessarily rethinking their methods and without creating a truly more sustainable and circular building. As an example, company A1 shared that a project with 11 $kgCO_2/m^2$/year, which is not a difficult target to achieve, can earn a good rating such as a gold certification using DGNB, whereas they are already offering their first product at 5.3 $kgCO_2/m^2$/year, but can't reference a commonly used sustainability rating system that fully captures the additional value of substantially reducing the environmental impact of their product. Therefore, company A1 started to explore methods to capture this additional value, by developing their own tracking and rating system. Company A2 made similar criticisms of the commonly available rating systems, explaining that they also developed their own tool to capture the benefits of their product spanning multiple building life cycles and show the environmental impacts and costs since there were none available. Conversely, Group B and Group C companies still measure the sustainability of their product relying on commonly used rating systems, showing that their product can reach good ratings such as Gold certification with DGNB and LEED and find that currently sufficient.

CONCLUSION

Our goal was to raise awareness among companies and policymakers by analyzing the context and the best sustainability practices adopted by leading IC companies in the US and Europe. Based on our analysis of six IC companies at the forefront of sustainability practices, we conclude that the presence of strict regulations that enforce sustainability and the collaborative approach of stakeholders play important roles in developing an environmentally sustainable final product, as demonstrated by the European IC companies analyzed. They show more advancements in sustainability than US companies because they tend to 1) evaluate tradeoffs when considering technical solutions; 2) consider disassembly, adaptability, and circularity principles; 3) adopt new business models; and 4) develop new sustainability rating systems.

CARBON EMISSIONS OF CONSTRUCTION OPERATIONS IN A COLD CLIMATE

Ergo Pikas[1], Rauno Lõhmus[2], Lauri Koskela[3], Müge Tetik[4] and Kädi-Riin Vendel[5]

TABSTRACT

This study focuses on the energy use of construction operations and explores the associated greenhouse gas (GHG) emissions. The case study methodology is used in this exploratory investigation to assess the energy consumption and GHG of eight construction projects in Estonia. The findings highlight the need to account for heating and illumination emissions, underlining the importance of including construction phase emissions in building lifecycle carbon assessments. No strong correlation between building size and energy consumption is found, but there seems to be a connection between project duration, use function, and emissions. It suggests that addressing the embodied carbon of construction operations, particularly when heating is required, is crucial for reducing the overall carbon footprint. This study develops and invites the lean community to establish a baseline for construction operations' energy use and related GHG emissions. A baseline is needed to facilitate the continuous improvement of construction processes from the sustainability viewpoint.

KEYWORDS

Sustainable construction, energy consumption of construction operations, greenhouse gas emissions, winter heating and illumination.

INTRODUCTION

The need to address the effects of climate change has highlighted the urgency of reducing carbon emissions globally (European Commission 2020a). The United Nations Environment Programme estimated that the greenhouse gases (GHG) from construction materials and operational energy emissions of buildings constituted 37% of worldwide emissions (United Nations Environment Programme 2022). Addressing the construction sector and the built environment emissions is deemed a key strategy for decarbonizing the European economy by 2050 (European Commission 2020b).

However, the construction and built environment status report published in 2022 revealed that the gap between actual and target performance is growing (United Nations Environment Programme 2022). The building and construction industry is behind in its efforts to meet the 2050 decarbonization target, which is the key objective of the Paris Agreement (Paris Agreement 2015). It is becoming clear that incremental changes are insufficient; substantial

strategic and structural reforms are necessary to face the escalating challenge of realizing a net-zero-carbon built environment (Council of the European Union 2023; Kibert 2022).

Thus far, the focus has been on reducing operational emissions from buildings, but emissions from construction operations remain underexplored (Tang et al. 2013; Weigert et al. 2022). The whole life cycle approach is needed (Kibert 2022). All embodied carbon emissions associated with construction products, transportation, and processes must be tackled to avoid undermining the carbon reductions achieved from energy efficiency and saving measures. The construction phase is expected to become increasingly significant as operational carbon emissions decrease due to enhanced energy efficiency in both new and existing buildings (Bahramian and Yetilmezsoy 2020). However, the baseline for construction operations' energy use and related GHG emissions is not well established.

This research addresses the greenhouse gas emissions associated with construction site processes and activities, with a specific focus on the energy use of construction operations during winter and summer seasons. The case study methodology is used for this exploratory investigation (Yin 2018). Data from eight construction projects of an Estonian building company were gathered, analyzed, and compared. Finally, ideas to reduce the emissions of construction operations are discussed.

RESEARCH BACKGROUND

Lean construction focuses on improving construction processes by eliminating or reducing waste (Koskela 2020), including among others unnecessary consumption of material and energy resources. Systematic literature reviews (e.g., (Moradi and Sormunen 2023)) and detailed studies (Osorio-Gómez et al. 2020; Wandahl et al. 2021) on synergies between lean construction (and lean in general) and sustainability have been conducted.

Osorio-Gómez et al. (2020) evaluated the influence of Lean Construction techniques on the environmental footprint of construction projects through a comparative case study of two projects, one employing Lean principles and the other using traditional methods. The study highlighted an 18–24% reduction in categories like acidification, ecotoxicity, eutrophication, global warming, and ozone depletion for the Lean Construction project. Wandahl et al. (2021) explored the impact of Construction Labour Productivity (CLP) improvements by adopting Lean tools and methods on the EU's renovation wave's energy efficiency targets. The study demonstrated a link between construction process improvement and reduced energy consumption.

While these studies present evidence of the direct relationship between Lean process improvement and environmental impact, most building codes and regulations tend to address operational energy carbon for heating, cooling, and lighting the indoor environment but do not account sufficiently for embodied carbon (United Nations Environment Programme 2022). The studies that address embodied carbon tend to be limited to the extraction, manufacturing, and transportation of construction products, emphasizing the design phase, including selection, methods, and tools (Joseph and Mustaffa 2021), and neglecting construction operations related emissions (Weigert et al. 2022).

A recent comprehensive systematic literature review on carbon assessment of construction operations identified the following themes as significant when considering construction-phase carbon emissions: (1) time and country trends, (2) carbon assessment methods, (3) construction stage-related carbon factors, (4) construction equipment classification, and (5) recommendations for reducing carbon emissions (Joseph and Mustaffa 2021).

Three research focus periods for carbon assessment were identified (Joseph and Mustaffa 2021). In the first period before 2010, there were a few studies focused on isolated aspects of buildings and carbon-related emissions. In the second period between 2010 and 2015, different Life Cycle Assessment (LCA) methods surfaced, including additional aspects and factors of carbon emissions. However, the scope and system boundaries for assessment varied significantly (Tang et al. 2013). That is, no standardized method was used for the LCA (Mastrucci et al. 2017). In the third period after 2015, standardized LCA methods and phases based on the ISO14040 began to be used (Arvanitoyannis 2008), including the different types of construction projects, phases, and construction methods (e.g., prefabricated versus on-site construction) (Bahramian and Yetilmezsoy 2020). This phase also incorporated modeling, simulation, and sensitivity analysis (Joseph and Mustaffa 2021).

The same studies revealed that the carbon emissions of construction operations are typically assessed using (1) LCA, (2) optimization method (3), simulation, and (4) on-site observations (Joseph and Mustaffa 2021). The two main approaches for LCA include the process-based LCA (the bottom-up approach) and input-output-based (I-O) LCA (the top-down approach) (Mastrucci et al. 2017). The selection of the LCA method depended on the main aim of the research (Mastrucci et al. 2017). Optimization methods focus on maximizing or minimizing the chosen function or parameter, such as the carbon impact of construction equipment or selecting the most appropriate construction method (Avetisyan et al. 2012; Szamocki et al. 2019). In simulation-based studies, discrete event simulation, for example, has been used to model and analyze construction operations (Liu et al. 2021). On-site field studies/observations are used to collect emissions data and to study carbon emissions management practices (Joseph and Mustaffa 2021). Also, remote monitoring to measure construction equipment emissions has become more broadly used.

The embodied construction phase-related assessment of different sources of carbon emissions typically includes (1) materials (including also auxiliary products), (2) transportation to and on the site, (3) machinery and equipment, (4) site accommodation and welfare, (5) building operation or energy use, and (6) construction waste (Joseph and Mustaffa 2021). Most studies have focused on construction machinery and equipment, materials, and transportation (Joseph and Mustaffa 2021), which comprise the largest proportion of embodied carbon (Weigert et al. 2022). Regarding construction equipment, the following are typically addressed (Joseph and Mustaffa 2021): (1) lifting and transportation machinery, (2) earthwork machinery, (3) concrete and mortar machinery, (4) processing machinery, (5) piling machinery, (6) welding machinery, (7) road construction machinery, and (8) pump machinery.

The LCA calculation in Europe follows the standard EN 15978:2011 (Van Gulck et al. 2022). In the A5 “construction phase”, all carbon emission sources need to be considered. In addition to the carbon sources listed above, the standard includes also heating and cooling of temporary spaces and the building during construction activities (e.g., during cast-in-place concrete or interior works), auxiliary works, materials and products, re-work, and water requirements on the construction site. However, these aspects are often neglected in the LCA studies (Joseph and Mustaffa 2021) or are addressed to a limited extent.

Estonia is situated in a cold climate zone, which means that construction operations carried out in the winter require heating and additional illumination. However, studies addressing the impact of construction operations that need heating and illumination during the winter period could not be found. This gap will be addressed in this study.

RESEARCH METHOD

This exploratory case study research aims to determine the carbon footprint of the energy consumption of construction site operations. The EN 15978:2011 standard was followed and the 2022 CO_2 emissions data for Estonian electricity production was used for all sites to ensure a common basis for comparison.

INITIAL DATA AND LCA CALCULATIONS

While EN 15978:2011 for LCA helps to classify life cycle phases and to categorize carbon emission sources, there is no detailed method for scoping (system boundary) and calculating the carbon footprint of construction operations. This has been addressed differently in various studies utilizing LCA calculations. In this study, for comparing different construction projects, the energy consumption of construction operations was converted into carbon footprint equivalent (kgCO_2e), and the total carbon footprint of energy consumption was divided by building net area (kgCO_2e/m^2).

For calculating the electricity consumption and district heating carbon emissions, the GHG factor 0.636 (kgCO_2e /kWh) for 2022 from the main Estonian utility company (Elering 2024) and the Estonian Environmental Research Centre (Eesti Keskkonnauuringute Keskus 2024) were used. For district heating, the district heating factor 0.200 (kgCO_2e/kWh) from the Estonian Environmental Research Centre (Eesti Keskkonnauuringute Keskus 2024) was used. The carbon emissions for the combustion of fuels for heat energy are calculated by multiplying the burned fuel volume with the fuel factor (kgCO_2e/kWh). For the comparison of electricity and heating energy intensity of different construction sites, the diesel and natural gas/propane energy density factors were also used. For the natural gas/propane, the average of the two was used in calculations. The initial values for calculations are summarized in Table 1.

Table 1. Carbon emission factors for the Estonian energy carriers in 2022 (Elering 2024; European Environment Agency 2023).

Energy Carriers/Sources	CO_2e Factor	Energy Density
Electricity (Estonia)	0.636 (kgCO_2/kWh)	
Diesel	0.250 (kgCO_2/kWh)	10.74 (kWh/l)
Natural Gas/Propane (Gas)	0.140 (kgCO_2e/kWh)	15.4/13.8 (kWh/kg) (average 14.6)
District Heating (DH)	0.200 (kgCO_2e/kWh)	

SELECTED CASE PROJECTS

The study included construction projects conducted between 2015 and 2023 where energy consumed during construction activities was available. Data on eight construction projects of an Estonian private sector building company were collected. All investigated sites were managed by different site teams and were organized according to ISO 9001, 14001, and 45001 requirements.

The electricity consumption data were obtained in two ways, including (1) monthly electricity meter data, and (2) the recordings of the initial and final meter readings. Meter data on electricity consumption came from the meters installed by the general contractor. For heating in the winter period, the fuel or district heating supplied by the general contractor was considered. Consumption data for the fuel and district heating energy were collected from invoices. Fuels consumed by subcontractors for construction machinery and equipment were excluded from the study.

Table 2 summarizes the main information about construction projects, including the project number (PR), building use function, net area of the building, construction start and end months and years, the duration of the construction project, and consumption of electricity, fuels, and district heating. On projects PR 1 – 3, no heating during construction was used. Different sources for heating were used on PR 4-8. For diesel and natural gas/propane, two energy consumption values are presented, including the natural unit and the equivalent in kWh. Most observed projects were industrial or office buildings, including the residential and warehouse buildings as exceptions. The building sites under investigation varied in size, ranging from 500 to 9000 m², and in construction durations ranging from 4 to 19 months.

Table 2. Information on selected construction sites (* the intended use is not available).

PR	Building Use Function	Net Area (m²)	Construction Duration: Start and End	Electricity (kWh)	Diesel (liters/kWh)	Gas (kg)	District Heating (kWh)
PR 1	Industrial Building; Office Building	1430	6 Months: July 2022 -January 2023	7278			
PR 2	Other Industrial Building; Office Building	500	4 Months: July – November 2022	3896			
PR 3	Other Warehouse Building	2170	10 Months: September 2021 – July 2022	25016			
PR 4	Other Industrial Building	1900	5 Months: October 2022 – March 2023	29894	2842/ 30535

PR 6	Other Industrial Building	1380	7 Months: December 2020 – June 2021	25721		731/ 10673	
PR 7	Residential Building with Three or More Apartments; Office Building	8150	19 Months: September 2020 – April 2022	161845		11551/ 168645	
PR 8	*	1280	15 Months: November 2020 – February 2022	29434			56280

RESULTS

In this section, the energy consumption and carbon emissions for construction operations with and without heating are presented. In the last subsection, the impact of future decarbonization scenarios for electricity and district heating production on construction operations is discussed.

ENERGY CONSUMPTION IN CONSTRUCTION PROJECTS

Table 3 depicts the electricity and heating energy consumption for the studied projects in kWh. The average electricity consumption for projects without heating was 12 063 (kWh), for projects with heating 76 092 (kWh), and across both categories 52 081 (kWh). The average heating energy consumption was 104 799 (kWh). When normalized by net area, the electricity across all sites was 14.56 (kWh/m^2) and heating 23.42 (kWh/m^2), which are 38% and 62% of the total energy consumption, respectively. The overall average per net area for projects without heating is 8.14 (kWh/m^2) and for projects with electricity and heating 41.84 (kWh/m^2).

The best-fit linear regression trendlines were calculated for the building size and energy consumption and between project duration and energy consumption. The trendline y=0.0024x+21.495 for the building size and energy consumption is characterized by a small slope (0.0024) and an R^2 value of 0.1429. This suggests a weak positive correlation, indicating a limited predictive capacity of the linear model. In contrast, the trendline y=2.6177x+4.6584 for the project duration and energy consumption exhibits a steeper slope (2.6177) with a moderate R^2 value of 0.4162, reflecting a stronger relationship and a moderate explanatory power. That is, while the connection between building size and energy consumption is minimal, there is a moderate relationship between project duration and energy consumption. The reason could be that projects with longer duration typically have higher construction scope and likely involve works in the winter season that may need heating. This requires further validation.

Projects with heating have a larger share of electricity consumption per net area. This could be because of the building use functions (see Table 2). Projects PR 4-8 with heating are buildings with residential and office functions, while projects PR 1-3 are mainly industrial. When compared to industrial buildings, residential and office buildings have a higher share of construction operations, mainly interior works, which typically require more electrical machinery, equipment, and heating.

Table 3. Energy consumption on construction projects by energy type.

PR	Net Area (m^2)	Duration (months)	Electricity (kWh)	Heating (kWh)	Electricity (kWh/m^2)	Heating (kWh/m^2)	Average per Category (kWh/m^2)
PR 1	1430	6	7278		5.09		
PR 2	500	4	3896		7.79		8.14
PR 3	2170	10	25016		11.53		
PR 4	1900	5	29894	30535	15.73	16.07	
PR 5	9000	9	133566	257861	14.84	28.65	
PR 6	1380	7	25721	10673	18.64	7.73	41.84
PR 7	8150	19	161845	168645	19.86	20.69	
PR 8	1280	15	29434	56280	23.00	43.97	
AVERAGE	3226	9	52081	104799	14.56	23.42	24.99

CO_2 EMISSIONS IN CONSTRUCTION PROJECTS

Table 4 depicts GHG emissions of consumed energy during construction operations for the studied projects. The average GHG emissions for projects without heating was 7 672 ($kgCO_2e$) and for projects with heating 26 646 ($kgCO_2e$). The average electricity emissions across all projects was 33 124 ($kgCO_2e$) and the average heating emissions across all fuels was 19 953 ($kgCO_2e$), which make up 62% and 38% of carbon emissions respectively. The largest share of carbon emissions comes from electricity consumption in construction projects. This high carbon footprint from electricity consumption is because electricity is the primary energy source on construction sites and Estonian electricity has high carbon intensity when compared to the other EU countries (European Environment Agency 2023). Results are in alignment with the carbon emission factors for the Estonian energy carriers in Table 1.

Table 4. CO_2 emissions of construction sites with and without heating.

PR	Net Area (m^2)	Electricity ($kgCO_2e$)	Diesel ($kgCO_2e$)	Natural Gas/Propane ($kgCO_2e$)	District Heating ($kgCO_2e$)	Total Emissions ($kgCO_2e$)	Average Emissions ($kgCO_2e$)	Average Emissions ($kgCO_2e/m^2$)
PR 1	1430	4629				4629		3.2
PR 2	500	2478				2478	7672.3	5.0
PR 3	2170	15910				15910		7.3
PR 4	1900	19013	7634			26646		14.0
PR 5	9000	84948	64465			149413		16.6
PR 6	1380	16359		1494		17853	26646.3	13.0
PR 7	8150	102933		23610		126544		15.5
PR 8	1280	18720			11256	29976		23.4
AVERAGE	3226	33124	36049	12552	11256	53076	17159	16.5

Figure 1 presents the GHG footprint per net area. The emissions are divided into two categories, including electricity (blue bars) and heating (red bars) emissions (CO_2e kg/m^2). Total carbon emissions per net area range from 3.2 to 23.4 ($kgCO_2e/m^2$), with an average of 5.2 ($kgCO_2e/m^2$) for projects without heating and 16.5 ($kgCO_2e/m^2$) for project with heating. The values for electricity emissions vary across different projects, ranging from as low as 3.2 ($kgCO_2e/m^2$) to as high as 14.6 ($kgCO_2e/m^2$). The heating emissions are lower than the electricity emissions, with values from 1.1 to 8.8 ($kgCO_2e/m^2$).

The chart also depicts an "AVERAGE" column for construction sites with electricity only and sites with electricity in addition to heating emissions, showing the average electricity and heating emissions per net area. For sites with electricity only, the average electricity emissions are 5.2 ($kgCO_2e/m^2$). For sites with electricity and heating consumption, the average electricity emissions are 11.7 ($kgCO_2e/m^2$) and the average for heating emissions is 4.8 ($kgCO_2e/m^2$). Again, these results seem to align with the observations above that building projects with longer duration and use functions related to more interior works tend to have much higher energy consumption. Also, electricity usage is responsible for most of the emissions on construction projects when compared to heating, with electricity making up 66% and heating 34% of the total construction operation emissions.

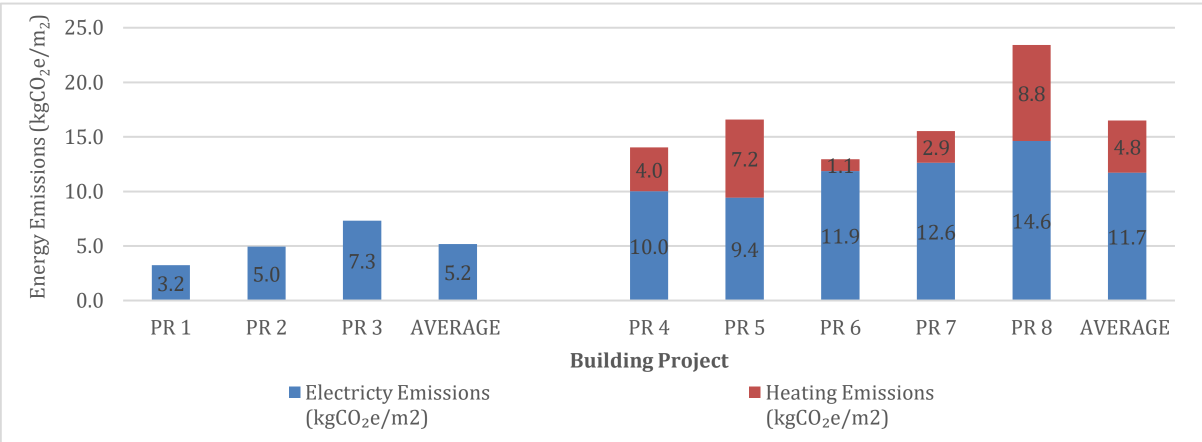

Figure 1. Electricity and heating energy consumption emissions per net area.

IMPACT OF ENERGY DECARBONIZATION ON CONSTRUCTION OPERATIONS

The European energy sector is expected to be the main contributor to the decarbonization of the European economy by 2050 (European Commission 2020a). The Estonian Ministry of Climate has developed a decarbonization strategy for the Estonian energy sector and the Estonian Environmental Research Centre (Eesti Keskkonnauuringute Keskus 2024) has estimated the projected GHG factors for electricity and district heating. In Table 5, the electricity and district heating emission factors are presented for the period from 2024 until 2050 with higher frequency in the early years.

Table 5. Future decarbonization scenarios for the construction operations.

Description	2024	2025	2026	2027	2028	2029	2030	2035	2040	2045	2050
Electricity Emission Factors (kgCO2e/kWh)	0.56	0.55	0.47	0.39	0.31	0.22	0.14	0.06	0.05	0.00	0.00
District Heating Emission Factors (kgCO2e/kWh)	0.10	0.09	0.09	0.08	0.08	0.07	0.07	0.06	0.05	0.04	0.04

Based on the new emission factors, the average electricity 14.56 (kWh/m^2) and heating 23.42 (kWh/m^2) emissions per net area, and average net building area 3226 (m^2) of the projects studied above, three future scenarios for carbon emissions of construction operations were generated: (1) electricity emissions + heating emissions with 25% share of district heating; (2) electricity emissions + heating emissions with 50% share of district heating; and (3) electricity emissions + heating emissions with 75% share of district heating. Different proportions of district heating are used to visualize the potential impact of heating sites with the combustion of fossil fuels versus district heating.

Figure 2 presents the three scenarios for construction operations with electricity emissions and the district heating share of 25%, 50%, and 75% of total heating. Currently, the electricity carbon emissions dominate. This is because Estonian electricity production has one of the highest carbon intensities in Europe (European Environment Agency 2023). However, if the national electricity decarbonization strategy goes as planned, the heating carbon emissions of construction operations become equal to electricity emissions around 2030 and continue to dominate afterward. From thereon, the combustion of fossil fuels becomes dominant, influencing the embodied carbon of buildings. For example, by 2050, in the scenario of a construction site, where half of the heating comes from the combustion of fossil fuels and the other half from district heating, the heating emission with 50% district heating is expected to be around 2.76 (kgCO_2e/m^2), while electricity emissions will be near carbon neutral.

This shows that when electricity production and operational carbon are reduced due to the increased renewable energy sources and energy efficiency of new and existing buildings (Bahramian and Yetilmezsoy 2020), the construction phase is expected to start playing a more important role. The execution of construction operations requiring heating and illumination in the winter season could become a major factor influencing the embodied carbon of buildings in the Estonian cold climate.

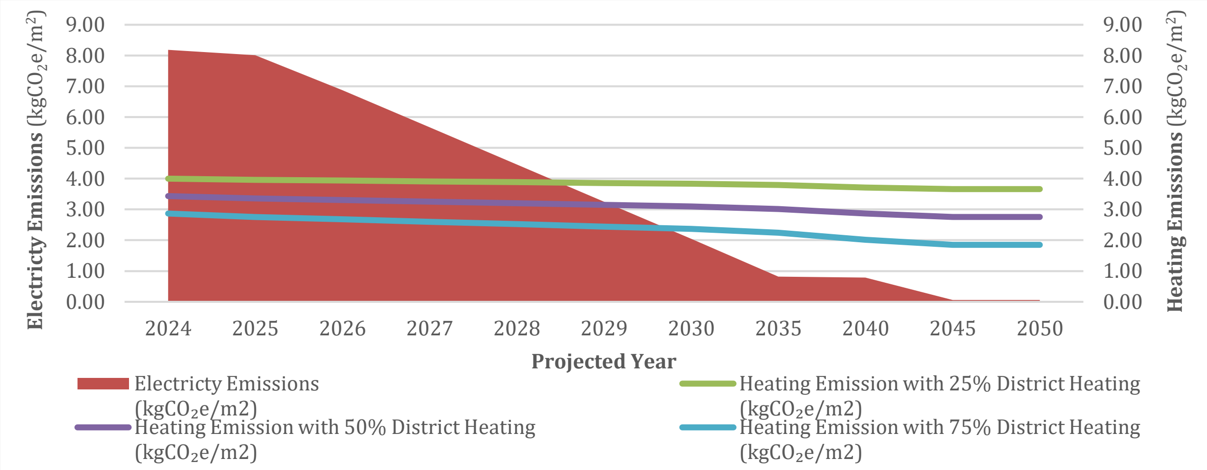

Figure 2. Electricity and heating emission scenarios.

DISCUSSION

To meet global climate objectives, it is necessary to decarbonize the construction and built environment sectors. The construction industry is lagging behind its climate goals. Much emphasis has been placed on enhancing the energy efficiency of buildings, considering the substantial carbon footprint of electricity and heating over their 50 to 60-year lifespan (Joseph and Mustaffa 2021; Weigert et al. 2022). This study highlights the importance of addressing the carbon emissions of construction operations, especially given the illumination and heating demands of winter months in Estonia.

While no direct correlation could be observed between a building's size and construction operations' energy consumption and GHG, a relationship seems to exist between the project's duration, its use function, and its energy consumption and emissions. Industrial projects without additional heating averaged electricity emissions at 5.2 $kgCO_2e/m^2$, while those with extensive interior work and additional heating saw a substantial increase, with average electricity emissions at 11.7 $kgCO_2e/m^2$ and heating emissions at 4.8 $kgCO_2e/m^2$. This means a threefold increase in total emissions, provided that in Estonia, electricity and heating are emissions-intensive.

This study, although limited to one company, offers insights that could contribute to the development of a more generalized approach. Findings demonstrate the great impact of the winter period on the carbon emissions of construction operations, especially regarding heating and illumination during colder months. This becomes increasingly crucial as Estonia moves towards decarbonizing its energy sector. A baseline and parameters for such assessments need to be established and standardized to consider and plan alternative improvement scenarios.

For a thorough assessment of construction activities' carbon footprint, more detailed case studies need to be made, looking at energy use in different types of work. Furthermore, action research for project-wise reduction of construction carbon emissions, as well as for continuous improvement at the construction company level, is needed. Establishing industry-wide methods and developing practical guidelines for reducing carbon emissions in construction operations across different climates and building types are important steps forward.

CONCLUSIONS

This study on carbon emissions from construction operations in Estonia's cold climate has demonstrated that winter demands for heating and illumination significantly contribute to GHG, with heating-required projects averaging 16.5 $kgCO_2e/m^2$ in emissions versus 5.2 $kgCO_2e/m^2$

for those without. While no strong correlation between building size and energy consumption was identified, a connection between project duration and emissions was observed. This emphasizes that it is important not to neglect the embodied carbon of construction operations in lifecycle assessments. The research suggests that significant emission reductions can be achieved through targeted improvements in construction processes, particularly in projects necessitating heating. The implementation of lean principles – prioritizing process improvement and waste reduction – emerges as a natural strategy in the pursuit of carbon footprint reduction in construction as well as of the broader objectives of sustainable construction.

ASSESSING ENVIRONMENTAL IMPACTS: A CASE STUDY OF CIRCULAR ECONOMY ON CONSTRUCTION MATERIALS

Michelle Diaz[1], Mauricio Neyra[2] and Sulyn Gomez [3]

ABSTRACT

The construction sector is a major contributor to environmental degradation, accounting for a significant portion of global energy-related carbon dioxide emissions. The traditional linear construction practices follow a "take-make-dispose" model, which entail the extraction of raw materials, manufacturing of construction products, their use in building projects, and ultimately the disposal of waste generated throughout construction projects. Both Lean and Circular Economy (CE) are philosophies that seek to minimize waste. While Lean promotes value through the reduction of production waste during design and construction, CE proposes the reduction of material waste by promoting closed-loop material flows throughout the construction lifecycle. Applying Lean and CE principles to construction waste management shows promise in reducing negative environmental impacts.

Despite increasing interest, a comprehensive assessment of CE's impact in this context has not been thoroughly presented yet. This study aims to close this gap by analyzing the environmental performance within a case adopting CE principles using Life Cycle Assessment information. Results indicate significant reductions in Global Warming and Ecotoxicity using CE. Meanwhile, Lean provides another approach to waste reduction by avoiding the generation of environmental waste through production control. This research underscores CE's efficacy in mitigating negative environmental impacts while identifying areas for further optimization.

KEYWORDS

Lean, Circular Economy, Life Cycle Assessment, Environmental Impact, Waste.

INTRODUCTION

The construction industry serves as both a vital component of global economic growth and a significant contributor to environmental degradation. According to the World Green Building Council (WGBC), construction activities contribute substantially to the waste stream and accounts for approximately 39% of global energy-related carbon dioxide (CO2) emissions during building construction and operation (WGBC, 2019). Traditional linear construction practices follow a "take-make-dispose" model, involving the extraction of raw materials, manufacturing of construction products, their utilization in building projects, and ultimately, the disposal of resulting waste (Ellen MacArthur Foundation, 2013). Due to the substantial waste generated, construction stands out prominently, making it a prime target for innovation within the framework of Circular Economy (CE) (Benachio et al., 2020). CE is diverse in its

3 Quality Leader, DPR Construction, Redwood City, USA, sulyng@dpr.com, orcid.org/0000-0003-2367-9880

existing definitions, and includes all activities carried out in a society.. A holistic approach with the construction of circular loops of material, energy, and waste flows embracing all society activities is the main feature of a CE, setting it apart from other attempts to minimize energy and material consumption (Masi et al., 2018).

While CE literature is relatively novel, it has deep roots in green production literature (Vargas & Medrano, 2020). The development of a green production philosophy revealed the benefits of lean manufacturing in reducing waste and its negative environmental effects (Huovila & Koskela, 1998). Green manufacturing has gained traction with Lean approaches of value promotion as a deeper treatment of waste beyond the boundaries of construction and design phases in the form of product life cycles (Salibi et al., 2022) Concurrently, CE has garnered comparable attention for its efficacy in curbing waste across the economic supply chain (Adams et al., 2017).

Lean's focus on process waste reduction complements CE's closed-loop approach to waste reduction and recovery from various materials (Johns et al., 2023). Numerous studies have highlighted the potential advantages of CE in the building industry by drawing parallels between its waste reduction focus and the Lean philosophy (Chen et al., 2021; Schmitt et al., 2021; Johns et al., 2023). For instance, Chen et al. (2021) proposed that Lean approaches can complement CE efforts during the construction phase by minimizing waste generated in the execution of construction processes. Similarly, Johns et al. (2023) identified beneficial overlaps between the tactics used in the design and production (i.e., construction) stages.

A study by El Machi, A., & Hakkou, R. (2024) demonstrated that adopting CE practices in construction can lead to significant reductions in resource consumption and waste generation. However, despite the growing interest in exploring and applying CE principles within the construction industry, there remains a pressing need for a comprehensive evaluation of the tangible environmental impact reductions achieved through CE implementation for the management of construction waste. This study aims to start closing this gap by presenting the results of a thorough analysis of the environmental performance of a case study in construction adopting CE principles. To achieve this, a collaborative research project was carried out with a company leading the business of CE in Peru to assess the environmental impact changes when applying CE.

LITERATURE REVIEW

WASTE IN CONSTRUCTION PROJECTS

Waste, from the Lean perspective, can be understood as any "activity that takes time, resources or space but does not add value" (Koskela, 1992). Ohno (1978) identified seven types of production waste (or *muda*): overproduction, time on hand (waiting), transportation, processing, stock on hand (inventory), movement, and making defective products. With the application of Lean in the construction industry, additional proposals for an eighth type of waste have been introduced, such as Making-Do (Koskela, 2004). Womack & Jones (1996) further categorized waste into necessary waste, which supports value-adding activities but can be minimized, and unnecessary waste, which can be entirely eliminated.

Environmental waste is closely linked to production waste, encompassing the environmental impacts stemming from production waste activities such as increased energy usage for transportation, waste from deteriorating or damaged inventory, energy wastage during production downtime, disposal of obsolete products, unnecessary processing leading to increased energy consumption and emissions, and disposal of defective components (U.S. EPA, 2007). However, integrating environmental waste into traditional lean management practices presents challenges due to the primary focus on productivity improvement rather than environmental impact reduction (Belayutham & Gonzalez, 2013). In that sense, environmental waste is regarded as a distinct category, moving away from the activity-centered concept of production waste but keeping its core concept of non-value addition, and encompassing environmental-related waste types such as emissions, solid and liquid waste, and energy consumption, among others (Arroyo & Gonzales, 2016).

CIRCULAR ECONOMY

Circular Economy (CE) aims to reduce waste throughout a product's lifecycle by increasing value and decreasing waste (Geisendorf & Pietrulla, 2018). To do this, a pull system must be established, and linear waste that lowers system value must be closed off. CE principles such as the 3Rs (reduce, reuse, recycle), 6Rs, and 12Rs delineate the objectives of CE, minimizing resource consumption, repurposing goods, and parts, and ultimately recycling waste back into the system to optimize resource value (MacArthur, 2013). Refuse, reduce, repair, reuse, repurpose, regenerate, rethink, remanufacture, recycle, recover, rot, and re-evaluate are the extra details found in the 6Rs and 12Rs, which expand on the 3Rs (MacArthur, 2013).

The adoption of CE within the construction industry is still relatively young (Adams et al., 2017). However, given the significant waste generated in construction, this industry is a prime candidate for CE innovation. CE strives toward waste-reducing or waste-eliminating product designs (Caceido, 2017). According to Balboa and Domínguez (2014), CE is a framework for eco-design that is inspired by living things. It aims to shift from a linear economy (produce, use, and discard) that is becoming harder to implement due to resource depletion to a circular and regenerative model. The concept by Balboa and Dominguez (2014) is intriguing because they highlight it as a potential solution to the resource shortage issue.

CIRCULAR-LEAN SYNERGIES

Although the Lean and CE philosophies are well developed in their respective fields, the synergies among the two philosophies are not widely studied in the construction industry (Benachio et al, 2021). Common strategies between the two philosophies, particularly in waste reduction principles, have been identified, including a focus on consumer-driven value creation, waste reduction, process simplification, long-term orientation, and continuous improvement (Johns et al, 2023). However, their approach for value promotion and waste reduction is slightly different.

Both Lean and CE aim to reduce resource consumption. Johns et al (2023) suggests that the overall similarities of the strategies are vast enough to be used complimentary to each other. Moreover, Schmitt et al (2021) studied the potential of the interdependencies between Lean and CE. Lean is focused mainly on product and process level, and CE is more focused to the system level, showing that these three levels are interdependent, and there is a great potential for the use of Lean and CE together (Schmitt et al, 2021). According to Chen et al. (2021), integrating Lean principles with CE can extend efforts, particularly during the construction phase, by reducing waste generated from activities and processes.

Schmitt et al (2021) stated that there is yet a current need of a research path to understand the complementarities and conflicts between "lean" and "circularity". Lean is a concept that has been widely accepted within the construction industry practitioners improving its productivity and sustainability profiles (Babalola et al, 2019). Meanwhile, CE adoption in construction industry still faces cultural barriers that are entrenched to their historical linear economy nature (Hart et al, 2019). Some of the cultural barriers for linear production to prevail over CE are the lack of collaboration between business, business functions, and the lack of engagement throughout the supply chain (Hart et al, 2019). Although this is the common trend, much research has evolved over the advantages of working with both Lean and CE (Johns et al, 2023) Many authors agreed that the combination of lean and circularity could lead to significant improvements (Johns et al., 2023; Benachio et al, 2020; Schmitt, 2021).

LIFE CYCLE ASSESSMENT

The use of Life Cycle Assessment (LCA) as a systematic methodology for evaluating the environmental effects of the built environment is growing in acceptance. Although the building industry depends on LCA to address social and environmental issues associated with construction, some barriers prevent LCA from being broadly and confidently embraced in the industry (Ingrao et al., 2018). For instance, completing an LCA research based on primary data is challenging due to several factors, including the laborious inventory procedure that needs an abundance of data as input for the analysis (Hetherington et al., 2014). Another major barrier is the complexity of LCA results that makes it difficult for stakeholders in the construction industry to apply them to improve their environmental performance. (World Business Council for Sustainable Development, 2016).

ISO 14044 presented four steps that must be followed to evaluate the environmental loads of processes and products over the course of their life cycle as presented in Table 1.

Table 1: Life Cycle Assessment (ISO 14044)

Process	Description
Goal and Scope Definition	Define the purpose, objectives, functional unit, and system boundaries
Life Cycle Inventory (LCI)	Gather, describe, and verify all data pertaining to inputs, processes, emissions, and other aspects of the entire life cycle
Life Cycle Impact Assessment (LCIA)	Quantify the environmental consequences and resources used. Three mandatory components make up this step: • Assigning LCI results to the impact categories that have been chosen based on goal and scope parameters. • Calculating category indicators (characterization) • Selecting impact categories based on those parameters. ISO 14044 describes Normalization and Weighting as two additional possible steps in the LCIA process.
Interpretation	Analyse the findings

Although many construction companies are adopting the Lean principles in their projects (Babalola et al,2019), some studies have shown that there is still cultural resistance within the implementation of CE principles (Hart et al, 2019). Many theoretical studies have been framed to show the mutual advantage of Lean and CE when implemented together (Johns et al., 2023; Benachio et al, 2020; Schmitt, 2021). Therefore, more quantitative research in the construction industry is needed to support the benefits of working with Lean and CE principles together. The presented research gives a quantitative approach to understanding the environmental impacts that are avoided when implementing a CE approach.

RESEARCH METHODOLOGY

This research adopted a quantitative approach based on a single case study, in collaboration with Company A, a Peruvian company known by its focus on Circular Economy (CE). According to Yin (2009), case studies are particularly suited for investigating "how" or "why" questions within real-life contexts where the boundaries between the context and phenomenon are not clearly defined. This paper explores the connection between CE principles and the environmental impacts of resources (i.e., materials and equipment) from construction projects.

The methodology employed encompasses the logic of design, data collection techniques, and specific approaches to data analysis (Stoecker, 1991). Yin (2009) identifies six crucial sources of evidence, each offering complementary insights and commonly utilized in well-executed case studies. This research used three of the primary sources of evidence that were identified by Yin (2009), including:

- Documentation such as reports of CO2 emissions avoided from 2019 to 2022.
- Archival records such as the clients served from 2019 to 2022 and the worker energy consumption for their time frame.
- Interviews with stakeholders to better understand the data and processes involved.

After the data gathering from Company A, the emissions reported by Vahidi et al (2016) on pipe materials were used for the PVC pipes emission factor using the UCEPA TRACI methodology. The emissions of transportation were obtained from EcoTransIT software showing results for complimentary impact categories. Finally, the energy emission factors were considered from the results of Santoyo-Castelazo et al (2011) who used the ISO 14040 guidelines to inform the emissions generated by hydroelectric power plants.

CASE OVERVIEW

The case study addresses the interaction between company A, company E1, and company E2 within two different scenarios S1and S2.

Company A works as an online commercial platform that sells the disused goods of large corporations to avoid CO2 emissions from the production of more goods of the same category. Company E1 is a construction company that has finished its construction process. This company has used all the materials that it needed, and it has surplus materials (PVC pipes) that will typically go to storage over a big period. Company E2 is a Company that has started its construction process. This company is looking for materials (among them, PVC pipes) to enter their construction process.

Figure 1 shows the two scenarios that are discussed in this research to understand the environmental indicators that might be changed by company A's approach of CE. In Scenario 1, base scenario, material, equipment, and resources entered company E1's construction phase. Once their construction phase is finished, some good materials are left and normally disposed of in storage or landfills. In Scenario 2, materials left from company E1 are transported into a second company E2 whose construction process is still ongoing. Both Scenarios considered transport emissions. However, material production emissions are only included in scenario 1, and energy consumption emissions are only considered in scenario 2 from company A's activities.

Input data for our analysis include a carbon footprint analysis commissioned by a consultant for sustainability and climate change. The data from Company A's 2019-2022 carbon footprint report was used. Additionally, interviews with Company A's CEO were carried out to understand the life cycle of the materials and equipment they typically process.

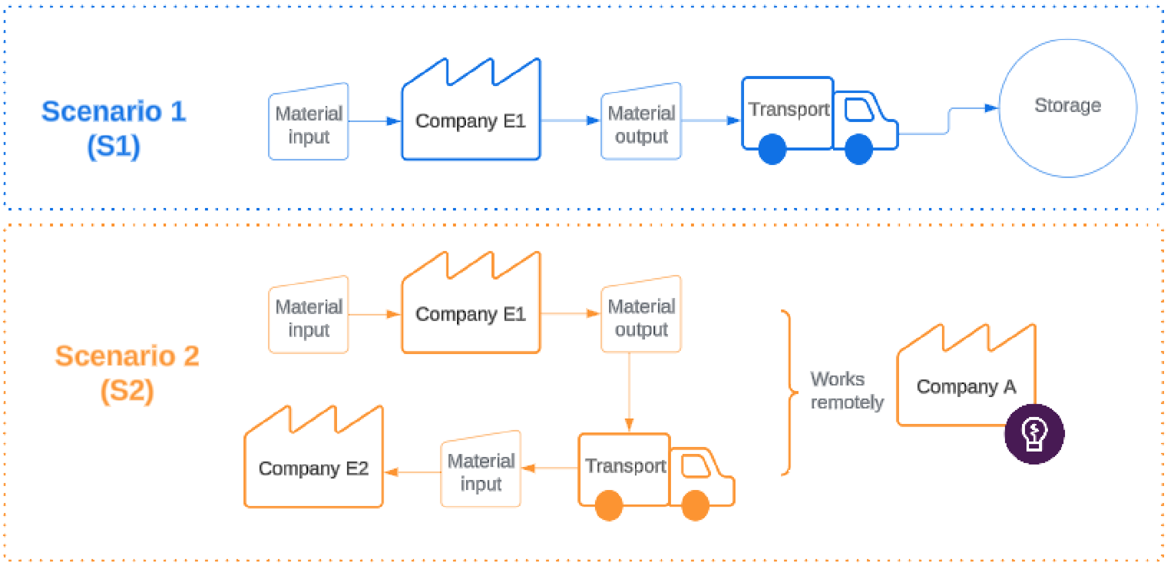

Figure 1: Scenarios with (S2) and without (S1) Circular Economy.

For over four years (2019-2022), Company A has worked with 33 companies, providing a recovery equivalent to 3006.6 ton of materials, including:

- Inoperative equipment (tractors, excavators, trucks, mining truck tires, telehandlers, cranes, mobile cranes),
- Damaged materials (industrial materials, paint, cement, iron rods, glue, personal protective equipment, pipe paint, pipe coating materials),
- Damaged equipment and minor tools (grinders, rotary hammers, drills, vibro-rammers, small equipment used for construction),
- Spare parts for inoperative equipment, computer equipment (laptops, computers), inoperative vehicles (trucks, cars),
- Furniture (office furniture, desks, campsites, containers, portable toilets).

This study scope is limited to the materials recovery analysis of one of Company A's clients. Table 2 shows the scope of materials that this client reported as residue, which is analysed in this case.

Table 2: Case Study Scope Description

Item	Description	Ton	Initial Location	Destination with Company A	Destination without Company A
Material	PVC Pipe	10	Arequipa	Lima	Lima

In the context of LCA, "end of life" refers to the final stage of a product's life cycle. It encompasses the product's disposal, recycling, or any other fate after it has reached the end of its useful life (Sandin, 2014). Since the case study is based on the final stage of the PVC pipes in company E1, the results were based on an "End of Life" approach for the analysis.

In this research, LCA analysis from other authors (Vahidi et al, 2016, Santoyo-Castelazo et al, 2011) were introduced in the results to compare which of the two scenarios S1, S2 has a better environmental performance.

RESULTS

LIFE CYCLE ASSESSMENT

Goal and scope definition

According to Hauschild (2018), goal definition sets the context for the LCA assessment and provides the basis of the scope. Table 3 frames the goal and scope of our case:

Table 3: Goal and Scope Definition

Goal/Purpose	Evaluate LCA comparing environmental impacts of the management of Materials from the construction stage
Application	Basis for decision on recovering Materials from the construction stage
Functional Unit	Three functional units were taken into consideration as a unit of measurement that serves as the basis for comparing different alternatives: • Transportation emissions, km is the functional unit. • Emissions related to waste (such us materials and equipment), ton is the functional unit. • Emissions related to storage area, m2 is the functional unit.
System Boundary	The following considerations were taken to define the boundaries of our analysis: • Materials (PVC Pipes) that are covered by Company A from the construction stages from 2021. • All processes contributing significantly to the life cycle impacts are considered. • In S2, there is no more raw material extraction emissions since they use material from S1. • There are transportation emissions in both scenarios S1 and S2. Both are considered to have the same results since their destination are near each other.

A thorough analysis of the "End of Life" phase of residual materials is used to determine environmental impacts in two different scenarios, as depicted in Figure 1. One basic scenario S1 in which Company A is not involved, and a second scenario S2 in which Company A participates and applies their CE approach.

Figure 1 shows Product System of S1 that consists of two main processes which are production of PVC pipes, and transportation of residual pipes from company E1 to their storage. While information for the transportation system and its relating input-output data was gathered from EcoTransIT software. Information for the PVC pipe input-output data was gathered from Vahidi (2016) who explained the main materials and processes that are considered in a LCA of PVC pipe production. Product System of S2 consists of another two main processes which are transportation of residual pipes from company E1 to E2, energy usage of Company A's workers to manage construction materials. The values and processes for electricity were considered to come from a hydroelectric source. In 2020 in Peru, electricity generation from hydroelectric plants increased their participation to 59.6%. Although electricity generation has year to year variations in the contribution of renewable energy sources (RESs), hydroelectric plants have been consistently producing around half of Peru's electricity over the past years (Campodonico, 2022).

Inventory Analysis

The inventory analysis collects information about the flows of input-output of resources, materials, and energy. The inventory data consists of Company A emission reports from 2019-

2022. Table 4 shows a summary of the main inputs and outputs considered in the analysis for both scenarios.

Table 4: Input-Output flows from S1 and S2

Flows	S1	S2
Input Flows	Pipe Production (Vahidi et al, 2016)	Electricity (Santoyo-Castelazo et al, 2011)
	Transportation (EcoTransIT)	Transportation (EcoTransIT)
Output Flows	M&E transported (Company A reports)	M&E transported (Company A reports)

Impact Assessment

Life Cycle Impact Assessment methodology was studied to evaluate and quantify the environmental performance across two different scenarios for the End of Life of construction materials (pipe production). The UCEPA TRACI methodology was developed for the pipe production (Vahidi et al, 2016). The ISO 14040 was used to delve into the emissions of energy consumption from hydroelectric sources (Santoyo-Castelazo et al, 2011).

The UCEPA TRACI methodology included the impact categories of ozone depletion (kg CFC-11 eq), global warming (kg CO2 eq), smog (kg O3 eq), acidification (kg SO2 eq), eutrophication (kg N eq), carcinogenics (CTUh), non carcinogenics (CTUh), respiratory effects (kg PM2.5 eq), ecotoxicity (CTUe), and fossil fuel depletion (MJ surplus).

The LCA results from ISO 1404 showed results for global warming (kg CO2 eq), (CH4), terrestrial acidification (kg SO2 eq), ozone formation (kg NOx eq), respiratory effects (kg PM2.5 eq).

The emissions of transportation were obtained from EcoTransIT software showing results for respiratory effects (kg PM2.5 eq), global warming (kg CO2 eq), terrestrial acidification (kg SO2 eq), ozone formation (kg NOx eq).

Table 5 shows the results of Company A's avoided emissions and produced emissions from S1 and S2 respectively. For this results, two Life Cycle Assessment studies were considered, their resulting emission factors were multiplied by the activity level from both scenarios (Vahidi et al, 2016, Santoyo-Castelazo et al, 2011).

Twelve environmental impact categories were identified in this analysis. The second scenario S2 showed better or equal performance on all of the environmental indicators, but Global warming and Ecotoxicity. Smog, Acidification, Eutrophication, Respiratory effects, Fossil fuel depletion, Ozone depletion, Carcinogenic, Non-Carcinogenic, Ozone formation and Air pollution showed similar results for both scenarios.

The CO2 emissions for S1 is approximately higher by three times compared to S2, showing that the CO2 emissions related to PVC pipe production are greater than CO2 emissions from company A´s energy consumption. Greenhouse gases are contributors to global warming and climate change, CO2 is one of the most relevant in this matter (Yoro et al, 2020). Although, the pandemic has slowdown the expected increase of CO2 emissions, the UNEP Emissions Gap Report 2020 shows that this will be an insignificant reduction of 0.01ºC by 2050 if the international community doesn't prioritize green recovery. There are many opportunities that have been increasingly more visible to the construction sector that recycling construction waste and applying it to new construction sites will reduce carbon emissions and its impact to global warming (Yang et al, 2023).

Table 5: Life Cycle Assessment results for S1 and S2

Impact Category	Reference Unit	S1	S2
Ozone depletion	kgCFC-11 eq	2.79E-05	0
Global warming	kg CO2 eq	2.45E+03	8.30E+02
Smog	kg O3 eq	2.90	0
Acidification	kg SO2 eq	9.27	3.13
Eutrophication	kg N eq	1.81	0
Carcinogenic	kg 1,4-DCB	9.75E-05	0
Non carcinogenic	kg 1,4-DCB	2.4E-04	0
Respiratory effects	kg PM2.5 eq	0.77	0.19
Ecotoxicity	kg 1,4-DCB	6.890E+03	5.9E-06
Fossil fuel depletion	MJ	1.70E+04	1.27E+04
Ozone formation	kg NOx eq	8.40	8.40
Air pollution	kg NMVOCx eq	0.53	0.53

Ecotoxicity was a major environmental impact by S1. The production of PVC can contribute to ecotoxicity because of the chemical composition of toxic vinyl chloride monomers, and other additives such as pigments to improve its performance (Bidoki & Wittlinger, 2010). Pigments and other additives or stabilizers such as lead compounds in PVC pipes can be toxic and harm aquatic life if released into the environment (Bidoki & Wittlinger, 2010). Additionally, the production of PVC involves energy-intensive processes such as manufacturing, polymerization, and manufacturing which would eventually affect the ecotoxicity indicator by the energy consumption emissions.

This result adds to the body of knowledge of the well-known benefits of recycled materials in a context of construction companies applying principles to manage more efficiently their waste. Although these results are only based on the impacts of one company (company E1) recycling it PVC pipes, it should be highlighted that company A has worked with 33 different companies (including company E1) in over three years. Further research should explain the overall impact of more environmental indicators that are related to the manufacturing of other materials.

CONCLUSIONS

The construction industry's significant environmental footprint necessitates urgent measures to reduce waste and mitigate environmental impacts. This paper examines the application of Circular Economy (CE) principles in construction waste management, aiming to evaluate its effectiveness in minimizing environmental degradation. By leveraging a case study approach and employing Life Cycle Assessment (LCA), the study provides valuable insights into the environmental performance of CE implementation within the construction sector. Our findings underscore the potential of CE to reduce environmental impacts associated with construction. Through the analysis of environmental indicators using different Life Cycle Assessment studies, it was evident that CE adoption led to notable reductions in various impact categories, aligning with the principles of waste reduction, resource optimization, and closed-loop material flows inherent in CE. Despite the promising results, our study highlights the need for further optimization and refinement of CE practices within the construction sector. Addressing regional energy sources and enhancing material recovery processes could further enhance CE's efficacy in mitigating environmental impacts.

In this study, data from the specific construction processes that produced the material wastes was not available. However, through diligent application, Lean principles provide an approach to reduce material waste before they are generated due to production wastes of inventory, overproduction, and rework from defective products. Therefore, the synergies between Lean and CE philosophies further amplify the potential for waste reduction and resource optimization within the construction industry. While Lean emphasizes process waste reduction, CE focuses on material waste throughout the lifecycle, offering complementary strategies for minimizing environmental impacts.

This study contributes to the growing body of knowledge on CE implementation in construction waste management, providing valuable insights for policymakers, industry practitioners, and researchers. By embracing CE principles and leveraging synergies with Lean methodologies, the construction industry can move towards a more sustainable and environmentally responsible future.

LIMITATIONS AND FUTURE RESEARCH

Despite the contributions of this study, several limitations should be acknowledged. First, while this case study provides in-depth insights into a specific context, generalizing findings to broader populations or contexts may be limited. Future research could complement the analysis with large-scale empirical studies to enhance the robustness and generalizability of findings. Second, the availability and reliability of data can pose challenges for conducting comprehensive assessments, such as the necessary for addressing material waste generation from the Lean perspective (production management) and CE perspective (construction life cycle). Future research can explore ways to improve data quality and accessibility. Third, certain assumptions and simplifications were made in the analysis, such as uniform transportation emissions and energy sources. Future research could consider certain nuances in the assessment. Fourth, this study was limited to a specific period, potentially overlooking long-term trends and changes in environmental performance. Future research could extend the analysis over longer durations to capture temporal variations and assess the durability of CE practices. By addressing these limitations, scholars and practitioners can continue to advance our understanding of CE implementation in construction waste management and contribute to the development of more sustainable construction practices.

TRANSITION TO A LEAN MINDSET THROUGH THE "HERO'S JOURNEY"

Tobias O. Malvik[1] and Atle Engebø[2]

ABSTRACT

Transitioning from a conventional, established, and familiar project mindset to a Lean mindset has proved challenging and is a barrier to implementing Lean Construction. It has been argued that shifting from traditional management thinking to a Lean mindset can be considered a paradigm shift. Such substantial changes will require overcoming innate resistance and adjusting ingrained habits to become progressive and open-minded to the potential benefits of new ideas. This conceptual paper investigates how the potentially demanding change from a traditional mindset to a Lean mindset can be dealt with by employing Joseph Campbell's "Hero's Journey" framework. The Hero's Journey describes a generic journey about overcoming challenges met when facing unfamiliar territory. It is found in antique stories but is also applicable in life. A way to tackle the challenging task of adjusting to the ongoing change in the construction industry using the Hero's Journey is proposed in this paper. The research shows that applying the Hero's Journey framework in a construction context can be valuable for making the transition to a Lean mindset less daunting for practitioners.

KEYWORDS

Lean construction, Hero's journey, Collaboration, Storytelling, Change

INTRODUCTION

The construction industry meets increasing demands for innovation to improve value delivery. However, the industry's characteristics appear to detain the innovation process. Development can be divided into two categories: innovation related to production or processes. Product innovation incorporates adding new materials or components into physical products. On the other hand, process innovation, representing a variety of management challenges, focuses on developing new organizational structures, management techniques, and other methods to enhance business processes and competitiveness (De Valence, 2010).

This paper relates to innovation – and changes. Implementing Lean Construction (LC) often requires a shift in organizational culture and structure (Nesensohn et al., 2012). Doubt or resistance to change are common challenges to implementing LC in construction projects. Porwal et al. (2010) write that one of the challenges of implementing the Last Planner® System (LPS) is organizational opposition through a "This is how I've always done it" attitude. Through a comprehensive literature review, Wandahl (2014) found that the most common barriers to LC implementation were insufficient knowledge about the LC approach, lack of training, and general maturity. Similarly, Albalkhy and Sweis (2021) identified 29 barriers to LC implementation, and among them were *management resistance to change, lack of adequate lean awareness and understanding, employees' resistance to change and fear of unfamiliar*

practices, and *insufficient training for workers.* All these relate to the challenges of embracing unfamiliar territories that require a change in mindset.

In traditional project delivery methods, the delivering parties are often incentivized to concentrate on their interests rather than owners and public project objectives. Due to the isolated organizational structure, the project actors' diverse interests may sometimes align or sometimes oppose. According to Ballard et al. (2014), maintaining scope stability is key to successfully applying traditional, non-lean project management methods. Korb and Ballard (2018) argue that transitioning from traditional management thinking to Lean thinking can be considered a paradigm shift, suggesting that adopting Lean requires considerable effort. Further, they encourage the LC community to address the challenges posed by the paradigm shift by presenting innovative measures and strategies to advance the progression of LC.

There is a lack of research addressing the challenges mentioned above regarding changing and transitioning to LC. Searching for "transition" or "change" on iglc.net only gives one hit (Riekki et al. (2023) suggest using takt production as a driver for the implementation of LC principles). This paper seeks to respond to this knowledge gap by addressing resistance to change during the introduction of an unfamiliar practice, such as applying a Lean mindset to a construction project. We explore strategies to enhance the transition from a traditional project management mindset to a Lean mindset, employing the narrative effectiveness of storytelling.

The "Hero's Journey" was introduced by Campbell (1949) and popularized by Vogler (1992). It is a narrative framework that outlines the typical stages a hero typically undergoes in a story. The framework has since been used as an illustrative metaphor in many fields. Williams (2019) writes that the Hero's Journey can be used as a comprehensive guide for individuals who willingly embrace or are forced to undergo change. Recognizing life as a "mudmap" with distinct phases and various substages enables life's chaos and challenging aspects to possess order and purpose. This paper has taken a conceptual approach. Supported by the narrative structure of the Hero's Journey framework, this study seeks to provide valuable insights and guidance for navigating and overcoming obstacles in the evolving landscape of construction practices. Thus, through the framework of the Hero's Journey, we aim to address the following research question: *"Can the Hero's Journey work as a tool for a successful transition from a traditional mindset to a Lean mindset in construction projects?"*

METHOD

This paper takes a conceptual approach to building theory. Conceptual papers are effective for theory-building (Cropanzano, 2009; Jaakkola, 2020). A conceptual paper does not have empirical data. According to Gilson and Goldberg (2015, p. 128), conceptual papers do not need to present new theories but rather "bridge existing theories in interesting ways, link work across disciplines, provide multi-level insights, and broaden the scope of our thinking."

Jaakkola (2020) presents four types of research design for conceptual papers: theory synthesis, theory adaptation, typology, and model. This paper has the theory adaptation design. Papers focused on theory adaptation aim to incorporate insights from other theories to improve an existing theory. This study employs theoretical insights from human storytelling, notably exemplified by the Hero's Journey, to enhance strategies for addressing the challenges of implementing LC posed by the paradigm shift in the construction industry. This paper utilizes the Hero's Journey framework of mythologist Joseph Campbell to illustrate how construction industry practitioners can move from a traditional mindset to a Lean mindset. Two books have been vital as core literature in this research. First, the third edition of Joseph Campbell's book from 1949, *The Hero with a Thousand Faces* (Campbell, 2008). Secondly, the popular screenwriter textbook *The Writer's Journey,* where Vogler puts Campbell's original work into a movie screenwriter context (Vogler, 1992). A literature study in the Google Scholar and Scopus databases was conducted for social sciences literature by searching for literature on words such as: "curiosity," "storytelling," "narrative," and "myth." Furthermore, we have looked at research examples where the Hero's Journey has been applied in various academic fields in the same databases. Also, since the Hero's Journey has been placed in the context of LC and collaborative project delivery, a literature review on these topics has been conducted for the research.

STORYTELLING AND NARRATIVE

According to Polletta et al. (2011), a *narrative* is a sequential account of events meant to convey a point, and they usually involve characters, often human or human-like, fostering audience empathy. McAdams (2019) writes about how storytelling creates the essential tools for *narrative identity*: constructing a self-defined life narrative that explains how a person has become who they are. This is because storytelling is a fundamental human characteristic. Lewis (2011, p. 505) writes, *"Humans are drawn to a story through our residence in narrative life."* Storytelling is a cornerstone of the teaching profession, with great teachers such as Homer, Plato, Jesus, and Gandhi using stories, myths, and personal history to instruct. Stories make information more believable and easier to remember (Zabel, 1991).

Stories are powerful means for communicating values, ideas, and norms, often proving to be more impactful tools than statistical data (Morgan & Dennehy, 1997). Campbell (2008, pp. 197-198) wrote: "We may doubt whether a scene ever actually took place. But that would not help us any; for we are concerned, at present, with problems of symbolism, not historicity. We do not particularly care whether Rip van Winkle, Kamar al-Zaman, or Jesus Christ ever actually lived. Their stories are what concerns us, and these stories are so widely distributed over the world - attached to various heroes in various lands - that the question of whether this or that local carrier of the universal theme may or may not have been a historical, living man can be of only secondary moment." Ideas embedded in mythology resonate with psychological truth, and the universal power of mythological ideas renders them applicable to comprehending almost every human challenge (Vogler, 1992). Stories want to teach you a lesson disguised as entertainment.

THE HERO'S JOURNEY

The hero's story is always a journey that can appear in many variations. The hero leaves his own well-known, familiar, and comfortable surroundings to venture on an inward journey (of the mind) or outward journey (physically). The Hero's Journey was introduced by Joseph Campbell (1949). Campbell showed how the standard path of the mythological adventure of the hero follows the same formula with three stages and associated sub-stages: 1) Separation/Departure, 2) Initiation, and 3) Return. Campbell named these three symbolic transitions the *nuclear unit of the monomyth.* Campbell contended that "whether presented in the vast, almost oceanic images of the Orient, the rigorous narratives of the Greeks, or in the majestic legends of the Bible, the adventure of the hero normally follows the pattern of the nuclear unit … a separation from the world, a penetration to some source of power, and a life-enhancing return" (Campbell, 2008, pp. 27-28).

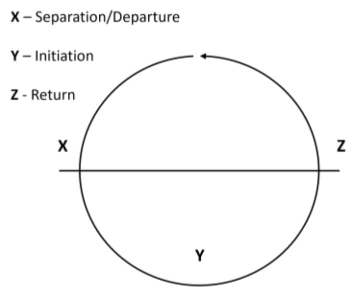

Figure 1: The nuclear unit of the monomyth (Campbell, 2008).

EXAMPLES OF THE HERO'S JOURNEY IN VARIOUS DISCIPLINES

The Hero's Journey is an illustrative metaphor in various fields, showcasing its diverse applications. Below, a selection of these disciplines will be listed to highlight the range and variety of contexts where the Hero's Journey finds relevance. As we can see from Table 1, there are many different segments where the Hero's Journey has been applied, and the list goes on.

Table 1: The Hero's Journey applied in different academic fields.

Author (year)	Area of Study	Summary
Vogler (1992)	Screenwriting	Adapted Campbell's work for screenwriting, using familiar Hollywood narratives like Star Wars.
Osland (2000)	Human Recourses	Applies HJ to expatriate experiences to aid the Hero's Journey professionals and individuals living abroad.
Senn (2002)	Religious Education	Discusses the Hero's Journey in the context of religious education.
Smith (2002)	Nursing	Examines myths in nursing, linking health and healing literature to the Hero's Journey.
Goldstein (2005)	Education/Teaching	Uses the Hero's Journey as a metaphor for managing stress in student teaching.
Ip (2011)	Video Games	Evaluate the Hero's Journey in narrative structures of video games.
Kelsey (2016)	Journalism	Investigate the Mail Online's articles about whether the former leader of the UK Independence Party, Nigel Farage, was portrayed in a heroic light through the ideological mechanisms of populist discourse.
Robledo and Batle (2017)	Tourism	Relates transformational tourism to the Hero's Journey as an archetypical transformation journey.
Williams (2019)	Humanistic Psychology	Proposes the Hero's Journey as a guide for personal change.
Moin et al. (2020)	Marketing	Argue for using the Hero's Journey in promotional videos for marketing.
Rogers et al. (2023)	Sociopsychology	Analyses the Hero's Journey in a socio-psychological context, discussing its impact on life's meaning.

STEPS OF THE HERO'S JOURNEY

In this paper, we will adopt Vogler's 12-step Hero's Journey (Vogler, 2007). The reason we prefer Vogler's journey is that it is simpler. Campbell's journey dives deep into ancient myths, folktales, and legends and uses a language that is harder to follow, while Vogler's version is more accessible and easier to communicate. It should be noted that Vogler's version is wholly based on Campbell's original journey, and scholars from different research areas have embraced both journeys. A detailed examination of the 12 steps will ensue as we discuss them in an LC context later in the paper. For now, we will settle by presenting the steps chronologically, as illustrated in Table 2.

Table 2: The Hero's Journey (Vogler, 2007, p. 205).

Character arc	Step of the Journey
Limited awareness of a problem	Heroes are introduced in the ORDINARY WORLD, where…
Increased awareness	They receive the CALL TO ADVENTURE.
Reluctance to change	They are RELUCTANT at first or REFUSE THE CALL, but…
Overcoming reluctance	Are encouraged by a MENTOR to…
Committing to change	CROSS THE FIRST THRESHOLD and enter the Special World, where…
Experimenting to change	They encounter TESTS, ALLIES, AND ENEMIES.
Preparing for a significant change	They APPROACH THE INMOST CAVE, crossing a second threshold…
Attempting a big change	Where they endure the SUPREME ORDEAL.
Consequences of the attempt (improvements and setbacks)	They take possession of their REWARD and…
Rededication to change	Are pursued on THE ROAD BACK to the Ordinary World.
Final attempt at a significant change	They cross the third threshold, experience a RESURRECTION, and are transformed by the experience.
Final mastery of the problem	They RETURN WITH THE ELIXIR, a boon or treasure, to benefit the Ordinary World.

LC AND COLLABORATIVE PROJECT DELIVERY

PROJECT DELIVERY METHODS

Numerous strategies have been developed over the years to ensure the successful completion of projects. These strategies are encapsulated in project delivery methods, which define how to achieve project objectives. Miller et al. (2000, p. 59) describe it as a "system for organizing and financing design, construction, operations and maintenance activities that facilitates the delivery of a good or service," while Love et al. (1998) define it as an organizational system that allocates specific responsibilities and authorities to individuals and organizations and outlines the different components in constructing a project. Furthermore, many different categories, or classes, of project delivery methods exist. Some scholars use a continuum ranging from separated to integrated (see Miller et al. (2000)). Others use the terminology of traditional (discrete) and collaborative (relational) (Ballard & Howell, 2005).

As Ian MacNeil outlines, the concept of relational contracts positions contracts on a spectrum from discrete to relational. He proposed that while some forms of contract are discrete, other forms of contract are relational in their conception and are, in many instances, a reflection of societal customs and norms (MacNeil, 1985). Relational contracting is a term used for transactions or agreements designed to acknowledge the partnership between contracting parties formally. The contract places greater emphasis on the relationship, with delivery mechanisms prioritizing trust and partnership (Colledge, 2005). In construction, integration of delivery evaluates how project components like planning, design, construction, and operation are combined throughout the production cycle, while separated-focused methods distinctly divide design and construction activities (Miller et al., 2000). Integration-focused methods merge design and construction responsibilities, rely on inter-organizational collaboration, and potentially offer competitive pricing through the contractor's market expertise and purchasing power (Davis et al., 2008).

LEAN CONSTRUCTION

Research in organizational behavior and psychology indicates that to implement new managerial practices successfully, there must be corresponding shifts in the culture or social relationship structure (Blader et al., 2015; Collins & Smith, 2006). LC represents a divergence from traditional managerial practices and culture. Scholars refer to Lean as a philosophy that requires a 'paradigm shift' so that practitioners adopt the 'lean thinking' mindset (Tommelein, 2015). To explain what constitutes a Lean mindset, we will refer to prior literature on the subject recognized and well-known for Lean practitioners.

Womack and Jones (2010) presented five principles of Lean: 1) The customer defines value, 2) A value stream creates value, 3) Make the value stream flow, 4) Use "pull" to drive flow, and 5) Continuous pursuit of perfection. Lean Project Consulting, Inc. presented the “Five Big Ideas that are Reshaping the Design and Delivery of Capital Projects” at a Sutter Health conference in 2004. The five ideas can be considered as a basis for shaping a Lean organization culture, and they are as follows (Macomber, 2004): 1) Collaborate, really collaborate, throughout design, planning, and execution; 2) Optimize the whole; 3) Tightly couple learning with action, 4) Projects are single-purpose networks of commitments, and 5) Intentionally build relationships on projects. Lastly, Lean Construction Institute (2024) has introduced the "Six Tenets of Lean": 1) Respect for people, 2) Optimize the whole, 3) Removal of waste, 4) Focus on process and flow, 5) Generation of value, and 6) Continuous improvement.

If we summarize these principles, the general purpose of Lean seems to be collaboration to generate value for customers while respecting all people. It also removes wasteful activities and increases process flow by optimizing the whole. In addition, it's essential to couple learning with action so you can learn from the process and continuously pursue improvement and perfection.

LEAN CONSTRUCTION IN THE HERO’S JOURNEY

For our purpose, the Hero's Journey is about transitioning from one mindset to another and can be regarded as an inward journey (transitioning from a traditional PM mindset to a Lean mindset). It will also arguably be a physical change in the workplace. However, due to limitations in the paper format, we choose to only reflect on the inward journey and change of mindset.

The steps associated with the hero’s story are symbols of universal life experiences and can be applicable to a simple comic book story or the most sophisticated drama (Vogler, 1992). The Hero's Journey is a structure that does not necessarily need to be followed precisely. Although all the stages in the framework are usually evident in any story, the order of the stages can be shuffled and come in different variations. Stages can also be deleted or added without losing their power. Therefore, the Hero’s Journey has endless flexibility, accommodating myriads of variations without compromising its features. In the following, we will use the Hero’s Journey as explained by Vogler (2007) and put it in a context where someone (e.g., an individual practitioner or organization) must switch from a traditional mindset to a Lean mindset.

Ordinary World

Most stories take the hero into a new, unexploited “special” world. To illustrate the new world, it is first necessary to show the hero in his comfortable surroundings, the “ordinary world.”

In our example, the ordinary world is a well-known work environment with familiar tried-and-tested techniques that fit a traditional mindset in the construction industry. However, the organization realizes the inefficiencies and waste in current methods and acknowledges the potential benefits of LC, which calls for adventure.

Call to Adventure

The hero is presented with a problem, challenge, or adventure. Once he or she is presented with the "call to adventure," the hero can no longer remain in the comfortable zone of the ordinary world.

In our example, the call to adventure can be the recognition of a need to change in the construction process. Or, as Korb and Ballard (2018) call it, a paradigm shift. A new strategy that relies more on interdisciplinary collaboration requires a Lean mindset. For our hero, accustomed to the comfort of doing things the old way, adjusting to this new, unfamiliar way of thinking is challenging. However, whether the new strategy is embraced or resisted, the situation requires a change, which is the call to adventure that represents our hero's challenge.

Refusal of the Call

At this point, the hero is normally reluctant to the expected change. Refusal of the call is usually tied to the fear of change. The hero is not fully committed to what's happening at this journey stage.

In our example, resistance to change might be due to the comfort of existing practices, skepticism about new methods, or fear of the unknown. As mentioned in the Introduction section, reluctance to change is one of the top barriers to LC implementation (Albalkhy & Sweis, 2021; Wandahl, 2014). Some kind of encouragement or change in circumstances might be helpful for the hero. For instance, some calming words from a person with LC experience (a *mentor*) can be encouraging.

Meeting with the Mentor

At this stage in the journey, most stories have introduced the mentor, which often comes in the form of a wise old man or woman (Gandalf in The Lord of the Rings, Prof. Dumbledore in Harry Potter, the Fairy Godmother in Cinderella). Still, they can come in different shapes (e.g., Aslan in Narnia or Rafiki in The Lion King). The relationship between hero and mentor is among the richest in symbolic value, as it represents the bond between parent/child, teacher/student, role model/protégé, etc.

In our LC example, the mentor could come in different shapes, from forward-leaning companies leading down to individual Lean champions. For instance, Raghavan et al. (2017) found that the drive by the top management, coupled with efforts from Lean champions in the project team, was essential for transitioning from a conventional project delivery method to an LC method. These mentors provide training, resources, and support to understand and implement Lean principles. They can typically be represented by the project manager or someone with experience and knowledge of LC or change management. However, the mentor can only go so far with the hero. Eventually, the hero must embrace and be open to the task himself. The hero must *want to* go through the change to a Lean mindset.

Crossing the First Threshold

Now, the hero commits to the adventure fully and enters the new special world for the first time by crossing the first threshold. Vogler (2007) writes that movies are built in three acts: 1) the hero's decision to act, 2) the action itself, and 3) the consequences of the action. The first threshold indicates the point of no return between acts 1 and 2. It's not always the hero's decision to act.

In a construction project, crossing the first threshold may be when a project commits to an LC approach. It can be at the start of a project where the involved are going into the uncharted territory of interdisciplinary and collaborative methods for the first time. It can also be a pilot project or an initial implementation phase where the LC principles are applied on a small scale.

Tests, Allies and Enemies

The first threshold is crossed, and the hero is now in the unfamiliar territory of the “special world.” The hero will now encounter new challenges, make allies and enemies, and start to learn the norms and expectations in the new environment. This is a stage where the hero usually can undergo stressful situations, but the hero gains a lot of experience. The challenges can be both inward and outward.

Challenges arise as the organization starts applying Lean principles. Wandahl (2014) found that mis-conceptualization and mis-implementation of LC, particularly the Last Planner System, are significant issues, with the consequence that benefits are not being realized, with inadequate knowledge, education, and communication identified as key contributing factors—other issues like adapting to new workflows, resistance from employees, or logistical challenges. Interdisciplinary collaboration, resources, unexpected events, etc., are challenges that make the transition to an LC approach difficult. There can also be inward challenges, such as a lack of understanding of the concept and its benefits or a transition to a Lean mindset during a stressful period at work. Our heroes might feel angry or frustrated at being outside their comfort zone. Luckily, the mentors are there to help, and after a while, people will steadily improve their understanding and mastery of the approach.

Approach to the Inmost Cave

The hero approaches the edge of "the inmost cave," which is a place where the object of the quest can be found. The inmost cave is usually the most dangerous place in the special world. Typically, this can be the enemy’s headquarters or where the object of special value is hidden. The approach covers all preparations to enter the innermost cave, where death or supreme danger can be expected. This is the second significant threshold in the journey.

As challenges are identified, the project organization needs to refine its approach. This might involve more training, better communication, or adjusting strategies to fit the context better. The *inmost cave* can, for example, be the construction phase. In the construction phase, you will determine if everything is going according to plan and how the new LC approach works. The planning phase can be considered as the *approach*, as this is where all the preparations for the “dangers” of the construction phase occur. Furthermore, research has stated that successful implementation follows the line from top organizational management down to its divisions and into construction projects, becoming embedded in the organization (Torp et al., 2018).

Supreme Ordeal

In this pivotal moment, the hero experiences a battle with his greatest fears. Faced with the possibility of death (figuratively), he is pushed to the edge in a fierce confrontation with a hostile force. In movies, the supreme ordeal serves as a “black moment” for the audience, leaving us uncertain about whether the hero will succeed or succumb to the challenges. This is a critical moment in any story. The hero must die or appear to die so he can be reborn.

Theoretically, this is the decisive moment for all organizational change processes. Despite the potential benefits, change is not easy to achieve in practice, and some have even stated that up to 70 % of change processes fail (Higgs & Rowland, 2000). In a construction project context, the supreme ordeal might be when our hero meets challenges that make him question the new approach. This is a critical point where the organization faces significant challenges that test its commitment to LC. This could be financial constraints, communication issues, opportunism, unforeseen events, different perspectives, external issues, etc. How our heroes confront these challenges and overcome the urge to return to safe traditional methods is vital and can be considered the supreme ordeal.

Reward

The hero can celebrate overcoming the supreme ordeal (slaying the dragon, finding the holy grail, finding love, etc.). The hero now takes possession of the treasure he was seeking, the reward. The reward comes in various shapes, either by tangible items or increased knowledge or experience. The hero may also become more attractive after surviving the supreme ordeal.

In our example, the reward is increased knowledge, experience, and understanding of how the Lean mindset works after overcoming major challenges in the construction phase. The organization started seeing the benefits of LC – improved efficiency, reduced waste, higher quality, and better interdisciplinary collaboration (Ashcraft, 2022; Cheng & Johnson, 2016). Additional long-term benefits may include an improved project outcome or the acquisition of expertise that will appeal to future projects intending to employ the LC approach.

The Road Back

However, the journey has yet to be finished. On the road back, we are crossing the third threshold as the hero deals with the consequences of confronting the dark forces of the supreme ordeal. The hostile forces are pursuing the hero after he seizes his reward.

Our heroes have survived the biggest challenge by gaining knowledge, understanding, and experience about the LC approach. However, unforeseen events can still occur, and they will be put to the test again. Aligned with the Kaizen philosophy (continuous improvement), often expressed with the PDCA cycle (Plan-Do-Check-Act) (Kunz & Fischer, 2020), lessons are applied to refine processes in the organization further.

Resurrection

The hero must be reborn and cleansed in one last ordeal and resurrection before returning to the ordinary world. This is the final exam, where the hero will be tested to see if he has learned his lessons.

In our example, this might be to ensure that the experience and insight from the project are saved and can be utilized in future work. LC becomes ingrained in the organization's culture. It's not just a set of practices but a way of thinking and working. Our heroes should be able to deal with unforeseen troubles using new tools, knowledge, and experience acquired during the LC journey.

Return with the Elixir

The hero returns to the ordinary world and brings back an "elixir," a treasure or lesson from the special world. This elixir can be both tangible and intangible. The hero is doomed to repeat the adventure if nothing is brought back from the special world to the ordinary world. But usually, the hero returns with increased experience and knowledge, which can hugely benefit the ordinary world.

In our example, the elixir will be the increased knowledge of LC, which will help us overcome the transition from a traditional mindset to a lean mindset. Our heroes have not forgotten the ways of the ordinary world but are now equipped with the knowledge to also handle the Lean mindset. Our heroes have now conquered the fear of change from the comfort of the old mindset, and this is no longer a barrier to future LC projects. The knowledge and experience gained can be shared with others in the industry, contributing to broader change.

CONCLUSIONS

We set out to answer if the Hero's Journey can work as a tool for a successful transition from a traditional mindset to a Lean mindset. Employing the Hero's Journey in a construction context can make the transition to a Lean mindset less overwhelming for practitioners. Going through each stage of the Hero's Journey, we have shown that it can easily be applicable in an LC context and work as a “mudmap” for change. Another interesting observation is how Joseph Campbell’s iterative cycle of the monomyth resembles the iterative process of continuous improvement in Lean.

Table 2 summarizes the Hero’s Journey for LC, drawing parallels between each step and the corresponding stage in the Lord of the Rings films. This approach provides a familiar comparison from the movie world, intending to enhance the reader’s understanding of the Hero’s Journey and how it can be applied. The steps proposed for LC are illustrative examples, and journeys might differ depending on the practitioner's or the organization’s purpose.

Table 2: A Hero’s Journey: Lean Construction versus the Lord of the Rings films.

Step of the Journey	Lord of the Rings	Lean Construction
Ordinary World	The Shire	A traditional PM mindset
Call to Adventure	Gandalf entrusts Frodo with the ring	Transition from a traditional mindset to a Lean mindset
Refusal of the Call	Frodo refuses that he, a simple hobbit, can be entrusted with such a task	Hesitation to change something well-known and comfortable
Meeting with the Mentor	Aragorn and Gandalf function as mentors	A project manager or an LC expert/consultant
Crossing the First Threshold	The hobbits leave the Shire	Committing to an LC approach or the start of an LC project
Tests, Allies and Enemies	The fellowship of the ring, Sauron, Gollum, trolls, orcs, the ring itself	Frustration, unexpected events, resistance from employees, trouble adapting to the approach
Approach to the Inmost Cave	Frodo and Sam’s journey through the pass of Cirith Ungol and into Mordor	Preparations for the construction phase
Supreme Ordeal	Frodo and Sam face Gollum, Sauron, and finally, Frodo’s own hesitation	The construction phase
Reward	The hobbits seize the reward of destroying Sauron to save Middle Earth	Increased knowledge, experience, and understanding of LC
The Road Back	The ring is destroyed, and the volcano erupts. The eagles rescue Frodo and Sam.	Dealing with new challenges by continuously improving the process
Resurrection	Frodo heals from the strains of destroying the ring. The hobbits are praised and honored for their contributions.	Making sure the new knowledge is saved for the future. LC is ingrained in the organization's culture.
Return with the Elixir	The hobbits return to the Shire scarred but wiser, wealthier, confident, and with peace.	The hero is now equipped with a Lean mindset and has conquered their fear of change.

PRACTICAL SIGNIFICANCE, LIMITATIONS, AND FURTHER WORK

The practical usage of the LC Journey depends on the user’s imagination. The framework’s flexibility makes it adaptable to various contexts. One possible area of use is within teaching, where the framework can describe the benefits of LC and how the Lean mindset differs from traditional management thinking. Another area can be at the start of a project where it is decided to implement LC principles or at any arena to present LC engagingly. A limitation of the research is that the study did not examine how the framework applies to a diverse range of projects. The framework has yet to be tested on people without LC knowledge, so further work on this topic might be done to design a journey for a selected purpose within LC and test the framework. Furthermore, looking deeper into how Campbell's monomyth can be used to demonstrate continuous improvement is possible.

MAGICAL VS METHODICAL: CHOOSING BY ADVANTAGES AS ANTIDOTE TO THE PLANNING FALLACY

Eran Haronian[1] and Samuel Korb[2]

ABSTRACT

Cost and schedule overruns are the bane of construction projects, in part due to overly optimistic predictions of project progression. This "optimism bias" is called the planning fallacy, a form of "magical thinking" where planners convince themselves that their project will be different (and better) than others. "Choosing by Advantages" (CBA) is a methodical approach for decision-making. By engaging "slow thinking" at the organizational level, CBA can help counteract the tendency to default to best-case scenarios when selecting among designs and production methods, even in the middle of a project. In this paper, a case study of a Pumped Hydroelectric Energy Storage facility that had to choose between a bottom-up raise boring and a top-down shaft sinking construction method for the vertical shaft connecting the reservoirs is presented. The paper then examines how CBA helped shift the thinking of the project team away from fallacious planning and overcome the sunk-cost fallacy.

KEYWORDS

Choosing by Advantages, Optimism Bias, Planning Fallacy, Risk Management, Monte Carlo

INTRODUCTION

The planning of a construction project is a process that involves making a number of assumptions (Gao et al., 2014). While construction professionals draw on their knowledge and experience, as well as the use of computer simulations and archived data, there comes a time when the humans involved with the planning are making their best assumptions: assumptions about durations of project tasks, likely contingences and how to react to them, and – if the project involves any excavation – what lies beneath the surface of the construction site. Again, these assumptions may be informed guesses that rely on models and empirical evidence like core sampling (in the case of the ground substrate), but until the project is underway there is no way of knowing exactly what the truth may be.

Thus, human psychology comes into play in the planning of any construction project. Humans are prone to some illogical thought patterns, including the optimism bias (Weinstein, 1980), which is a tendency to assume the best case scenario when considering future events. It is likely in part due to this tendency that construction projects experience a mismatch between how they are planned to be carried out versus the reality of their implementation, leading to the budget overruns and schedule delays that plague the industry (Egan, 1998).

During tendering (especially in tenders that put most of the weight on price) owners and contractors often have a tendency to take an optimistic approach (Chadee et al., 2021; Son & Rojas, 2011), which allows a lump sum fixed price to be reached. But once construction begins,

[1] Lecturer, Department of Civil Engineering, Ariel University, Ariel, 40700, Israel, eranha@ariel.ac.il
[2] PhD, Graduate of the Faculty of Civil and Environmental Engineering, Technion - Israel Institute of Technology, Haifa, Israel, m1uwv6junqzd@opayq.com

it may turn out that risks have been underestimated, and assumptions regarding various aspects – including the construction methods selected to complete the project – must be re-examined. The question at this point is what do they do – continue as planned or re-think? Here too, human psychology comes into play, as there is a tendency to want to continue an earlier-planned course despite new information coming to light. This is referred to as escalation of commitment (Staw, 1981) or the sunk cost fallacy (Arkes & Blumer, 1985). Overcoming these innate tendencies is difficult in practice, and again runs into the optimism bias. Project personnel tend to want to project an aura of competence and project optimism, not wanting to expose bad news that could make them, or the project, look bad.

One way to combat these fallacious approaches is to institute rigorous approaches to decision making. The Choosing by Advantages (CBA) method (Suhr, 1999) is a systematic decision-making strategy that can help to confront hard truths. When implemented in a project, it can assist in addressing issues more effectively at an earlier stage, rather than "kicking the can down the road" due to the combined forces of the optimism bias and the sunk cost fallacy. The CBA method is transparent, which helps in communicating the issues across the project organization and building consensus. And yet, the existing literature has not explicitly used CBA to address the planning fallacy.

In this paper, we attempt to close that knowledge gap by presenting a case study of an infrastructure construction project which encountered the issues described above. After planning the project for a "best case" scenario, upon commencing the project it was discovered that the reality of the implementation did not meet the assumptions. CBA was used to assist a mid-course correction, selecting a construction method that, while costing more in the short term, would lead to the best outcome for the project. We present the issues at play in the project and how CBA helped address them, showing that methodical approaches like CBA can serve as an "antidote" to tendencies like optimism bias.

LITERATURE REVIEW

CHOOSING BY ADVANTAGES

CBA is a Multi-Criteria Decision Making (MCDM) system (Köksalan et al., 2011), developed by Suhr (1999), and applicable for a wide range of decisions, from mundane daily individual-personal decisions through strategic-organizational-collaborative decisions. Though CBA is a relatively new approach in the MCDM field, it has been widely implemented by academic and industry practitioners, assisting project teams in building consensus that includes different perspectives and addresses sometimes-conflicting interests (Arroyo et al., 2022; Arroyo & Long, 2018; Martinez et al., 2016; Parrish & Tommelein, 2009; Schöttle et al., 2019; Schöttle & Arroyo, 2017). Successful applications of CBA can be found regarding design alternatives (Arroyo et al., 2012; Arroyo & Long, 2018; Kpamma et al., 2017; Parrish & Tommelein, 2009) or for operational decisions (Martinez et al., 2016). Arroyo et al. (2012) describe the "Lean" properties of CBA that include: a systemic multidisciplinary approach for global optimization, enhanced involvement of stakeholders, consideration of cost only at the last phase of the process once an objective basis has been established, and good visualization of the process and the outcome which enables transparency and collaboration.

In CBA, it is important to document assumptions (and the thought processes that led to them) for decisions, so they can be revised later in the project when new considerations arise (Parrish & Tommelein, 2009). This becomes even more valid in high-risk projects, as decision makers must re-evaluate their decision as the project progresses. Additionally, CBA may assist in making "difficult" long-term decisions that need to be transparent across the organization in order to be approved by stakeholders (Schöttle et al., 2023).

The seven steps of CBA (Arroyo, 2014; Suhr, 1999) were followed in this project, where the "factors" are the decision criteria for all options whereas "attributes" are the ways in which an individual option realizes a particular criterion:

1. Identify alternatives
2. Define factors
3. Define criteria for each factor
4. Evaluate attributes for each alternative
5. Decide the advantages for each alternative
6. Decide the importance of each advantage
7. Evaluate cost data.

OPTIMISM BIAS AND THE PLANNING FALLACY

Optimism bias is the tendency for people to overestimate the likelihood of positive future outcomes and/or underestimate the likelihood of negative future outcomes (Sharot, 2011). The term was coined by Weinstein (1980) and has repeatedly been documented in a variety of settings (Klein & Helweg-Larsen, 2002). Optimism bias is somewhat insidious in that it resists efforts to "inoculate" people to its effects; efforts to do so can actually increase the amount of optimism bias displayed (Weinstein & Klein, 2002). Since optimism bias reflects a divergence between thought processes/assumptions and objective reality, it constitutes a form of "magical thinking", which entails drawing correlations not based on evidence (Hutson, 2013).

The application of optimism bias to project planning has been called "the planning fallacy" by Kahneman and Tversky (1977). This refers to the tendency to assume only the best-case scenarios when laying out the plan for a project (Buehler et al., 2010), which is reflected in unrealistic project timelines. Planning fallacy contributes to projects costing more and taking more time than expected (Flyvbjerg, 2011). Kahneman (2011) has suggested that while humans have a default thinking mode that is more fallible, deliberate thinking can help arrive at more logical conclusion; these two modes are referred to as "fast thinking" and "slow thinking" respectively. In the realm of Lean Construction, Senior (2012) has looked at documented psychological biases and suggested that Lean Construction techniques such as Last Planner (Ballard, 2000) can combat some of the biases that are inherent to human psychology leading to overly-optimistic planning. Roch et al. (2022) have suggested that cognitive biases like the planning fallacy are an obstacle to the introduction of the Lean concept of "flow" in the construction industry, as human brains have been shown to struggle with internalizing (and exploiting) stochastic and statistical realities.

CASE STUDY: SHAFT CONSTRUCTION METHOD FOR PUMPED-STORAGE HYDROELECTRIC FACILITY

The project in this case study, where CBA was successfully applied to combat the tendency towards optimism bias, is a Pumped Hydroelectric Energy Storage (PHES) facility. PHES is a method of storing excess electricity generation (Rehman et al., 2015) when demand and supply levels are out of sync. In times of excess supply, energy is used to pump water "uphill" from a lower water reservoir to an upper reservoir. In times of excess electricity demand, the flow of water is reversed, with the water from the top reservoir driving generators to put energy back into the grid. An "engineering, procurement, and construction" (EPC) contracting method (Carrillo, 2005) was used, with the PHES project structured as a turnkey project where the General Contractor was responsible for design, procurement, construction, and commissioning.

Within the scope of the PHES facility, the main focus of this case study is the construction of the underground chambers that would connect between the upper and lower reservoirs. The main components of a PHES facility are shown in Figure 1.

The following components of the PHES facility appear in this figure:

1. Upper and lower reservoirs, that contain the bulk water storage.
2. Power House (PH), in which the pumps/generators/turbines are located.
3. Horizontal tunnel, which connects between the lower reservoir, the PH, and the bottom of the shaft.
4. Vertical shaft, which connects between the elevations of the upper reservoir and the lower reservoir, horizontal tunnels, and the PH

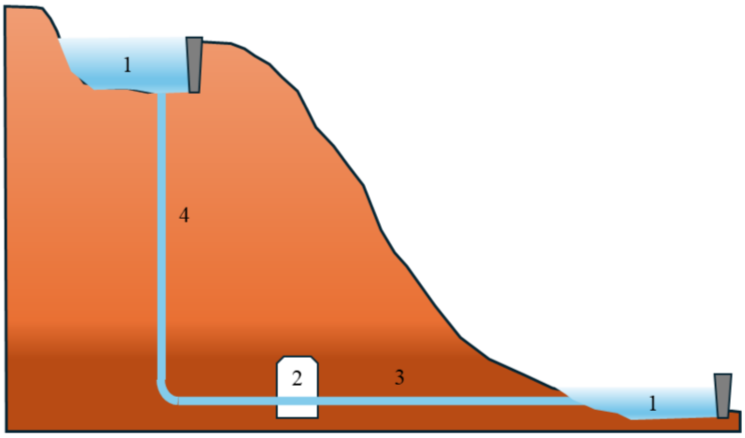

Figure 1: Cross-section of the PHES facility

The main focus of this case-study is on the selection of the construction method that was used to excavate the 700-meter vertical shaft as well as the interplay between the timing of digging the tunnel and the shaft.

Background

For this project, two options were considered for the method of excavating the vertical shaft, as shown in Figure 2.

The following sections describe these two methods of drilling, as well as their impact on the project's critical path.

Raise Boring

Raise Boring (RB) is referred to as a "bottom up" method of drilling (Liu & Meng, 2015), and it requires access to the bottom of the shaft for most of the work. A small-diameter pilot hole is sunk from the top of the shaft, just wide enough to accommodate a drill string. Then a large-diameter reamer head is attached to the drill string at the bottom of the shaft (i.e. via the tunnel in this case study). The reamer head is then raised back towards the top of the shaft, which means the drill face for the shaft is oriented towards the bottom of the shaft. The material dislodged by the reamer head falls down the shaft to the bottom (the tunnel) via gravity, where it can be collected and removed with loaders and dump trucks.

Shaft Sinking

Shaft Sinking (SS), by contrast, is a "top down" method of drilling, where the entire excavation takes place from the top side of the shaft (Lashgari et al., 2011). It can be based on conventional "drill and blast" excavation or mechanical equipment, but both the equipment for extraction and the excavated debris enter and exit through the top opening of the shaft. As a safety feature preventing loose or unstable soil or rock from falling into the shaft, the sides of the shaft are supported with shotcrete as the shaft is excavated.

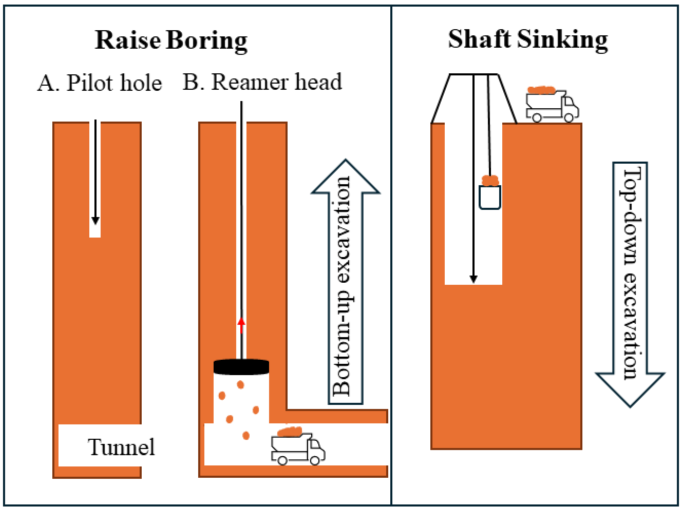

Figure 2: Raise Boring vs Shaft Sinking, for excavating the vertical shaft

Project Timeline and Critical Path

Due to the fact that in RB, the reamer head has to be installed from the bottom of the shaft, in this approach the shaft can only be dug once there is access to the lower level of the shaft. In this case, this meant after the tunnel was completed. Likewise, the rubble that the reamer dislodges must be extracted via the tunnel, which further increases the dependence of RB on tunnel completion. While it is possible to sink the pilot hole prior to tunnel completion, this is a relatively minor component of RB and thus does not effectively decouple the two steps.

SS does not have the same constraint, as the top of the shaft is used exclusively for entry and exit of both equipment and excavated materials. Thus in terms of the project steps, SS can take place in parallel with tunneling – a potential time savings for the project – whereas RB is in series with tunneling. After the tunnel and shaft are completed, the project can progress to testing and commissioning. The two options are portrayed in Figure 3.

The tunneling was found to be on the critical path for the overall project, which means that RB would also be on the critical path, if selected, whereas SS would not be on the critical path as it takes place in parallel with tunneling.

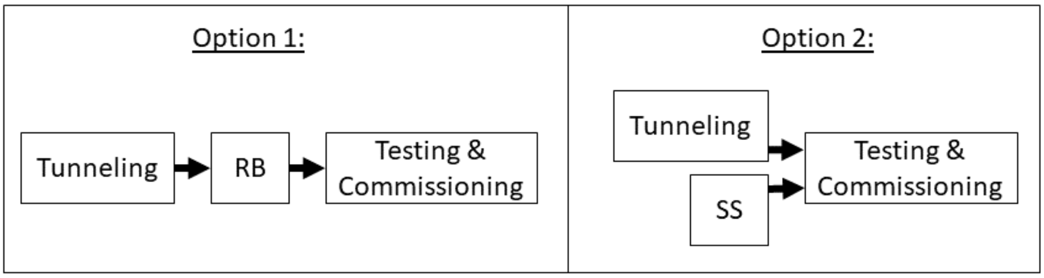

Figure 3: Impact of RB vs SS on project process flow

Before Applying CBA

Prior to project commencement, the project team was faced with the decision about whether to choose RB or SS as the method of digging the vertical shaft for the PHES facility. While CBA (or any other systematic decision-making approach) was not employed, this does not mean that the subject was not given some thought.

The major factor that contributed to the decision was cost. RB is a more "technically advanced" method of shaft digging, requiring less human input, which brings down costs. Removing the excavated material is logistically less complex since it uses loaders and dump trucks running on the effectively-flat tunnel floor. SS, on the other hand, is a more "basic/traditional" method that requires the ground excavated to be removed through the top of the shaft (which becomes progressively further from the drill face as the shaft progresses) as well as shotcrete along the sides of the excavation.

The duration of each alternative also played a part in the initial selection of RB; it was estimated to take 14 months versus 24 months for SS. Finally, the impact of each option on other steps in the project process was a factor, with RB having less impact and SS having more of an impact. This was due to the fact that SS required more logistical work in and around the upper reservoir, which also was undergoing construction (including drill and blast excavation) at the time same time.

Though at the time of the decision to use RB these factors were not formally tabularized, we have done so in this paper to sum up the considerations, as shown in Table 1.

Table 1: Factors leading to the selection of RB prior to applying CBA

Factor	RB	SS
Price	Lower	Higher
Sophistication/ Resources	High: advanced equipment, low labor input	Low/Traditional: basic equipment, extensive labor input required
Duration	14 months	24 months
Impact on other works	Low	High
Logistics	Low complexity	High complexity

For all these reasons, and mostly due to the cost, the choice that seemed obvious was to select RB, and that was what was indeed done on the eve of commencing the project.

APPLYING CBA

Soon after the project got underway, it became clear that certain assumptions that had been made during the project planning phase might not be correct. In particular, the ground consistency was not in line with the statistical assumptions that had been made regarding the geological condition of the site. The excavation method, equipment, and required levels of support for the tunnel/shaft, were planned according to the Geological Base Report (GBR), which reflects statistical analysis of field investigations for the soil classification.

However, once construction of the tunnel commenced, the project began to encounter unpredictable and problematic ground conditions that differed from the initial assumptions, instabilities potentially leading to cave-ins. The worse-than-expected ground conditions significantly affected the tunneling works, as much greater support levels were required than what was planned, causing schedule delays, cost overruns, and unexpected safety hazards. As a result, questions arose regarding the construction method for the vertical shaft: was the execution method that was initially selected suitable for the latent ground conditions? Was it reasonable to rely on a construction method that required the completion of the lower tunnels to begin the work on the vertical shaft? Given the developments with the ground conditions, risk considerations rose to a more prominent position in terms of project attention, so it was decided to reexamine the alternatives for the vertical shaft.

A team was assembled that consisted of six engineers (with professional experience that ranged from 15 to 40 years each): the Project Manager, the Construction Manager, the Head

Tunneling Engineer, the Head Civil Engineer, the Project Geologist, and the Planner (also the first author of this paper). The team was tasked with re-evaluating the construction method for the shaft in light of the difficulties encountered during the tunneling. In order to work as methodically as possible, and make sure decisions made sense to both members of the committee and the ownership of the construction company, the decision was made to work according to CBA.

It was at this time that the factors listed in Table 1 were formally codified. Three additional risk factors were recognized and added to the analysis: schedule risk, soil stability risk, and safety risk.

Schedule Risk

With the tunneling works delayed, the start of RB would also be delayed. Likewise, the ground instability that plagued the tunneling could possibly delay the RB progress. As these both were on the critical chain if RB was selected, a much more detailed analysis was required. A Monte-Carlo simulation (Mohsen et al., 2022) was used to assess the probability that the project would be completed on time, due to the uncertainties regarding the underground soil, which affected the tunneling excavation rate and introduced possible risks during the shaft excavation (due to groundwater ingression or shaft collapse).

First, the Monte-Carlo simulation examined the tunneling works, as these would need to be completed in either case. The duration of the tunneling tasks were represented by a beta probability distribution function, which required defining three scenarios: optimistic, most likely, and pessimistic. The tunneling works were divided into several segments with different geological properties. For each segment, the duration was calculated according to the segment length and the production rate for the three scenarios. For the optimistic scenario the duration was calculated according to the assumptions regarding structural reinforcement made in the preliminary design and the GBR. For the most likely scenario the duration was calculated according to the actual decrease in the production rate in the tunneling work up to the date the simulation was run. For the pessimistic scenario, the duration was calculated according to the most conservative structural reinforcement.

Then, both RB and SS were simulated in a similar manner. Since SS includes the installation of supports throughout, it was more robust in the face of the uncertain ground conditions as opposed to RB. RB remained the faster option, taking six fewer months to complete, but as shown in Figure 3, because SS could be conducted in parallel to tunneling, it had the advantage. It was found that RB would lead to a probability of less than 30% of completing the project on time, whereas SS would introduce a Total Slack of several months, which meant that the probability of completing the project on time was higher.

Soil Stability Risk

With the soil instabilities that were discovered, this factor examined the risk of collapse of the shaft excavation. The evaluation criteria employed a 5x5 Impact-Probability Matrix (Ni et al., 2010) to quantify the risk, by multiplying the impact ranking (which ranged from 1 [negligible] to 5 [catastrophic]) by the probability ranking (from 1 [Rare] to 5 [Almost Certain]). The resulting product was graded as very low (1-2), low (3-4), medium (5-9), high (10-12), very high (15-19), and extreme (20-25).

For RB, in light of the unpredictable ground conditions, it was decided that instability events were likely (ranked 4). Based on experience from previous projects in which incidence of instability occurred, it was decided that the damage that could be caused by such an event would be major (ranked 5). Thus, the rank for the risk was extreme (a total of 20).

For SS, support work is performed on the walls of the shaft as the excavation progresses. As a result, the risk of instability events was unlikely (ranked 2), and if an event occurs, the coping ability would be good leading to a relatively minor impact (ranked 2). Thus, the rank for the risk was low (a total of 4).

Safety Risk

Underground instabilities in the ground condition meant that worker safety had to be considered. Similar to the soil stability risk, this criterion was evaluated with a 5x5 Impact-Probability Matrix, as part of the periodic risk management meetings.

For RB, the excavated material falls down to the bottom of the shaft, which is a significant safety risk for the workers tasked with removing it through the tunnel. Based on experience from previous projects, it was assumed that the probability for safety events caused by the removal of material through the hole made by the reamer head was possible (ranked 3). If a safety event had occurred it could lead to costs of human life, and therefore was severe (ranked 5). Thus, the total rank was very high (15).

For SS, the safety risks derive from possible collapses and falling pieces of rock and soil from the shaft walls down to the working area. Because temporary supports are erected along the shaft as a matter of course, the risk of collapse and falling debris was deemed unlikely (ranked 2). If a safety event were to occur it could lead to costs of human life, ranked as severe (ranked 5). Thus, the total rank for the risk was high (10).

Applying CBA Weighting to the Factors

The additional factors that were identified are summed up in Table 2

Table 2: Additional Risk Factors

Factor	RB	SS
Schedule Risk: Probability of completing project on time	Low: <30%	High: >90%
Soil Stability Risk	Extreme: 20	Low: 4
Safety Risk	Very high: 15	High: 10

In the CBA method, once the factors have been enumerated and evaluated for the options, the next step is to compare the factors to decide their relative weighting. The factor that is considered the most significant is pegged at a weighting of 100, and then the others are scaled accordingly. The option with the greatest advantage for that factor receives the full value of the weighting for that factor, and (in the case of two options like in this project) the other option receives zero. This process is carried out collaboratively by the team, and necessarily carries a degree of subjectivity, while based on the objective observations gathered previously. Then the values are summed to determine the relative advantage of each.

Schedule risk was given the highest weighting, since the project team felt that delivering the project late to the owner would have negative side effects in terms both financial and reputational, and even possibly litigious. Of note, cost is not on this list, as under CBA, cost is not an advantage. Only once the advantages have been assessed is the cost considered, and a determination is made about whether the cost is justified to obtain the advantages of the respective option.

The CBA summation appears in Table 3, which combines the factors from Table 1 and Table 2 and adds the assignment of the advantage points to each factor/option.

The cost of SS was determined to be roughly double the cost of RB. Thus, at the final stage of the process, considering the costs of the alternatives, it was clear that the decision came down to a tradeoff between cost and risk: a high risk alternative at a relatively lower cost, and a low risk alternative at a relatively higher cost. Ultimately, it was decided that the higher cost of this one component of the overall project was indeed worth the advantages that SS offered, primarily in terms of reduced risk to the entire project, and the decision was made to switch from RB to SS.

Table 3: Summarized Advantages/Conclusions for the Alternatives

Factor	RB		SS	
Schedule Risk (Probability of completing project on time)	Att: Low: <30%		Att: High: >90%	
			Adv: 60% Increase in probability to complete the project on time	Imp: 100
Soil Stability Risk	Att: Extreme: 20		Att: Low: 4	
			Adv: Risk reduction from very high to medium	Imp: 60
Safety Risk	Att: Very high: 15		Att: High: 10	
			Adv: Risk reduction from very high to medium	Imp: 80
Resources	Att: Advanced equipment & low labor input		Att: Traditional equipment & extensive labor input required	
		Imp: 40		
Impact on other works	Att: Low		Att: High	
	Adv: Less impact on other works	Imp: 40		
Logistics	Att: Low complexity		Att: High complexity	
	Adv: Lower complexity	Imp: 35		
Duration	Att: 14 months		Att: 24 months	
	Adv: Shorter duration	Imp: 30		
Total Sum of Advantages		**145**		**240**

DISCUSSION

The case study above demonstrates the phenomenon of optimism bias in construction and suggests a coping mechanism based on sound and transparent decision-making processes, achieved through CBA implementation. It is likely that if we ask the "5 Whys" (Ōno, 2008) regarding many of the faults in construction, optimism bias may be among the root causes. From the contractor's side, optimism bias may lead to unrealistically low tender-winning prices (leading to the "winner's curse"), perhaps with the hope that additional profit sources will be found along the way (e.g. change orders, acceleration incentives, etc.). From the owner's side, optimism bias may push immature projects to the construction phase before all preconditions are met, assuming things will work out along the road. Optimism is also reflected in the way a project status is reported to stakeholders and financing bodies, so funding won't be jeopardized by hints of doubt. But a dose of reality is often exactly what the project needs to steer it back to on track to a successful outcome.

The case of the PHES facility demonstrates how taking the right action, especially at the last responsible moment (Howell and Lichtig 2008), requires a sound process that relies on objective facts and supporting data (like statistical analyses) that are communicated to decision makers and stakeholders. Despite the hindsight observation that changing construction methods was required once the soil conditions were discovered, in practice it was not simple at all. SS was more expensive and considered “less advanced”, two strikes against it for the instincts of many professionals in the organization. It took a lot of deliberation, and the CBA process was the key to making the right decision for the project. Thus, this implementation reinforces and demonstrates the findings of previous research (Arroyo et al., 2015; Schöttle et al., 2023), emphasizing it being a simple, clear, transparent, and well documented MCDM process, which assists in avoiding falling into optimism bias. Ultimately, using CBA, the team was able to determine that paying more for SS was worth it as it reduced the project risks.

In addition, this paper adds to the body of knowledge on CBA, by providing framework to emphasize risk factors as part of the decision-making process. The Monte Carlo simulation was found immensely useful to quantify the likelihood and impact of the risks to the schedule, which in turn led to it being recognized as the anchored advantage for the CBA analysis. Additionally, it demonstrated how the different (and sometimes fragmented) disciplines of traditional project management practice (budget, schedule, quality, risks, etc.) can be drawn together by the CBA process, making them relevant and influential to the path of the project.

CONCLUSIONS

Decision making in a complex, multi-input and multi-variable setting like a construction project is hard, made only more-so by the innate psychological biases that humans possess. But as shown in this paper, systematic approaches to decision making can help.

The reality is that most people involved in construction projects want the project to succeed, and want to believe that it will succeed. But choosing only the most optimistic interpretations of the situation and future outcomes does not ultimately serve the long-term interests of the project outcomes. Therefore, picking what seems to be the cheapest or quickest path based on those assumptions could lead to getting stuck in a less-globally-optimal path, if it is dependent upon everything going smoothly. CBA can create the space to have the tough conversations in a proactive manner and not only once everything has gone awry, and it puts consideration of cost as the last step, instead of following the industry convention of always going with the low-cost alternative. As such, this paper contributes to the body of knowledge around CBA by suggesting a key use-case for the approach in addressing the planning fallacy.

In terms of limitations, like any case study, our data set is severely limited. The authors think that, on the balance, the case study indicates that CBA can be an effective antidote to the optimism bias, and one that would benefit from further study. The “gold standard” for future work would be a randomized trial, examining outcomes of some projects that employ CBA versus a non-CBA intervention (to combat the Hawthorne Effect (Landsberger, 1961), particularly as a double-blind trial is not feasible in this case), and applying metrics for measuring optimism bias and/or the planning fallacy. This would admittedly be quite a challenge to implement, so at a minimum more case studies could be trialed.

AN EXPLORATION OF PSYCHOLOGICAL SAFETY AND TEAM BEHAVIORS IN A CONSTRUCTION GLOBAL TEAM

Sulyn Gomez Villanueva[1], Glenn Ballard[2], Stephen Terni[3], Paz Arroyo[4] and Kevin Bello[5]

ABSTRACT

Psychological safety is a construct that has garnered attention in academia and industries over the last two decades. Research has shown the connection between psychological safety and several team behaviors, from learning to active caring. Most research however has focused on exploring psychological safety within traditional teams. This paper extends the research on psychological safety by capturing the psychological safety and behavioral dynamics of a global virtual corporate team in the construction industry. We found that psychological safety positively relates to some behaviors such as making reliable promises and active listening, and these in turn positively relate to better team performance. This paper also describes actions the team in the study committed to follow to improve, based on the assessment conducted in this study. Future research should concentrate on using longitudinal assessments to explore variations within the team over time and understand what interventions can improve team dynamics.

KEYWORDS

Psychological safety, behaviors, team dynamics, global teams, learning, reliable promising.

INTRODUCTION

Edmondson and Bransby (2023) highlighted the boom of research focused on psychological safety due to the recognition of the “challenge of navigating uncertainty and change.” Psychological safety has been studied in-depth in many industries such as healthcare, manufacturing, and technology. However, its exploration in the construction industry is still nascent (Shen et al. 2015; Gomez et al., 2019; Gomez et al., 2020; Gomez, 2023). Moreover, the literature exploring psychological safety in construction is limited to studying project teams working geographically together to deliver a construction project.

A team is a “collection of individuals who are interdependent in their tasks, who share responsibilities for outcomes, who see themselves and who are seen by others as an intact social entity embedded in one or more larger social systems (for example, business unit or the corporation), and who manage their relationship across organizational boundaries.” (Cohen & Bailey, 1997). Psychological safety within a team depends on a number of variables such as

1 Quality Leader, DPR Construction, Redwood City, USA, sulyng@dpr.com, orcid.org/0000-0003-2367-9880
2 Research Associate, Project Production Systems Laboratory (P2SL), University of California, Berkeley, USA, gballard@berkeley.edu, orcid.org/0000-0002-0948-8861
3 Quality National Leader, DPR Construction, Pasadena, USA, stephent@dpr.com, orcid.org/0009-0008-1217-2842
4 Quality Leader, DPR Construction, San Francisco, USA, paza@dpr.com, orcid.org/0000-0002-8098-8172
5 Principal Researcher, The University of Chicago, USA, bellok@uchicago.edu, orcid.org/0000-0002-3661-8158

interpersonal relationships, organizational norms (Kahn, 1990), leader behavior, group dynamics, trust and respect, organizational context (Edmondson, 1999; Zhang et al., 2010). Psychological safety is established through interactions in which team members make assessments of how they treat one another (Duhigg, 2016; Gomez et al., 2019). For instance, leaders using hostile verbal and non-verbal behaviors can negatively affect their team psychological safety (Tepper, 2000; Burris et al., 2008; Agarwal & Anantatmula, 2021). However, leaders using inclusive behaviors can positively affect psychological safety (Feitosa & Salas, 2021). Psychological safety is a key differentiating factor in understanding teams that thrive and learn together versus those who build defensiveness routines (Argyris, 1985; Schein, 1985; Schein, 1992; Edmondson, 1999). Such routines, typically triggered for personal protection, can hinder the team learning process (Sterman, 1994). Many studies explored the role of psychological safety on team behaviors (what we refer to as team dynamics), from learning with the seminal work of Edmondson (1999) to speaking up, (Detert & Burris, 2007) to being respectful and actively caring for others (Gomez et al., 2019; Gomez et al., 2023), etc.

The purpose of this study is threefold. First, we review the literature on psychological safety, team dynamics, and global teams. Second, we explore these within a specific team: a corporate services global team that oversees the quality department for general contractor company with presence in America, Europe, and Asia. To the authors knowledge, this is the first study focused on understanding psychological safety in a global team in the construction industry. Third, we describe some actions the team decided on taking that can lead to further improvements. The following questions were explored in this study:

- *RQ1: what is the relationship between psychological safety and team behaviors in a global team?*
- *RQ2: what actions can global teams take to foster psychological safety?*

LITERATURE REVIEW

TEAMS IN THE CONSTRUCTION INDUSTRY

Most teams in the construction industry are assembled at the project level with people from diverse backgrounds (e.g., builders, architects, electrical engineers) who come together temporarily with one objective, delivering a project within certain constraints (Jefferies et al., 1999). Although team members share this common goal, each might have their own priorities ranging from job stability to optimizing the profitability of their companies. These teams need to learn quickly how to work together as a team and build the project to achieve the expectations safely using the resources they have (Cornick & Mather, 1999). Other teams, typically at the corporate service level, are assembled for longer durations to plan corporate strategies concerned with "operations of the entire organization" (Cheah & Garvin, 2004).

Project and corporate teams' complexity may vary depending on several factors, from team size to geographical distribution (e.g., teams being co-located versus geographically dispersed) to diversity of skills and backgrounds. Corporate teams of large multinational corporations, the core of this research, typically function as global virtual teams. Our understanding of global virtual teams is those who are constituted by "geographically and culturally dispersed individuals assembled through communication technologies" (Massey et al., 2003).

CHALLENGES IN GLOBAL TEAMS

Development Dimensions International (DDI) et al. (2018) analyzed leadership readiness in this digital era and reported that *leading virtual and remote teams* is still a weakness in leaders' readiness and suggested paying attention to developing this competency. Some of the challenges when working in these teams include:

- Communication problems and misunderstandings due to different languages (Chen at al., 2006). Positives of global teams (e.g., diversity of perspectives) can be hindered if members are not able to communicate effectively (Berg & Holtbrügge, 2010).
- The lack of social cues in virtual meetings, such as eye contact or voice inflections (Straus & McGrath, 1994), make it difficult to assess participants' reactions or engagement.
- Higher instances of members feeling isolated or getting distracted (Edmondson & Daley, 2020).
- Cultural differences and its impact on how people interact with each other, including individualism-collectivism, power distance, masculinity-femininity, uncertainty avoidance (Hofstede, 2001; Hofstede et al., 2010).

Dusenberry and Robinson (2020) highlighted a common but probably wrong assumption. They said, "we (when working in teams) assume that how to collaborate is already known or emerges from practice." However, global virtual teams may struggle with less cohesion, engagement, and satisfaction (de Pillis & Furumo, 2006), resulting in lower productivity than face-to-face teams (Straus & McGrath, 1994). One mitigating strategy to the challenges faced in these teams is fostering psychological safety (Gibson & Gibbs, 2006; Feitosa & Salas, 2021).

TEAM DYNAMICS: PSYCHOLOGICAL SAFETY AND TEAM BEHAVIORS

Literature that explores speaking up and the organizational conditions that favor voice or silence behavior have looked at several things, from the individual's personality and characteristics (e.g., LePine & Van Dyne, 1998) to their attitudes (e.g., Rusbult et al., 1988) to their assessment of whether it is safe for them to speak up (e.g., Edmondson, 1999, Milliken et al., 2003). For the latter, people assess the perceived costs of speaking up to themselves (e.g., humiliation, termination) in order to decide whether to do so (Edmondson, 1999; Gomez et al., 2019).

Cheah and Garvin (2004) suggested that organizations should treat human resources (the people in a team) as one of the building blocks of corporate strategy. They pointed out that a "new technological process in construction by itself may not create a sustainable advantage unless the process also draws support from proper human resource strategy (e.g., a proper training program in place)." Given that the attention to the construct of psychological safety in construction is growing, understanding how it applies to global teams in this context is critical for the development of corporate strategies. To illustrate, psychological safety can help corporate teams deciding what efforts to pursue by improving the concept screening process used to assess go/no-go decisions for moving forward with an idea (Cole et al., 2022)

Psychological safety is one of the most important factors distinguishing high-performing teams from average ones (Rozovsky, 2015). Researchers have found positive correlations among psychological safety and learning, performance (Edmondson, 1999), knowledge creation (Cauwelier et al., 2019), knowledge sharing (Mura et al., 2016), creativity (Agarwal & Farndale, 2017; Liu et al., 2021), innovation (Gu et al., 2013). Gomez (2023) conducted a number of case studies and analyzed how psychological safety impacted team members' behaviors such as active caring, active listening, and making reliable promises. A team's psychological safety and the behaviors displayed in this context represent what we understand as the team dynamics (i.e., how a team functions together). Gomez' work was focused on teams managing quality, therefore we used her framework to explore the team dynamics for this research.

LEADING GLOBAL TEAMS

Knowing that psychological safety creates favorable conditions for speaking up (Edmondson, 1999, Edmondson & Bransby, 2023), a number of leadership constructs have been studied as precursors to psychological safety, e.g., leader-member exchange (Cong et al., 2023), inclusive leadership (Carmeli et al., 2009), shared leadership (Gu et al., 2016). Detert and Burris (2007) highlighted the importance of leaders in fostering psychological safety to promote voice behavior. He said, “a subordinate’s current overall performance likely includes his/her manager’s reaction to prior speaking up.” Due to the key role of leaders in driving or not a psychologically safe work environment, we highlight some of the strategies to lead these teams:

- Take advantage of virtual platforms to get to know each member at a deeper level (Feitosa & Salas, 2021). For instance, recording sessions when deemed necessary to allow access to those who cannot join the meeting live, facilitating connections through virtual happy hours, encouraging e-introductions when new members join, setting time aside in team meetings to allow and promote members participation in the conversation.
- Design strategies to allow team members socialize and get to know each other in a personal way (Lagerström & Andersson, 2003; Ford et al. 2017).
- Model behaviors that enhance psychological safety such as listening, competence, and transparency (Edmondson & Bransby, 2023).

Edmondson and Daley (2020) said that “(virtual) teams can be lonely places… building psychological safety in virtual teams takes effort and strategy that pays off in engagement, collegiality, productive dissent, and idea generation.” Team dynamics may improve when people are well acquainted as members feel more psychologically safe, improving therefore the team’s effectiveness and efficiency (Chevrier, 2003)

METHODOLOGY

We used an exploratory case study (Yin, 2013) to conduct a detailed analysis of a particular team, explore its dynamics, and describe the opportunities for improvement proposed. Our case is a team within a company that placed among the top 10 of the Engineering News Record’s 2023 Top 400 Contractors ranking. This team, known internally as the “Quality Leadership Network (QLN)”, had 16 active members at the time the study took place.

We used a questionnaire to assess the constructs of our study (i.e., psychological safety and team behaviors) from a single global team. The questionnaire included some questions measured on a 7-point Likert scale that were adapted from prior research, and some open-ended questions (see full list of questions used in Gomez (2023)). Participation was voluntary and individual responses were kept confidential and reported at a team level for research purposes.

The numbered questions were used to measure the team dynamics on a scale. The open-ended questions were used to gather participants input on what actions their team could take to help them feel safer. This input served the team to discuss how to nurture the desired behaviors to continuously grow and commit to specific actions for improvement.

RESULTS AND DISCUSSION

A total of 12 team members answered the questionnaire, representing a 75% participation rate. We included the following control variables: (1) team tenure (time spent working with this team), (2) company tenure, and (3) role. Members of this team played one of the following roles: quality engineer, quality manager, project manager, or superintendent. Other control variables (e.g., ethnicity, race, age, gender) were not included due to the team size limitation.

PSYCHOLOGICAL SAFETY, TEAM BEHAVIORS, AND PERFORMANCE

Although some authors measure psychological safety at the team level using one score only, combining team members’ perspective regarding their coworkers and supervisors, we used Gomez’ (2023) scale that assesses psychological safety, both in relation to coworkers and to supervisors separately. Past research shows that supervisor behavior is “one of the most important sources of cues about whether it is worthwhile and safe to voice” because they are typically the target of voice and because of the power they hold over employees’ outcomes such as promotions and pay (Morrison 2011). However, the influence of coworkers on employee behaviors has also a role to play on whether they are more willing to speak up, e.g., by modeling speaking up (Subhakaran & Dyaram, 2018; Ng et al., 2021). Construction, particularly, can be a very hierarchical industry so we treat psychological safety with respect to both targets as separate but related facets. A high score indicated high levels of psychological safety. Sample items include, “I am able to bring up problems and tough issues to my team leader”, and “If I make a mistake while doing my work on this team, I feel safe speaking up to my team leader.”

Table 1 shows the results for the team members’ perception of psychological safety broken down with respect to the team leader and their coworkers. Table 2 breaks down the results by tenure. Previous studies measuring psychological safety by tenure identified some curvilinear relationship between psychological safety and team tenure (Koopmann et al., 2016) while others suggest a positive relationship between tenure and voice behavior (Detert & Burris, 2007; Burris et al., 2008), which can be partially attributable to psychological safety. Due to the team’ sample size, we cannot make an assessment with statistical validity, but results show more variation when comparing tenure in team versus tenure in company, which is consistent with the construct of psychological safety measured at the team level.

Table 1: Team Psychological Safety Results (1=low, 7=high psychological safety)

Psychological Safety in Relation to	Team Perception
Team leader	5.604 (sd=0.98)
Coworkers/other members of your team	5.833 (sd=1.18)

Table 2: Team Psychological Safety Results by Tenure (1=low, 7=high psychological safety)

By Team Tenure	By Company Tenure	Team Psychological Safety
< 1 month		4.188
1 – 6 months		5.938
6 – 12 months		6.281
> 1 year		5.742
	1 – 5 years	5.800
	5 – 10 years	5.828
	> 10 years	5.438

The open-ended responses provided more insight into what the team was doing well to foster psychological safety. These responses can be used to foster awareness and reinforce the actions that were helping the team move toward a more psychologically safe environment. Examples below illustrate the team’s input:

“I feel my team provides a lot of comfort when it comes to discussing day-to-day issues or upcoming deadlines. I don’t feel like I have a fear of speaking up or mentioning something that I feel would improve our processes.”

"I feel extremely blessed to be a part of [this team]. I hope that we can be the leading example for other work groups within [our company]."

Some opportunities for improvement were also raised, which were used along with the team dynamics assessment in the team's brainstorming session to determine actions moving forward:

"I would say an opportunity for improvement could be to assure that the team is doing well outside of work as well… Opening the floor to the team to talk about external problems that may be affecting their work could be a way the team feels more supported."

"I'll avoid bringing up simple issues, as I do not match the academic or professional status as others have."

"Create more vulnerable moments within the team. Give the team members more opportunities to participate."

Our study of team dynamics included measuring the behaviors described in Gomez (2023) due to its relevance for a corporate team managing quality. We used the questions developed in that study to assess each of the behaviors shown in Figure 1. To illustrate, a sample item to assess the behavior of *being respectful* was, "Members of my team are valued and their contribution to the team matters." Similarly, an item to assess the behavior of *making reliable promises* was, "Members of my team make sure there is clarity around acceptance criteria before proceeding."

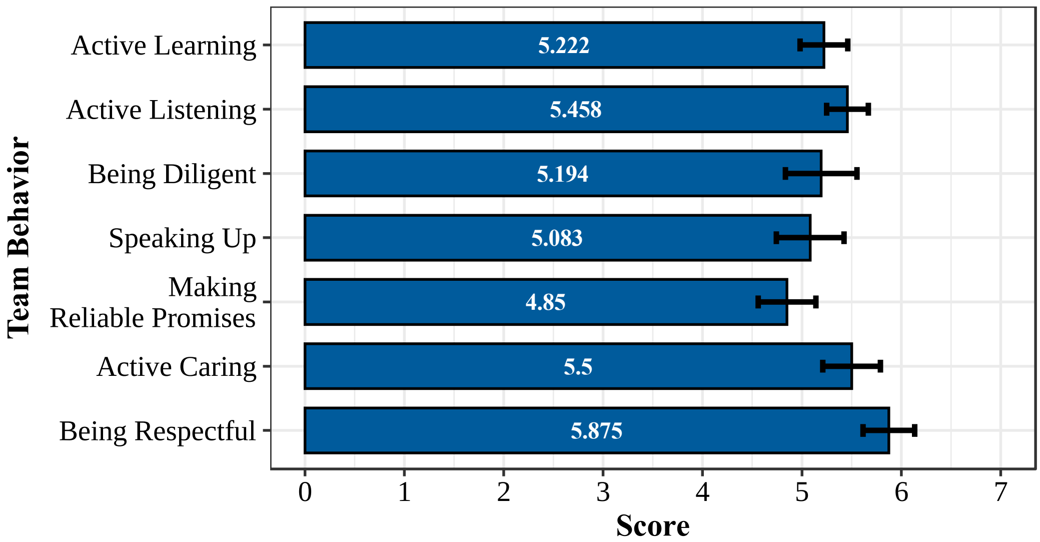

Figure 1: Team Behaviors Assessed

Measuring the team dynamics by breaking the analysis down to specific behaviors helped the team to analyze their strengths and opportunities for improvement on specific areas. These behaviors, connected through social interactions, are intertwined. In some ways, psychological safety promotes respect and respect promotes psychological safety. For instance, when individuals feel psychologically safe and express their ideas, others will react in ways that show respect and appreciation. Similarly, when team members are trusted to act independently, they perceive a sense of well-being and respect that in turn fosters psychological safety (Fenner et al., 2023). Actions the team decided to implement based on analyzing these results are described in the next section.

We also measured performance using the questions developed in Gomez (2023). Table 3 shows the correlations we found between our study variables, grouping the behaviors we deemed to study as one variable called "desired team behaviors." As shown, psychological safety is highly correlated to the behaviors we studied (r = 0.729), and this, in turn, is highly correlated to team performance (r = 0.909).

Table 3: Correlations of Study Variables

n = 12	Psychological Safety	Desired Team Behaviors	Team Performance
Psychological Safety	1.000	0.729	0.691
Desired Team Behaviors		1.000	0.909
Team Performance			1.000

All correlations shown in this table are significant at $p < 0.01$

Since the sample size in our study is limited, we cannot properly make statistical conclusions. However, our results are consistent with past studies that identified positive relationships, for example, between psychological safety, team behaviors such as learning, and resulting performance (Edmondson, 1999; Wilhelm et al. 2019; Gomez, 2023), psychological safety, learning, and knowledge creation (Cauwelier et al., 2019), and listening, psychological safety and creativity (Castro et al., 2018).

TEAM'S ACTIONS FOR IMPROVEMENT

Reviewing the team dynamics assessment results allowed the team to start acting on it. The team hosted a start-stop-continue working session to analyze the study results and brainstormed ideas for a path forward. Some of the actions the team decided to take included:

- Launch a book club to dive deep into specific concepts. Salas et al. (2008) found that training may improve a team's outcomes. Dusenberry and Robinson (2020) proposed that psychological safety can be improved through training interventions that can foster personal awareness of how team members depend on each other for their teams to be successful. For instance, the team behavior that needed further improvement per the survey was making reliable promises. The team committed to go over the seminal book Conversations for Actions and Collected Essays from Flores (2012).
- Be intentional in celebrating big and small wins as a team and keep shoutouts as an agenda item consistently in weekly team meetings. Team leaders inviting and showing appreciation for other member's input fosters psychological safety (Nembhard & Edmondson, 2006) and therefore members participation and engagement (Carmeli et al., 2009; Zhang et al., 2010).
- Continue hosting an annual in-person meeting. Dixon (2017) described an in-depth study of a virtual team that used face-to-face interactions as part of their strategy to facilitate learning and foster psychological safety. Some strategies he highlighted for these in-person meetings included, for example, having the team codesigning an agenda, and the use of facilitators and whiteboards to encourage experimentation. This leader in this team stated how he envisioned these meetings to help the team, "In order to advance our team, it was critical that we met face-to-face at least once over the year. The focus of our in-person meeting was largely on fostering trust, openness, and to create alignment around our goals and priorities. All too often remote teams use the face-to-face meeting formats to get as much done as possible and miss the critical (and often only) time to truly align the team culturally."

- Use video in virtual meetings, to the extent possible. Ford et al., (2017) suggested that leaders in virtual environments should use gestures (e.g., facial expressions to convey emotions and show attentiveness, smiling to create a welcoming atmosphere, nodding to indicate agreement or understanding) and be trained on virtual skills such as detecting early signs of conflict or withdrawal (e.g., lack of eye contact, participants joining late or leaving early consistently, frowning eyebrows but not voicing their thoughts).
- Align on weekly meeting rules regarding content and format (e.g., making sure an agenda is sent out before meeting, so members know what the meeting purpose and topics are ahead of time, avoiding running over time as participants may have other commitments to attend, rotating meeting facilitators).
- Spend time on project sites to oversee the implementation of corporate strategies and provide feedback to the team (e.g., what processes project teams are struggling with, what resources they need).
- Assess team dynamics once a year, review commitments from prior year , and rethink actions for improvement (interventions) for the upcoming year. The team leader pointed out that this assessment was a critical step in the endeavor of creating an environment where deeper conversations can occur, one of psychological safety.

Additional opportunities to explore from the literature include:

- Considering the challenges of global teams due to a number of cultures coming together, conduct interventions that focus on cultural intelligence, which is a "person's capability to adapt effectively to new cultural context" (Earley & Ang 2003, p. 59).
- Deliberately plan interventions to foster open communication and make interventions team-specific. Cong et al. (2023) suggested that "high-quality exchanges with leaders help improve the psychological safety of construction workers." Also, Dusenberry and Robinson (2020) described that when training is specifically designed for a target, it increases "personal awareness of interdependence among team members."
- Modeling the behaviors expected from the team so others can imitate them. The social learning theory suggests that behaviors can be acquired through role modeling, involving the observation of others' behaviors and their associated consequences (Bandura, 1977).Other team members' behavior plays a key role in creating psychologically safe spaces (Subhakaran & Dyaram, 2018; Gomez et al., 2019; Ng et al., 2021). For instance, if team members observe that speaking up to share mistakes is not only encouraged but welcomed and rewarded in the team, resulting in the person getting help to solve the mistake rather than punishment, then they would be more willing and open to sharing when they make a mistake rather than trying to hide it.
- Design actions to strengthen coworker-to-coworker and supervisor-worker communication. Both coworkers and supervisors have great influence on shaping employees' beliefs about what behaviors are acceptable and valued in the team (Zohar & Polachek, 2014; Gao et al., 2016).

CONCLUSIONS

Research on psychological safety, although prominent in many industries, has "largely studied old-fashioned intact teams" (Edmondson & Bransby, 2023). Our study represents the first attempt to document psychological safety and the behavioral dynamics of a global virtual team in the construction industry. Our findings have important implications in practice. We confirmed a relationship identified in past studies between psychological safety, learning, and team performance for a "non-traditional" team. In addition, we extended this analysis to explore whether this relationship remains for other behaviors such as making reliable promises. Teams looking to nurture the behaviors assessed here can start paying attention to also fostering psychological safety, so these behaviors occur more naturally. Further, we described actions that this team committed to do for improvement based on the team dynamics assessment used. While the impacts of these actions had not been analyzed yet, they serve as inspiration for other teams trying to foster similar team dynamics or struggling with the challenges of global work.

This research explored psychological safety and its implications in one global team, which poses some limitations. First, generalizability of our findings is limited. Our sample, even though representative for the team considering its participation rate, is small and only represents the results of a single team. Although not a large enough sample to undertake reliability analysis of the constructs used in this study, we used previously designed instruments that showed reliability in Gomez (2023). Second, because our study describes the team dynamics at a single point in time, we cannot predict the impact of the actions for improvement the team designed as a result of the initial diagnosis. Little research exists about what creates psychological safety and the longitudinal nature of team dynamics (Dusenberry & Robinson, 2020; Edmondson & Bransby, 2023), highlighting the need to first understand how these dynamics shift over time and second to identify specific interventions that can facilitate building psychologically safe environments. A longitudinal study with this team over several time periods, currently planned, could provide a better understanding of the results of implementing the efforts for improvement proposed. Third, this case study is limited to one global team in the construction industry. Future research could include cross-team and company comparisons, within construction and other industries, using longitudinal data to assess whether the relationships found in this study represent other contexts and are maintained over periods of time, or the nuances that can be observed.

AN INVESTIGATION OF PSYCHOLOGICAL SAFETY IN CONSTRUCTION PROJECTS AND ITS INFLUENCE ON TEAM LEARNING BEHAVIOUR: A SURVEY-BASED STUDY

Selina Häringer[1], Sulyn Gomez[2] and Annett Schöttle[3]

ABSTRACT

Due to a construction project's dynamic, interdependent, and complex environment, it is crucial that team members are able to talk openly about risks, mistakes, ideas and best practices without fearing interpersonal risks such as punishment or dismissal. Sharing knowledge is especially critical as team structures change over a project. Therefore, psychological safety is an essential key enabler in such project environments. This paper is built upon a cross-sectional survey-based study (N=163) used to assess the current level of psychological safety within teams of the Owner, Architect, Engineering, and Construction (OAEC) industry based on the views of individuals in different teams. Furthermore, the study aimed to identify factors that can enhance psychological safety in construction project teams. These include, for example, a good failure culture, communication, and a mindset toward collaboration. The results show a strong positive relationship between psychological safety and team learning behavior, with psychological safety as a predictor explaining 50% of the variance in team learning behavior.

KEYWORDS

Construction project teams, psychological safety, team learning behaviour.

INTRODUCTION

One of the biggest challenges within construction projects is fostering open communication to create synergies, address mistakes, and thus learn together (Baiden et al., 2006). However, based on mainly traditional structures, competitive relationships and a lack of collaboration are particularly prevalent in the industry, highlighting issues such as a low level of trust, inadequate communication, and unfair risk sharing. The resulting time and cost overruns due to disputes, for example, are commonplace within the industry, so poor performance is often attributed to the lack of effective working relationships between project participants (e. g., Faris et al., 2019; Sumner & Slattery, 2010; Schöttle & Gehbauer, 2013; Fulford & Standing, 2014; Rooke, 2014; Rosenfeld, 2014; Schöttle, 2022). This can have a significant impact not only on the success of the project but also on its execution, especially on the physical safety of those involved (Gomez et al., 2020; Faris et al., 2019). By addressing issues and mistakes early on and collaborating to benefit from shared information and experience, risks and mistakes can be reduced or eliminated during the design and construction phases (Howell et al., 2017).

Due to the dynamic and uncertain nature of a construction project's environment, errors and hazards are frequently unavoidable. Therefore, it is essential that they are addressed openly and that the team is given the opportunity to learn from them so that they do not recur and that long-term solutions can be found through shared learning and innovative approaches (Gomez et al., 2020). However, the fact that those who have pointed out errors or a lack of knowledge have been punished with negative consequences, has led to significant inadequacies (Gomez et al., 2020). In many cases, an environment where employees are ignored, ridiculed, or even disciplined for speaking out can be dangerous, especially when employees feel that their word counts for nothing and conclude that it is not worth speaking out due to self-protection (Edmondson, 2019). This is particularly difficult in a traditional sector such as construction, where the credo "we've always done it this way" often applies (Santorella, 2011).

As conceptualized by Edmondson (1999), psychological safety refers to a person's perception of the team environment as safe for taking interpersonal risks. When team members perceive a high level of psychological safety, they are more willing to engage in open discussions, share knowledge, and experiment with new approaches, leading to improved team learning (Edmondson, 1999; 2002). This includes, among other things, team members feeling encouraged to contribute their expertise, share their ideas, and provide constructive feedback to improve team performance and, thus, project performance. The interpersonal risk of raising a concern or question with a more senior person is also described by Santorella (2011) as “showing vulnerability,” which is distinct from psychological safety as a construct. In general, vulnerability requires courage to be open and authentic and often involves a degree of risk as you cannot be sure how others will react (Brown, 2018). Nonetheless, the two constructs are generally closely related and can have a positive reciprocal effect, as showing vulnerability by individuals can help to build trust and psychological safety within a group or team (Edmondson, 1999). Consequently, the construct of psychological safety within the construction industry is vital in reducing the anxiety of interpersonal risk, thereby creating essential conditions for improving productivity, safety, quality, and innovation (Gomez, 2023).

Zhang and Fai Ng (2012) describe the construction industry as a knowledge-intensive industry in which it is crucial for professionals to share their knowledge, build mutual understanding, and work together to find effective solutions to improve the efficiency of project delivery. According to Howell et al. (2017), learning organizations are essential in construction projects to minimize the difference between as-found and as-planned work. They argue that the need for organizational learning is demonstrated by workers speaking up when there is a potential obstacle to the execution of a job or by the team on a construction project working together to find the safest way to execute a job (Howell et al., 2017). Furthermore, studies have shown that psychological safety is a driver of team learning behaviors (Gomez, 2023; Gomez et al., 2019; Newman et al., 2017; Van den Bossche et al., 2006; Edmondon, 1999).

The main aim of the study is to address a significant research gap by examining the concept of psychological safety within a portion of the OAEC industry and its impact on team learning behavior. Additionally, the study seeks to raise awareness within the construction industry regarding the importance of psychological safety and offer valuable insights and practical recommendations. The research questions were:

- How psychologically safe do people feel in the OAEC industry?
- How can psychological safety be enhanced in construction project teams?
- How does psychological safety affect team learning behavior?

Also, the following research hypothesis was proposed:

H_1 Psychological safety is positively correlated with team learning behavior in construction project teams.

H_0 There is no significant correlation between psychological safety and team learning behavior in construction project teams.

THEORETICAL BACKGORUND

PSYCHOLOGICAL SAFETY AND LEAN

The concept of psychological safety, as defined by Edmondson (1999), has started to gain traction in the construction industry, particularly in terms of its connection to Lean and the impact it's having on project teams (Gomez et al., 2019; Gomez et al., 2020; Howell et al., 2017; Demirkesen et al., 2021; Gomez, 2023). For example, Demirkesen et al. (2021) discovered in a multi-method study conducted in the U.S. that projects using lean construction had more psychological safety. Gomez (2023) also investigated the relationship between psychological safety, Lean, and team behavioral dynamics, highlighting how some Lean principles, such as "respect for people," relate to psychological safety and the interdependent role that one plays in promoting the other.

Psychological safety is achieved when team members trust and respect each other and are able to open up (Edmondson, 2002). Edmondson's (1996, 1999, 2019) definition differs from Kahn's (1990) definition by expanding the construct of psychological safety for the first time as "a team-level climate" rather than an individual's perception of a feeling (Newman et al., 2017, p. 523). It was found that people working closely together tended to have similar perceptions of psychological safety, whereas scores varied between groups within the same organization (Newman et al., 2017). This difference in an employee's feeling of psychological safety within an organization, from department to department and from team to team, can be attributed primarily to differences in the behavior of local managers and supervisors, regardless of how strong the corporate culture is (Edmondson 1999, 2003).

TEAM LEARNING BEHAVIOUR

Team learning is particularly important for working together effectively in a constantly changing environment, which is the case for construction project teams (Decuyper et al., 2010; Zhang & Fai Ng, 2012). There are several definitions of team learning. Each of them describes it as a complex concept that can be viewed from different perspectives, and its meaning can vary depending on the context and discipline (Decuyper et al., 2010; Edmondson et al., 2007). Edmondson et al. (2007) referred to team learning as an umbrella term that encompasses and connects multiple theories and studies. Generally, the well-known definitions can be divided into learning as a process (Edmondson, 1999; 2002), learning as an outcome (Ellis et al., 2003), and learning as a mixture of both (Storm et al., 2010).

Edmondson's (1999) definition of team learning is adopted for this study as it describes several concrete and different learning behaviors and is dominant in research (Savelsbergh et al., 2009; Edmondson, 2002; Storm et al., 2010). Edmondson (1999) defines team learning as "an ongoing process of collective reflection and action characterized by (a) exploration, (b) reflection, (c) discussion of mistakes and unexpected outcomes of action, (d) seeking feedback, and (e) experimentation within and as a team" (Savelsbergh et al., 2009, p. 582). She distinguished the learning process from the learning outcomes using the phrase "team learning behavior," which was also adopted for the present study (Edmondson, 1999).

METHODOLOGY

RESEARCH DESIGN AND SAMPLING APPROACH

The research design of the present study is based on a quantitative cross-sectional survey in which data was collected in the form of an online-based questionnaire for self-completion. In addition, to give participants a chance to contribute their perspectives and possibly uncover novel insights in the field, as in a qualitative research approach, the questionnaire included an open-ended question providing qualitative data about psychological safety and how it can be improved within construction project teams.

The selection of the sample was guided by predetermined criteria to fulfill the research questions and hypotheses precise demands and guarantee the data's comparability. The desired sample consists of people who work within the construction industry (filter question 1) and are members of an interdisciplinary construction project team when answering the questionnaire (filter question 2). In order to keep the complexity of the questionnaire low with regard to the different disciplines of a construction project team, only the superordinate areas of design, execution, project management and control, consultancy, and the owner or owner's representatives are considered (filter question 3). Chan et al. (2004) also identified these as key areas.

INSTRUMENT OF DATA COLLECTION

The questionnaire comprises a total of 36 items and offers the option to be completed in German or English. Furthermore, the questionnaire is structured into five main sections: sample filtering, control variables, psychological safety, team learning behavior, and personal information (such as gender and age). The following control variables were asked to ensure generalizability: project volume, team size, team meetings (regularity, online vs. face-to-face vs. hybrid), existence of informal team events (e.g., joint lunches, after-work events), country of work, and whether the respondent is in a management position. Furthermore, the respondents of the desired sample were asked to answer from the perspective of the project on which they are presently spending the majority of their working hours.

To measure psychological safety, the seven items (questions) developed by Edmondson (1999) were used to maintain high content validity (Newman et al., 2017). She used a 7-point Likert scale to assess participants' responses, ranging from "very inaccurate" to "very accurate," including a neutral middle category. This study employed a 6-point scale without a neutral middle category, ranging from "strongly disagree," coded as 1, to "strongly agree," coded as 6. In the context of interpreting the values, it is considered that values equal to or beyond 4, which align with the category of "slightly agree" or higher, are indicative of psychological safety. By removing the neutral middle category, participants are required to adopt a distinct stance on either low or high psychological safety. This is also important due to a statement by Edmondson and Bransby (2022), in which they say that it does make more sense that psychological safety is reported at the individual level for individuals working with different people at different times rather than aggregated in a group context, as in most studies, due to a lack of stability.

Given that each study participant may be responding from the perspective of a different team, the scores for psychological safety are thus left at the individual level. Therefore, the calculated mean score of individuals can be better interpreted without a neutral middle category. The seven questions used to assess psychological safety, including the response options, can be seen in Figure 1.

Psychological safety

Please select the answer option that applies.
The answer depends on how much you think the statement applies to the team on the project on which you currently spend most of your working time.

If you make a mistake on this team, it is often held against you.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
Members of this team are able to bring up problems and tough issues.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
It is safe to take a risk on this team.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
It is difficult to ask other members of this team for help.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
No one on this team would deliberately act in a way that undermines my efforts.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
Working with members of this team, my unique skills and talents are valued and utilized.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
People on this team sometimes reject others for being different.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree

Figure 1: 7-item scale to measure psychological safety and answer options.

Similarly, as for psychological safety, for the measurement of team learning behavior, the 7-item scale by Edmondson (1999) was used due to its strong content validity. The items for team learning behavior are also assessed using a 6-point scale without a neutral middle category. This was modified due to the measurement of psychological safety to facilitate a more accurate comparison of the mean scores of the two variables in subsequent analyses. Consequently, in the context of interpreting the values, it is considered that values equal to or beyond 4, which align with the category of "slightly agree" or higher, indicate team learning behavior. The seven questions used to assess team learning behavior, including the response options (see Figure 2).

Team learning behavior

Please select the answer option that applies. The answer depends on how much you think the statement applies to the team on the project on which you currently spend most of your working time.						
We regularly take time to figure out ways to improve our team's work processes.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
This team tends to handle differences of opinion privately or off-line, rather than addressing them directly as a group.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
Team members go out and get all the information they possibly can from others, such as specialists or other companies.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
This team frequently seeks new information that leads us to make important changes.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
In this team, someone always makes sure that we stop to reflect on the team's work process.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
People in this team often speak up to test assumptions about issues under discussion.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree
We invite people from outside the team to present information or have discussions with us.	☐ Strongly disagree	☐ Disagree	☐ Slightly disagree	☐ Slightly agree	☐ Agree	☐ Strongly Agree

Figure 2: 7-item scale to measure team learning behavior and answer options.

DATA COLLECTION AND SAMPLE

To ensure the questionnaire's validity and reliability and minimize any misconceptions in the wording of the questions and instructions, a pilot test (N = 10) was undertaken prior to the distribution of the survey. The data collection itself took place between June 23 and August 12, 2023, using Unipark's EFS 22.2 Survey software. The survey was distributed via hyperlink and QR code through online social media platforms, as well as directly via email to the researcher's network of construction industry professionals.

As shown in Table 1 on the next page, the participants in the sample are distributed across various sectors within the construction industry, with the majority originating from Germany. Additionally, the gender distribution is nearly equal, with a slight female predominance. Furthermore, a significant proportion of participants aged between 20 and 40, with 1 to 10 years of professional experience, contributed to the study. This demographic profile should be taken into account when interpreting the findings.

RESEARCH FINDINGS

Considering the population of individuals working in the construction industry in the surveyed countries, the sample size of N = 163 is sufficient to provide general conclusions, with the research findings demonstrating a 90% confidence interval with a margin of error of 10%.

MEASURING PSYCHOLOGICAL SAFETY

First of all, a reliability analysis was conducted to assess the internal consistency of the construct of psychological safety prior to the final calculation. Cronbach's alpha is (α) =.78, which is, according to Field (2018), "acceptable." Therefore, the seven items could be summarized as psychological safety. Utilizing a descriptive frequency analysis afterwards, it was possible to determine the current state of psychological safety within construction project.

Table 1: The sample's sociodemographic characteristics

Attributes		Frequency	%	Min.	Max.	Mean	SD
Gender	Female	88	54%				
	Male	75	46%				
Work country	Germany	140	85,90%				
	Austria	16	9,80%				
	Switzerland	7	4,30%				
Working area	Design	30	18,40%				
	Construction	59	36,20%				
	Project Management/Control	34	20,90%				
	Owner	20	12,30%				
	Consultancy	20	12,30%				
Age in years	20-30	67	41,10%	20	62	35	8,72
	31-40	65	39,88%				
	41-50	19	11,66%				
	51-60	9	5,53%				
	61-70	3	1,83%				
Work experience in years	1-5	53	32,52%	1	40	11	8,86
	6-10	48	29,45%				
	11-15	25	15,34%				
	16-20	14	8,59%				
	21-25	9	5,52%				
	26-30	5	3,07%				
	31-35	6	3,68%				
	36-40	3	1,84%				
	41-45	1	0,06%				

The results indicate that the participants in the study (N = 163) perceive a high level of psychological safety within their interdisciplinary project teams, where they currently spend the most working time. The mean score for psychological safety was calculated to be 4.5, with a standard deviation (SD) of 0.76. The result corresponds to a high value for psychological safety, as the value of 4.5 is to be classified within the higher end of the scale, ranging from 1 (indicating little to no psychological safety) to 6 (indicating a high degree of psychological safety). In addition, the participant who reported the lowest level of psychological safety has an individual mean score of 2.29, while the participant who reported the highest level of psychological safety has an individual mean score of 6.00. The graph in Figure 3 illustrates the distribution of the mean values within the sample.

Using an independent-sample t-test, a one-sided statistically significant difference was found between individuals who reported having *regular team meetings* to exchange information and their psychological safety score and those who did not, $t(161) = 1.7$, $p<.044$. The mean score of psychological safety for those with regular meetings was around 0.45 points higher on average (90%-CI [0.016, 0.87]) (see Table 2). Another statistically significant difference in psychological safety was found between individuals who have *informal team events* in their team, such as joint lunches and after-work gatherings (53.4%), and those who do not (42.9%), using a t-test for independent samples, t (120.53) = 3.26, p<.001. The mean score of psychological safety was around 0.40 points higher on average for those who reported informal team meetings (90%-CI [0. 20, 0.60]).

Figure 3: The level of psychological safety

Table 2: Group statistics for the independent-samples t-tests

Team meetings	**N**	**Psychological safety Mean**	**SD**	**Std. Error Mean**
Yes	154	4,53	0,75	0,06
No	9	4,08	0,83	0,28
Team events	**N**	**Psychological safety Mean**	**SD**	**Std. Error Mean**
Yes	87	4,69	0,61	0,07
No	70	4,29	0,86	0,10

However, *no significant mean differences or correlations* could be found between the psychological safety scores and variables such as gender, age, work experience, managerial position, country of work (Germany, Austria, Switzerland), area of work (design, execution, project management/control, consulting, owner), team size, or project volume.

WHAT WOULD HELP TO INCREASE PSYCHOLOGICAL SAFETY?

The open-ended question in the questionnaire was: "What would help you to feel safe in this team to raise concerns, make suggestions, ask questions, and talk about risks and mistakes?" In total, 64 of the 163 participants responded to this question. A content analysis was conducted to identify ways to improve psychological safety on a construction project team. The content analysis resulted in nine themes, along with their respective subcategories. The nine categories are: Feeling safe (12,5% (8 mentions) of the participants mentioned that they already feel very secure in their team and have no suggestions for improvement); failure culture (39,1% (25 mentions)); communication (34,4% (22 mentions)); relationship with other team members (20,3% (13 mentions)); mindset (12,5% (8 mentions)); support (7,8% (5 mentions)); environment (6,3% (4 mentions)); clarity/Structure: (3,1% (2 mentions)); extra time slots for psychological safety (3,1% (2 mentions)).

THE INFLUENCE OF PSYCHOLOGICAL SAFETY ON TEAM LEARNING BEHAVIOR

Before running the analysis, the internal consistency of team learning behavior was checked using a reliability analysis. Cronbach's alpha is (α) =.79, which is "good" according to Field (2018). Consequently, the construct of team learning behavior could be formed as a dependent variable via the mean of the seven items. Subsequently, a correlation analysis and a simple regression analysis were conducted between the two variables to examine the presence of a positive correlation and gain a deeper understanding of the extent to which the variance can be accounted for in the model team learning behavior.

Using Pearson's correlation, a strong positive correlation between psychological safety and team learning behavior could be demonstrated according to Cohen (1988), $r = .709$, $p<.001$. This means that the more psychologically safe team members in construction project teams felt within this study, the more likely team learning behavior could be perceived within the team. Due to the significance level of $p<.001$, the H0 can be rejected, and the H1 can be accepted. This means that psychological safety positively correlates with team learning behavior in construction project teams.

The result of the simple regression analysis with team learning behavior as the dependent variable and psychological safety as the explanatory variable is significant, $F(1,161) = 162.47$, $p < .001$. In addition, the regression analysis yielded an R-squared of .50, which means that psychological safety can explain 50% of the model team learning behavior. Since there are no similar studies within the industry yet and the pilot study data is no longer accessible, according to Cohen (1988), the smallest effect size can be used that is still perceived as practically relevant. For the present study, R-Square= .50, according to Cohen (1988), is considered a very large effect. Due to the significance level of $p<.001$, the H0 can be rejected, and the H1 can be accepted, which means that psychological safety has a statistically significant influence on team learning behavior.

DISCUSSION OF THE RESEARCH FINDINGS

HOW PSYCHOLOGICALLY SAFE DO PEOPLE FEEL IN THEIR CONSTRUCTION PROJECT TEAMS?

Although a first impression guided by the mean score of 4.5 on a scale from 1 (low) to 6 (high) regarding psychological safety can be that the level of psychological safety in the population studied is quite high, Figure 1 shows a good number of respondents' scores being closer to a value of 1-3. This high deviation in the results shows that while some people in this industry feel safe, we still have plenty of work to do to improve the work environment. Other studies in construction industry teams reported means of 5.68 and 6.66 (on a 7-point scale), differentiating the perception of psychological safety from the perspective of craftworkers and staff members, respectively (Gomez et al., 2023). While we cannot directly compare these results because this study collected responses from the view of individuals in different teams, other studies in construction have focused on analyzing psychological safety within one team (Gomez et al., 2019; Gomez, 2023), the results of this study expand upon prior work that focused on ways to enhance psychological safety within this population done by Gomez et al. (2020).

HOW CAN PSYCHOLOGICAL SAFETY BE ENHANCED IN CONSTRUCTION PROJECT TEAMS?

According to Demirkesen et al. (2021), lean construction projects typically have a greater level of psychological safety because meetings are more collaborative and transparent, resulting in improved communication. The study's findings suggest that regular team meetings and informal gatherings can improve psychological safety. This phenomenon can be attributed to two key factors that improve psychological safety: familiarity and the level of prior interaction among team members (Roberto, 2002; Newman et al., 2017). Furthermore, promoting equal interactions between leaders and team members through informal events fosters an environment that encourages open expression regardless of hierarchical structures, as the supervisory relationship is critical for psychological safety in construction projects (Gomez et al., 2020). This, in turn, can decrease the phenomenon of "status anxiety," as discussed by Santorella (2011).

Furthermore, a good failure culture enhances psychological safety, as previously discussed. The participants in this study interpreted a good failure culture as an inclusive setting where team members feel comfortable discussing and acknowledging mistakes as well as engaging in subsequent reflection (Edmondson, 2019). It is important to note that it is primarily up to the manager to establish such a robust failure culture (Edmondson, 2019). However, other coworkers' behaviors can also influence individuals' perceptions of how safe the work environment is (Subhakaran & Dyaram, 2018; Ng et al., 2021). Based on the participants' responses in this study, mindset is primarily about openness to new ideas and innovations that do not correspond to the traditional way of thinking: "We have always done it this way." Additionally, this also includes a collaborative attitude towards working together and driving continuous improvement. Therefore, it is primarily the manager's responsibility to adopt a curious, productive mindset instead of an avoidant one, as well as to reframe problems and mistakes as opportunities to learn and develop.

HOW DOES PSYCHOLOGICAL SAFETY AFFECT TEAM LEARNING BEHAVIOR?

The present study found a significantly strong positive correlation between psychological safety and team learning behavior. Therefore, evidence suggests that the more psychological safety is present in a construction project team, the more team learning behavior is indicated. Thus, in terms of practical implications, enhancing psychological safety in a construction project team is worthwhile, as it is one of the essential prerequisites for team learning behavior. The study aligns with previous research conducted by Edmondson (1999) in terms of examining the strength of the link. Nevertheless, it is important to be aware that a direct comparison of these values is not feasible due to different response scales. However, as previously emphasized by Edmondson and Lei (2014), psychological safety is not the sole determinant of team learning and performance. Instead, it is dependent on the existence of certain conditions that necessitate learning and communication. This is confirmed by the regression analysis conducted as part of this research, as psychological safety is only able to explain 50% of team learning behavior.

LIMITATIONS OF THE RESEARCH

First of all, it is important to acknowledge that there are certain limitations related to the definitions of the variables. Although scientifically accepted definitions were used, there are many definitions of a construction project team, as well as the concepts of psychological safety and team learning behavior, which can make comparisons with studies difficult. Furthermore, by choosing a quantitative research design, the study is limited in terms of the depth and complexity of the examined constructs, as psychological safety and team learning behaviors are multi-layered constructs that are difficult to represent in one single study. Therefore, it is important to note that the study's cross-sectional methodology limits the ability to demonstrate causal links as the data were obtained at a singular time. In addition, self-completion questionnaires are vulnerable to the influence of social desirability and response bias. Also, removing the neutral middle category in the response scales of the constructs of psychological safety and team learning behavior may introduce certain constraints in the results because participants who lack a neutral option may feel obligated to select an opinion that does not accurately reflect their true sentiments just to provide a response. Moreover, the survey participants came from different organizations and teams, which has the disadvantage that other unknown variables may have had an impact on the constructs that were not captured. Finally, it is important to note that the findings of this study have limited generalizability because the sample comprises solely of construction project teams, and the number of participants is limited and biased according to their sociodemographic. As a result, the findings are only applicable to the construction industry and cannot be easily adapted to other industries or contexts.

CONCLUSION

In conclusion, the study was able to enhance the recognition and importance of psychological safety within construction project teams. The study revealed that the sample's current level of psychological safety was high. However, there was also a considerable percentage of participants with low levels of psychological safety. Consequently, it is important to enhance the industry's comprehension and awareness of psychological safety. In particular, fostering regular team interaction through collective meetings or informal team events improves psychological safety. Additionally, cultivating a good failure culture and an open mindset towards collaboration can also contribute to establishing a psychologically safe environment. However, it is important to acknowledge that psychological safety should not be regarded as a cure-all for addressing every challenge related to organizational collaboration and learning (Edmondson & Lei, 2014). It is more about psychological safety being seen as an 'engine' — an interpersonal climate of safety— which, combined with other essential components (e.g., strategy, goals, supportive leadership, etc.), can facilitate better learning and performance (Edmondson, 2019). To conclude, any unacknowledged voice or unspoken mistake, risk, or idea from a team member can contribute to a culture of silence, thereby decreasing psychological safety. Not only can this affect the project's success, but in a dangerous industry like construction, it could even be a matter of life and death (Sumner & Slattery, 2010) and inhibit improvement and change within the industry.

THE RIGHT KIND OF WRONG IN CONSTRUCTION: ANALYSIS FROM A GENERAL CONTRACTOR PERSPECTIVE

Paz Arroyo[1] and Sulyn Gomez Villanueva[2]

ABSTRACT

The idea that not every mistake is preventable and that we can make mistakes and not be ashamed of them if we learn from them is not new in Lean Construction; however, new research from the field of psychology sheds light on human behavior and our willingness to explore and learn from failure. This paper explores how these new findings apply to construction. In this paper, we study different types of failure using Edmonson's classifications of basic, complex, and intelligent failure. We illustrate with cases of failure collected in the Building Quality Builders Class, which is an internal training provided by a general contractor in the USA. Finally, we present strategies for preventing basic and complex failures and encouraging intelligent failures in the context of construction projects. More research is needed to develop a culture to foster learning from all types of failure.

KEYWORDS

Failures, psychological safety, continuous improvement, quality, and learning.

INTRODUCTION

Understanding how mistakes happen, what the consequences are, and how to learn from them and prevent them has been at the center of lean and quality research for a long time. However, there is a lack of a comprehensive framework to make sense of how to deal with different types of mistakes or failures and how to understand human behavior in relationship with failure. Are all mistakes preventable? What messages are we sending to construction workers when we believe that?

Many construction companies use slogans such as "Do things right the first time," "zero defect zone," etc. According to Latzko & Saunders (1996), Dr. Edwards Deming was very clear that these slogans, even though well-intentioned, alone do not create change and can also work against a culture of reporting mistakes.

What type of culture allows the creation of high-performance teams? Amy Edmonson's research points out that teams that have a better reporting culture perform better; they are not afraid of sharing their mistakes and create an environment of psychological safety (Edmonson, 2023; Edmonson, 1999; Edmondson & Bransby, 2023). The concept of psychological safety has been studied in construction, as well as its relationship with lean construction and positive impacts on quality performance (Gomez et al., 2019, 2020, and 2023; Gomez, 2023).

Creating a culture where people feel safe and empowered to share and learn from each other's mistakes is not an easy task. This paper explores the different types of mistakes that

[1] Quality Leader, DPR Construction, San Francisco, USA, paza@dpr.com, and co-founder CollabDecisions, orcid.org/0000-0002-8098-8172

[2] Quality Leader, DPR Construction, Redwood City, USA, sulyng@dpr.com, orcid.org/0000-0003-2367-9880

happen in construction using Edmondson's (2023) classification of mistakes, tries to make sense of these problems, and discusses strategies to encourage learning in a General Contractor context.

LITERATURE REVIEW

This section presents a literature review of both the ideas presented in Edmonson's (2023) book and lean management practices.

RIGHT KIND OF WRONG

Edmonson (2023) published a book called *Right Kind of Wrong*; in this book, the Harvard professor summarizes years of research on the topic of understanding failure and our emotional and social response to it. Edmondson has studied the human capacity to learn from mistakes for a long time; she has stated that this is easier said than done (Edmonson, 1996). She is well known for leading the research on Psychological Safety (Edmonson, 1999), which she defines as feeling safe to take interpersonal risks, speak up, disagree openly, and surface concerns without fear of negative repercussions or pressure to sugarcoat bad news. This concept is key to avoiding the fear of learning from mistakes.

In addition, and what is more relevant to this paper, is her recent differentiation in the different types of failures and the strategies that can be applied in organizations to deal with them. Table 1 describes the classification she proposed according to the context in which they occur.

Table 1: Types of failure (Modified from Table 1.1 in Edmonson, 2023)

Context	Uncertainty	Stage of Knowledge
Basic Failure	Low	Well- developed
Complex Failure	Medium	Well-developed knowledge, vulnerable to unexpected events
Intelligent Failure	High	Limited

Cannon & Edmondson (2005) defined strategies to fail intelligently. Different types of failure will require different strategies, given that the context and the reasons they might happen are different.

LEAN AND MISTAKES

In Lean philosophy, mistakes are not viewed as failures but rather as opportunities for learning and improvement. The Lean approach encourages a culture of continuous improvement, where identifying and addressing mistakes is an integral part of the process. This perspective aligns with the broader Lean principles of minimizing waste, optimizing processes, and creating value for the customer. The Lean literature is wide in its approach to dealing with mistakes; we highlight some of the core concepts from our review:

Mistake proofing

Nakajo and Kume (1985) observed that humans are prone to making mistakes in the face of complex information or when subject to various interpretations. Mistakeproofing "makes it impossible for an error [mistake] to occur or makes the error [mistake] immediately obvious once it has occurred" (ASQ, n.d.). The process of mistake-proofing involves a thorough examination of mistakes, analyzing their consequences, and implementing measures to prevent their recurrence (Nakajo and Kume 1985, Shingo 1986, Godfrey et al. 2005, Tommelein and

Demirkesen 2018). In the event of an error, the aim is to detect the error as close as possible to its occurrence to minimize associated damages.

In construction projects, mistakes can stem from misinterpreting information or individual judgment. Within the framework of Built-in Quality (BiQ), mistakeproofing principles contribute to fostering a culture of prevention and enhancing people's awareness of improvement opportunities (Shingo 1986, Tommelein and Demirkesen 2018).

First Run Studies

FRS involves prototyping production processes to gain insights and identify areas for enhancement. This aids in developing efficient operations that align with established expectations (Ballard and Tommelein, 2016; 2021).

Continuous Improvement and Plan-Do-Check-Act (PDCA) Cycle

Mistakes are seen as valuable learning opportunities. When mistakes occur, they provide insights into what went wrong and why. Understanding the root causes of mistakes allows organizations to implement changes that prevent similar issues in the future.

Lean philosophy emphasizes continuous improvement, also known as Kaizen. Mistakes are considered important feedback for this improvement process. Teams are encouraged to analyse mistakes, make adjustments, and implement changes to enhance processes and outcomes.

PDCA involves a cycle of formulating hypotheses, conducting experiments, testing, and acting based on the outcomes. The emphasis is on learning and perpetual enhancement by implementing corrective measures and averting the recurrence of issues. This iterative process is set in motion either through proactive planning, execution, and the identification of improvement opportunities or as a response to the failure to deliver high-quality products (Shewhart, 1939; Deming, 1986).

The PDCA cycle is a fundamental concept in Lean. When mistakes happen, the PDCA cycle plans improvements, implements changes, checks the results, and acts on the findings. This iterative process ensures that organizations are continually refining their processes.

Root Cause Analysis

When mistakes occur, Lean principles encourage a thorough investigation into the root causes. This involves repeatedly asking " why " to uncover the underlying issues rather than addressing only the surface symptoms. By addressing root causes, organizations can implement more effective and sustainable solutions. It is a methodical approach to learning from breakdowns or failures, promoting continuous learning and improvement (Fischer et al., 2014

Blame-Free Culture:

Lean promotes a blame-free culture where individuals are not punished for making mistakes. Instead, the focus is on identifying systemic issues and finding solutions collaboratively, and allowing for innovations to happen (Angelis and Fernandes, 2012). This approach fosters a positive and open working environment, encouraging employees to share insights without fear of reprisal, which is connected with the concept of Psychological safety (Edmonson 1999).

Respect for People:

Lean philosophy places a strong emphasis on respecting people and their contributions. This includes recognizing that everyone is fallible and can make mistakes. Organizations can create an environment that encourages creativity and problem-solving by acknowledging mistakes without blame.

In summary, the Lean philosophy views mistakes as opportunities for improvement rather than failures. Embracing a mindset that values learning, continuous improvement, and a blame-free culture helps organizations foster innovation and resilience in the face of challenges.

METHODOLOGY

The research questions are:

- *RQ1: what are examples of the three types of failure in construction (basic failure, complex failure, and intelligent failure)?*
- *RQ2: what strategies can we use for each type of failure in a construction company?*

This paper uses exploratory case studies (Yin, 2013) to analyze documented mistakes and lessons learned documented by a General Contractor. The researchers also worked on the construction company at the time of the research and had access to several data points. The following data inputs were used to explore the kind of mistakes or failures reported by employees:

- Cases were documented through Building Quality Builders (BQB) classes (Arroyo and Gomez 2021, Arroyo et al. 2022), where project participants were asked to share a story on the misalignment of expectations resulting in rework. Please note that not all these examples happened at their current employment; some of these stories are from early in the person's career, and many happened in a different company. Both researchers are also facilitators of this class.
- Insurance claims and lessons learned from them. The first author participated in a one-day workshop prepared annually by the insurance team, where several instances of mistakes were studied and analyzed. The results of these findings are not shared publicly. However, it helped guide the selection of cases to understand typical problems or mistakes in the construction industry.

This study does not present a comprehensive study of all mistakes that happen in the company. Rather, we are more interested in understanding the nature of the mistakes and examples to categorize them according to Edmonson's (2023) classification: *basic failures*, which are preventable in nature; *complex failures* that happen when multiple people and factors interact in somewhat unpredictable ways; and *intelligent failures*, which are calculated risks to learn something new. After understanding the nature of each type of example we propose strategies to deal with them based on the literature review and the company best practices.

RESULTS AND DISCUSSION

The following section presents examples of each type of failure documented in the BQB class and discusses strategies to prevent them.

BASIC FAILURES

There is no shortage of basic failure examples in the data set; in every BQB session, people tell their stories of misalignments of expectations and re-work. Here are some that we are qualifying as basic failures because they are preventable and with low uncertainty:

Wrong layout.

"Had a surveyor measuring floor levels for a building tie-in and did not communicate long enough about his exact scope. I took measures, and I assumed he was going to pull measures off a benchmark on the print and correlate back. He never saw the benchmark on the drawing and used a "0" datum. Luckily we caught later that a BM on the drawing for first floor was off that tied into the whole civil package." – Senior Superintendent

This mistake is clearly a human error, easily preventable by setting a clear benchmark for surveying and making sure all surveyors know such a point was defined; the cause of this could have been a lack of communication or knowledge from the surveyor.

Bathroom Pod manufacturing error.

"*At (Bathroom Prefab Facility), consistency is key. We had a lack of communication recently which resulted in not installing a piece of door trim consistent with the customer approved mock-up bathroom pod. This resulted in rework for about 30 pods. This could have been easily avoided with a simple visual board showing expectations, or just a look at the mock-up pod." – Production Control at Prefab*

To prevent the mentioned mistake, ensure consistent communication and adherence to customer-approved requirements; the cause could have been a lack of internal communication in the prefabricated plant or a lack of education of plan workers. Readily available visuals in the field are also a great way of avoiding basic failure.

Ordering the wrong equipment.

"During my first internship, there was a discrepancy with the data communication and power supply equipment as 1-phase power supply was ordered on bulk while the equipment called for (in the specs was*) 3-phase power. The project was a demolition, add-on to existing Main Computer Room .... the facility was the main operation center for the airport.." – Project Engineer*

The need for constantly back-checking information is crucial in construction, especially for bulk and long lead items. Ordering the wrong equipment can have devastating consequences for the project; clear roles and responsibilities and diligent checking of documentation are needed.

Concrete finish unrealistic and misaligned expectations.

"On multiple projects recently, polished concrete has been a finish chosen by the project architect. As it is a trending finish these days, the designers love the look of the concrete in small doses and then tend to apply that look to large format areas and typically it doesn't work or doesn't meet with clients expectations. The design team has an acceptable level of defects in the concrete but it is rarely ever completely understood by the client and rejected because of the misunderstanding or miscommunication of what's expected. Everyone loves a 10' x 10' mock up in a controlled environment, but in the harsh realities of construction, the end product is very difficult to deliver to a client or designer who wants a level of perfection that cannot be provided." – Senior Superintendent

This mistake is preventable by setting a clear expectation of what level of finish can be achieved on a large scale for concrete; the cause of this could have been a lack of communication from the contractor to educate the architects and owner. We have seen other teams clearly defining metrics for success in Concrete. Making Mock-ups more realistic is key to success.

"On our project, we are having a misunderstanding between the owner & architect and the concrete contractor. The owner knows the look they want, and they know 1 way to achieve it, but it requires a lot of rework. They've specifically said they want to minimize the rework on this project while achieving the same look. The concrete contractor has been stood down multiple times to review that the owner wants them to control everything they can to minimize the rework. Part of the struggle is based on the assumptions at buy-out and going the extra mile in the field and making sure the terms are fair to all involved in putting the work in place. Getting the trade partner to slow down and focus on the quality has been a difficult process and they haven't had a real "win" yet." – Project manager

In this case, the owner knows what they want; however, the conditions for the trade partner to execute the job were not aligned early on during the buyout process.

Strategies to prevent basic failures.

Some human factors that create basic failure are inattention, neglect, overconfidence, and faulty assumptions (Edmonson, 2023). We can see those across the examples displayed in the previous section. Typically, basic failures do not have a huge impact if they are caught early on; however, if we keep making the same mistakes as in the case of the bathroom pods, this has severe negative consequences for the project and the company. What are strategies to avoid this type of mistake, and what can we do at a company level? Here are some strategies from the literature review:

- **Befriending error**, according to Edmonson (2023), human beings hate to be wrong, and naturally, this induces shame; we see admitting a mistake as a choice vs. protecting our self-image. To choose to learn is to choose to go past our instincts of finding excuses to protect ourselves from shame. Psychologists have studied *fundamental attribution error* bias; Edmonson (2023) provides a clear example: If I am late to a meeting, it is because the traffic is terrible. If my colleague is late to a meeting it is because he is lazy or disorganized. For people in the construction industry, this is hard; the way the information is requested to learn from a mistake, the way that supervisors respond, and whether there are personal consequences will affect the willingness of a person to speak up; these behaviours set the norms of the project. It requires a psychologically safe environment.
- **Befriending vulnerability**, in addition to befriending error, we must have the courage to admit mistakes and be willing to dig deeper to see one part of it, regardless of how large or small. Edmonson (2023) states that the practice of admitting errors is good for two reasons: one, it makes it easier for others to do the same, and second, other people will see you as more approachable and trustworthy. Brene Brown make the topic of vulnerability relevant, and it is deeply connected with shame (Brown, 2015). The practice of sharing failure stories in the BQB training during the first session helps with both befriending error and vulnerability. Anecdotally, when people do not have a failure story to share from their carries, it brings a warning sign for facilitators; maybe the person is not open to learning yet. However, as the weeks go by in the BQB training people relax and bring up personal failure stories more naturally.
- **Safety first policies** help create a “habit of excellence” when people commit to attention to detail and a culture where every employee is willing to push back against unsafe practices and point out others' small errors; it creates the basis of a psychologically safe workplace. This is consistent with what we have seen in practice when safety leadership encourages and promotes a culture of excellence that every employee is part of., we believe will bring long-term benefits for quality, work environment, and profitability too.
- **Culture of blameless reporting**. Expect and catch errors. A lean example of this is the Andon Cord that Toyota created, where any worker in the manufacturing plant can report a mistake, then the supervisor comes, and together they assess the error and find a solution; if they can't solve it quickly, the line stops. Blameless reporting is key; the promise is that reporting will not be penalized (Edmonson, 2023).
- **Codification (or checklist):** Learn as much as you can from failures, then codify it and create checklists. Gawande (2009) has studied extensively the benefits of checklists in the medical field. However, checklists are not infallible, and they need to be updated

and adapted to the context, especially in construction settings where buildings have unique expectations according to local regulations and owners' needs and wants.

- **Preventive maintenance** programs: processes like identifying distinguishing features to align on measurable acceptance criteria for the project (**add our DFs papers here**), pre-construction meetings, and built-in quality (checking own work before passing it on) can help identify misalignment of expectations of the final product, communicate the right sequence, and catch mistakes as early as possible respectively.
- **Required Training** is key to avoiding basic failure; industries such as aviation are at the forefront of preparing pilots for flying in the first place. Unfortunately, construction industry segregation and hyper-segmentation make the base knowledge very variable; many construction workers are trained by the union, but that is not universal everywhere in the USA. Also, the hourly pay system makes it harder for the project to make the budget and time to educate workers.
- **Error-proofing, or Poka-yoke,** originated in the Toyota production system. This is a very practical tool in the construction industry, too. Tommelein (2008) presents examples to illustrate how mistake proofing applies to the work done within one specialty trade, how manufacturers and fabricators can design their products so they cannot be constructed defectively, and how architects and engineers may conceive of system designs that are less likely to fail during construction or in a product's life cycle. In the case of the GC, one of the bathroom pods, the workers created a Poka-Yoke tool, a C-shaped wood assembly that will help to measure that the total dimension of the pod is within tolerances.

COMPLEX FAILURES

Complex failures are harder to document and understand the whole story. This happens in a more complex environment and is not easily preventable. According to Edmonson (2024), they often include at least one external seemingly unforeseeable factor; here, it is easy to think about supply chain issues during the COVID-19 pandemic that was not foreseeable for most construction projects going on at that time. Another typical unexpected factor is severe weather conditions. The following are some examples of recent complex failures reported by BQB participants where the main issue is a misalignment of expectations among several parties or mistakes where many stakeholders interact:

Managing Tolerances

"…On an exterior of a building to meet schedule and long lead time items we ordered Metal Panels, Concrete Panels and Curtain wall with "Hold to dimensions" Tolerances that threw this work off were the 1st two installations were the Concrete slab on grade and the Steel. These were both installed per their tolerances but it would ultimately throw off the framing, curtain wall, and everything following it. The architect's intention was for the joints of the concrete and metal panels and curtain wall to match, lights, and architectural shade devices to match as well. Some hold to dimension were unachievable because the steel and concrete didn't allow for all of the next finishes to be installed properly and keep the hold to opening sizes. Some of the framing and blue skin and roll on water proofing thicknesses didn't match the mock ups and the variances in the framing didn't allow for proper alignment of the supporting bracket for the Metal and Concrete panels. Several trades had to do quite a bit of shimming and added work to make this work out. Lots of rework in general and the start of all of this work from was tolerances." – Super Intendent

We classified this as a complex failure; there are several components coming together, the team preordered material ahead of time and when installing it the tolerances of all the assembly did not work. Even though tolerances are a known problem, the variance of materials is hard to predict, in addition the was added mistakes in the thickness of the materials received vs the ones the team used in the mock-ups, not sure is this was a procurement mistake or material variation. Finally, the last trades installing had the worst conditions to execute their work.

New Flooring Material Installation

"The client and designer had never before specified or worked with a specialty flooring material (concrete based). Additionally, the flooring material had never been attempted in the city where it was intended to be installed. After a lengthy qualification and bid process, we selected a installer (who met the requirements of the specifications). We performed several mockups, with multiple configurations (stair nosing's, reveals, strips). During the pre-construction portion of the project, the owner stressed the importance of maintaining the schedule and controlling of costs. Once a large section of flooring was installed, the owner was displeased. The designer reached out to factory representatives, and industry experts, who explained the limitations of the product (hazing, wavy finish, cracking at sharp corners). In the end, the owner was painted in a corner (leaves one with no good alternative or solution), no option to remedy the unpleasant installed product, no budget or schedule remaining to pursue other options (hard tile, terrazzo, lvt, etc). Everyone walked away empty." -Regional Quality Leader

This example was hard to classify because it started as an intelligent failure by recognizing uncertainty in the use of a new flooring product, apparently seeking to innovate with a new product, and making mock-ups to learn and select the right installation partner. However, it is not an intelligent failure because of the big risk taken when the review with the client was made, "*Once a large section of flooring was installed, the owner was displeased".* The team did not allocated enough resources (time and money) to explore alternatives to this new product if it did not meet owner's expectations. Basically, it was not planned to be an experiment. They understood the limitations of the product when applied at a large scale after there was no option to change it.

Strategies to learn and prevent complex failures.

In this section we discuss some strategies to prevent complex failures pointed out in Edmonson (2023) in the context of construction projects considering the previous examples:

- Learn from past complex failures. One of the tools this GC uses that can help in this process is Cause Mapping, where several courses can be understood to lead to the failure. The team can decide to implement changes in multiple aspects of the process, this can be applicable to any complex failure in constructions, from tolerances to unwanted finishes.
- Pay attention to early warnings. In this context, some of the early warnings are new materials, new assemblies, and new trade partners. In addition, having a culture that supports project team members raising issues that can lead to mistakes downstream is important. In the case of tolerances issues, a warning before buying metal and concrete panels and coordination early with trade partners can help.
- Leverage the recovery window: Mock-ups- give a recovery window; between what we can learn from the mock-up and the actual installation, there is a window of opportunity for learning and changing the plan; if mock-ups are planned with enough anticipation, construction teams can learn to change the sequence, materials, finishes, among other aspects of the work. Learning from issues in the same building also provides a recovery window. If you have a repetitive construction project and make a mistake on the floor 1, you can improve on floor 2, and so on.

- Welcome false alarms: Edmonson (2023) highlights the strategy of creating a Rapid Response Team (RRT) so employees can raise concerns to them, regardless of them being a false alarm; she provides the example of Andon cords in Toyota. Can we have experts ready to help when a problem starts in construction? This is an interesting approach; many construction companies have expertise in-house, but are experts available and ready to be summoned when needed?
- Embracing the possibility of failure to reduce the occurrence of failure, again practicing, rehearsing, testing, and learning from it is key. The use of first-run studies in construction presents an opportunity to learn in a more controlled environment, Tsao et al. (2000) present an example of how this is applied in metal framing.

According to Edmonson (2023), organizations that do well at avoiding complex failure are not because they somehow figure out how to eliminate human error; on the contrary, they have good records because they learn how to catch and correct errors. That takes practice and includes a culture that celebrates it. Moreover, Edmonson (2023) states "*It's not possible to build a contingency plan for every failure. But it is possible to build the emotional and behavioural muscles that allow us to respond to human error and unexpected events alike with speed and grace.*"

INTELLIGENT FAILURES

Intelligent failures, by definition, happen under uncertain conditions, and they are not preventable because you are testing something you want to learn in new territory. In general, innovation projects and pilots are classified in this category. According to Edmonson (2023), how to tell if a failure is intelligent includes:

- It takes place in a new territory.
- Opportunity driven.
- Informed by previous knowledge.
- As small as possible. Limiting risk exposure.
- Bonus: You learned from it.

The following is an example of an intelligent failure as reported by BQB participants:

Exterior Skin Mock-Up alignment

"We had a very complex exterior skin system with Terracotta tiles. The drawings and specs called out for a specific standard joint dimension, and the specs allowed for a certain tolerance in tile sizes. The mock-up was built, and although it held to the requirements in the contract documents, the design team still did not like the aesthetic. New MACs (Measurable Acceptance Criteria) *had to be negotiated, which was a long and painful process. Fortunately, we discovered this misalignment at a mock-up and not the final install."- Project Engineer*

This is an intelligent failure because the team was able to learn from the mock-up of the exterior system, which is a calculated risk, and understood how to achieve all requirements in addition to the owner's expectations that were not aligned with the trade- partners at that point, which avoided failure at the final installation. As the project engineer reports the process was long and painful, probably because they were learning and adjusting to the new understanding.

Promoting intelligent failures and learning from them.

How do we promote intelligent failures in construction teams? How can we ensure they are willing to take calculated risks to learn something new? According to Edmonson (2023), here are some high-level strategies to overcome barriers to failing well (Figure 1):

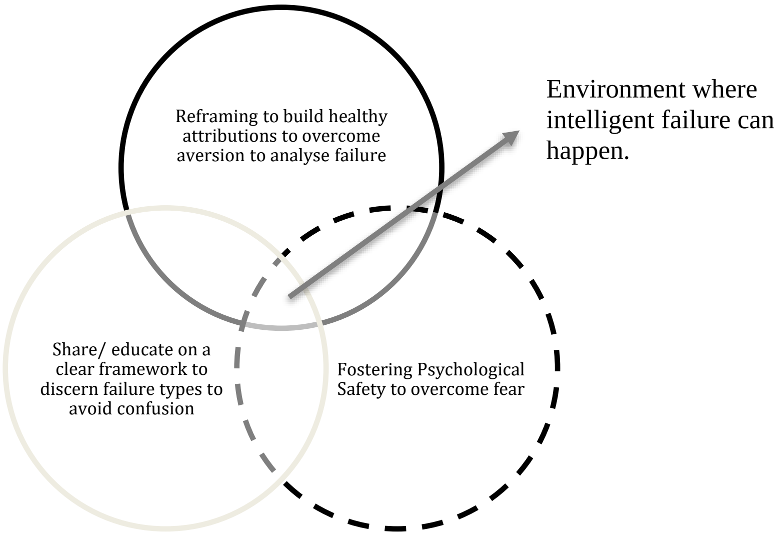

Figure 1: Strategies for creating a culture of intelligent failure.

How can we create a psychologically safe environment in construction? According to Gomez et al. (2019 and 2020), some key skills people must develop are active caring and active listening. None of these skills are common in construction. However, they can be improved if training and practice are provided. It is also important to assess how psychologically safe a project or team is. Doing this opens the possibility of sharing ideas for improvement.

How can we have a healthy attribution to the failure and be willing to understand what role one has played in it? First, we must understand our human pre-conditioning, such as acknowledging that learning from our failures is hard, accepting negative feedback and learning from it does not come naturally to most people, accept that we are blind and limited by our previous experiences. Therefore, our emotional preparation, and the culture we are working on takes a big part on the possibility for learning from intelligent failure or any other type of failure. Edmonson (2023) recommends practices that allow us to learn from failure:

- Thinking carefully about what went wrong and what factors might have caused it. This means avoiding the human tendency to skip the analysis and think we will try harder next time.
- Analysing what different causes of the failure suggest on what to try next. This is particularly useful for creating new best practices for new projects in similar circumstances.
- Digging in to understand your own contribution to the failure (small or large) means avoiding self-serving analysis.

Additionally, to allow for intelligent failures, project teams in construction must set aside the right resources to try new things. For example, many projects do mock-ups with the intention of succeeding in them and probably unconsciously avoiding the potential for learning. Ideally, a mock-up is representative of how the work will be performed at a large scale, and we are testing different ideas; this means that the result of the mock-up can lead to changes in materials or construction assemblies. We wonder how many projects are set up to allow for that learning to happen. In practice, many projects do not have other options to move on with whatever the result of the mock-up is because there is no time allocated for changes. Building a project to allow for true experimentation and learning requires a different setup; an Integrated Project Delivery (IPD) project can probably set the stage for intelligent failure if the right culture is in place.

Finally, education to recognize the different types of failure helps to know when you are dealing with an intelligent failure, which avoids confusion and creating the right incentives.

CONCLUSIONS

This paper studies different types of failure in the construction industry and the human aspects implicit in the possibility of learning from failure. We also illustrated cases of failures in the construction industry and offered a possible categorization within the failure types presented in Edmondson (2023). Understanding failure and its different categories helps us understand what reasonable strategies are to prevent basic failure, learn from complex failure, and encourage intelligent failure in the General Contractor company and in construction projects in general. More research is needed to test recommended strategies in the context of construction projects and see potential improvements. In addition, researchers are curious about how these failure classifications could help teams approach construction mistakes differently, how to train people to reframe their relationship with failures, and how to create a psychological safety culture at a large scale in construction to improve our learning from all types of failures.

ACKNOWLEDGMENTS

DPR Construction, including several employees who have attended Building Quality Builders training over the years, supported the development of the ideas presented in this paper.

A FUZZY EXPERT SYSTEM FOR MEASURING THE DEGREE OF LEAN IMPLEMENTATION IN CONSTRUCTION PROJECTS

Rana Ead[1], Kexin Liu[2], Amira Saleh[3], Sena Assaf[4], Vicente Gonzalez-Moret[5] and Farook Hamzeh[6]

ABSTRACT

Lean construction has emerged as a production management philosophy that can achieve significant performance improvements within the construction industry. However, the industry has not yet achieved full potential in terms of the implementation of Lean principles as compared to other industries. Such achievement necessitates continuous improvements throughout the project lifecycle. However, it is first necessary to understand the current level of Lean implementation to identify opportunities for improvement. Previous researchers have developed frameworks for measuring the degree of Lean implementation of an organization as a means to assess continuous improvements. However, being on the organizational level, these frameworks might not provide the means for assessing the incremental improvements toward transforming into a "Lean" construction company. There is a need to gauge the level of lean implementation at the project level, serving as a crucial stepping stone for overall organizational achievement. Accordingly, this study aims to develop a framework for measuring the degree of Lean implementation in a construction project using fuzzy expert systems (FES). This system provides decision-makers with an evaluation of the current implementation of Lean in construction which, in turn, provides a direction on further opportunities for improvement.

KEYWORDS

Lean construction, Lean implementation, fuzzy expert systems (FES).

INTRODUCTION

Lean is the application of a set of principles developed by Taiichi Ohno and Eiji Toyoda to reduce waste in processes and increase production efficiency (Koskela et al., 2007). This

[6] Professor, Department of Civil and Environmental Engineering, University of Alberta, Edmonton, Alberta, Canada, hamzeh@ualberta.ca, https://orcid.org/0000-0002-3986-9534

requires reducing the impact of factors that might not add value to the end user. If applied correctly, Lean principles can transform organizations to be more flexible and profitable in the long term (Womack & Jones, 1996).

In the construction industry, practitioners have been adopting several Lean tools in their projects including 5S, the Last Planner System, visual management, error proofing and many others. Such integration has shown to be beneficial in terms of reducing waste, reducing and mitigating mistakes, managing inventory, reducing rework, etc. (Koskela et al., 2007; Singh & Kumar, 2020). Despite these benefits, the construction industry has not yet achieved the level of improvement seen in other industries upon Lean implementation (Pantazis et al., 2022). As such, it is necessary to first understand the current status of Lean implementation in a construction project in order to identify potential opportunities and areas of improvement in the pursuit of continuous improvement. This can potentially be achieved by developing a Lean construction implementation index that helps quantify and assess the implementation of Lean tools and techniques (Cocca et al., 2019). Developing such an index can be supported with fuzzy logic approaches given their ability to mimic humans when making decisions especially when the context of the data is ambiguous (Tavana & Hajipour, 2020).

Numerous researchers have introduced metrics to assess the implementation of lean practices in the construction industry (Amaral et al., 2019; Cano et al., 2020; Comelli et al., 2019; Dragone et al., 2021; Elfving & Seppänen, 2022; Kallassy & Hamzeh, 2021; Salvatierra et al., 2020). However, existing studies have primarily concentrated on evaluating the extent of lean adoption at the company or organizational level. While this approach is advantageous, it may pose challenges for companies aiming to implement lean practices comprehensively from the outset. Therefore, it is crucial to establish a methodology for measuring the incremental progress toward transforming into a "Lean" construction company. Specifically, there is a need to gauge the level of lean implementation at the project level, serving as a crucial stepping stone for overall organizational achievement. Consequently, the objective of this paper is to formulate a fuzzy expert system (FES) designed for assessing the degree of lean implementation in construction projects either before or during execution. This involves the creation of a Lean Construction Implementation Index (LCII) that considers the unique characteristics of each project.

LITERATURE REVIEW

The literature review section is divided into 3 subsections. The first subsection tackles the successful implementation of Lean in the construction industry and the need for continuous improvement. The second subsection elaborates on the LCII along with the assessment approaches adopted in the manufacturing industry. As for the third subsection, it provides an overview of FESs.

LEAN CONSTRUCTION

It is well-know that the applications of Lean originated from the manufacturing industry. However, its principles were adopted to a wide spectrum of industries one of which is the construction industry. Several studies in the construction industry have investigated the application of Lean principles and tools in construction and identified the factors that could facilitate or impede their implementation (Singh & Kumar, 2020).

Some of the tools that were regarded as being efficient in the implementation of the Lean principles include the 5S, Last Planner System, Poka Yoke and visual management. The application of these tools was proven to be effective in terms of waste reduction, mistake proofing as well as inventory management (Li et al., 2019; Salvatierra-Garrido & Pasquire, 2011). Additionally, collaborative process making, Heijunka and Andon were proven to be beneficial in terms of reducing the amount of rework, standardizing scheduling and improving workplace cleanliness (Ansah & Sorooshian, 2017; Dombrowski & Mielke, 2013).

The successful implementation of Lean principles and techniques in construction requires a cultural shift towards collaboration, continuous improvement, and stakeholder involvement. Effective leadership, communication, and training are also essential for creating a Lean culture and sustaining Lean practices. Successful implementation of Lean in construction can lead to improved project outcomes, including reduced waste, increased productivity, and enhanced stakeholder satisfaction (Al-Aomar & Hussain, 2018).

Some researchers argue that the construction industry has not yet reached its full potential in terms of Lean implementation as compared to other industries (Pantazis et al., 2022). As such, it is deemed necessary to understand the level of Lean implementation in a construction project in an effort to identify opportunities for continuous improvement. One potential way to achieve this is through developing certain indices or metrics that help quantify the level of Lean implementation.

LEAN MEASUREMENT APPROACHES

With the increased adoption and improvement of Lean applications in the construction industry (Elfving & Seppänen, 2022), it becomes significant to measure and evaluate its implementation. The development of Lean implementation metrics has the potential to support decision makers to first monitor and evaluate the current status of the project or organization given Lean tools implementation, and to second propose the integration of new tools and techniques based on the evaluation outcome. This approach ensures that the organization continuously pursues and adopts improvements (Cocca et al., 2019). For this reason, researchers have developed various Lean implementation metrics to quantify the impact of the introduced Lean tools and initiatives in the construction industry.

Nesensohn et al. (2014) proposed a Lean Construction Maturity Model (LCMM) designed to measure the maturity within organisations embedding Lean Construction. This model consists of five maturity levels, 11 key attributes and 60 defined behaviours. Subsequently, Nesensohn et al. (2016) validated the LCMM they proposed using focus groups. In 2017, Nesensohn (2017) established a self-assessment template of the LCMM to obtain the current maturity level of any organization. Comelli et al. (2019) developed an audit protocol to evaluate the level of Lean implementation. This protocol was initially shaped by existing literature and refined through its implementation in four companies. The refined protocol was evaluated and validated through interviews with Lean construction experts. Barth et al. (2019) adapted the performance metrics of five construction companies to assess the performance of Lean production system. Amaral et al. (2019) collected data from six construction companies to evaluate the impact of each criterion in the Lean Construction Assessment Tool (LCAT) on the level of Lean implement. Kallassy and Hamzeh (2021) developed a Lean Culture Index (LCI) to assess the readiness of construction companies in Lebanon to apply Lean. Results demonstrated that while some companies had a flexible and consistent approach, there remained room for improvement in training, trust, and human focus. Mohamed (2021) proposed a Lean Construction Assessment Tool (LCAT) to evaluate the lean awareness in a company. He provided nine steps for lean construction assessment, formed 20 questions covered in 10 categories, and generated 5 levels of maturity as results.

However, despite the development of valuable metrics in these studies, their focus remains primarily on the organizational level (i.e., the company). There are only a few researchers who developed metrics for Lean implementation at the project level. Salem et al. (2006) developed a new Lean assessment tool including six Lean construction elements to quantify the results of Lean implemenations in construction projects. The tool was tested in two teams in one project through on-site survey. Cano et al. (2020) proposed a model to assess the maturity level of construction project management. They identified the elements related to maturity by consulting existing literature and experts in Lean Construction. Salvatierra et al. (2020) established 12 main dimensions to evaluate the Lean approach in construction projects. These dimensions were identified, and their relative importance was evaluated through online questionnaires and interviews.

Despite their valuable exploration, the subjectivity cannot be completely avoided due to the use of site visits and interviews in assigning scores for questions. Furthermore, the interactions between metrics is often not considered. Thus, it is necessary to further investigate Lean implementation assessment tools at the project level in the construction industry, while integrating approaches that help reduce subjectivity such as fuzzy-based approaches.

FUZZY EXPERT SYSTEMS (FES)

Expert systems mimic the ability of humans to make decisions in a certain area of specialty. As such, they can be beneficial for decision makers when solving certain problems (Tavana & Hajipour, 2020). Given that real-world problems are often described ambiguously and might hold elements of uncertainty, FES can be used for reliable data-driven decision making (Zadeh, 1983).

A FES uses a collection of fuzzy membership functions and rules to emulate the reasoning process of a human expert within a specific domain of knowledge; it synthesizes knowledge and experience from different experts and makes it available to non-experts (Klir & Yuan., 1995). In order to reduce the subjectivity, other FES approaches were developed such as that proposed by Shaheen et al. (2009). In this method, he develops a structured approach to defining the if-then rule base rather than determining them subjectively in consultation with domain experts. Accordingly, FESs are useful in decision support, learning, diagnosis and research, and planning.

Given the above conducted literature review, there seems to be a gap in the effective evaluation of Lean implementation in the construction industry on a project level. As such, this paper aims to develop a FES to evaluate the level of Lean implementation in construction projects through developing a LCII.

RESEARCH METHOD

This section describes the research method used to develop the FES for measuring the degree of Lean implementation in a construction project. **Error! Reference source not found.**Figure 1 illustrates the steps the authors followed to develop the FES. The first step, factor identification and analysis, establishes the knowledge base pertaining to the problem, i.e. the input factors that will affect the final output. The second step involves the development of the fuzzy expert system including the fuzzy membership functions and fuzzy rules. Both steps will be described in further detail below. The different components will be encapsulated in the expert system shell to be re-used in the future.

FACTORS' IDENTIFICATION AND ANALYSIS

As discussed above, several factors have been employed in the literature to measure the degree of Lean implementation. The authors reviewed previous research studies to identify the relevant factors for construction projects and proposed a number of new factors that capture the degree of implementation of Lean construction.

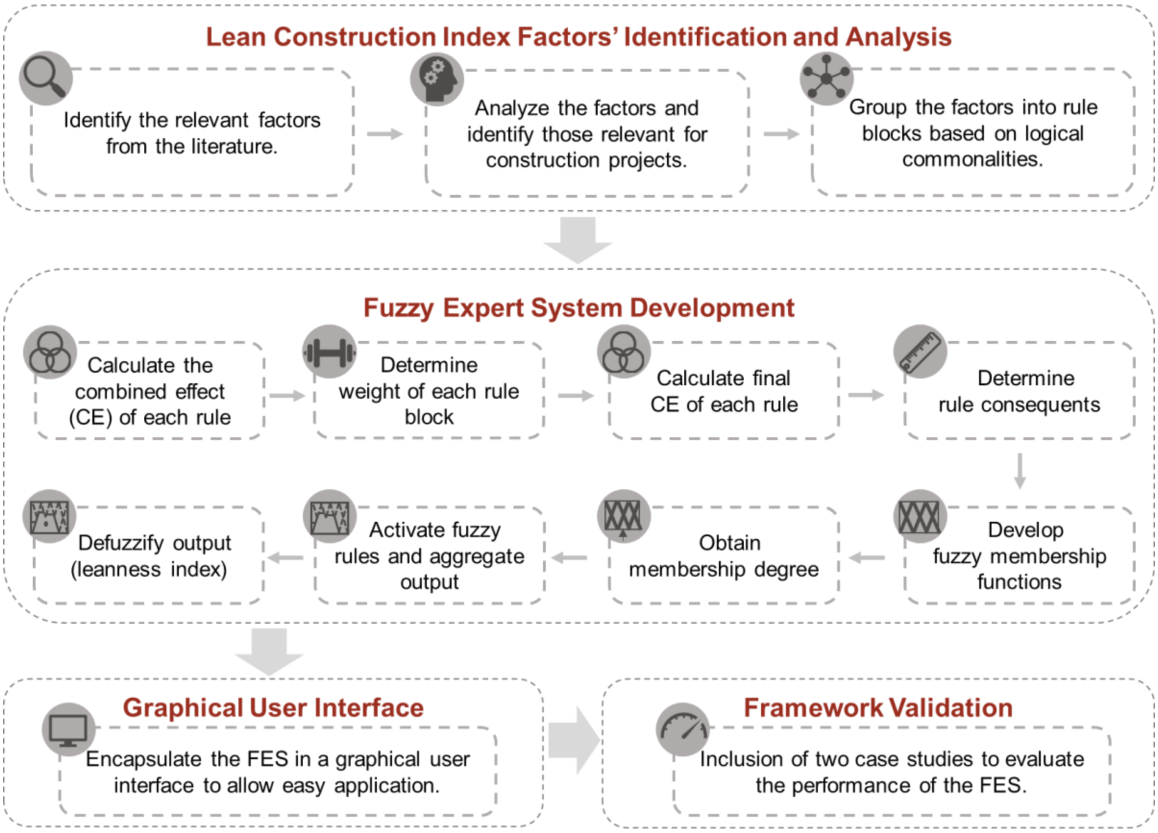

Figure 1 Research Method

FUZZY EXPERT RULES

The development of the rule consequents for the FES follows the method proposed by (Shaheen et al., 2009). This structured approach reduces the subjectivity associated with defining the if-then rules that capture the experts' ways of thinking (Shaheen et al., 2009). Additionally, it

controls the exponential growth of the rule base by grouping factors based on logical commonalities, as performed above. **Error! Reference source not found.** illustrates the steps to defining the rule consequents based on this technique. In this method, the impact of each state of a certain factor on the output (degree of Lean implementation) and the relative importance (RI) of that factor are solicited from experts. For each rule, the combined effect (CE) is calculated as shown in equation (1):

$$CE(R_n) = (F_1)_{RI} \times F_1(state_1)_{Impact} + (F_2)_{RI} \times F_2(state_1)_{Impact} + \cdots (F_m)_{RI} \times F_m(state_1)_{Impact}$$

Once the CE is calculated for each rule, the importance of each rule block relative to the final output is determined. Weights are assigned to each rule block and the normalized weight is calculated. Next, the final CE is calculated by multiplying the CE of each rule by the normalized weight of the rule block to which the rule belongs.

$$CE_{final}(R_n) = CE(R_n) \times Rule\ Block\ weight$$

The normalized combined effect is then calculated as:

$$CE_{Normalized}(R_n) = [CE_{final}(R_n) - CE_{min}]/[CE_{max} - CE_{min}]$$

The reader is referred to Shaheen (2009) for further details on the process. In this case, the factors correspond to those factors described in the previous section, and the states correspond to the 3 linguistic variables that describe the level of implementation of each factor (i.e., low, medium, and high). The relative importance of all factors is considered equal and the impact of being at a certain state is determined on a scale from 1-5, where 1 corresponds to very low and 5 corresponds to very high. Once the CE for each rule is calculated, the values are normalized using the equation above. The normalized combined effect is compared to a 5 -point scale where each interval corresponds to a linguistic term of the consequent (LCII) as shown in Figure 2.

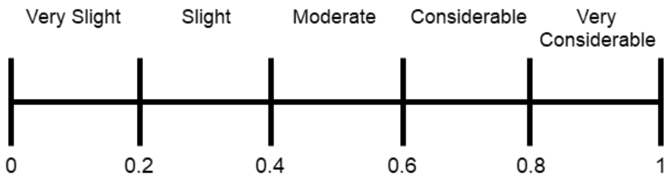

Figure 2 5-point scale for defining rule consequents

FUZZY MEMBERSHIP FUNCTIONS

The next step is to develop the fuzzy membership functions for the different factors. Although expert opinion or historical data are generally preferred for the development of membership functions, due to the limited time for this research, the authors assumed the values for the membership functions. Additionally, for ease of implementation, the same membership function was used for all the factors (inputs) as illustrated in Figure 3. The membership function for the output, the LCII, was also assumed (Figure 4).

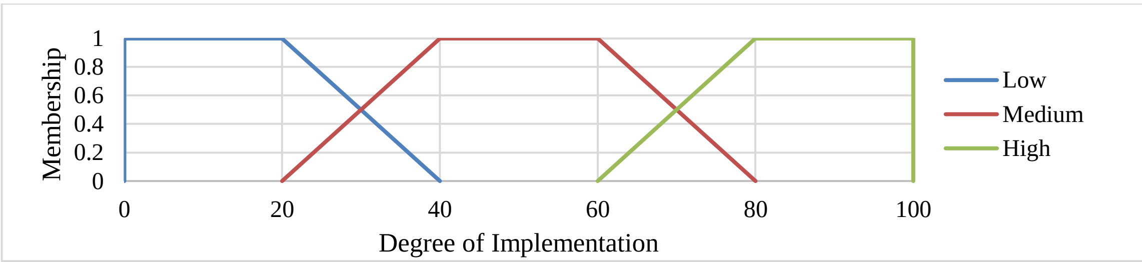

Figure 3 Membership function for factors

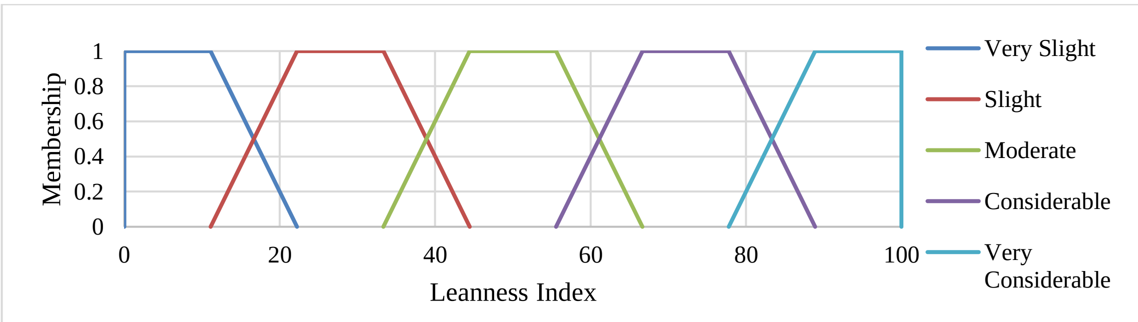

Figure 4 Membership function for LCII

FUZZY INFERENCE SYSTEM

Users of the FIS would input the level of implementation of each factor, whether expressed as crisp values or linguistic term, to calculate the degree of membership for each linguistic term defining those variables based on the fuzzy membership functions. The FIS model then uses the following operators: (1) input aggregation is minimum, (2) output aggregation is maximum, (3) implication method is minimum, (4) defuzzification method is the center of area method, and (5) all rules are given equal weighting. The LCII is then calculated as the defuzzied output of the model.

RESULTS

IDENTIFIED FACTORS

After an extensive literature review and analysis, several factors were identified from the literature. Table 1 shows the factors that were collected and the different categories that they were grouped into.

GRAPHICAL USER INTERFACE

A graphical user interface was developed on MATLAB to allow the user to enter scores for each of the defined factors to reach a LCII for the project being assessed. Figure 5 shows a sample of the interface window, where the user would drag the pointer assigned to each factor until the desired score is attained. The 30 factors are distributed over 5 pages, which the user can navigate between by selecting the required tab.

Once the scores are assigned to all the factors, and the user clicks on the "Evaluate" button on the last window, the model will calculate the LCII. The LCII will be displayed to the user in the same window, and a graphical representation of the equivalent degree of Lean implementation will also be generated to give the user a better sense of how Lean the project is.

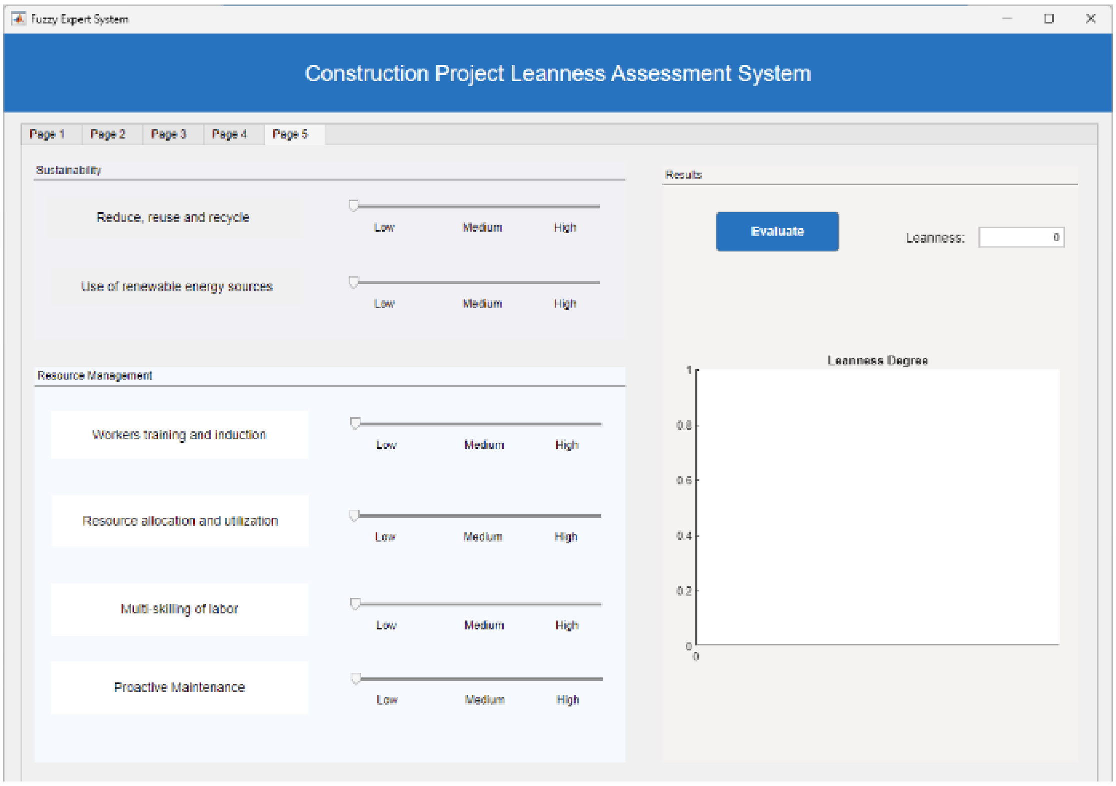

Figure 5 FES User Interface

Table 1 LCII Factors

Category	Factor	References
Collaboration	F1: Transparency in information sharing	(Cano et al., 2020; Comelli et al., 2019; Salem et al., 2006)
	F2: Efficient communication system	Proposed
Construction Methods	F3: Integration of prefabricated and modular construction	Proposed
	F4: Adoption of autonomation tools	Proposed
	F5: Incorporation of the Last Planner System or its alternatives	(Salem et al., 2006; Smith & Ngo, 2017)
Continuous Improvement	F6: Implementation of kaizen strategy	(Comelli et al., 2019; Dragone et al., 2021; Saleeshya & Binu, 2019; Salem et al., 2006; Salvatierra et al., 2020)

	F28: Proactive maintenance	Proposed
Sustainability	F29: Reduce, reuse and recycle	(Comelli et al., 2019; Salem et al., 2006)
	F30: Use of renewable energy sources	Proposed

ILLUSTRATIVE EXAMPLE

In order to evaluate the proposed FES's capability to assess the degree of Lean implementation in construction projects, the model was tested on two construction case studies. The first project is an industrial project that follows a traditional project delivery method (non-IPD) while the second one is a wastewater treatment facility project that follows an IPD project delivery method. The authors selected an IPD project and a non-IPD project to showcase the model's potential in providing a reasonable LCII as it is anticipated that the non-IPD project is likely to have low Lean implementation as opposed to the IPD one. The authors interviewed an expert on each of the two projects and were able to get a general idea about the Lean implementation on each of the two projects. In the first one, although the expert was well informed about the different Lean tools and techniques that can be potentially applied in the project, it did not seem that these were implemented. As for the second project, the interviewed expert was comfortable discussing the different applications of Lean tools in the project. As such, the authors collected data from the experts on the 30 factors previously identified using the developed interface. Tables 2 below summarize the scores obtained for the case studies.

Table 2 Case studies' data

Case study 1						**Case study 2**					
Factor ID	Score	**Factor ID**	Score	**Factor ID**	Score	**Factor ID**	Score	**Factor ID**	Score	**Factor ID**	Score
F1	20	**F11**	5	**F21**	80	**F1**	100	**F11**	80	**F21**	50
F2	50	**F12**	5	**F22**	15	**F2**	100	**F12**	90	**F22**	50
F3	55	**F13**	60	**F23**	10	**F3**	33	**F13**	66	**F23**	66
F4	65	**F14**	80	**F24**	10	**F4**	33	**F14**	90	**F24**	85
F5	15	**F15**	65	**F25**	65	**F5**	90	**F15**	95	**F25**	85
F6	65	**F16**	15	**F26**	60	**F6**	75	**F16**	90	**F26**	85
F7	40	**F17**	55	**F27**	10	**F7**	40	**F17**	75	**F27**	66
F8	60	**F18**	85	**F28**	15	**F8**	95	**F18**	85	**F28**	80
F9	15	**F19**	50	**F29**	10	**F9**	95	**F19**	66	**F29**	66
F10	65	**F20**	45	**F30**	10	**F10**	85	**F20**	50	**F30**	66
LCII: 30.64						**LCII: 55.92**					

Given the above scores, the LCII for each project was obtained. The first case study has a slight implementation of Lean tools and techniques whereas the second one has a moderate to considerable implementation. As expected, the LCII obtained for the second case study is higher than that for the first case study. As such, the developed FES model to measure the degree of Lean implementation in a construction project portrayed modeling robustness.

MODEL VERIFICATION

Sargent (2007) defines model verification as "ensuring that the computer program of the computerized model and its implementation are correct" Since the FES described in this study was developed in MATLAB, it was important to verify it. The authors performed a sensitivity analysis where the values of the inputs were changed to observe the effect on the output. Accordingly, the authors performed two tests, where the values of all the factors were set to '0' in the first test and to '100' in the second test. The results of the sensitivity analysis are shown in Table 3.

Table 3 Sensitivity Analysis

Test	Input Value for Each Factor	LCII
1	0	8.38
2	100	91.61

The results of the sensitivity analysis align with the predicted expectations. Notably, when all factors receive a rating of 0, the LCII is determined to be "very slight," whereas a rating of 100 for all factors results in a "very considerable" LCII. However, contrary to initial assumptions, the LCII is not necessarily 0 and 100 when all inputs are 0 and 100, respectively. This observation can be attributed to the influence of the FES design on the output, including the selection of operators and the consequences of the fuzzy expert rules.

CONCLUSION AND RECOMMENDATIONS

In summary, this study has made a valuable contribution to the development of frameworks for measuring the degree of Lean implementation in the construction industry. By proposing a fuzzy expert system, decision makers now have a reliable and easily applicable tool for evaluating the current level of Lean implementation on construction projects. Additionally, the use of fuzzy logic allows decision makers to capture and evaluate uncertain information, leading to more accurate and reliable evaluations. The proposed framework can help decision makers to identify opportunities for improvement and guide future Lean initiatives in the construction industry. Additionally, decision makers can use the proposed tool on projects that are already in the execution phase and on projects that are to be executed given that the identified factors used in the evaluation process apply to both.

One limitation of this study is that the fuzzy membership functions were assumed. Future research could involve experts in the development of these functions to improve the accuracy of the system. Additionally, future research could investigate the use of different quantifiable indicators that can objectively capture the level of implementation of each factor to reduce bias. Improvements to the GUI also have the potential to enhance the application and make it more user-friendly. These include labelling the inputs and outputs to provide a clearer explanation of the different categories and adding different features such as the ability to save and export results.

The proposed framework has the potential to facilitate the adoption and implementation of Lean principles in construction projects. This can lead to better project outcomes, such as improved productivity, reduced waste, and increased profitability. Moreover, the adoption of Lean principles can contribute to overall industry performance and competitiveness.

In conclusion, the development of a FES for evaluating the degree of Lean implementation on construction projects is an important step towards achieving continuous improvement throughout the project lifecycle. Furthermore, while the proposed framework is designed for project-level application, its adaptability allows implementation in organizations and broader contexts. Future research can build upon the findings of this study to further refine the FES and explore additional factors.

ABSTRACT

The construction industry must adapt to contemporary challenges; there is a need to change the paradigm of the industry, including in Indonesia. Lean thinking is an example of the evolving paradigm in the construction industry, called lean construction. It emphasises maximising efficiency, minimising waste, and delivering value to the customer through collaborations, optimised workflows, and project performance enhancement. For a construction company such as PT PP (Persero) Tbk (a government-controlled construction & investment company), which have adopted the lean concept in the last five years, there is a need to create an environment that supports lean as quickly as possible. For a company that is relatively new to lean involvement and methodology, education is crucial for raising awareness and understanding of lean construction among the company members. This paper presents an exposition of effort and learning for lean transformation by using Community of Practice as a method to disseminate lean knowledge and experience and share details of the activities about programs as an action learning. The authors will share their experience and learning of making the sustainable change in the company through the lessons learned.

KEYWORDS

Lean Construction, Sustainable, Collaboration, Lean Education, Action Learning, Community of Practice

INTRODUCTION

The construction industry is one of the biggest industries in the world. Like others, the construction industry has been evolving because of many issues such as inefficiencies, productivity, overrun cost, technological advancement, labour, regulation, expectation, environmental impact, etc. For the construction industry to adapt to these challenges, there is a need to change the paradigm of the industry. Lean thinking is an example of the evolving paradigm in the construction industry where the principle was adopted from manufacturing. The Lean Management (LM) system was first brought to bear by the Toyota Motor Corporation in the late 1950s and was named Toyota Production System (Shingo, 1981), while the lean

[2] Faculty Lecturer, Institut Teknologi Bandung, Bandung Indonesia, prama.putra@itb.ac.id, orcid.org/0000-0003-4045-9628

construction (LC) terminology emerged in the 1990s initiated by the work of Koskela (Koskela, 1992). It emphasises maximising efficiency, minimising waste, and delivering value to the customer through collaborations, optimised workflows, and project performance enhancement. Different studies have suggested that the implementation of lean construction improves performance, raises the value of money and resources, and reduces waste (Amaro et al., 2019; Shaqour 2022; Bajjou & Chafi, 2018, Tezel et al., 2020, Singh et al., 2018, Erol et al., 2017). Despite the benefits, the slow adaptation of lean concepts in the construction industry created a wide gap and broad interpretation of lean construction (Common et al., 2000). This condition produced some barriers for implementation such as skill-and-knowledge-related, behaviour-related, management-related, financial-related, technical-related, and government-related issues (Sarhan & Fox, 2013; Kanafani, 2015; Nwaki et al., 2021; Albalkhy et al., 2021; Shang & Pheng, 2014; Albalkhy & Sweis, 2021, Ayarkwa et al., 2011; Bashir et al., 2015).

LC has been disseminated and taught across the world, including Indonesia. The specific introduction of the LC concept in Indonesia has yet to be officially documented (Abduh et al., 2005). However, we may be able to say that the first major brick of lean construction was the *Kompetisi Konstruksi Ramping (K2R)* event in 2016 (Faculty of Civil and Environmental Engineering, Bandung Institute of Technology 2024). The concept was introduced through a simulation of construction projects. Since LC in Indonesia is relatively young and still in the dawn phase, there is a need to increase contractors' understanding and awareness of lean principles in the construction industry. Studies from other countries implementing LC suggested that barriers vary between countries. For example, the lack of backing from upper management, limited awareness of LC, inadequate training, and a lack of transparency were vital obstacles that significantly impede the acceptance of LC in Jordan (Albalkhy et al., 2021), incomplete or intricate designs, the cyclical nature of the construction industry, limited engagement of contractors and specialists in the design process, insufficient understanding of lean principles, and inadequate communication among all stakeholders represented the top five significant barriers in the UAE (Kanafani, 2015), the major obstacles in China included the absence of a long-term philosophy, a lack of a lean culture within the organisation, and the use of multi-layer subcontracting (Gao & Pheng, 2014), insufficient awareness and comprehension of lean principles, a lack of commitment from top management, and cultural and attitudinal challenges among the workforce were prominent issues in the UK (Sarhan & Fox, 2013), challenges in grasping lean concepts, variability in government policies, unclear project definitions, incomplete designs, absence of standardisation, and a lack of enduring relationships with suppliers were obstacles that impeded the implementation of lean practices in Ghana (Ayarkwa et al., 2011). However, we underline from these studies that people and systems are key factors in determining the success of lean implementation.

This paper aims to present an exposition of effort and learning at an Indonesian contractor, PT PP (Persero) Tbk (called PTPP), that has initiated and adopted LC since 2019. The major effort to achieve the code of conduct of LC at the company was the education of lean principles. The first purpose was to raise awareness of LC amongst company members and to increase their understanding of LC. Another effort was providing in-house training about the Last Planner System (Ballard & Howell, 1994; Lehman & Raiser, 2000) as a tool of lean construction that describes a comprehensive system to address project variability (Maradzano et al., 2019), to optimise the planning, and execution of a construction project (Sarhan & Fox, 2013). The trainers of this training were from the same company. Further effort in implementing LC at PTPP was waste-register method implementation at construction works (Aisyah et al., 2023). This accomplishment was an example of the successful execution of the lean principles at the company. The last effort was to standardise the LC system at the company, although it still needs to be finished. All the above-mentioned efforts were conceptualised under the Community of Practice (CoP) Lean Construction PTPP. CoP is usually used for an event in a country or larger region. To our knowledge, the notion of CoP at the level of a company is the smallest unit of CoP compared to the usual form of CoP, and it is now well-recognised at the company.

In the next section, we will review the concept of CoP and lean construction education. Sections 3 and 4 will describe the initiation and journey of CoP at PTPP, while Section 5 will explain further challenges towards sustainable lean construction. Ultimately, Section 6 gives the overall conclusion of our work.

LITERATURE REVIEW

LEAN CONSTRUCTION EDUCATION

People and systems are two striking keywords of the identified barriers from different studies on lean construction implementation. Although other factors, such as technical and behavioural issues, are also important, creating awareness and understanding is crucial in preparing for LC. Different studies have suggested that the lack of knowledge hinders people from adopting a new concept (Albalkhy & Sweis, 2021; Gao & Pheng, 2014; Bajjou & Chafi, 2018; Nwaki et al., 2021; Sarhan & Fox, 2013; Moradi & Sormunen, 2023). The problems could be a lack of skill, low level of education, insufficient training, or lack of understanding related to lean (Albalkhy & Weis, 2021). Ultimately, the problems could unconsciously affect the implementation of LC as a system. Due to unawareness, top management could ignore the adoption process, leading to an unsupportive environment. To overcome such barriers, providing training and development investment as part of education was considered a good strategy (Gao & Shang, 2014). The solution could lead to a change in perspective at the top management level and cultural change.

Transferring lean knowledge and skills involves training individuals in the principles of lean thinking. The goal is to provide professionals with sufficient knowledge and skills to improve project delivery, efficiency, and value and reduce waste. Lean education was widely offered at universities worldwide (Tsao et al., 2013). The university-based lean education consisted of theoretical coursework and practical simulations (Rybkowski et al., 2018). The teaching usually contained reading assignments, paper-based reflections, class and online discussions, and simulation exercises to develop students' strong understanding of lean concepts (Tsao et al., 2013; Hamzeh et al., 2016).

The university-based lean education, without question, becomes an ideal notion for learning lean concepts where students can learn and deepen their understanding through theory and practice. However, for a construction company such as PTPP, which have adopted the lean concept in the last five years, there is a need to create an environment that supports lean as quickly as possible. For a company that is relatively new to lean involvement and methodology, the education at the company is typically conducted as training for project teams (Forbes et al., 2018). Forbes et al. took examples and learnt from different companies in the US. For example, JE Dunn introduced the lean concept through the LegoTM Airplane Game, the Parade of Trades, and Silent Squares. In addition to the simulations, it provided training that focuses on introducing lean principles and tools that a project will use. DPR Construction took another path to teach lean thinking, involving Stanford and UC Berkeley to run workshops. Another example from a regional manager of an owner organisation provided hands-on training at the project level and found that the internal construction administration plays a key role in creating a lean culture. The last example was aligned with the finding that transferring and sharing lessons learned within the organisation encourages a successful lean education and culture (González et al., 2014).

Based on the above, there were many forms of lean education at the level of construction companies. The goal was to disseminate and raise awareness of lean thinking within the company as rapidly as possible. Companies could engage universities or lean consultants to provide education.

COMMUNITY OF PRACTICE IN LEAN CONSTRUCTION

One of many ways to teach and accelerate lean manifestation was through a community of practice (CoP). It is known as a group of people who have the same interests and discuss and explore things for their future goals. They used any methods, especially brainstorming and sharing sessions, through their knowledge and experience (Wenger & Snyder, 2000). CoP was initially developed as a learning theory that promotes self-empowerment and professional development, but as the theory evolved, it became a management tool for improving an organisation's competitiveness (Li et al., 2009). Despite many views, the CoP concept emphasises learning and sharing knowledge and supports formal and informal group interactions.

In the context of lean construction itself, CoP Lean is a group of people interested in LC. The event was usually regional based around the US. An official Community of Practice of Lean Construction was held by the Lean Construction Institute (LCI) (Lean Construction Institute, n.d). Their goal was achieving industry-wide collaboration through communities of practice; whether a skilled practitioner in Lean Design and Construction or just getting started, there was support and a chance to keep learning. LCI nationally supported CoPs after opportunities to connect locally, participate in education courses and workshops, hear from local lean project teams, attend Gemba walks, and more. Since LCI was also present in some European and Asian countries such as the UK, France, Japan, Singapore, and India, the CoP was held chiefly regionally. As the construction industry in Indonesia is growing, such activity is strongly needed to disseminate and teach the lean principle and manifest it in construction in Indonesia.

COMMUNITY OF PRACTICE INITIATION

CoP Lean Construction (CoP LC) is one of the CoPs that exist in the PTPP. The other CoPs are the CoP Green Building, CoP Mechanical & Electrical, CoP Strategic Business Management, CoP Seaport, CoP Power Renewable Energy, CoP Building Information Modelling (BIM), CoP Innovation, and CoP Lean Construction. The CoP LC has three fundamental elements: domain, community, and practice. The domain element is divided based on their operational expertise: building, bridge and road DAM, and Engineering, Procurement and Construction. The community element consists of people who are curious or as simply as they want to know about LC. The last element consists of the method and module used for knowledge sharing of LC. The coordination of all elements is through three divisions of the company: Division of Strategy, Planning and Technology (Stratec), Division of Operation, and Division of Project. These parties determine the operation of CoP LC and improve it. The Division of Stratec is responsible for planning and monitoring corporate LC and innovation implementation, choosing value creation, workshops, socialisation and refreshment as a corporation. The Division of Operation is accountable for monitoring LC of all the projects based on their expertise. The Division of Project is responsible for gaining value creation for the corporation.

CoP LC in PTPP was established in October 2019 after management declared committing to implementing lean construction in March 20219. This idea came when the company followed the LC Villego competition, called K2R 4.0 (Kompetisi Konstruksi Ramping), held by Institut Teknologi Bandung in 2019. There were many projects representing different sectors, such as building, toll-road, and infrastructure. The CoP LC took a role in uniting the PTPP representatives and won the contest. Based on that, the CoP LC creates big goals for having big impacts on the company as much as possible. CoP Lean PTPP was supported by the Human

Capital Management System in order to build awareness. The group organised gathering events in the first year to share CoP LC's agenda. The group collected advice and remarks to highlight the needs of the projects. CoP Lean PTPP is basically under the Department of Knowledge Management System in the Division of Strategy, Planning and Technology and held by the Division of Creative, Engineering and Technology, which is now known as the Division of Innovation, Lean, BIM and Technology.

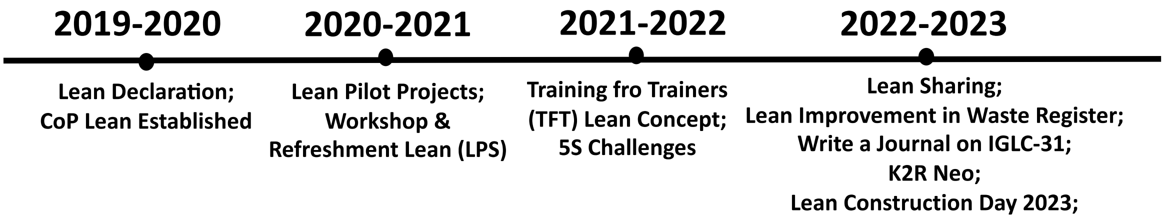

Figure 1 Timeline of CoP Lean Construction PTPP Journey

COP LEAN PTPP JOURNEY

2019 – 2020

As mentioned in Figure 1, CoP LC PTPP was established in October 2019; that year, we focused on all the LC competitions held in Indonesia: Construction Funday GAPENSKI 2019 and Villego Competition (K2R 4.0) 2019. Firstly, we started by doing a site visit project in PLTD Senayan Jakarta to benchmark LC that was implemented first there. This project ran the Last Planner System (LPS) because the project owner was Wartsila, a foreign country. For some project owners, it was usual to do a daily collaboration. This condition was an opportunity for us to know directly how their experience was in it and get some insight through that project.

Because of that experience, we exercised regularly until we won that competition. This initiative project was a milestone in gaining another success story in the next section. In that history, CoP LC did a Sharing Session with the winning team, discussing how strategy, collaboration, and planning affected their win to get some lessons learned that reflect on being implemented in their project. Some lessons learned were how to produce a building that meets the values desired by its users (owners), effective and efficient implementation (time), fit the design (quality), and there was little waste production (cost).

After the competition, we focused on making the modules of The Last Planner System to be implemented in the project. There were so many adjustments from the Villego Competition to the actual project condition, so we learnt to arrange how the methodology was implemented using that basic understanding of LPS through Villego games. On the other side, we initiated the digitalisation of the concept of LPS itself using The PP Planner. It made us collaborate with the Information & Technology (IT) system to apply the project to using LPS as a digital-based project management system.

From the journey of this year, we remark on three key lessons learned that made the CoP LC succeed. First, Last Planner System is crucial in understanding lean construction and its implementation. The members of CoP LC covered the gap of LC understanding in the beginning and LPS was an important first step. Second, collaboration with academic universities becomes vital. The collaboration was done through the competition held by a university, and this event became a milestone in checking the understanding of LC within the company, at least among CoP LC members. Third, the information gathered must be formulated quickly and it was based on experience. By doing such activities, the CoP LC helped the company design lean education and implementation within the company.

2020 – 2021

The work program of CoP LC PTPP continued the year after it was established. We did some correspondence between the CoP LC PTPP committee and the project. The first was to do a workshop on the topic and go back to basics, which was about scheduling and planning. The first workshop was held in April 2020, Workshop Ms Project Integrated with LPS and Workshop Optiwaste (The method for knowing cutting-off reinforcement in the field).

After that, because we should have a recommendation and suggestion to do next, we often did regular *focus group discussions* over time, both directly and indirectly. Directly, we did *Lean Sharing* each month with multitopic, which was an option for following the issue and problem in the project. This lean sharing was an easy and effective method of sharing knowledge over poor construction. We got some suggestions through the discussion and Question & Answer after the materials were disseminated by the speaker. Besides lean sharing, we continued workshops with different experts to minimise the gap in knowledge and experience of poor construction. Indirectly, we made the group to get instant messages and discussions through WhatsApp. Another thing was the newsletter knowledge (PP WIN), a weekly magazine PTPP, and we ended up with the online meeting/ workshop.

This methodology was used to develop CoP LC PTPP, which was customised with the COVID-19 limitations that we got to reach more closely. Still, we also found out how to make an effective and efficient method that could be accepted by all the projects throughout the Indonesian region from Sabang to Merauke.

From this journey, we highlight that creating a medium for sharing and learning boosts awareness and understanding of lean construction. Sharing and learning must not be limited, and it is better to start with the company members' experience related to lean theory and application.

2021 – 2022

In 2021, CoP LC was trying to explore knowledge widely by benchmarking abroad nationwide. We held Training-for-Trainers (TFT) by Chyntia Tsao (NAVILEAN). This TFT ran for eight months (sixteen meet-ups) from May until September 2021 during the COVID-19 pandemic.

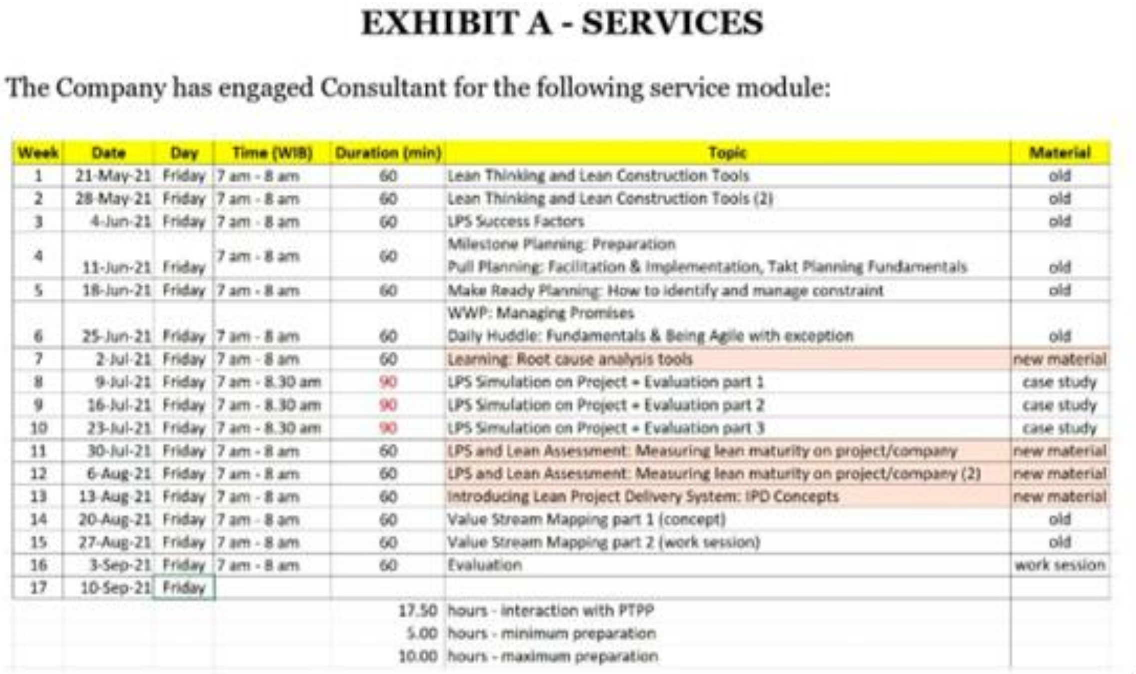

EXHIBIT A - SERVICES

The Company has engaged Consultant for the following service module:

Week	Date	Day	Time (WIB)	Duration (min)	Topic	Material
1	21-May-21	Friday	7 am - 8 am	60	Lean Thinking and Lean Construction Tools	old
2	28-May-21	Friday	7 am - 8 am	60	Lean Thinking and Lean Construction Tools (2)	old
3	4-Jun-21	Friday	7 am - 8 am	60	LPS Success Factors	old
4	11-Jun-21	Friday	7 am - 8 am	60	Milestone Planning: Preparation Pull Planning: Facilitation & Implementation, Takt Planning Fundamentals	old
5	18-Jun-21	Friday	7 am - 8 am	60	Make Ready Planning: How to identify and manage constraint	old
6	25-Jun-21	Friday	7 am - 8 am	60	WWP: Managing Promises Daily Huddle: Fundamentals & Being Agile with exception	old
7	2-Jul-21	Friday	7 am - 8 am	60	Learning: Root cause analysis tools	new material
8	9-Jul-21	Friday	7 am - 8.30 am	90	LPS Simulation on Project + Evaluation part 1	case study
9	16-Jul-21	Friday	7 am - 8.30 am	90	LPS Simulation on Project + Evaluation part 2	case study
10	23-Jul-21	Friday	7 am - 8.30 am	90	LPS Simulation on Project + Evaluation part 3	case study
11	30-Jul-21	Friday	7 am - 8 am	60	LPS and Lean Assessment: Measuring lean maturity on project/company	new material
12	6-Aug-21	Friday	7 am - 8 am	60	LPS and Lean Assessment: Measuring lean maturity on project/company (2)	new material
13	13-Aug-21	Friday	7 am - 8 am	60	Introducing Lean Project Delivery System: IPD Concepts	new material
14	20-Aug-21	Friday	7 am - 8 am	60	Value Stream Mapping part 1 (concept)	old
15	27-Aug-21	Friday	7 am - 8 am	60	Value Stream Mapping part 2 (work session)	old
16	3-Sep-21	Friday	7 am - 8 am	60	Evaluation	work session
17	10-Sep-21	Friday				
				17.50	hours - interaction with PTPP	
				5.00	hours - minimum preparation	
				10.00	hours - maximum preparation	

Figure 2 Module Planning Example

This was followed by the top ten CoP LC participants. During the training, we learnt step-by-step how lean could be implemented; the success story project implemented lean and then discussed many things related to lean construction implementation in PTPP. To know how we understand the result of TFT, in parallel, we gathered by did an online workshop to transfer the knowledge to the project and continue Lean Sharing, which has several topics:

1. Lean Sharing-1: LPS Project Story PLTD Senayan
2. Lean Sharing-2: PP Planner (Implementation LPS by the digital tools)
3. Lean Sharing-3: Book Sharing – “Lean Thinking”
4. Lean Sharing-4: Between BIM & Lean
5. Lean Sharing-5: Value Stream Mapping
6. Lean Sharing-6: Introducing Lean Construction and Its Development
7. Lean Sharing-7: Waste Identification - DOWNTIME
8. Lean Sharing-8: Lean Culture – The Key to Lean Implementation
9. Lean Sharing-9: LPS – Lean Project Execution
10. Lean Sharing-10: Improve Productivity with Lean Project Execution
11. Lean Sharing-11: Lean 5S Implementation
12. Lean Sharing-12: Digital Lean Construction

Lean Sharing invited both an internal and external PTPP speaker to gain knowledge through its lean construction expertise. We rewarded the participants who actively reached out during the Q&A and often follow skinny sharing. Also, the community members got rewards from Knowledge Center (KC) point platforms when they became speakers in lean sharing, contributed to the CoP product output, did sharing through the CoP LC agenda and participated in the Training-For-Training (TFT) workshop. The other event was the 5S Challenge. CoP LC held this competition, and the participants were from different projects. This was a review of what and how the project implements 5S in the project. There was a winner of that competition: Stadion Banten Project, Engineering, Procurement & Construction (EPC) Divisions, and the Depo Makassar Project—three top projects chosen by assessment by internal and external PTPP expertise.

In the third year of CoP LC PTPP, we note that continuous improvement is a key factor that makes lean education successful and sustain at PTPP. This is aligned with approaches taken by the CoP lean, for example, providing a Training-for-Trainers and creating a structured and systematic sharing and learning means within a year. The provided training becomes a tool to yield new agents of lean within the company. The lean education is boosted not only by systematic sharing sessions, but also by providing reward to the company members who contribute to lean construction improvement at the company. Continuous improvement becomes a core value of CoP lean PTPP and it motivates CoP lean to provide novel topics for lean construction sharing sessions and yield an important milestone explained in the next section.

2022 – 2023

In 2022, CoP LC were continuing lean sharing with a new topic to be discussed:

13. Lean Sharing-13: Book Sharing – “The Second Lean”
14. Lean Sharing-14: Construction Waste Register
15. Lean Sharing-15: Integration LPS & CPM
16. Lean Sharing-16: Lean Implementation for Cost Performance

17. Lean Sharing-17: Takt Time Planning for Schedule Project Improvement
18. Lean Sharing-18: Dealing with Construction Waste by Lean Project Execution
19. Lean Sharing-19: Lean Canvas: The Simple Business Model
20. Lean Sharing-20: Lesson Learned K2R Neo 1.0 & Pull Planning Concept

Another learning that we have been through was by following The Lean Construction Conference online. There were so many topics that were related to current conditions, so we were equipped with knowledge and experience from aboard. In 2023, CoP got some highlights of the agenda; one of them was to present our journal of production, planning and control with focusing waste registered. The title of PTPP's journal was Lean Construction Through Waste Register Method: A Case Studies Project in Indonesia. The journal focuses on implementing lean construction for physical construction waste. Furthermore, this article presented Indonesian case studies to illustrate the impact of lean construction on building projects. The study analysed waste management impacts across three periods of time. Lean waste management provided an early warning evaluation in the short term that was used as an indicator so the project could evaluate and follow up as an effort to reduce waste, which in this study showed a reduction of waste from 2.1% to 1.7%. Addressing common waste in the medium-term increased project productivity by 50% and improved cost and duration efficiency. It reduced many possible wastages due to defects, overproduction, non-utilised talent, inventory, transportation, motion, waiting, and extra processing (DOWNTIME). Sustainable waste reduction practices could become a productivity standard in the long term by continuously improving the cycle of writing, categorising, analysing, and writing for each job.

We presented our journal in Lille, France, for the first time and only for Indonesia as a presenter. The goals were reaching out insights through the lean construction international conference, establishing strategic partnerships with practitioners and academics in the international scope, improving PTPP's branding in the implementation of lean construction and getting insight into lessons learned on project site visits on an international scale to increase lean construction awareness for the futures. After IGLC's 2023 in June-July 2023, we moved into the Indonesian competition of lean construction (K2R Neo) event on 1 October, 2023. As mentioned before, this agenda was held by academic institutions and followed by Indonesian construction practitioners and academicians. CoP prepared seriously until we won two champions at once. The goal following this event as an innovative collaboration platform was to gain a deep understanding and competency in the lean construction concepts of the LPS.

The other agenda by CoP LC presents Lean Construction Day 2023 (LCD 2023). PTPP's Lean Construction Day 2023 was one of the agendas for increasing the competency of project participants in the form of sharing sessions, talk shows, workshops, and other similar activities regarding the implementation of lean construction, which were carried out by PTPP through its CoP LC. A similar agenda was previously carried out in 2022 and was then carried out again on 3 November, 2023. The purpose of LCD 2023 was to: 1. Accelerate the increase in corporate knowledge in implementing lean construction; 2. Refreshment of knowledge and experience of implementing lean construction from the perspective of regulators (Ministry of Public Works & Housing - PUPR), academics (Dr. Gao Shang) and practitioners (PTPP) and 3. Creating value-added in the form of positive branding to stakeholders that PTPP was concerned with implementing lean construction and PUPR Ministerial Regulation No. 9 of 2021: Guidelines for Implementing Sustainable Construction.

FURTHER CHALLENGES TOWARDS SUSTAINABLE LEAN CONSTRUCTION

Lean implementations (in construction and beyond) because of barriers hindering successful implementation, including respect for people who are not specific to construction. These challenges involved an excessive focus on continuous improvement and a lack of complete understanding or underestimation of the importance of respect for people to the sustained success of lean principles (Korb, 2016). Beyond those initial barriers, a further challenge towards sustainable lean construction was creating the same perception of future constructions. People, which is one of the critical aspects, can be developed through CoP at the company and have the same vision to disseminate lean principles as a community. In the CoP Lean PTPP, the majority of CoP members were young people who tended to have the courage to make a better change through continuous improvement actions. After people, the big challenge towards LC implementation was the systems, which we identified to three points. The first point was that the company needed agents of lean. These people had roles to continue, evaluate, and improvise LC implementation. The second point was that LC implementation standards and legal were mandatory for every project in PTPP. The last point was the involvement of the top management, which could influence the adoption and implementation of LC at the company.

CONCLUDING REMARKS

This work describes the effort and learning of lean construction education at the PTPP, which started adopting lean thinking in 2019. In particular, lean education at the company was conducted through a community of practice, which became a place to learn and share theories, experiences, practices, and tools related to lean construction. CoP lean at PTPP, in the last four years, has disseminated learning throughout the company members, including top management level and company experts. Lean sharing has become the most frequent activity for raising awareness and understanding of the concept. It was then made into a more significant event, Lean Construction Day, which disseminated lean construction to broader participants and involved universities. At the project level, team members also received hands-on training about the Last Planner System using Villego. CoP was an excellent strategy to raise people's awareness and understanding. The company must have agents of lean to ensure that the learning process continues throughout the time and did not depend on the company member's position. However, some challenges remained regarding the system for developing sustainable lean construction at the PTPP. Top management support was the most important because of their influence and authority in establishing standards and legal lean construction implementation at the company.

COLLABORATION STRATEGIES FOR INFRASTRUCTURE PROJECTS OF GERMANY'S FEDERAL WATERWAYS AND SHIPPING ADMINISTRATION

Elisa Schwarzweller[1] and Shervin Haghsheno[2]

ABSTRACT

The improvement of collaboration in construction projects can lead to a more stable and efficient project delivery. Nevertheless, Germany's Federal Waterways and Shipping Administration (WSV) has limited experience with strategically implementing elements to promote collaboration in construction projects. Therefore, initial steps have been taken in the WSV by identifying major infrastructure projects along Germany's waterways to initiate the implementation of collaborative elements, such as Lean Construction methods. The aim thereby is to make experiences to improve future projects. This article describes a research project which was set up to systematically record and document experiences with collaboration elements in selected pilot projects. Also, the outcomes of an initial survey which gives insights into the pilot projects are presented. Furthermore, the results of a survey regarding experiences during the procurement phase of one chosen pilot project are presented. The results show that there is no clear definition of collaboration within construction projects in the WSV and that there is a need for further research to develop solutions and recommendations for the improvement in future projects by utilizing collaboration elements.

KEYWORDS

Collaboration strategies, infrastructure projects, waterway construction, system change.

INTRODUCTION

Collaboration between the participants of construction projects promotes the achievement of objectives and increases efficiency in planning and building services. Therefore, the implementation of elements to improve collaboration in projects is recommended in the Reform Commission for Major Construction Projects, the Planning Acceleration Strategy, as well as in the Major Projects Guideline by the German Federal Ministry for Digital and Transport (BMDV 2015, 2017, 2018).

Especially, large and complex construction projects are not usually accomplished within the intended time frame and budget. This also applies to projects of the Federal

[2] Professor, Department of Civil Engineering, Geo- and Environmental Sciences, Director, Institute of Technology and Management in Construction, Karlsruhe Institute of Technology, Karlsruhe, Germany, shervin.haghsheno@kit.edu, orcid.org/0000-0002-0602-6370

Waterways and Shipping Administration (WSV). For example, in some projects of the WSV the prescribed budget was exceeded by more than 30 %, and the construction time was doubled. In various water lock projects along Germany's waterways, it even has been observed that both the construction time and costs have quadrupled. (Schwarzweller et. al 2023) For example, these problems can be addressed by the utilization of methods that promote collaboration in construction projects, such as Lean Construction methods or Building Information Modeling.

Up to this point, there are only limited experiences within the WSV of implementing collaboration elements that potentially lead to more stable and efficient project deliveries. With this background, initial steps have been taken by the Federal Waterways and Shipping Agency (GDWS) to gather experiences with a strategic promoting of collaboration elements in the delivery of construction projects along Germany's waterways. Therefore, several infrastructure projects were identified throughout the WSV. Additionally, in 2022, a 'Charter for Collaboration on Construction Sites along Federal Waterways' was created and signed between the Association of the German Construction Industry (HDB) and the WSV. (WSV 2022)

The Institute of Technology and Management in Construction (TMB) of the Karlsruhe Institute of Technology (KIT) supports the GDWS, as organization unit of the WSV, with a systemized recording and documentation of the experiences in the selected projects. The aim hereby is to develop solution approaches and recommendations for the strategic implementation of collaboration elements to improve project deliveries of future projects along Germany's waterways. This paper presents the first results of the systemized recording and documentation of experiences up to this point.

COLLABORATION ELEMENTS IN CONSTRUCTION PROJECTS

In construction projects, the terms collaboration and cooperation are commonly used interchangeably in literature as well as intentionally distinguished from each other (Camarinha-Matos et al., 2009, p. 47). Therefore, it is not consistently possible to precisely delineate what is meant by these terms. Below are exemplary definitions for collaboration and cooperation.

Cooperation can be defined as "the authentic pursuit of the goals of the respective contracting partner or a goal alignment of the partners, in order to achieve a 'win/win' situation" (Schlabach, 2013, p. 50). Furthermore, according to Camarinha-Matos et al. (2009, p. 48), cooperation can also be understood as communication, information exchange, mutual activity adjustments, and shared resource utilization aimed at achieving common goals.

In contrast to cooperation, collaboration can be understood as a more enduring and comprehensive form of cooperation, where previously separate organizations work intensively on a common mission within a new structure (Mattessich & Monsey, 1992, p. 42). Additionally, collaboration is also perceived as a more communicative, intensive, and holistic form of cooperation, where the shared commitment to achieving project success and the establishment of a communal project culture are essential (Ibrom, 2022, p. 46).

Based on a literature review of various definitions of cooperation and collaboration, Schöttle et al. (2014, p. 1274) have developed an overview that allows differentiation based on various factors. The resulting definition of collaboration is meant when using the term within this study:

> *Collaboration is 'an interorganizational relationship with a shared vision to create a joint project organization with a collectively defined structure and a new and*

> *collaboratively developed project culture based on trust and transparency, aiming to maximize customer value collaboratively by solving problems through interactive processes that are jointly planned, and by sharing responsibilities, risks, and rewards among the key stakeholders'*
>
> (Schöttle et al., 2014, p. 1275).

There are various elements to promote collaboration in construction projects. These can be categorized into project culture and conflict management, organizational and procurement models, incentive systems within the compensation model, as well as methods to promote collaboration.

In many countries the necessity to improve collaboration in construction projects has been identified. Therefore, the implementation and utilization of work methods as well as project delivery models that promote collaboration are intensively discussed, e. g. in France (Attouri et al. 2023), Norway, Denmark (Paulsen et al. 2023), Peru (Prado Lujan & Murguia 2022), India (Pal & Nassarudin 2020), Lebanon (Abou Dargham et al. 2019), China (Li & Ma 2017), Saudi Arabia (Alsaggaf & Parrish 2016) or Colombia (Forero et. al 2015).

ANALYSIS AND EVALUATION OF COLLABORATION ELEMENTS IN WATERWAY INFRASTRUCTURE PROJECTS

OBJECTIVES AND STEPS OF THE RESEARCH PROJECT

Based on the assumption that successful implementation of construction projects is facilitated, among other factors, by the utilization of collaboration elements, the GDWS has developed a procurement strategy for major projects. Within this strategy, pilot projects were identified to initiate the implementation of collaborative elements and to gather experiences. Table 1 contains the 8 selected infrastructure projects in the field of waterway construction for this purpose.

Table 1: Overview of selected pilot projects

No.	Type of structure	Location	Brief description of undertaking
1	Weir	Wieblingen at River Neckar	Replacement construction
2	6 Weirs	Erlabrunn, Harrbach, Steinbach, Rothenfels, Faulbach and Freudenberg at River Main	Complete maintenance
3	Water lock	Oberesslingen at River Neckar	Maintenance during operation
4	Water lock	Hessigheim at River Neckar	Landside soil improvement
5	Water lock	Kriegenbrunn at Main-Danube Canal	Replacement construction
6	Water lock	Herbrum at Dortmund-Ems Canal	Demolition of old lock & new construction
7	2 Water locks (small)	Kiel at Kiel Canal	Replacement construction
8	Dry dock & gate berths	Brunsbüttel at Kiel Canal	New construction

The Institute of Technology and Management in Construction (TMB) of the Karlsruhe Institute of Technology (KIT) supports the GDWS with a systemized recording and documentation of the experiences in the selected projects. In the course of the scientific support, the following overarching goals are pursued in particular:

- Development of common terms and systematic approach of the diverse elements to promote collaboration in waterway construction projects.
- Elaboration of a systematic approach ('Roadmap') and an overview ('Project Map') for testing relevant elements, considering already initiated experiences.
- Project-accompanying systematic recording and documentation of experiences within the projects.
- Development of recommendations for implementation of elements within the structure and processes of the WSV based on the evaluation of projects.

All the selected projects share a high level of complexity. Furthermore, all projects are of great relevance for ensuring the operational functionality of waterways in Germany. However, table 1 indicates that the projects not only differ in terms of the type of structure but also in terms of the respective undertaking (e. g. new construction, complete maintenance). In addition, the chosen project delivery models differ, as well as the current stages of completed phases in each project. Due to this variety and complexity, a suitable systematization of data becomes necessary to enable a proper capture of experiences.

A high number of project participants must be involved when it comes to the collection and evaluation of experiences within the projects. To improve the exchange of experiences among project participants a platform called Soundingboard was established in the WSV. It takes place semi-annually in person and facilitates feedback with those responsible for the procurement strategy of GDWS, as well as with the scientific support of TMB. Additionally, a so-called 'Online-Board' takes place digitally in shorter cycles to keep the project participants up to date about relevant topics, e. g. Lean Construction methods.

To systematically collect experiences, methods of empirical social research are being utilized. At first, structural and general correlations as well as the measurement of social incidents need to be examined within the pilot projects. Therefore, a quantitative research method has to be used. As a second step, a qualitative research method has to be used to explain the reasons for the outcome of quantitative research methods. (Raithel 2008)

The first quantitative approach to collect experiences within the pilot projects is described in the following chapter 'data collection with project questionnaires'. The second quantitative approach to collect experiences in the procurement phase of a chosen pilot project is described in chapter 'experiences during the procurement phase'. In both cases the qualitative approaches are in progress and will be part of further research. For example, expert interviews can lead to a deeper understanding of the participants‘ statements in the foregoing surveys (Marotzki 2006).

DATA COLLECTION WITH PROJECT QUESTIONNAIRES

For the data collection in the pilot projects, a questionnaire was designed to be filled out semi-annually by the respective project managers. This questionnaire will be continuously adjusted to fit the projects' development. In the following, the segments of the questionnaire for the first data collection are presented:

- brief project description
- alternative organization and procurement model
- incentivized compensation structure
- further approaches to improve collaboration
- involvement of external support
- insights and suggestions for further development

The segment *'brief project description'* contains the project's title, a summary of content and tasks, volume, duration, and necessity of the project. These details enable a quick overview of the selected projects and are intended to be incorporated into a project map which can be used as a control tool in the future by the GDWS.

Originally, the procurement strategy for major projects mainly focused on testing procurement models which were utilized rarely in the WSV up to this point. However, within the scientific support a holistic approach is being pursued, amongst others including organizational and compensation-related approaches.

Therefore, in the segment *'alternative organization and procurement model'* the questionnaire contains the procurement model for planning services, the procurement model for construction services, the utilization of a 2-phase-model, and the type of performance specifications. Additionally, the current label of the project's alternative strategy, costs for the procurement phase and the reasons for choosing an alternative strategy are requested. The segment *'incentivized compensation structure'* currently focuses on the compensation system for building services and requests the existence of a bonus malus system.

The alternative organization and procurement model as well as the incentivized compensation structure themselves are considered as elements that can improve collaboration within a project. Hence, the questionnaire contains *'further approaches to improve collaboration'*, such as a project kick-off, team reflections, conflict-solving mechanisms and other collaborative project management and work methods.

With a view to future projects, it is also of high relevance to the GDWS to estimate the costs and necessity of external services. That is why the segment *'involvement of external support'* was included. It contains the information about the support of legal advisors, support of technical advisors, services of coaches (e. g. Lean Coaches), costs for external support and special experiences made with the external support.

Furthermore, an additional segment *'insights and suggestions for further development'* was added. This segment enables an open collection of additional findings and can be used to share suggestions for further development.

INSIGHT IN ANALYSIS OF QUESTIONNAIRES

In the following, a selection of the data given in the first questionnaires is presented and discussed. The data show that the project volumes range from 16.7 million (project No. 4) to 650 million (project No. 7) euros. However, these numbers should be questioned critically because the included costs are interpreted differently for each project. A similar issue appears for project durations. For example, in some projects the start is interpreted as the project's approval whereas in others as the beginning of the planning phase.

A clearer picture is drawn by the utilized type of procurement model in each project. As shown in table 2, in 7 projects a negotiated procedure with prior competition was chosen. Only in 1 project no information is provided due to the project's early status. In 5 projects a functional specification is utilized and in 2 projects a detailed specification is utilized. Moreover, in two projects a 2-phase model is established. In 5 of the projects a general contractor is contracted for the building services. Moreover, there is 1 project with a total contractor and 1 project using a multi-party-agreement within an Integrated Project Delivery. The compensation models are distributed to 3 projects using a fixed price, 1 using direct costs, 1 using a mixed model, 1 using unit prices and 2 have no information provided yet. In 3 projects an incentive system is established and in 2 projects the utilization of an incentive system is currently discussed. In 2 projects no information is provided yet and 1 project replied that no incentive system is utilized.

Table 2: Elements: procurement model, 2-phase model, organization, and incentivized compensation

Project Element	No. 1	No. 2	No. 3	No. 4	No. 5	No. 6	No. 7	No. 8
Procurement model	neg. wpc.*	neg. wpc.	neg. wpc.	neg. wpc.	neg. wpc.	neg. wpc.	neg. wpc.	neg. wpc.
Service specification	func.**	func.	func.	detailed	detailed	-	func.	func.
2-phase model	yes	no	yes	no	no	-	no	no
Organization model (build)	general contr.***	general contr.	total contr.	general contr.	general contr.	-	general contr.	multi-party
Compensatio n model	-	fixed price	fixed price	mixed forms	unit prices	-	fixed price	direct costs
Incentive system	-	perhaps	perhaps	yes	no	-	yes	yes

*negotiation with prior competition; **functional; ***contractor

The combination of the organization and procurement model, and the type of performance specifications, together with the incentivized compensation structure will lead to specific terms to describe each project's delivery model. This is necessary to address the lack of commonly used terms in the WSV.

Besides the elements mentioned above the projects implement further approaches to improve collaboration, as shown in table 3. In 6 projects a project kick-off is or will be utilized, 5 projects include team-reflections. Conflict-solving mechanisms are included in

5 projects. Additionally, Lean methods and/or Building Information Modeling are named as further approaches to improve collaboration in 5 projects.

Table 3: Elements of further improvement of collaboration

Project Element	No. 1	No. 2	No. 3	No. 4	No. 5	No. 6	No. 7	No. 8
Project kick-off	-	yes	yes	yes	yes	-	yes	yes
Team reflections	-	yes	yes	yes	yes	-	no	yes
Conflict-solving	-	yes	yes	no	yes	-	yes	yes
Collaborative methods	-	no	yes (Lean)	yes (BIM)	yes (BIM, Lean)	-	yes (BIM)	yes (Lean)

A lack of information in the filled-out questionnaires can generally be explained by a project's early status. Additionally, it can be mentioned that after the first data is collected the questionnaires must be partly specified to avoid room for interpretation for any following data collections to ensure a better comparability between projects.

COMPREHENSIVE INSIGHTS INTO A R&D WATERWAY INFRASTRUCTURE PROJECT

PROJECT DESCRIPTION

In a second quantitative approach the experiences in the procurement phase of one particular pilot project are examined. The project 'Component Tests Oberesslingen' (Project No. 3, table 1) is an R&D project and aims to gain practical experiences in several methods for maintaining water locks under continuous operation. This means that the maintenance is alternating with the locking of ships. The definition of the duration for the maintenance per day is project specific. (Westendarp 2017) The maintenance of the 'Component Tests Oberesslingen' on River Neckar must be performed within 12 h per day.

Generally, to maintain a complete water lock can take up to 3 or more years. During this time, the water lock is out of operation, which is unacceptable considering the consequence of shifting freight transportation to alternative traffic carriers, like streets and railways. The significance of this circumstance becomes even clearer when looking at a high demand for maintenance and a lack of redundancy, with a total amount of circa 260 water locks in Germany that only have one chamber. To bypass this problem, the only alternative to conventional maintenance currently is to construct a replacement lock, which generally comes with high costs and needs significant space. Therefore, maintenance under continuous operation can be a meaningful alternative for the WSV in future. (Westendarp 2017)

The component tests include amongst others: a mobile inspection closure, the installation of dam boards in guide rails, the demolition of chamber walls by milling and high-pressure water jetting, reprofiling chamber walls with pre-cast segments, in-situ concrete, bulkheads, and shotcrete. The different methods will be tested on different blocks of the chamber while the filling and draining within the 12 h closure will be simulated. Adding to this, the reprofiling of chamber walls with pre-cast segments and in-situ concrete containing micro-hollow spheres will be tested during a full closure.

Due to the high complexity in planning and construction, a project specific so called ‘Partnering Package Model’ was chosen for the delivery of the project. In this context, the term ‘Package’ means that planning and construction services are awarded to a total contractor through a negotiated procedure with prior competition. This allows the expertise of construction companies to be already incorporated during the preparation of bids before the award of the contract. (HKLW 2020) Regarding the term ‘Partnering ’, the preamble of the contract between the client and the contractor notes that the parties intend to shape a project collaboration based on the ‘Charter for Collaboration on Construction Sites along Federal Waterways’ (WSV 2022).

Furthermore, the contract includes a section related to the implementation of a collaborative decision-making process. Additionally, other project documents, such as the functional performance specification, contain expressions like ‘collaborative coordination’, ‘collaborative processing’, or ‘collaboratively decided’. However, the specific implementation of this collaboration is not conclusively defined, allowing a level of creativity for the project participants.

EXPERIENCES DURING THE PROCUREMENT PHASE

For this particular project a survey was used to save the experiences made in the procurement phase, including a foregoing market study, the prior competition, and the negotiated procedure including two negotiation rounds, as shown in Figure 1.

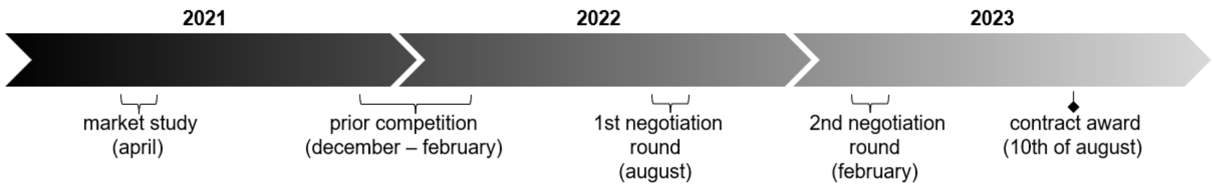

Figure 1: Procurement phase of the project 'Component Test Oberesslingen'

Both perspectives, of the client and the bidders, were taken into account. The condition to be contacted as a participant of the survey was the participation in least one of the procurement phase’s steps (market study, prior competition and negotiated procedure). This includes in total 64 persons on the bidders’ side and 17 persons on the client’s side who received a survey link via email. 19 of 64 persons on the bidders’ side and 10 of 17 persons on the client’s side filled out the survey. A higher number of participants might have been achieved by sending the survey earlier. However, the survey was sent 2 months after the contract had been awarded. The effect may have been enhanced for bidders that had not been awarded due to a loss of interest in the procurement phase.

Due to the number of participants and the fact that this survey concentrates on a project-specific procurement phase the data cannot be generalized. Nevertheless, it shows tendencies and gives ideas for further research. In the following, a selection of data focusing on the negotiated procedure is presented and discussed. The examples in Figures 2 through 7 give an insight of the different perspectives on client’s and bidders’ point of view in the procurement phase of the ‘Component Test Oberesslingen’.

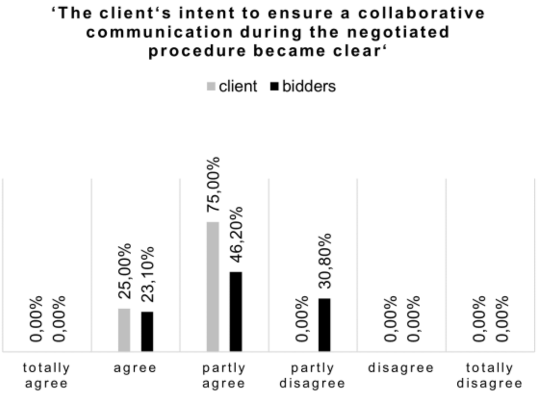

Figure 2: communication with bidders

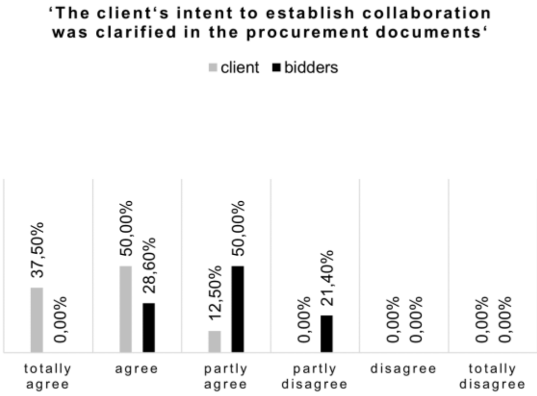

Figure 3: procurement documents

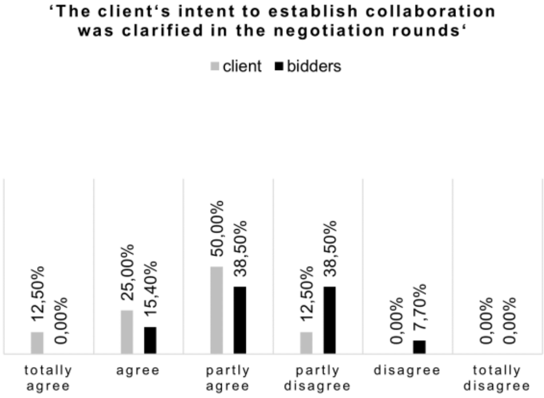

Figure 4: negotiation rounds

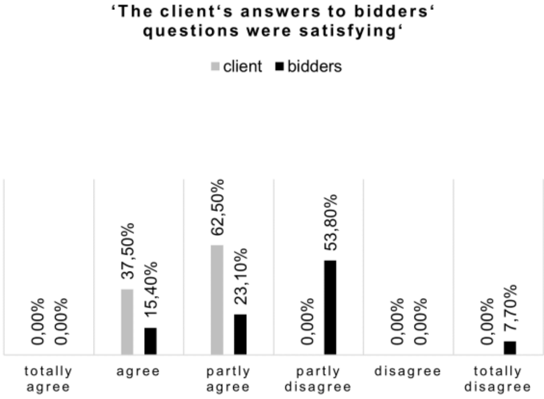

Figure 5: bidders' questions

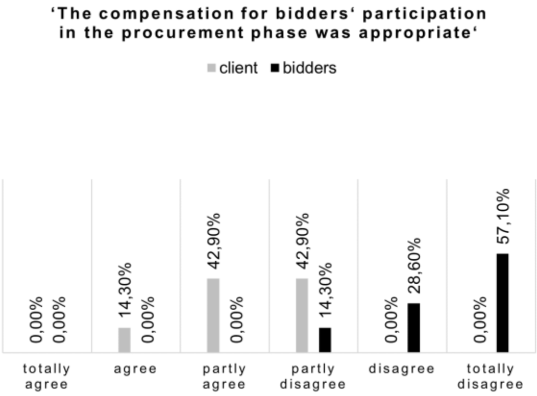

Figure 6: procurement phase compensation

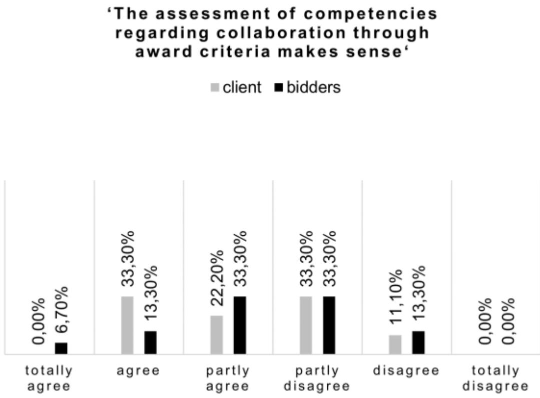

Figure 7: collaboration in award criteria

On the client's side as well as on the bidders' side 0,0 % of the participants disagreed or totally disagreed on the statements 'the client's intent to ensure a collaborative communication during the negotiated procedure became clear' (Figure 2) and 'the client's intent to establish collaboration was clarified in the procurement documents' (Figure 3). Nevertheless, it is noticeable that the tendency to agree to both of the statements is higher on the client's side. This tendency is also visible in the answers regarding the statement 'the client's intent to establish collaboration was clarified in the negotiation rounds' (Figure

4). A possible reason for the discrepancies between both perspectives could be a different understanding of the term collaboration. Even though the client had developed an understanding about collaboration on his side, the term might not have been defined and communicated clearly enough and by this also left room for interpretation in the procurement documents.

During the negotiated procedure bidders' questions were answered by the client via a digital platform. The tendency to agree with the statement 'the client's answers to bidders' questions were satisfying' (Figure 5) again is higher on the client's side. A possible reason for the discrepancies could be that the client answered bidders' questions as detailed as possible but could not address each question as needed to remain equal treatment of each bidder. On bidders' side this could have led to confusion or to unsolved problems during the work on their offers.

In the end of the procurement phase all bidders providing a final offer received a compensation of 75,000 euros. A majority of 57,1 % on bidders' side totally disagreed with the statement that 'the compensation for bidders' participation in the procurement phase was appropriate' (Figure 6). Participants on client's side tend to respond more favorably to this statement. Possible reasons for this distribution of answers could be that the client might have underestimated the required work on bidders' side to fulfill the requirements for the final offers. Also, the procurement phase lasted longer than expected. On the other hand, the required work described in the procurement documents might have been underestimated by the bidders as well.

The award criteria in the procurement phase of the 'Component Test Oberesslingen' did not include any criteria regarding collaborative competencies of the bidders. Nevertheless, in a general question the participants were asked about their opinion on the assessment of these criteria. Besides others, this question was included in the survey to receive an insight into the motivation to participate in future procurement procedures including award criteria regarding collaborative competencies. As shown in Figure 7 there is no clear tendency shown in the distribution of answers on the bidders' and on the client's side.

Currently, experts on bidders' and client's side are interviewed to find out more about the possible reasons for the discrepancies in the survey's outcome. It is intended to take the same steps (survey and following expert interviews) within the other 7 pilot projects to ensure a better comparability between projects.

CONCLUSION

In the WSV, first steps have been taken to establish and promote collaboration in construction projects. This includes, for example, the 'Charter for Collaboration on Construction Sites along Federal Waterways' with the HDB. Additionally, another charter is currently being developed between the WSV and design offices. Nevertheless, there are limited experiences with the strategic promoting of collaboration in projects along Germany's waterways, such as the implementation of Lean Construction methods. Therefore, major infrastructure projects were identified throughout the WSV to initiate the implementation of collaborative elements and to gather experiences.

The strategic implementation of collaboration elements in the WSV as a public client in Germany is a new use case for academia. Furthermore, the upcoming changes require the adaptation of the construction industry to new forms of project deliveries in projects along Germany's waterways.

This contribution hereby focuses on 8 selected infrastructure projects and discusses first outcomes of a data collection. This data is intended to be systematized and analyzed to develop solution approaches and recommendations for future projects. The first results show that there is no clear definition of collaboration within construction projects in the WSV and that there is a need for further research because it is not possible to make sound recommendations for future projects yet. The need for further research can also be emphasized by the current lack of qualitative research results. Adding to this, more quantitative research results are needed to deduce general conclusions from the first gathered tendencies.

Major projects within the WSV tend to significantly exceed cost and time frames. The solution approaches and recommendations made in further research potentially have a meaningful influence on the stability and efficiency of future project deliveries of projects along Germany's waterways.

ACKNOWLEDGMENTS

We would like to thank Dipl.-Ing. Thilo Wachholz and Markus Feltgen of the Federal Waterways and Shipping Agency (GDWS) for their constructive cooperation and providing the information that made this contribution possible.

DRIVING THE MOMENTUM TOWARDS ADOPTING WEARABLE COGNITIVE ASSISTANCE IN LEAN CONSTRUCTION 4.0

Amira Eltahan[1], Lynn Shehab[2] and Farook Hamzeh[3]

ABSTRACT

Despite the transformative potential of Wearable Cognitive Assistance Devices (WCADs), their integration into the construction industry remains limited, marked by challenges such as practicality and regulatory barriers. Additionally, the increasing interest in implementing Lean principles in construction for enhanced project performance creates a potential intersection. This study aims to bridge both concepts by developing a conceptual framework for the implementation of WCADs in construction tasks within the Lean Construction 4.0 paradigm. It first explores the current state of WCAD in various industries and proposes a WCAD implementation framework for construction. The framework employs a stepwise approach, and its theoretical implementation in masonry works illustrates its adaptability to specific construction contexts. This framework's contribution lies in its potential to offer dynamic, adaptive, and personalized support, optimizing cognitive functions, and promoting safer and more productive task execution. This framework utilizes wearable sensors as one it's data collection methods; thereafter, the integration of the data collected will then provide users with near real-time feedback to mitigate risks and enhance workers performance. As a theoretical foundation, this research paves the way for practical validation and future enhancements, aiming to enhance the construction industry's approach to worker well-being and performance.

KEYWORDS

Lean Construction, Design Science, Continuous Improvement, Wearable Cognitive Assistance.

INTRODUCTION

In the dynamic nature of construction, where innovation meets the rigors of the job site, Wearable Cognitive Assistance Devices (WCADs) emerge as transformative tools to redefine how tasks are executed and managed. These devices, equipped with advanced sensing technologies and real-time cognitive support capabilities, hold the potential to improve the construction industry's approach to worker well-being, safety, and overall productivity.

WCADs can be envisioned as intelligent companions for construction professionals and practitioners, seamlessly integrating into their work environment to provide not only physical assistance but also cognitive support. These devices comprise of a combination of wearable sensor devices (WSDs), including but not limited to Electrocardiogram (ECG) sensors, Skin conductance sensors, Temperature sensors, Electrodermal Activity Sensors (EDA), Electroencephalogram (EEG) Sensors, and more (Shehab & Hamzeh, 2023). By collecting physiological data from WSDs, such as heart rate, skin conductivity, and brainwave patterns,

WCADs gain holistic insights into the wearer's cognitive state and physical well-being. These devices transcend traditional wearables by not only tracking physical activities but also offering real-time feedback and assistance based on the wearer's cognitive state and the specific tasks at hand (Belletier et al., 2021). Imagine a construction professional receiving instant alerts about potential safety hazards, personalized guidance on optimal work postures, or timely reminders to mitigate fatigue—all delivered through a compact, unobtrusive wearable device.

Despite their transformative potential, the integration of WCADs into the construction industry has not been fulfilled yet. Therefore, this study seeks to explore the merging of WCADs with Lean Construction 4.0 (LC 4.0) —a paradigm that converges traditional Lean principles with the transformative capabilities of Industry 4.0 technologies (Sanders et al., 2016). Through the lens of this merging, the aim of this study is to develop a conceptual framework for the effective implementation of WCADs in construction tasks. LC 4.0, a strategic merging of methodologies, emphasizes efficiency, waste reduction, and continuous improvement while leveraging advanced digital tools.

The principles of LC 4.0 prioritize the well-being of the construction team and are complemented by cutting-edge technologies (Hamzeh et al., 2021), including sensor network devices that are suggested in this study. These technologies not only monitor the site but provide real-time insights that enhance safety and allow immediate responses to challenges, aligning with the objective of improving workers' well-being, safety, and productivity through WCADs.

The synergy between LC 4.0 principles and WCADs offers a dynamic and adaptive system, connecting the transformative potential of both methodologies to drive sustainable improvements in construction project management. The proposed framework offers near-real-time feedback based on the collected cognitive data from construction workers. To achieve this, a stepwise approach is developed where it includes three major stages with a total of five steps.

Whereas the major objective is to gain a refined understanding of the worker's cognitive and physical state during task execution and thereby provide near-real time feedback. This paper begins with a literature review on LC 4.0 and WSDs. Afterwards, WCADs are introduced, and the conceptual framework is proposed. A theoretical implementation of the framework is presented, followed by final conclusions.

LITERATURE REVIEW

LEAN CONSTRUCTION 4.0 PRINCIPLES AND TOOLS

Lean Construction 4.0 (LC 4.0) represents a convergence of traditional Lean Construction principles with the transformative capabilities offered by Industry 4.0 technologies. Industry 4.0, characterized by the integration of digital technologies, automation, and data-driven processes, has ushered in a new era of efficiency and innovation across various industries (Lasi et al., 2014). In construction, the integration of Industry 4.0 into Lean Construction practices has the potential to enhance productivity, improve workers' safety and wellbeing, and optimize resource utilization (Noueihed & Hamzeh, 2022).

Several researchers have explored the relationship between Industry 4.0 and Lean Construction, recognizing the similar nature of both approaches. Studies such as that conducted by Sanders et al., (2016) have explored the impact of Industry 4.0 technologies on traditional Lean principles, shedding light on how advancements like Internet of Things (IoT), big data analytics, and automation can reshape lean methodologies.

Other studies (Hines et al., 2023; Karmaoui et al., 2023) have also provided perspectives on the interplay between Industry 4.0 and Lean Construction through the analysis of existing practices, applications, and technologies. They collectively emphasize the transformative potential of integrating digital technologies and lean principles in construction.LC 4.0, therefore, is not merely an integration of terms, but a strategic merging of methodologies aimed at creating a holistic and technologically advanced approach to construction project management. The utilization of Industry 4.0 technologies within Lean Construction practices presents opportunities for real-time monitoring, predictive analytics, and improved decision-making throughout the project lifecycle (González et al., 2022). As the construction industry continues to evolve, LC 4.0 emerges as a pivotal paradigm that not only embraces the advancements of the Fourth Industrial Revolution but also harnesses them to drive sustainable improvements in the construction industry's overall efficiency and effectiveness.

At its core, LC 4.0 emphasizes the relentless pursuit of efficiency, waste reduction, and continuous improvement, all while leveraging advanced digital tools to enhance these objectives (González et al., 2022). However, the principles and tools are not just about cutting-edge technologies; they are centered around enhancing the human experience within construction projects. The principles prioritize the well-being of the construction team, focusing on minimizing risks and overburden and ensuring that every effort contributes meaningfully to the project.

Some of the main technologies for Construction 4.0 were discussed by (McHugh et al., 2022), such as Building Information Modeling (BIM), which acts like a shared visual language that brings everyone together, fostering collaboration and understanding. Moreover, Artificial Intelligence (AI) enables analyzing data to predict potential obstacles or threats and offers valuable insights for informed decision-making. Reality capture is another technology that captures construction sites as point cloud models for depicting real site conditions, providing significant aid in building spatial awareness within the production team, producing realistic ad systematic construction logistics and site planning, and more (McHugh et al., 2022).

From a human-centric perspective, these technologies can be used to train construction teams for safety and hazard prevention and recovery drills, all while avoiding real injuries or risks. Finally, Internet of Things (IoT) and sensor network devices act as essential enablers, not just monitoring the site, but providing real-time insights that enhance safety and allow immediate responses to challenges. Safety and hazard indicators are described as sensors that detect potential safety hazards and notify the production team by providing safety alerts are warnings (McHugh et al., 2022). They also aim at capturing worker health and safety conditions with the ultimate goal of maintaining productive and healthy workspaces.

WEARABLE SENSOR DEVICES (WSDS)

The advancement of wearable sensing technology in recent years has expanded the potential for monitoring workers’ behaviour on construction sites. Researchers have explored the potential of using wearable sensors for worker behaviour monitoring. Such sensors collect data including physiological responses (W. Lee et al., 2017; Shehab & Hamzeh, 2023), gaze movement (Cheng et al., 2022), musculoskeletal engagement (tendons, bones, etc.) (Alwasel et al. 2011), gait (Inertial measurement unit IMU sensors) (Ren et al., 2022), and posture (Nath et al., 2018; Ren et al., 2022). These studies have demonstrated the effectiveness of using sensing-based approaches to study the factors affecting workers’ safety behaviour, such as emotion and stress levels. Physiological response data can be collected through various WSDs, such as Electrocardiogram (ECG or EKG) sensors, Skin conductance sensors (Galvanic Skin Response), Temperature sensors, Electrodermal Activity Sensors (EDA), blood pressure sensors, Electroencephalogram (EEG) Sensors, Electromyography (EMG) Sensors, Camera sensors, microphones and audio sensors, moisture and sweat sensors, chemical sensors, etc.

Regarding musculoskeletal involvement, gait, and posture, numerous studies have explored the movement patterns of physical activity, with a specific focus on the lower body movements of workers. These studies propose that the sensory data derived from lower body movements can offer valuable insights into workers' safety behaviours, particularly their responses to slip, trip, and fall hazards (Ren et al., 2022). This is attributed to the cyclical nature of lower body movements, where monitoring these movements can unveil individuals' responses to various environments or objects through alterations in leg movement patterns. For instance, research in construction safety has utilized gait data obtained from inertial measurement unit (IMU) sensors to examine how workers modify their walking patterns in high-risk conditions (Ren et al., 2022) or in proximity to slip/trip/fall hazards at construction sites (Yang et al., 2016). These studies indicate that employees alter their walking style upon identifying a nearby hazard or sensing a potential risk. Different sensory signals, including visual, auditory, and somatosensory inputs, influence the intentional regulation of human walking, impacting factors such as locomotion direction, speed, and the adjustment of stride to environmental limitations.

THE CURRENT STATE OF WSDS IN CONSTRUCTION

WSDs are becoming increasingly prevalent in the construction industry due to their potential to enhance safety, productivity, and overall efficiency on job sites. These sensors can provide real-time data and insights to both workers and management, helping to prevent accidents, optimize workflows, and improve decision-making. WSDs in the construction industry are gaining traction, but their adoption is not yet universal. They have witnessed a tremendous advancement over the course of the past 10 years. Yet the challenges that come with implementing it on construction sites have hindered the industrial use of these devices.

The emergence of wearables started in early 2010s with the first generation of smartwatches and fitness trackers (Mukhopadhyay, 2015). Thereafter, in mid 2010s the introduction of safety helmets and safety wearables were explored (Park et al., 2015). These helmets were designed to monitor workers’ movements to improve safety on construction sites. In late 2010s the augmented reality (AR) technology led to more advancement in the field of wearable technology including the development of eye tracking and AR glasses (Cheng et al., 2022).

The common objective in implementing WSDs in construction has been occupational safety and hazard assessment (G. Lee et al., 2021). Ahn et al. (2019) have divided the applications for implementing WSDs in construction health and safety as reported in literature into: preventing musculoskeletal disorders, preventing falls, assessing physical workload and fatigue, evaluating hazard recognition abilities, and monitoring workers’ mental status. Shehab & Hamzeh (2023) have summarized the use of physiological sensors in construction. They have identified 20 studies that measured physiological markers using wearable sensors and correlated it with performance (safety behaviours and productivity). Anwer et al. (2021) used textile wearable sensors measuring heart rate, breathing rate, and skin temperature to monitor physical fatigue. This study was conducted on bar bending and fixing construction tasks and a moderate to excellent correlations was concluded between physical fatigue and the measured physiological markers.

Ke et al., 2021 have attempted to detect distraction in workers using wearable electrocochleography (EEG). This study has established a link between attention (cognitive ability) and the measured signals of EEG. Exoskeletons (Nnaji et al., 2023) are used to reduce strain on workers body when strenuous activities are executed where WSDs are used to collect data related to fatigue and musculoskeletal engagement to reduce the risk of musculoskeletal injuries. Also, Kinematic sensors, including accelerometers and gyroscopes, were employed to record instances of workers narrowly avoiding falls and uncomfortable postures during their work (Nath et al., 2018).

Research on WSDs aimed to establish a link between using wearable sensors and individualized performance (safety behaviours, and self-reported productivity). However, no study has no study has systematically investigated the integration of Wearable Cognitive Assistance Devices (WCADs) within the context of LC 4.0 to enhance both the physical and cognitive aspects of worker performance. Existing studies often focus on the physiological aspects, neglecting the potential of cognitive support through real-time feedback. Therefore, this study aims to explore the application of these technologies as a tool to enhance workers' cognitive abilities and decision-making process through real-time feedback to proactively introduce remedial measures. By addressing this gap, our research aims to contribute valuable insights to the effective implementation of WCADs in construction, aligning with LC 4.0 principles and advancing the holistic well-being, safety, and productivity of workers.

METHODOLOGY

This paper aims to develop a conceptual framework for the implementation of WCADs in construction from an LC 4.0 perspective. To achieve this goal, this paper follows a Design Science Research (DSR) methodology. DSR is a scientific method for developing a new artifact that addresses an identified problem, followed by the evaluation of this artifact (Rocha et al., 2012).

In this study, the problem is identified as the unsafe conditions that prevail on construction sites and the lack of a real-time feedback system that provides workers with cognitive support to enhance their safety and well-being. Therefore, and in order to contextualize the study within LC 4.0, the paper begins with a comprehensive review of Lean Construction (LC) 4.0 principles and tools, followed by a review of WSDs in general and their current state in construction. Afterwards, the study proceeds to identify the gap: the absence of a real-time feedback system supporting workers' cognitive functions. This identification sets the stage for the introduction of WCADs and their applications, followed by the development of a conceptual framework for adopting WCADs in LC 4.0.

This framework aligns with LC 4.0 principles, which include continuous improvement, real-time monitoring, data-driven decision-making, worker-centric focus, and utilizing advanced digital tools. The framework is divided into three major phases which include model design, model development and cognitive assistance feedback as explained in section 5. To validate the theoretical implementation of the framework, it is tested theoretically on a masonry construction example.

WEARABLE COGNITIVE ASSISTANCE DEVICES

Wearable Cognitive Assistance Devices (WCAD) are wearable devices that offer real-time cognitive assistance. These devices can provide support and guidance through sending warnings or alerts based on the wearer's cognitive state and the tasks at hand (Belletier et al., 2021). They integrate the data collected using WSDs to offer a real time feedback using the collected data. There are various applications of WCADs, including healthcare, manufacturing industry, education and training, sports and fitness, and military and defence. In healthcare, they are used to monitor the patients' cognitive states to provide real time updates to healthcare professionals to ease timely interventions. In the manufacturing industry, they can be used to enhance safety by providing safety alerts to workers once it detects unsafe conditions. In sports and fitness, these devices are used extensively by various competing companies to provide users with personalized feedback and fitness programs based on the collected psychological data using wearable sensors. Regarding military and defence, WCADs can be used to track the vital signs of soldiers as well as enhancing their situational awareness. Table 1 lists some of the examples where WCAD are used in different industries and the objective of each of those applications.

Table 1. Examples of WCAD Applications in different Industries

Industry	Study	Objectives
Healthcare	Zhao et al., 2020	An automatic external defibrillator
	Wu et al., 2018	Wearable watch for monitoring patients with chronic compulsory pulmonary disease
Manufacturing	Oyekan et al., 2021	Tracking assembly tasks and ergonomic indicators
Sport and fitness	Hajj-Boutros et al., 2023	Tracking stress levels by monitoring heart rate, EDA, ECG, and skin temperature using wearable watch
	H. Jung et al., 2022	Provide a holistic view of wellbeing through sleep tracking, heart rate monitoring, and stress levels using a wearable watch
Military and Defence	Admile & Barguje, 2023	Situational awareness and monitoring vital signs

DEVELOPMENT OF CONCEPTUAL FRAMEWORK FOR USING WCADS IN LEAN CONSTRUCTION 4.0

The developed conceptual framework offers a way to implement WCADs in construction within the context of LC 4.0 by using the established work by various researchers, confirming the correlation between various physiological markers and various indicators on the performance of construction workers. Thereafter, such indicators could be used to offer near real-time feedback to workers to enhance their performance.

To achieve this, the conceptual framework presented in Figure 1 was developed. This framework is generic and could be tailored to any construction task of interest. Construction tasks requires physical strength for various activities such as lifting heavy materials, digging, carrying, welding, operating machinery, and performing tasks that require physical endurance. Therefore, enhancing individual performance is a key contributor to the overall project success. In this study, the definition of individual performance as introduced by Hurrell & McLaney, 1988 was adopted. It includes self-reported productivity and safety behaviours.

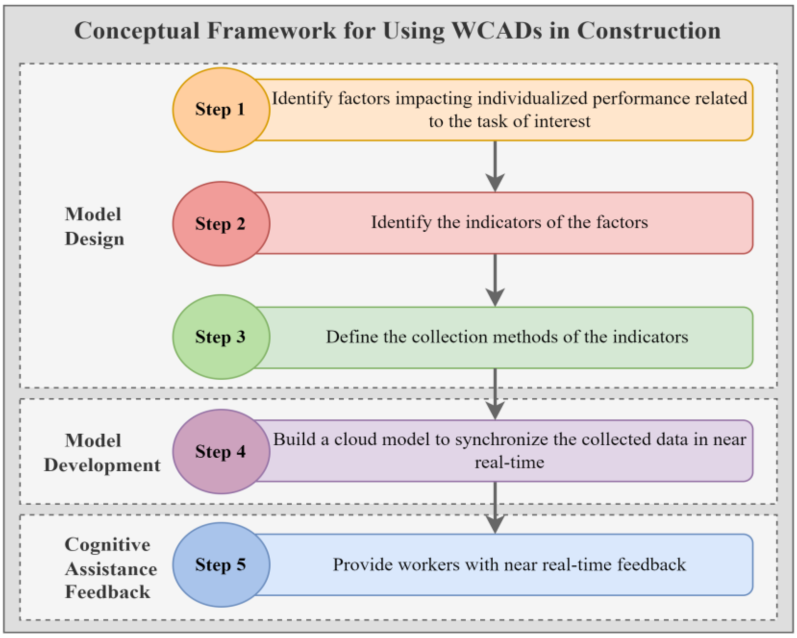

Figure 1. Framework for implementing WCADs in Construction

The first step in the framework is identifying the factors that could impact the individualized performance in the task of interest (Step 1). The purpose of this step is shortlisting the contributors to poor safety behaviours and loss of productivity. The nature of the task of interest is an important factor to consider, as construction tasks vary in terms of the required physical and mental workloads. For example, the demands and risks associated with masonry works are different than those of concrete works. Drawing from LC 4.0 principles, which prioritize efficiency and continuous improvement, the critical role of individual performance in overall project success is recognized.

After identifying the factors influencing performance, Step 2 involves determining the means to detect the existence of these factors. These detection methods, referred to as indicators, encompass various measures such as physiological markers, site conditions (e.g., environmental factors), and worker-based data (e.g., sleep patterns, stress levels, fitness levels). This step focuses on recognizing and quantifying the elements impacting individualized performance in construction tasks. It aligns with the LC 4.0 emphasis on real-time monitoring and data-driven decision-making.

Afterwards, the collection methods of these indicators need to be defined (Step 3). This step describes how these indicators are to be converted into quantifiable data to be able to perform further analysis. Such data could either be quantitative (physiological data from WSDs) or qualitative (questionnaires). Inspired by LC 4.0, where principles emphasize the relentless pursuit of efficiency and waste reduction, this framework ensures a harmonious integration of quantitative measures, such as physiological qualitative inputs. This holistic approach aligns with LC 4.0's emphasis on utilizing advanced digital tools for enhancing project objectives.

This framework aims to enhance the cognitive abilities through merging various forms of data collection methods to provide users with a proactive near real-time support during tasks execution. Since humans are not commodities, and since individual performance varies from one individual to another, it is important to capture these individual differences to be able to tailor the expected performance from one user to another. Therefore, step 4 involves the integration of diverse data collection methods, such as the aforementioned WSDs capturing physiological responses and qualitative inputs from questionnaires. These data then undergo a comprehensive sorting process. This sorting is executed in a secure cloud-based infrastructure that serves as the central repository for data integration and analysis. Within this cloud environment, data analytics are performed. These analytics examine the attributes of the collected data, recognizing patterns, correlations, and individual characteristics. The objective is to gain a refined understanding of the worker's cognitive and physical state during task execution. Individual differences are thoroughly calibrated during this analytical phase. External factors, including environmental conditions, and internal factors, including physiological responses, are factored into the calibration process. This ensures that the feedback provided is not only constructive but also highly personalized, acknowledging the unique characteristics of each worker. The aim of this step is to harness the power of data analytics within a cloud-based framework, offering a dynamic and adaptive system that goes beyond generic support. By tailoring feedback based on individual characteristics, the model optimizes its effectiveness in enhancing cognitive functions and promoting safer and more productive task execution. In alignment with LC 4.0 principles, this step emphasizes the individualized calibration of feedback considering external and internal factors.

Finally, in Step 5, users receive proactive near real-time support during task execution, aligning with the LC 4.0 principles of continuous improvement and worker-centric focus. Recognizing the inherent variability in individual performance among workers, this step underlines the significance of capturing these differences to customize expected performance tailored to each user. By integrating the LC 4.0 principles of optimizing human experience within construction projects, this model not only seeks to boost cognitive functions but also to contribute to LC's overarching goal of creating a safer, more productive, and efficient construction environment. Ultimately, this integration ensures that advancements in technology are employed not just for technological sake but with a profound commitment to improving the well-being and performance of the construction workforce, echoing the human-centric principles inherent in LC 4.0.

THEORETICAL IMPLEMENTATION OF THE FRAMEWORK IN MASONRY WORKS

In this section, a theoretical implementation of the developed framework in masonry construction is presented. Various factors impact the performance of construction workers and can lead to loss in reported productivity and poor safety behaviours, as listed in Table 2. Regarding the first factor, physical fatigue and posture are significant considerations in the occupational health and safety of masonry workers. The nature of masonry work, which often involves repetitive tasks, heavy lifting, and prolonged periods of standing or kneeling, can contribute to musculoskeletal issues and fatigue. Various researchers correlated between physical exertion/ fatigue and labour productivity using WSDs (Umer et al., 2020). In this study we adopted the technique used by Umer et al., 2020 by using the EQ02 LifeMonitor (Akintola et al., 2016) with embedded ECG electrodes, skin temperature sensor and respiration sensor interwoven invest to monitor masonry workers' physical exertion on construction sites. The selection of this method takes into consideration the comfort of the workers and the nature of movement during task execution. The state of personal well-being is another factor, which varies among individuals and can also fluctuate within the same individual from day to day. Therefore, it is suggested to demonstrate some questions to workers at the beginning of every day as a daily check in for their mental status, including their number of sleeping hours, perceived health status on a scale of 1-5, and a ranking of personal stressors (if any) on a scale of 1-5 (Alhola & Polo-Kantola, 2007). It has been reported that the average sleep length to maintain adequate cognition is between 7 and 8.5 hours per day (Carskadon & Dement, 2005).

Biomechanical stress, along with considerations of posture and body mechanics, plays a significant role in influencing musculoskeletal health and the potential for injuries among construction masonry workers. Therefore, it is one of the crucial factors to include for masonry works. Various researchers have linked gait and ergonomics with safety behaviours and enhancing occupational health and safety of workers (Ren et al., 2022) to prevent musculoskeletal injuries and fall hazards. The suggested collection methods are wearable electromyography (EMG), Inertial measurement units (IMUS) which includes accelerometers and gyroscopes.

Situational awareness for construction masonry workers is crucial for ensuring safety, productivity, and the successful completion of projects. Situational awareness involves being aware of one's surroundings, understanding the current situation, and anticipating potential hazards or challenges (Lappalainen et al., 2021). Therefore, time is of essence when it comes to notifying workers with surrounding hazards, which could include chemical exposure, temperature extremes, fall hazards, electricity hazards, moving equipment as well as oxygen levels in confined spaces.

External factors including time of day and noise have been reported to affect productivity and postural control (Weizenbaum et al., 2020). Therefore, including the time of day could reduce the potential errors of the system and help calibrate the system in a realistic way to mimic expected human behaviour. Also, excess noise level should be detected and mitigated to support performance.

The level of stress and emotional responses can have a substantial impact on the performance of individuals working in construction. Research in construction has established a link between performance and emotional states through using WSDs including electrocochleography (EEG) and wearable tracking glasses that monitor gaze and eye movement to detect the individual's emotional state (Arpaia et al., 2020).

Table 2. Factors, Indicators, and Collection Methods for WCADs in Masonry Works

Factors Affecting Individualized Performance in Masonry works	Indicators	Collection method
Fatigue/Physical Strain (Umer et al., 2020)	Electrical Activity in the heart	ECG
	Skin Temperature	Infrared Skin Temperature Sensor
	Respiration Rate	Respiration Sensor
Personal well-being (Alhola & Polo-Kantola 2007)	Sleeping hours, perceived health status, personal stressors	Questionnaire
Biomechanical Stress/ Posture and Body Mechanics (musculoskeletal injuries) (Ren et al., 2022)	Gait Analysis, Posture and Ergonomics	Wearable EMG
		Wearable Strain Sensors
		IMUs
	Fall detection	Wearable fall detection devices
	Material handling Excess weight	Wearable EMG
	Medical History of musculoskeletal injuries history	Questionnaire
Surrounding Hazards - Situational awareness (Lappalainen et al., 2021)	Chemical Exposure	Gas Sensors on site
	Temperature Extremes (heat stress or cold stress)	Thermal Sensors, EDA sensor
	Electricity Hazards	Voltage Detectors
	Moving Equipment	Proximity sensors
	Confined Spaces	Oxygen Sensors
External Factors (Weizenbaum et al., 2020)	Time of day	Sensor Networks
	Noise	Sound level metrics
Stress level and emotional responses (Arpaia et al., 2020)	Gaze, Eye movement, Facial expressions	Wearable Eye Trackers
	Electrical activity in the brain	EEG
Attention levels (Ke et al., 2021)	Electrical activity in the brain	EEG
Perceived Risk (G. Lee et al., 2021)	Heart volumetric change	PPG
	skin electric properties	EDA
	skin temperature	Thermopile
Demographics of worker (Murman, 2015)	Years of Experience, age, fitness level	Questionnaire

Additionally, attention level could also be detected using wearable EEG (Ke et al., 2021), which contributes to safety behaviour and individual productivity. Moreover, perceived risk is one of the influences of safety behaviours demonstrated by workers on construction sites and it was quantified by G. Lee et al., 2021 by measuring the heart volumetric change, skin electric properties, and skin temperature.

Finally, demographics of the workers will aid the calibrations and personalization of the model according to the individual's years of experience, age, and fitness level.

This section establishes how the factors - that are expected to impact the performance of masonry construction workers - can be collected on site. Future steps could include uploading collected data to the cloud-based model that can be developed to mimic the expected cognitive performance tailored to the individual's input data. Once the analysis is complete, proactive near real-time support is offered to masonry construction workers during task execution.

CONCLUSION

This paper presents a comprehensive conceptual framework for the implementation of WCADs in construction, with a LC 4.0 perspective. The primary aim is to enhance workers' well-being, safety, and productivity by leveraging WCADs to provide near real-time feedback. The developed framework, presented in five sequential steps, offers a generic yet adaptable approach applicable to various construction tasks.

The framework begins with the identification of factors impacting individualized performance, acknowledging the diverse demands and risks associated with distinct construction activities. Following steps involve determining detection methods (indicators), defining collection methods, and integrating diverse data collection methods, including WSDs and qualitative inputs. The cloud-based analytical phase plays a pivotal role in calibrating individual differences, considering external and internal factors.

The theoretical implementation of the framework in masonry works exemplifies its practical application. Factors influencing masonry workers' performance, such as physical fatigue, personal well-being, biomechanical stress, situational awareness, external factors, and emotional responses, are considered. The proposed collection methods offer a holistic approach to understanding and enhancing workers' cognitive and physical states. Moreover, the inclusion of worker demographics facilitates the calibration and personalization of the model, reflecting individual variations in experience, age, and fitness level. The result of the model, housed within a cloud-based system, provides users with proactive near real-time support during task execution, accommodating the inherent variability in individual performance.

This research contributes to the evolving environment of LC 4.0 by bridging the gap between theoretical advancements and practical implementation in the construction industry. The proposed framework, centred on WCADs, not only addresses safety and productivity concerns but also prioritizes the well-being of construction workers. As the construction industry continues to embrace technological innovations, this framework stands as a progressive step towards fostering a safer, more efficient, and worker-centric construction environment.

While this conceptual framework provides a foundation for integrating WCADs into construction tasks, certain limitations are acknowledged. First, the effectiveness of the framework heavily relies on the current state of WCADs and their technological capabilities. Rapid advancements in wearable technology are expected, and the framework may need adjustments to accommodate future innovations. The integration of cloud-based systems for data analytics could also raise concerns about data privacy and security. Adequate measures must be in place to ensure the protection of sensitive information collected from workers.

Recommendations for future work include evaluating the proposed framework practically through a longer-term study that should include surveys questionnaires with an expert panel focused on the use of WSDs and WCADs in construction.

THE IMPACT OF LEAN KNOWLEDGE AND LEAN OPERATION ON CONSTRUCTION WORKERS' JOB SATISFACTION

Cristina T. Pérez[1], Malik Madushanka[2], Lorenzo Loyola[3], Melisa Ergul[4], Stephanie T. Salling[5] and Søren Wandahl[6]

ABSTRACT

This study is part of an ongoing research project that aims to understand workers' job satisfaction in the construction industry. For that, a survey was applied among construction workers in Denmark. This paper aims to identify the impact of Lean Construction on job satisfaction. Data from 2176 responses were analysed using framework analysis, shorting the answers into three categories: Lean knowledge; Lean application; and Lean operation, even though they declared not knowing Lean. The study investigated the impact of the different levels of Lean familiarity on job satisfaction within five aspects: Project progress; Management-employee relationship; Employee work monitoring; Workload; and Workflow. Findings indicate that only 15% of respondents have some knowledge of Lean concepts, with only 8% confirming its application. The strongest correlation (R^2=0.557) was found between the Lean practice of "organization attempt to keep workers informed" and the job satisfaction factor of "manager-worker relationship". Allowing the workers to evolve and improve presented, also, a strong correlation with job satisfaction. The study highlights that Lean practices that lead or require Respect for People are the aspects that impact the most on job satisfaction. The results emphasize that implementing Lean principles effectively matters more than merely being familiar with them.

KEYWORDS

Job satisfaction, Survey, Respect for people, Communication.

INTRODUCTION

Successful organizations are often characterized by an environment in which mutual respect prevails (Coetzee et al., 2019). With that in mind, Lean successful management philosophy, and its two principles Respect For People (RFP) and Continuous improvement can be a good choice when organizations want or need to improve. The concept of RFP is not of the emotional kind, but rather *ought-respect*; in other words, respect is due consideration (Coetzee et al., 2019). RFP corresponds to the Japanese term of "ningensei" - personhood/humanity - that according to Toyota is about bringing out the capacity of thinking and producing in every human being.

In the study conducted by a Ljungblom and Lennerfors (2021), the authors identified that "hitozukuri" – the development of people – is deeply connected to "monozukuri" – the art of

making things or craftsmanship – and that the RFP principle is related to hitozukuri. This message of definition can be seen as: Toyota does not just build cars. They build people. This is in line with the motto that "monozukuri is hitozukuri". At the same time, RFP means enhancing workers' involvement and their voluntary efforts and drawing out their full capacity. This message of definition could be: Toyota build cars, using people (Ljungblom and Lennerfors, 2021).

Thus, implementing RFP in the organizational culture can positively impact team effectiveness. The principle is also strongly correlated with job satisfaction (McKinnon et al., 2003). In a construction context, job satisfaction has also been identified as one of the most influential motivators for improved labor productivity (Kazaz & Ulubeyli, 2007). Hence, knowledge about workers' job satisfaction is highly valuable. Job satisfaction includes all aspects of working life, including health and safety, leadership and management, communication, worker engagement, work environment, rewards, and compensation (Memon et al., 2023). In light of these considerations, the research seeks to address the following Research Question:

- How does the level of familiarity with Lean Construction (LC) impact on job satisfaction among construction workers?

LITERATURE REVIEW

Questionnaires, Interviews, and Checklist have been widely applied in research to investigate various topics that affect job satisfaction and the mental and physical well-being of employees. Table 1 offers a summary of the primary themes explored in the existing literature about job satisfaction surveys, particularly within the construction industry.

Table 1: Themes evaluated in job satisfaction surveys and their adopted approaches (Q=Questionnaire, I=Interview, C=Checklist)

Themes	Rani et al.	Nidadhavolu	Hassan et al.	Ni et al.	Kharo et al.	Raziq and Maulabaksh	Emmanuel et al.
Health and Safety	√		√	√	√	√	√
Leadership and Management	√	√	√	√	√	√	√
Communication	√	√	√	√	√	√	
Worker Engagement				√	√		√
Work environment	√		√			√	√
Rewards and Compensation		√	√		√	√	√
Method	Q+I	Q+I	Q+C	Q	Q	Q	Q

Rani et al. (2022) have identified critical factors influencing workplace well-being in construction projects, those being: Health and safety; leadership and management; communication; and work environment. However, the authors emphasize that the factors affecting workspace well-being were mainly highlighted by project managers, quantity surveyors, architects, and engineers, not hands-on construction workers worker. Thus, suggesting that future scholars can conduct similar research using construction workers as the target population. There might be new and different factors that affect construction workers.

Another study discussed the crucial connectedness of types of leadership and job satisfaction on construction sites (Nidadhavolu, 2018). Enyan; Michael et al. (2023) have explored communication and how it plays a pivotal role in shaping employees' job satisfaction, as it functions as a keyway to share information and foster collaboration. Health and safety can be a wide term with different aspects and questions. Risk behavior is one topic of health and safety, which by Hassan; Che C.R. et al. (2007) was measured and analysed in construction. Furthermore, Ni et al. (2020) studied the mediating roles of work engagement and safety knowledge sharing. In contrast, Khahro et al. (2023), explored job satisfaction models and even proposed an integrated job satisfaction model for construction industry workers. Among many themes, work environment is an important factor in job satisfaction.

The work environment can be, according to Raziq and Maulabakhsh (2015), represented through topics such as salary packages, working hours, workflow, or relationships between management and employees. Additionally, Emmanuel et al. (2015) dived into the organizational factors influencing worker satisfaction. This included recognition, work environment, wage and so on. Finally, a study by Ullah (2018) dived into how the organization's contribution through rewards and recognition is a must to enhance the contribution of the workers.

A common thread across the studies is the recognition of the complex interplay between organizational dynamics, leadership and management styles, communication between managers to workers, and employee engagement in shaping job satisfaction. Health and safety is also an ongoing theme across the studies. While the studies collectively emphasize the importance of different factors, there may be variations in their interpretations and research methodologies. In general, those studied did not associate those factors with the LC philosophy and how Lean practices could impact workers' well-being. For that reason, the present study aims to identify the impact of the adoption of LC on construction workers' job satisfaction.

RESEARCH METHODOLOGY

The study adopted the survey method as the main research approach. This paper represents an ongoing research project that aims to understand the job satisfaction of construction workers. The detailed activities conducted during the survey development were described in detail in Salling et al. (2023) and briefly described as follows:

1. **Link to the theoretical level:** The authors identified nine themes mainly applied for understanding job satisfaction through the literature review of survey studies in different industries. The authors categorized those job satisfaction themes into Project Management (PM), Work Environment (WE), and Health and Safety (HS).
2. **Survey design:** A 48-question questionnaire was designed. The study population was limited to all construction workers affiliated with a union and working in Denmark. The survey used non-probabilistic sampling to obtain as much data as possible.
3. **Pilot test:** Conducted two rounds of assessment, including an online meeting with experts and individual evaluations, resulting in a final 39-question questionnaire. The questions are grouped into: (1) 12 demographic questions; (2) 12 questions related to PM; (3) 8 questions of WE; and (4) 7 questions of HS. The questionnaire was available in the four predominant languages spoken on Danish job sites: Danish, Polish, Romanian, and Italian.
4. **Data collection:** The survey was administered through SurveyXact via email, open for responses from January to March of 2023. A sum of 3393 survey participants responded. In the previous study Salling et al. (2023), the authors presented a descriptive analysis of the answers related to the 12 PM questions. In the present paper, the goal of the study was to

understand the impact of the adoption of LC on workers' job satisfaction. Hence, the authors performed a data cleaning to handle missing values and inconsistencies in the data set.

5. **Data Cleaning:** To ensure result consistency, unanswered or mostly incomplete surveys were discarded. The percentage of responses per survey was calculated, and only those with 50% or more responses were considered, resulting in the exclusion of 1217 surveys. Despite the 62% reduction from the initial quantity, the set of 2176 surveys remain relevant for subsequent analysis and correlations. Subsequently, category mapping was performed, associating integer values with each response to facilitate the analysis of relationships between variables. These operations were carried out using routines programmed by the authors, allowing for a massive analysis and treatment of the information.
6. **Data analysis:** The analysis was designed with the aim of revealing the influence of LC on job satisfaction. Although, the survey had been constructed with the purpose of gathering comprehensive data in the fields of PM; WE, and HS; few sections in the questionnaire can be highlighted, as which the Lean knowledge and practices had been emphasized.
7. **Identify correlations:** For identifying questions with higher correlation, a correlation matrix was utilized. That is, by comparing all questions with each other, the Pearson coefficient is determined for each pair. Once this was done, the analysis focused on questions related to Lean Knowledge and Lean Operation. In particular, a list of the top twenty pairs showing the highest correlation coefficient was compiled, thus allowing the identification of the most relevant response pairs for analysis. To validate the obtained results, a cross-validation was performed, consisting of randomly dividing the data into subsets, on which Pearson coefficients were recalculated for each pair. The results obtained did not differ in the most unfavourable groups by almost 5%, which is acceptable and indicates consistent results.

DATA ANALYSIS CONDUCTED

The analysis has been performed using Python and MS Excel. Python was used majorly in correlation analysis while Excel was used in data visualization. The authors selected 10 questions from the questionnaire that can be related to the knowledge and/or application of Lean as expressed in Table 2. Data were analysed using a framework analysis, which consisted of classifying the answer into three categories: (1) Lean Knowledge; (2) Declaration of Application of LC, named for short Lean "Application"; and (3) Lean application even though they declared not knowing LC, named for short "Lean Operation". The study conducted four kinds of analysis: (1) descriptive analysis of the Lean knowledge and Application, (2) impact of Lean Knowledge on job satisfaction; (3) impact of Lean Operation on job satisfaction; and (4) comparison between knowing Lean and applying Lean.

Table 2: Analysis framework

No.	Questions	Answers classification			ref. Fig 8
		Lean Know.	Lean Appli.	Lean Operation	
2.3	I participate in planning meetings on site.	-	-	Always, very often	A
2.4	I finish my work on time according to the plan.	-	-	Always, very often	B
2.5.1	Regarding the project schedule, I know… ...the tasks that I should do according to the plan	-	-	Strongly agree, Agree	C
2.5.3	Regarding the project schedule, I know… ... my tasks one week from now.	-	-	Strongly agree, Agree	D
2. 7	I am encouraged to come up with better ways of doing things.	-	-	Strongly agree, Agree	E
2.11	State whether you know the following LC concept/tools/methods.	Yes	-		-
2.12	State whether the following LC concepts/tools/methods are applied on the project you work on.	-	Yes		-
3.1.	How satisfied are you with the following factors in your current job:	-	-	Very satisfied, Satisfied	-
3.3.1	This organisation does an excellent job of keeping employees informed about matters affecting us	-	-	Strongly agree, Agree	F
3.3.4	My work gives me the opportunity to evolve and improve my skills (also through formal training)	-	-	Strongly agree, Agree	G

1. Descriptive analysis of the knowledge of Lean

The first analysis consists of a general overview of the answers regarding the LC knowledge and application (knowingly) of six tools/methods/concepts in questions 2.11 and 2.12, those being: (1) Last Planner System (LPS); (2) Percent Planned Completed (PPC); (3) Location-Based Scheduling (LBS); (4) Just-in-time (JIT); (5) Value Stream Mapping (VSM); and (6) Work Sampling (WS). The answers have also been examined by trade, nationality, position in the company, and size of the current project.

2. Impact of Lean Knowledge on job satisfaction

The second analysis aimed to understand how Lean knowledge impacts on **some** job satisfaction factors. It was considered that a worker knows Lean if at least he knows three of the six tools/methods/concepts asked in question 2.11, however the question does not provide in detail whether the worker (a) has heard about Lean or (b) has a thorough grasp of the concept. But, assumed it can be both (a), (b) or in between. Under section 3.1 of the questionnaire, workers had been asked to answer about their job satisfaction under 14 aspects. For this study, only five aspects are being discussed, namely (1) Workflow of the work; (2) Project progress; (3) Relationship between management and employees; (4) Employee work monitoring; and (5) Workload.

3. Impact of Lean Operation on job satisfaction

The third analysis aimed to evaluate the impact of applying Lean on job satisfaction. Workers who have declared that they know the LC, necessarily do not have to practice them. Apart from direct declaration, indirect implications of Lean practices also had been identified. In the questionnaire, there are seven questions, which it can be assumed about the application of Lean practices in the job site. Despite not knowing about LC, workers have been practicing it unknowingly on the site. The seven indicators of Lean application at the job site are summarized in Table 2 (see letters from A to G). To make sure that workers are practicing Lean, only certain answers were selected. As an example, for the question 2.3 where it obtains the statement "I participate in planning meetings on site"; people who had given answers "Always" and "very often", were categorized as workers practicing Lean (can be seen as example of the LPS) in their site. Another example is "2.7. I am encouraged to come up with better ways of doing things", it can be considered as a RFP practice. Compliment to that, answers given as "sometimes", "rarely" and "I don't know" would suggest that they might not follow Lean strictly. Hence, those workers were categorized as the workers who do not practice Lean.

4. Comparison between Lean knowledge and Lean operation

Lastly, a correlation analysis was carried out to explore the degree of influence of Lean knowledge and Lean operation per the analysis framework, impact on job satisfaction factors (selected) by the seven Lean operation factors will be investigated. As per the criteria in Table 2, a correlation analysis had been conducted to identify significant influences. After the identification, major aspects of the nature of the influence have been discussed.

SAMPLE CHARACTERIZATION

Figure 1 displays an overview of the 12 survey answers regarding the participants' demographics and work-related information. These results offer insights into the gender distribution, ethnic composition, age demographics, trades represented, years of experience, positions within companies, and various aspects of companies' operations.

The initial graph highlights a male majority among respondents (92%), followed by a visualization indicating a dominance of Danish individuals (95%). Over 62% of respondents are aged 40 and above, signalling a lack of younger individuals in the industry. Carpenters lead the trades (26%), with varying experience levels: 21% having over 35 years in the field and 20% with 1-5 years of experience. Notably, 42% have spent 1-5 years in their current company, indicating a significant number of changes despite their considerable experience. Journeyman positions dominate. Companies mainly fall within the 10-49 employee range (34%), predominantly Danish-owned (96%). Regarding contracts and projects, most respondents' companies serve as contractors (39%) or subcontractors (37%). Project size remains uncertain for 31% of respondents, while 50% are engaged in building renovations.

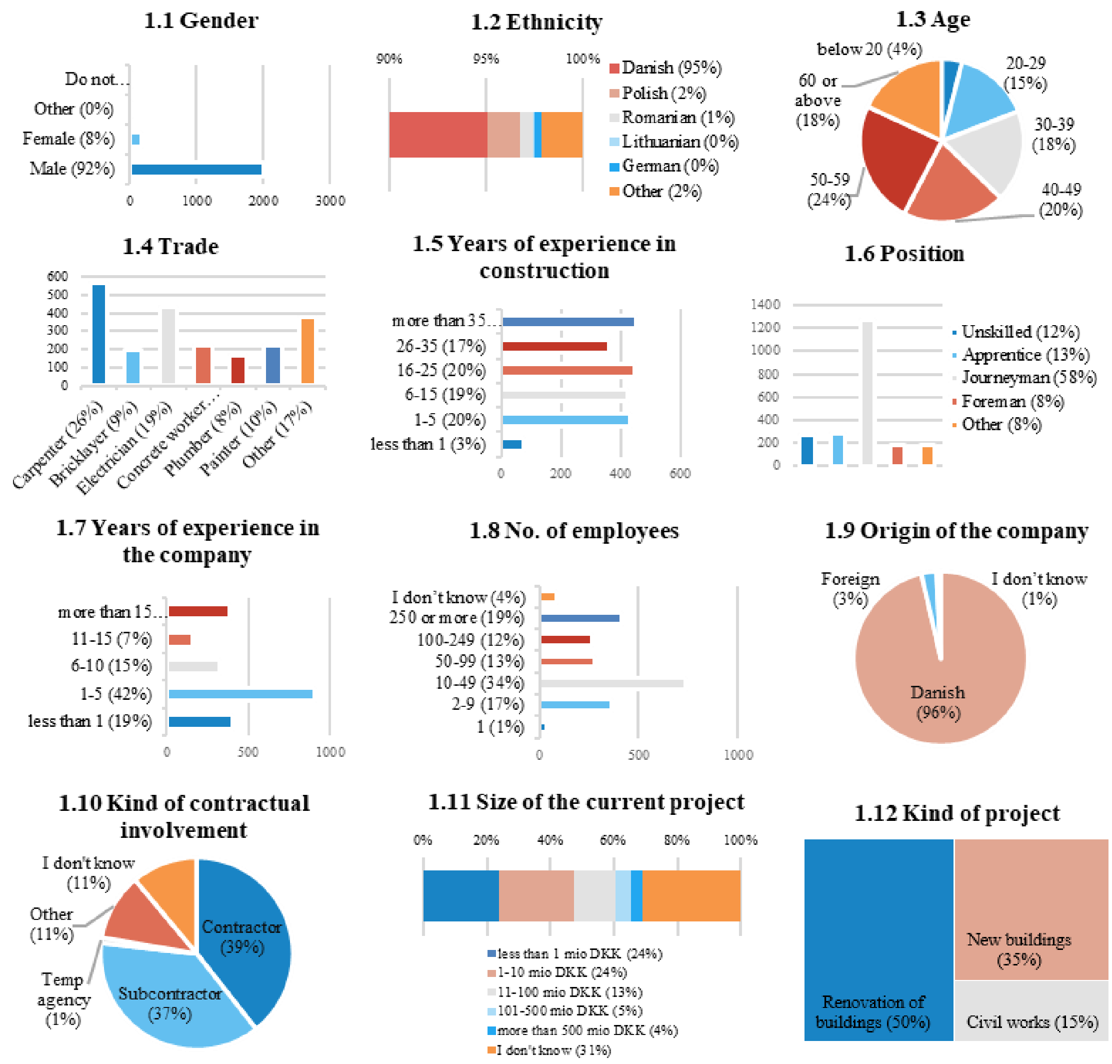

Figure 1: Demographic Profile of Respondents

RESULTS AND DISCUSSION

DESCRIPTIVE ANALYSIS OF THE KNOWLEDGE OF LC

The survey results revealed a substantial lack of familiarity among respondents regarding various LC tools, methods and concepts (Figure 2a). In addition to respondents' familiarity rates, the practical application of these Lean tools remained limited (Figure 2b). Uncertainty about their application ranged from 71% to 77% among respondents. VSM stands out as the least known methodology with 92% unfamiliarity. Among those evaluated concepts, LBS and JIT were the most two known concepts among the respondents, knowing by 18% and 14% of respondents respectively. However, the known adoption of those two concepts rates are 10% to 8% respectively.

Figure 3 provides a view of LC awareness and its distribution across trades, position, and project size. Across all trades (Figure 3a), the LC knowledge is uniformly low at 16%. There is a little difference with bricklayers displaying the highest awareness at 21%, while carpenters and bricklayers lag at 13%. The analysis also included positional variations (Figure 3b), which highlighted the influential role of leadership. The foreman exhibits the highest awareness at 36%, emphasizing the importance of leadership in LC implementation. On the other hand, the apprentices and unskilled show a low awareness, suggesting the need for targeted training programs to foster the same comprehensive understanding. Considering the project size (Figure 3c), a positive relationship is noted between project cost and LC knowledge. Smaller projects demonstrate lower awareness (11%), while larger projects exhibit higher awareness (25%). This can be possible explained because the significance of resource allocation for training on smaller projects to ensure comprehensive LC implementation.

Figure 4 illustrates attendance for planning meetings in relation to different trades (Figure 4a) and positions (Figure 4b). For instance, plumbers and electricians exhibit a significant presence, with 22% and 20% reporting "always" and "very often" attendance. Similarly, in the position-based attendance chart, foreman position stands out predominantly, with 49% "always" and "very often" reporting attendance.

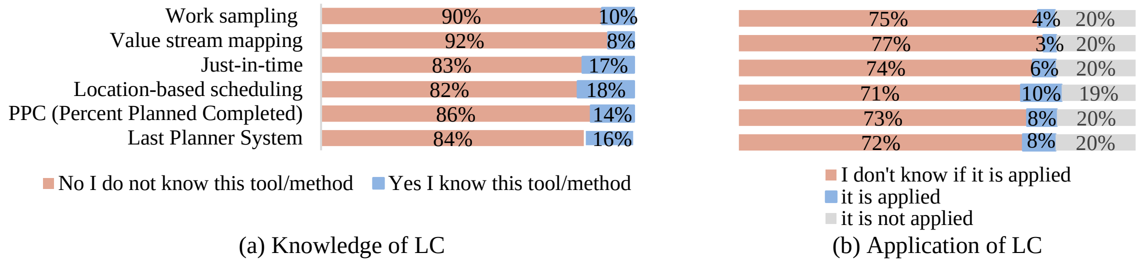

Figure 2: LC responses: (a) knowledge; and (b) application

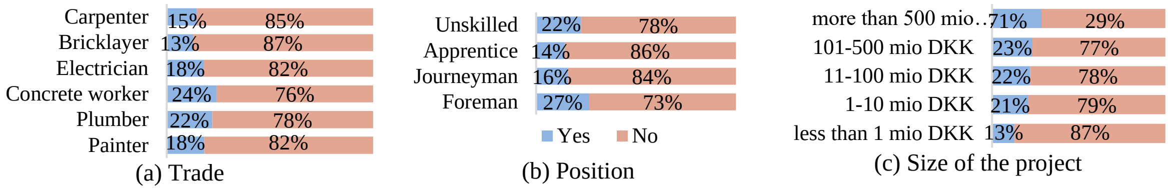

Figure 3: Knowledge of LC regarding: (a) trade; (b) position; and (c) project size

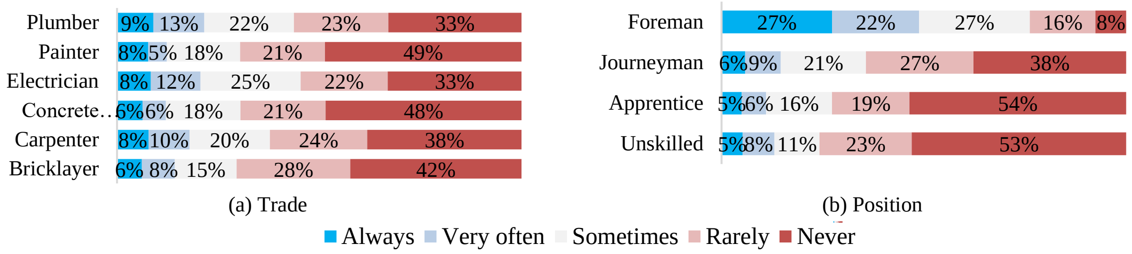

Figure 4: Meeting participation on site regarding: (a) trade; and (b) position

IMPACT OF LEAN KNOWLEDGE ON JOB SATISFACTION

Two of the five factors asked in question 3.1 were selected to understand the impact of declaring knowing Lean on job satisfaction. Figure 5 represents the effect of knowing the Lean concept of JIT and the Lean Technique of WS within the level of satisfaction regarding "work monitoring" and "management-worker relationship". As per the Figure 5a, job satisfaction of workers who declared knew JIT ('Yes' bar in Figure 5a) in employee work monitoring was marginally higher than workers who did not know ('No' bar in Figure 5a). It was 41% and 38% respectively. However, as per Figure 5b; workers who did not know JIT had barely more job satisfaction (52%) than rest (51%) in "manager -worker relationship". As per Figure 5c and Figure 5d, knowing WS has a slight edge out, than whoever else in job satisfaction on both selected aspects. Statistically, workers knew WS has shown 10% and 3% improvement in job satisfaction under "work monitoring" and "manager-worker relationship" respectively. Hence, these representations implies that the impact of declaring knowing some Lean tools/concepts/method is not significant for affecting job satisfaction. Hence, to examine the impact of LC application on job satisfaction, the next approach was adapted.

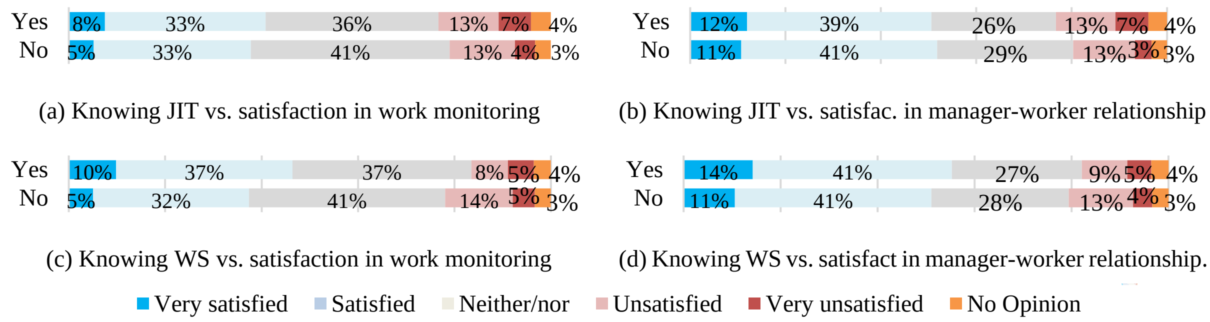

Figure 5: Impact of Lean knowledge of JIT and WS in satisfaction: (a & c) work monitoring, (b & d) manager-worker relationship.

IMPACT OF LEAN OPERATION ON JOB SATISFACTION

For understanding the impact of applying Lean on workers satisfaction, the authors selected how the "attendance in meetings" impact the satisfaction regarding "the workflow of the project" and the satisfaction regarding the "manager-worker relationship".

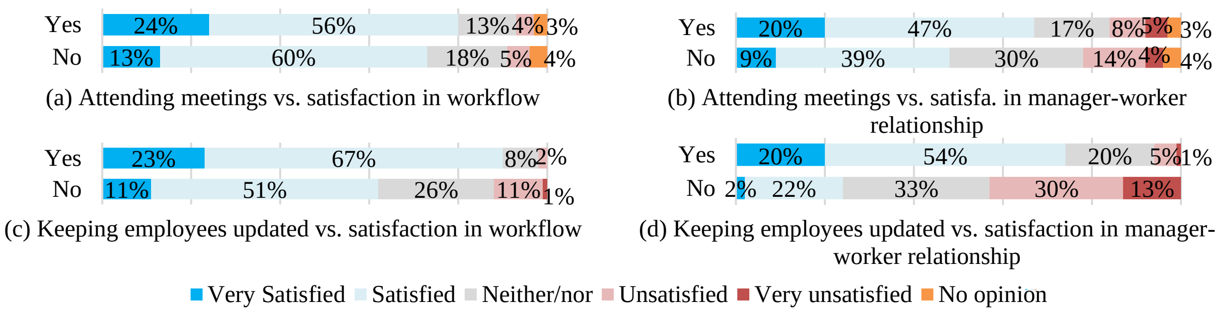

Figure 6: Impact of "attending planning meetings" (a & b), and "keeping workers informed" (c & d) on job satisfaction in "workflow" and "manager-worker relationship"

From Figure 6a and 6b, it can be seen that "participating in planning meetings" have a slight, but a noticeable impact on the job satisfaction criteria selected. When the workers did not attend the planning meetings job satisfaction in both the workflow and the "manager-worker relationship" was respectively 73% and 48%. However, workers who participate in the planning meetings show 80% and 67% satisfaction in the same criteria (Figure 6a and b). Although the relationship was weaker compared to other variables, it shows a 7% and a 19% (respectively) increase in job satisfaction. "Keeping workers updated" shows a relatively remarkable influence (Figure 6c and d). The impact on job satisfaction under "manager-worker relationship" has improved from 24% to 74% which is nearly three times of the percentage of the "workers who was not kept informed about the things mattered". Noteworthy, the influence of Lean operations is more apparent when compared to Lean knowledge.

Another noticeable observation was, how participation in planning meetings affected PM aspects. As illustrated in Figure 7, workers who participate always and very often in planning meetings ("Yes" in Figure 7) have better chance of finishing their work on time (Figure 7a), know better about their tasks according to the plan (Figure 7b), know better of their tasks ahead of one week (Figure 7c) and one month (Figure 7d). In essence, this indicates how regular engagement in planning meetings contributes to improved project management outcomes.

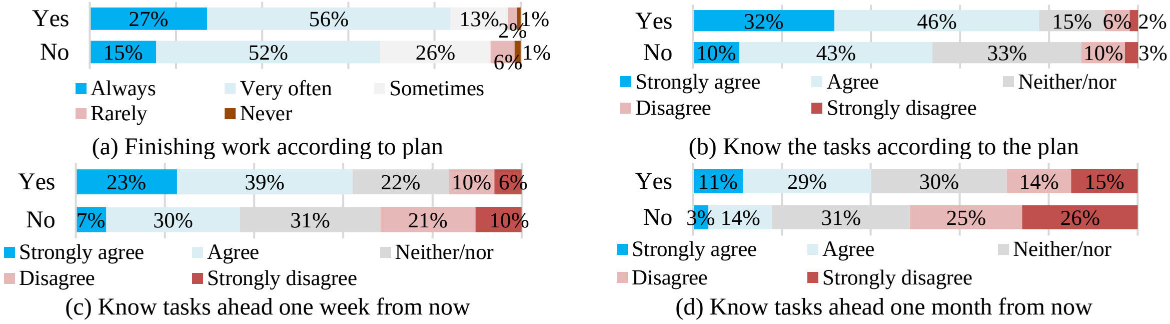

Figure 7: Effects of attending planning meetings on PM

COMPARISON OF LEAN KNOWLEDGE AND LEAN OPERATIONS

The last analysis aimed to understand the impact of having Lean knowledge on the job satisfaction (selected five fields) using the correlation analysis. As per Figure 8a, knowing Lean showed a varied influence on the selected factors. The correlations observed were barely noticeable, indicating a weak association between the variables considered, which infer that there is no correlation between the variables at all. However, for the sake of further investigation, it was noted that the largest correlation factor was found to be between WS and the satisfaction in "workload of the workers" (R^2 value of R^2=0.067) and the least being between PPC and the job satisfaction in "relationship between managers and workers" (0.001). Another observation is that JIT shows a negative correlation to all the job satisfaction factors besides job satisfaction in "work monitoring". However, it can be assumed that these correlations do not imply causation due to their insignificant magnitude.

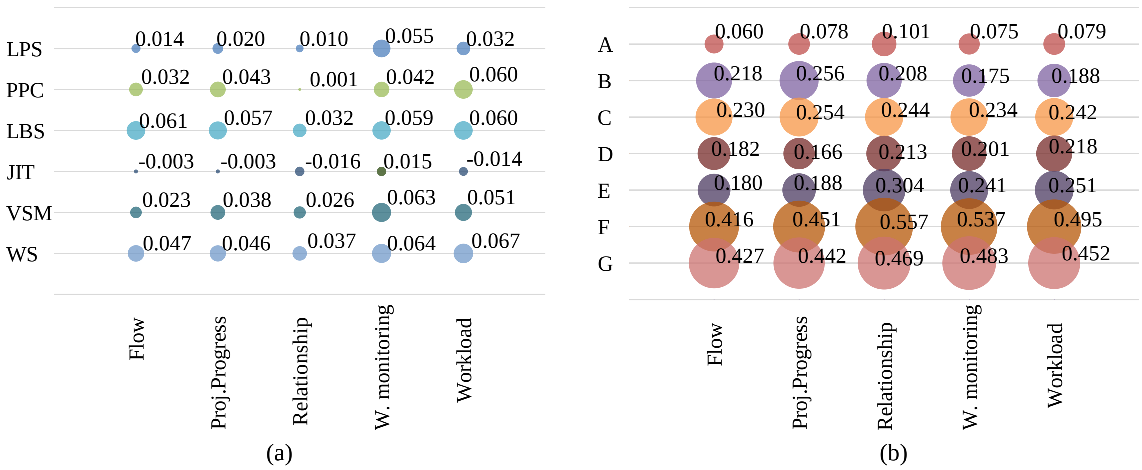

Figure 8: Correlations (R^2) of Job satisfaction: (a) Lean knowledge and (b) Lean operation

Within the designed analysis framework, correlations were explored for Lean operations (Figure 8b). The first observation was that the correlations were significantly higher than in Figure 8a, which suggests that Lean operations have a stronger influence on job satisfaction than Lean knowledge. Possessing Lean knowledge doesn't necessarily reflect whether that knowledge is actively implemented and practiced in a job site. However, it is the active practice of Lean that generates tangible results and could directly impact job satisfaction within the selected criteria. Further, when the attention is directed towards Lean operations, "3.3.1. organizations' attempt to keep workers informed about matters affecting them (Letter F in Figure 8b)" and "3.3.4. allowing the workers to evolve and improve (Letter G in Figure 8b)" have the greater influence on job satisfaction. R^2 value of R^2=0.557 is the strongest correlation factor of them, which is between "organization keeping workers informed" and satisfaction in "manager-worker relationship". This observation seems obvious, and it can be inferred that effective and efficient communication between the organization and the workers is crucial. The least significant correlation (0.060) in the lot was with “3.1. Participation in planning meetings (Letter A in Figure 8b)”. Even though “meeting participation” is expected to impact more on job satisfaction, the intended objective of planning meetings might not have been achieved. Frequently, meetings might be perceived as time-consuming, and workers may feel that extensive meeting participation takes away from their productive time. Nevertheless, operations related to RFP (F and G), has shown significant effect on task execution and planning awareness.

CONCLUSION

This study is part of an ongoing research project that aims to understand workers' job satisfaction in the construction industry. Data from 2176 responses were analysed using framework analysis, shorting the answers into three categories (Lean knowledge, application, and operation) to understand how the level of familiarity with LC impacts on job satisfaction.

The answers analysis has revealed a significant lack of awareness in various Lean approaches and their applications; meaning that most of the construction workers did not know LC and, they didn’t even know whether they are practiced. Apart from that, “participation in planning meetings”, which was classified as a Lean operation in this paper, was given closer attention as well. This unveiled that meeting attendance had a positive impact on PM where workers attending meetings had more tendency to finish work on time and knowing the project plan and their tasks 1- 4 weeks ahead.

The main contribution of this paper is understanding the influence of Lean knowledge and Lean operation on job satisfaction. The correlations between Lean knowledge and job satisfaction demonstrated a generally weak association, suggesting that the variables considered do not exhibit significant correlations. Shifting the focus to Lean operations, the strongest correlation was found between organizational communication practices and satisfaction in manager-worker relationships. Thus, Lean practices that lead or require RFP are the aspects that impact more on job satisfaction.

The study has some limitations that should be addressed in future research. Firstly, the results are limited to the Danish construction scenario. Thus, caution is necessary when extrapolating findings to other countries. For that, a broader data collection across various countries and regions could facilitate comparisons and offer insights into the impact in Lean in job satisfaction. To overcome that, the authors have been working with other researchers from other countries and the questionnaire is going to be applied in France, Lebanon, UK, Peru and Chile. Secondly, the assumption considered during the categorization into knowing Lean or not could have impacted in the results. The respondents were considered familiar with Lean when affirming knew at least three concepts. However, other assumptions could be considered for that categorization. For example, a Lean knowledge degree and/or a Lean implementation degree could be used. Thirdly, the impact of having Lean knowledge and Lean operation on job satisfaction was conducted only considering five selected factors; however, other factors asked in question 3.1 could be considered.

Despite the need for caution in applying the study's findings to different countries, they still offer valuable insights into the factors influencing job satisfaction in construction projects. Future research could focus on developing roadmaps based on these findings, tailored to meet specific local needs and contexts to promote RFP.

ACKNOWLEDGMENTS

The authors would like to thank the BAT organization for the collaboration and for providing access to their members.

ABSTRACT

Respect for People (RFP) is a crucial element in Lean Construction philosophy, along with continuous improvement. However, despite its importance, research on RFP is still limited. Therefore, the following article aims to identify good practices, benefits, and barriers generated by its implementation on the construction site. The research begins with a literature review, following the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) criteria. Subsequently, with the list of good practices, benefits, and barriers, nine lean experts were interviewed, validating the information obtained from the literature review. This process identified eleven good practices, eleven benefits of implementing RFP in construction projects, and nine barriers. The upcoming research will serve as a valuable contribution for professionals seeking to implement good practices of RFP on the construction site and researchers aiming to delve deeper into this concept.

KEYWORDS

Respect for People, Lean Construction, benefits, barriers, good practices

INTRODUCTION

The construction sector stands out as one of the most relevant economic sectors globally (Sarmiento-Rojas et al., 2020), employing many individuals in its diverse activities. Despite its importance, construction faces several challenges, such as lack of productivity (Barbosa et al., 2017 and Del Savio et al., 2022), inadequate planning in work (Gomez & Morales, 2016), limited collaboration, fragmentation of the supply chain (Schöttle et al., 2014), environmental impact (UNEP, 2022). These problems are primarily related to people in construction projects. Since people play a crucial role in the construction industry's success (e.g., workers and managers), strategies to improve the construction industry should consider people and try to understand the role of people involved in construction projects (Golzad et al., 2023).

Within the Toyota Production System (TPS), there are two fundamental pillars: continuous improvement and Respect for People (RFP), as highlighted by Miller (2017). Therefore, in the context of Lean philosophy, people play a crucial role, as it acknowledges that the success of any system or process depends significantly on the commitment, motivation, and respect for the individuals who comprise it. Thus, it promotes a work environment that values and respects individual contributions, fostering collaboration, innovation, and personal and organizational growth.

Despite its importance in Lean Construction, literature regarding RFP is scarce. Korb (2016) conducted a literature review and defined the concept of RFP based on various perspectives, examining barriers to developing this principle and analyzing ways to cultivate RFP in lean construction implementation. His research revealed a significant disparity in the number of papers dedicated to RFP compared to those focused on continuous improvement. Specifically, only 33 papers related to RFP were found, while 451 papers were identified on continuous improvement in the International Group for Lean Construction (IGLC). Current results obtained from a quick review in Scopus conducted by the authors confirm the trend observed previously by Korb. Only 166 papers on RFP and a culture of respect were identified, compared to 19,905 papers on continuous improvement. This significant difference in the number of publications again underscores the lack of attention and study dedicated to RFP compared to continuous improvement in Lean Construction. These findings highlight the need for further research and recognition of the importance of RFP in successfully implementing Lean Construction.

Therefore, the following research aims to delve into the concept of RFP in the context of Lean Construction. A comprehensive literature review identified a list of good practices, barriers, and associated benefits concerning people in construction projects. Subsequently, this information was validated and supplemented through interviews conducted with nine experts in the field. This paper aims to generate guidelines or good practices that can be effectively applied in various construction projects. Additionally, it seeks to identify the barriers and benefits associated with implementing RFP in terms of the professionals' perceptions and the obstacles that could hinder its full implementation on the construction site. This research aims to enrich the understanding of the concept of RFP in Lean Construction and provide practical tools for its successful application in the construction industry.

BACKGROUND

RESPECT FOR PEOPLE AND LEAN PRODUCTION

In the 1950s, the TPS laid the foundation for Lean Manufacturing, focusing on waste elimination and continuous improvement. The first pillar of TPS, continuous improvement, enables the expected results to be achieved; however, the second pillar, RFP, makes the former possible in the first place, considering Toyota's statement: "We make people before we make cars" (Korb, 2016).

Liker (2004) highlights RFP as critical for achieving operational excellence and sustainable efficiency. On the other hand, Womack and Jones (1997) emphasize how RFP is integrated into the Lean organizational culture, recognizing the importance of each individual in the production process. Finally, Rother (2009) mentions that lean tools are structured frameworks with the fundamental objective of developing and improving people's problem-solving capabilities. Together, these authors offer an in-depth view of the early history of Lean, revealing how the harmonious interaction between efficiency and RFP shaped a philosophy that transcends manufacturing to impact various sectors positively.

According to Ljungblom and Lennerfors (2021), RFP is understood as consideration and respect for individuals, emphasizing developing their capabilities in a positive, not necessarily emotional, atmosphere. On the other hand, key topics related to RFP include teamwork, personal development, motivation, problem-solving capacity development, waste elimination, and safety (Coetzee et al., 2019). Additionally, teamwork helps improve construction safety (Yin et al., 2023). Teamwork is about collaborating in an organized way to achieve a common goal. This involves understanding the interdependencies among team members and making the most of them (Cardona et al., 2006).

RESPECT FOR PEOPLE AND LEAN CONSTRUCTION

Korb (2016) emphasizes that RFP in Lean Construction goes beyond treating people fairly and safely, focusing on actively engaging employees in identifying waste and improvement opportunities. Furthermore, it is highlighted that RFP is crucial for the success of Lean Construction, as it enables continuous improvement and sustained employee engagement at all levels of the organization. This approach involves empowering people to identify improvement opportunities and value their contributions. Additionally, Filho et al. (2018) conducted a study on RFP from the meditation perspective, confirming the feasibility of its implementation because workers agreed that meditation valued it and recommended its implementation in other projects. Furthermore, they concluded that the company was building people before houses with these actions, thus demonstrating RFP.

Furthermore, other authors have explored the concept of RFP, relating it to psychological safety. In this regard, Gomez et al. (2019) analyze psychological safety in a construction project to create a safer environment that promotes RFP; Gomez et al. (2020) explore psychological safety and how it fosters a better working environment and RFP, allowing individuals to feel free to voice their opinions and participate more actively in the project; Demirkesen et al. (2021) demonstrate that construction workers feel more psychologically safe and respected in projects implementing Lean Construction.

In this context, the authors conceive respect for people as crucial. They recognize the importance of each individual in the development of the Lean construction project and value their skills, knowledge, and contributions. This focus on respect promotes a more positive work environment and stimulates collaboration and innovation in the workplace.

RESEARCH METHOD

Figure 1 illustrates the two phases of the research development. In the first phase, a literature review on RFP in construction was conducted to extract a list of good practices, benefits, and barriers. In the second phase, nine semi-structured interviews were conducted with expert professionals to validate the lists found in the literature and gather their professional experience regarding RFP.

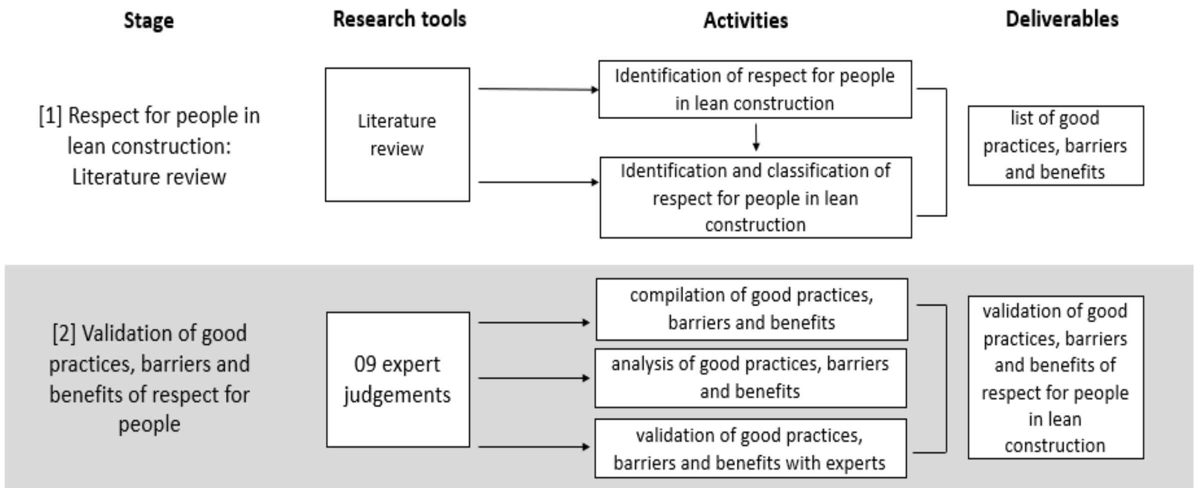

Figure 1: Research Stages

First stage: Prisma review

A literature review was conducted to identify and select the articles evaluated in this study, following each step of the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) methodology. For the literature review, a search was conducted in the IGLC database and Scopus for "Lean Construction" and "RFP" publications. Scopus is one of the databases with a broader domain in construction research compared to others (Galaz-Delgado et al., 2021), and the IGLC database hosts most publications on the application of Lean Construction worldwide (Daniel et al., 2015). For the Scopus database, the keywords used for the search were "Respect for People" AND "lean construction," and for the IGLC database, it was "Respect for People." No publication year filter was applied, resulting in 22 articles.

Nine duplicate publications were removed for the eligibility phase, leaving 13 papers. Subsequently, it was reviewed whether articles that did not refer to RFP in Lean Construction should be excluded. In this phase, all articles referenced the evaluated item, so there were no exclusions. In total, 13 articles were considered for the research.

Second stage: Qualitative Study

The qualitative research approach examines variables such as experience, attitudes, behavioral aspects, and participants' opinions in the data collection process (McCusker & Gunaydin, 2015). This method is suited for gathering human opinions and knowledge on a subject from different perspectives (Malterud, 2016).

It has been previously used with topics related to Lean Construction, for example, to identify the positive impacts and challenges of LPS in Brazilian companies (Viana et al., 2010) and to identify tools and facilitators for lean adoption (Marhani et al., 2018). Moreover, qualitative studies have been used for issues related to people, in the construction sector. For example, Demirkensen et al. (2021) conducted a study to evaluate the influence of psychological safety in the USA using qualitative studies to identify the relationship between the principles of Lean Construction in the context of safety. Similarly, in Chile, Paez et al. (2024) employed the qualitative study with the objective of analyzing the perceptions of experts related to emotional intelligence in the construction sector, using interviews with 11 Chilean professionals.

Given the scarcity of research on the topic of respect for people within Lean Construction, this study aims to serve as a foundational piece for future investigations. By identifying good practices, barriers, and benefits associated with respect in Lean Construction, it endeavors to pave the way for further exploration into this important aspect.

Therefore, expert judgments were used due to the need to obtain insights and specialized perspectives in the field of Lean Construction and respect for people in this discipline. For this stage, 15 experts were initially contacted, following the snowball criteria; however, only 9 of them agreed to the interview, Table 1 describes the profile of the interviewees.

For the selection of the experts, a careful process was carried out in which professionals and academics with extensive experience and knowledge in Lean Construction were identified. Experts with a minimum experience of 10 years in the Lean philosophy were considered, as well as in issues related to respect for people in work environments. Geographic and professional experience diversity was prioritized to ensure a diverse representation of opinions and approaches. Although the sample is not large (nine experts), it can be considered appropriate for qualitative studies. Several studies mention that additional responses do not significantly increase the information, like Demirkensen et al. (2021), where they achieved saturation after the 12th interview in their study that was also related to people in the construction industry. In the case of the present research, saturation was observed after the 8th interview.

The interviews were conducted via Zoom or Meet video calls and lasted 30 to 60 minutes with each participant. The interview was divided into two stages: a first stage where information about the interviewee was collected, including years of experience applying Lean Construction, types of projects they worked on, company size, and their position. In the second stage, the identified good practices, barriers, and benefits from the literature review were validated. The experts were asked if they had observed any additional good practices, barriers, or benefits throughout their careers that were not included in the lists presented.

Table 1: Expert profiles

ID	Academic level	Country	Experience	LC Experience	Current role
EX1	Ph. D.	Ecuador	32 years	32 years	Director of Civil Engineering
EX2	Ph. D.	Chile	14 years	11 years	Professor and researcher
EX3	Ph. D.	Brazil	15 years	15 years	Professor and researcher
EX4	Ph. D. (c)	Ecuador	15 years	10 years	Manager
EX5	Ph. D.	España	13 years	12 years	Professor
EX6	Ph. D.	Chile	18 years	18 years	General Manager
EX7	Ph. D.	Chile	40 years	32 years	Director of a Research Center
EX8	Magister	Perú	42 years	28 years	General Manager
EX9	Magister	Perú	12 years	10 years	General Manager

RESULTS AND DISCUSSION

GOOD PRACTICES

During the literature review, nine good practices were identified. These were subsequently validated and supplemented with two good practices from expert interviews. The details of these practices are presented in Table 2.

BP1 suggests the pressing need to establish an organizational environment conducive to continuous process optimization and reducing inefficiencies (Richert & McGuffey, 2019). All experts are in favor of this good practice. EX1 emphasizes the positivity of this practice but stresses, *["It is necessary to link it with a performance measurement culture."]*. EX2 highlights that *["It is important to establish a suggestion system in conjunction with this practice*."].

Regarding BP2, the importance of valuing individual successes and collective achievements is highlighted (Korb, 2016). This approach acts as a motivational catalyst for employees and strengthens the culture of continuous improvement, contributing to creating a positive work environment. EX1 shares their experience, stating that *["This practice is beneficial without incurring significant additional costs."*]. On the other hand, EX4 cautions about the careful design of incentives *["This could promote negative practices related to tight deadlines, compromising safety and work quality."]*. EX7 emphasizes, based on their experience, that *["This practice satisfies motivational needs at work."]*. Experts unanimously support this practice, considering that it would significantly contribute to fostering respect for individuals in the workplace.

Table 2: Good practices associated with RFP.

N°	Good practice	References
BP1	Establishing a culture that promotes continuous improvement	(Korb, 2016); (Richert & McGuffey, 2019)
BP2	Recognizing and celebrating achievements	(Korb, 2016)
BP3	Providing regular constructive feedback to support personal and professional development	(Korb, 2016)
BP4	Establish Clear and Shared Objectives	(Gomez et al., 2020); (Howell et al., 2017)
BP5	Encourage active participation of employees in decision-making related to their work and processes.	(Gomez et al., 2020); (Demirkesen et al., 2021); (Gomez et al., 2019); (Howell et al., 2017); (Filho et al., 2018)
BP6	Ensure safety in the construction environment by implementing measures that safeguard workers' physical integrity.	(Howell et al., 2017); (Gomez et al., 2020)
BP7	Establish a warm and friendly working environment.	(Richert & McGuffey, 2019); (Filho et al., 2018)
BP8	Ensure the recruitment and retention of high-quality employees.	(Filho et al., 2018)
BP9	Create a psychologically safe environment that fosters collaboration and learning.	(Howell et al., 2017); (Demirkesen et al., 2021); (Gomez et al., 2019); (Arroyo et al., 2018)
BP10	Value jobs with fair wages	Suggested by the expert panel
BP11	Instill a culture of respect among each team member.	Suggested by the expert panel

Concerning BP3, the importance of continuously providing positive and constructive feedback to support personal and professional growth is highlighted (Korb, 2016). EX1 maintains that *["This good practice should be applied to both technical staff and field personnel of the company."]*. Experts express that the lack of training is due to high employee turnover in the industry.

For BP4, EX1 mentions that *["It is a good practice that should be addressed in planning meetings with the team."]*. EX3 agrees, noting that it will depend on the formality level of the company. EX4 highlights the importance *of ["Objectives being cross-cutting and benefiting everyone."]*. EX5 emphasizes that *["Involving others in the common goal is a sign of respect."]*. EX6 expresses disagreement due to a lack of interest. The other four experts agree with this good practice.

The BP5 refers to involving employees in decision-making that directly affects their responsibilities (Howell et al., 2017). EX3 comments*: ["When studying resilience in workplace safety, safety should be addressed collaboratively."]*. Other six experts also express their agreement.

About BP6, which refers to implementing measures and protocols aimed at ensuring a safe working environment for employees, EX6 highlights that: *["This demonstrates concern for workers and is a good practice."]*. The other experts validated this practice.

BP7 suggests cultivating a positive and welcoming work environment (Filho et al., 2018). EX2 notes that *["The terms are very general and should mention how to achieve a warm and friendly environment."]*. EX4 prefers a friendly environment over a warm one to promote a collaborative atmosphere. EX5 emphasizes that *["Working in a happy place increases productivity."]*. EX6 mentions that, although the good practice should be applied, making friends is unnecessary to create a warm work environment. The other experts validated this good practice.

Regarding BP8, which refers to the importance of selecting and retaining highly competent and skilled professionals in the organization, EX6 and EX7 expressed their disapproval, mentioning that *["The construction industry is characterized by its temporary nature and fluctuation, so implementing this practice would not be suitable in this context"]*. The other seven experts approved this good practice.

BP9 ensures that workers are not punished for reporting errors or asking questions. Expert 1 mentions that ["It is difficult to implement due to the diversity of individual issues."] The other eight experts validate this good practice.

BP10 involves recognizing and adequately compensating employees' work and ensuring that salaries are fair and reflect each individual's contribution and value to the organization. The majority of experts supported this recommendation, with five mentions.

BP11 refers to knowing that each team member is essential for the project's completion and cultivating norms within the company that promote respect, incentivizing values and ethics. Three of the experts suggested this good practice.

BENEFITS

Six benefits were found during the literature review. These were then confirmed and reinforced by five further benefits that surfaced from expert interviews. Table 3 presents the benefits identified in this study.

B1 involves cultivating a sense of belonging and recognition among collaborators. Eight experts have validated this benefit. EX3 highlighted that: *["While this benefit could be a consequence of implementing good practices, it is crucial to conduct further research, such as a pilot test, to validate its effectiveness"]*.

Regarding B2, which entails recognizing the importance of maintaining a comprehensive approach within the Lean framework, over 88.8% of experts endorsed this benefit according to their opinions.

Concerning B3, which involves creating an organizational environment conducive to employees' professional and personal growth, this benefit was corroborated by the experience of three experts.

Table 3: Benefits identified.

N°	Benefits	Reference
B1	It creates an environment where employees feel valued and an integral part of continuous improvement.	Suggested by the expert panel
B2	Prevents Lean tools from deviating from their primary focus on continuous improvement.	(Korb, 2016)
B3	Facilitates development and innovation	Suggested by the expert panel
B4	Leads to increased productivity.	(Demirkesen et al., 2021); (Filho et al., 2018)
B5	Encourages an open and transparent communication environment	(Filho et al., 2018); (Demirkesen et al., 2021); (Arroyo et al., 2018)
B6	Employee loyalty to the company	Suggested by the expert panel
B7	Eliminates inefficiencies and waste	(Demirkesen et al., 2021)
B8	Facilitates the creation of a culture of adaptability and flexibility	Suggested by the expert panel
B9	Contributes to the development of more potent and more respectful working relationships	(Richert & McGuffey, 2019)
B10	Contributes to the emotional well-being of employees	(Filho et al., 2018)
B11	Increases occupational safety and security	Suggested by the expert panel

Regarding B4, which involves various improvements and approaches that contribute to increased efficiency and performance in the workplace, experts 2, 4, 5, 6, 7, 8, and 9 validated this benefit. EX1 emphasized that *["productivity is enhanced by at least 10% by improving worker performance"].* However, EX3 noted the need for further research to validate this claim due to the various variables that may influence it.

Concerning B5, which involves fostering an environment of open and transparent communication, EX3 mentioned that *["By having open communication with the team, not only does it strengthen trust and collaboration among members, but it also facilitates the efficient identification and resolution of challenges"].* All experts validated this benefit.

As for B6, according to EX5, applying good practices of respect for individuals can generate loyalty in high-quality workers, thereby increasing the company's personnel quality.

Regarding B7, which allows for eliminating inefficiencies and waste, all the showed their approval. EX1 mentioned that *["By using 5S, material waste and accidents are eliminated"],* while other experts highlighted eliminating unused talent waste and reducing waiting times due to coordination.

Regarding B8, which implies that applying good practices of respect for individuals establishes an environment conducive to continuous adaptation and flexibility, experts 3 and 4 mentioned that, based on their experience, this benefit has been observed. They emphasize that ["People, when feeling heard and in a positive environment of respect, show a higher likelihood of flexibility towards ideas and working methods"].

Regarding B9, EX5 expressed skepticism and suggested the need to verify it, as relationships between people depend on multiple factors that are difficult to measure. Despite this, other experts approved based on their experience with projects.

As for B10, EX3 disagreed, arguing that *["There are other factors that can affect emotional well-being"]*. However, other experts have validated this good practice.

Seven experts validated the last benefit (B11), which increases occupational safety by creating a safer work environment. EX1 mentioned having achieved zero accidents on a construction site by applying these concepts of good practices, thus supporting the effectiveness of such measures.

BARRIERS AND CHALLENGES

During the literature review, a total of 6 barriers were identified. These were subsequently validated and supplemented with three additional barriers, which emerged from expert interviews. The details of these barriers are presented in Table 4.

Table 4: Barriers and Challenges Associated with RFP.

N°	Barriers and Challenges	Reference
Ch1	Lack of active employee participation	(Gomez et al., 2020); (Richert & McGuffey, 2019)
Ch2	Lack of transparent communication	(Gomez et al., 2020); (Richert & McGuffey, 2019)
Ch3	Culture of blame for mistakes	Suggested by the expert panel
Ch4	Technocracy exists in the construction industry	Suggested by the expert panel
Ch5	Authoritarian decisions	(Filho et al., 2018)
Ch6	Inequality and discrimination	(Richert & McGuffey, 2019)
Ch7	Resistance to Change and lack of flexibility in working methods	(Richert & McGuffey, 2019)
Ch8	Lack of career development opportunities and recognition	(Korb, 2016)
Ch9	Destructive skills	Suggested by the expert panel

The Ch1 implies that employee reluctance or lack of commitment to continuous improvement initiatives could pose a significant obstacle. While most experts (8 in total) endorsed this barrier, EX1 presented a different perspective by arguing that *["This barrier reflects more an organizational culture where responsibility is assigned based on specific training for a task"]*. Additionally, EX5 pointed out that, *["Employee active participation may be underestimated, as some apply lean practices without full knowledge of it"]*.

Regarding Ch2, EX1 highlighted its impact, especially in supplier communication. Other eight experts supported the existence of this barrier. Furthermore, EX5 noted that *["Sometimes workers are communicated to without fully explaining the reason behind tasks, which can lead to lack of participation"]*.

Although EX5 did not fully validate Ch3, seven other experts endorsed a culture of blame and stigmatization for errors, emphasizing the need to address this aspect in the workplace.

Regarding Ch4, according to EX7, *["Many companies prioritize indicators and performance without considering people"]*. EX3 and EX5 supported the existence of this barrier in the construction industry, pointing out the lack of consideration for human aspects in process optimization.

Ch5 refers to "Authoritarian Decisions." Although EX1 does not fully support this barrier and highlights that *["There is a contradiction with the Lean philosophy of integrating knowledge from the bottom up"]*, other five experts corroborated the presence of this barrier. In this regard, EX7 presents the perspective that *["Rather than being a barrier, it could be considered a bad practice"]*, suggesting that although this dynamic may represent a challenge, it can also be interpreted as inefficient behavior within the operational framework.

Regarding Ch6, according to EX1, *["This barrier involves wage disparities and discrimination against female crews"]*, while EX4 and EX8 highlighted wage inequality, although most experts supported the existence of this barrier, EX7 mentioned that *["This barrier was seen more as a bad practice than as a structural barrier"].*

Regarding Ch7, experts 1, 3, and 6 supported the existence of this barrier, pointing out cultural resistance and rigidity in traditional practices. The remaining experts also expressed their agreement with its presence.

Concerning Ch8, EX1 considered that *["This affects employee contribution"],* while another three experts are not entirely in agreement with classifying this as a barrier. However, other experts have expressed their agreement with this barrier.

As for Ch9, EX1 and EX2 emphasized that *["This occurs because there is a lack of a collaborative culture"].* Although some experts (3 and 5) do not strictly consider it a barrier, all the other experts in the interview validated its existence, highlighting the importance of fostering a collaborative environment to prevent destructive competition.

CONCLUSIONS

This study identified eleven good practices, eleven benefits, and nine barriers related to respect for individuals in construction projects. Nine experts validated these findings. Based on these results, guidelines have been established that can be applied in various construction projects to implement these practices, identify barriers present in companies or projects that hinder their full implementation on the construction site, and ultimately reap the benefits after implementing respect for individuals.

It is important to note that this study may have some limitations. For example, the identified good practices could be influenced by the cultural characteristics of the places where Lean Construction is implemented. Additionally, it is crucial to validate these good practices, benefits, and barriers in various construction projects to ensure their widespread applicability, and further research is suggested to expand the list of good practices.

EXPLORATION OF LEAN CONSTRUCTION IN JAPAN AND ITS PARADOXICAL STANCE

Jeferson Shin-Iti Shigaki[1], Lauri Koskela[2], Algan Tezel[3] and Barbara Pedo[4]

ABSTRACT

Japanese construction, appraised for its high quality and production efficiency, holds virtues that Lean advocates have long admired in the Toyota Production System. However, Japanese building construction academia and industry organizations have remained disconnected from the mainstream IGLC community until recently. Therefore, its current state is insufficiently understood overseas. This study has employed a literature review, including resources in English and Japanese languages, and gathered first-hand testimonials to shed light on such a gap. This paper identified practices and routines from Japanese construction sites that could be incorporated into the Lean Construction repertoire, and identified points from which Japan could learn, such as the role of dynamic ecosystems in the birth and expansion of the Lean Construction movement and the presence of heavy-weight champions who nurtured conduit leaders. Japanese constructors have aspired to pull their engineering strength to the next level and combine it with innovative management practices, including incorporating good ones learned from overseas. That is where the role of Lean resides. Lean may help fill the gap of converting tacit knowledge into structured knowledge, increasing transparency, smoothing the transmission of know-how, creating more efficient project deliveries, and turning itself into a more attractive business.

KEYWORDS

Lean Construction, Japan, Theory, Toyota Production System, Ecosystem.

INTRODUCTION

The 1990s provided a fertile ground for rethinking construction engineering and management from the perspectives of technology, processes, and people (Tzortzopoulos et al., 2020). It was when (Western) construction started to apprehend quality management as in manufacturing. Improvements observed in the automotive sector have not been a product of a radical technology change but the result of the application of a new production philosophy, which was the generalization of partial approaches such as JIT and TQM (Alarcón, 1996). The seminal report *Application of the New Production Philosophy to Construction* (Koskela, 1992) led to the reconceptualization of production theory and practice in construction, which has matured over 30 years to a large extent around the International Group for Lean Construction (IGLC).

Lean Construction is the counterpart to Lean Production evolved in the context of construction. Lean Production is a generalization of the Toyota Production System (TPS), which is successfully applied in diverse business scenes. However, in Japan, the birthplace of the TPS, the conceptualization of Lean, in general, has been less evident. Iwao (2021) identifies a "conceptualization weakness" related to its high-context culture. Consequently, outstanding management techniques have been conceptualized in other countries and brought back to Japan later. Nonaka and Takeuchi (2019) praise the role of practical wisdom (phronesis) in continuous innovation but emphasize the necessity of both informal and formal interactions to convey the essential meaning of strategies in action. Japanese construction has arguably succeeded without formalized Lean, but there is room for improvement by adopting the "old-new" approach.

When it comes to the construction sector in Japan, it is intriguing that signs of applications of Just-in-Time (JIT), Total Quality Control (TQC), Concurrent Engineering (CE), and Value Engineering (VE) existed since the 1970 and 1980s. They have been little explored, perhaps due to the language barrier. For example, Tamura (2009) cited Taylor's influence in the incorporation of good practices from manufacturing, while Furusaka (2009) and Matsumura (2010) mentioned TQM and VE as innovations that transformed the construction gemba with tools and mindset. Still, there was no clear demonstration of how Lean Construction works at Japanese construction gemba and in white-collar offices, whether it exists in the first place.

Despite the "feel" that something tacit exists, there was no evidence in the "open" literature.

> *Many people are interested in the Japanese state of Lean Construction because Lean Construction has been born out from the Toyota Production System. Although I have been studying and introducing Lean Construction for some years, even now people who know the term "Lean Construction" seem to be less than 50 in number inside Japan (Dr. Inokuma to the Lean Construction Blog, 2017).*

Motived by the unprecedented exchange between Japan and the IGLC community in recent years and the approaching IGLC 2025 scheduled to take place in Osaka and Kyoto, this study aims to revisit the origins of the Lean Construction movement and discuss the paradoxical stance of the Japanese building industry, providing a historical background and reflections aspiring to trigger future exchange opportunities for mutual evolution.

RESEARCH METHOD

This study has employed an interpretivist research philosophy, holding a relativist ontological position, lying closer to a subjective epistemology and a constructivist axiology, according to the classification suggested by Saunders et al. (2009). It is exploratory and aims to shed light on the paradox that has kept the Lean Construction community apart from the Japanese construction academia and industrial societies (and vice-versa), even though a critical source of inspiration came from their manufacturing counterparts.

Quantitative tertiary data were collected from the IGLC proceedings. Qualitative secondary data were attained through a bibliographic review, including untranslated materials. Primary data were obtained through semi-structured interviews. The targets were three experienced engineers from a major Japanese General Contractor, hereinafter (J_n), and Western academics (co-authors to this paper) with a long track record in Lean Construction, hereinafter (W). Participants included: (J_1) Senior Chief Researcher from the R&D (32 years of experience), (J_2) BIM Lead from the Construction Division (21 years of experience), and (J_3) General Manager of Planning & Administration from the Construction Division (33 years of experience).

The approach was inspired by the "catch-ball" game, whose concept has been employed in organizational contexts, conveying the idea of an iterative dialogue, in this case, by correspondence. The specific questions can be followed along with the testimonials, which provide first-hand impressions based on empirical background. The expression "*nama no koe*" (literally *raw voice*) refers to the collection of heartfelt experiences. The discussed topics have long been the object of curiosity in this field and disclose hitherto little-known faces of history.

HISTORICAL BACKGROUND AND CURRENT SITUATION

The origins of the Japanese-style management are not uncontroversial. It is believed that Scientific Management principles met the post-war technocratic rationality of the *Sangyō Gōrika* movement to set the foundations for Japanese manufacturing (*Monozukuri*) as a "revised Taylorite" model (Tsutsui, 1998). Monozukuri practices emerged from unrelated improvements whose underlying principles that led to success were hazy in their inception.

In the realm of building production (*Kenchiku Seisan*), innovations were not understood as "Lean" efforts. Instead, they were likely the product of consecutive kaizens until becoming "ordinary" routine practices. Despite the skepticism toward accepting methods employed in manufacturing, there was a sense of admiration regarding the outstanding performance of TPS. TQC (later renamed to TQM) policies were how those ideas penetrated construction sites, suggesting activities and tools associated with Lean Production without calling them Lean.

To provide a concrete example, Takenaka Corporation has promoted Total Quality Control (TQC) efforts since 1976 and won the Deming Prize in 1979. The following passage conveys the context and spirit of that period (free translation from the original text in Japanese):

> *My father [Ren'ichi Takenaka] began exploring more fundamental business improvements and turned his attention to the automotive industry, where TQC was already advancing. With the guidance of Hino Motors, he came to know the name of Prof. Tetsuichi Asaka (Professor Emeritus at The University of Tokyo and a pioneering leader of TQC). We immediately requested Prof. Asaka's guidance, but he initially declined to accept. However, driven by our determination to ensure the continuation of the Takenaka's family business, we persisted and finally obtained his approval on the third attempt. This happened in 1976. Prof. Asaka had a policy of guiding one company per industry, and our company was chosen for guidance in the construction industry. By the way, in the automotive industry, Toyota Motor Corporation received his guidance. In the electric power industry, it was Kansai Electric Power Company (Toichi Takenaka in Kigyō sonzai kachi no sōzō: Hinshitsu keiei, Takenaka Corporation, TQM Promotion Department, 2022, p.26).*

Endeavors based on a similar philosophy antecede the creation of the IGLC. Nevertheless, the Japanese academia did not devise a formal theory of Lean Production for construction. As a result, Lean-like applications were and, arguably, continue to be essentially tacit.

Recently, prominent former UTokyo Prof. Fujimoto (Economics) collaborated with Prof. Yashiro (Architecture) to "theorize" building production through the lenses of Monozukuri. The joint research resulted in the untranslated book *Kenchiku Monozukuri-ron* (Fujimoto et al., 2015). Intriguingly, it did not mention Lean Construction's TFV theory. Also, there is no report of firms intentionally reformulating their production systems into formal Lean inspired by it.

Fig. 1 illustrates the transmission routes across the movements, including the obstructed but existing path from TPS to Japanese construction and the gap with the formal Lean Construction.

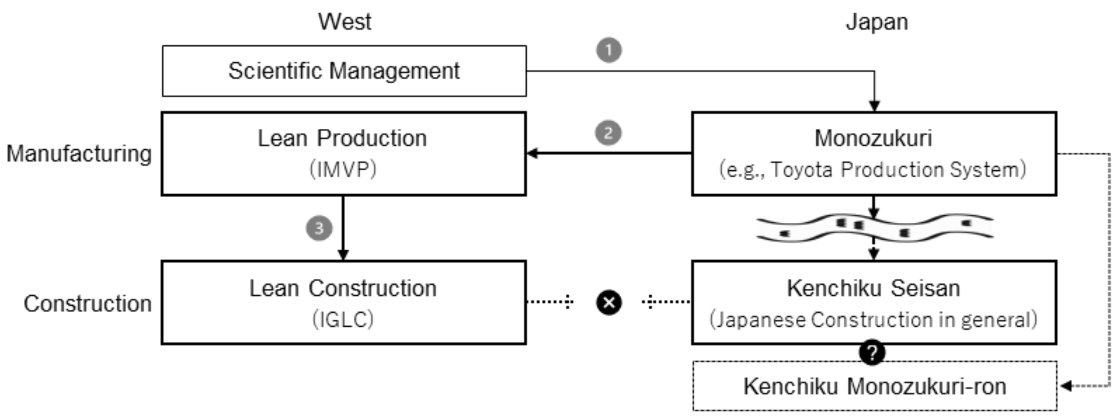

Figure 1: The path to Lean Construction and the disconnection with the Japanese construction

On the whole, Japanese construction has elements of Lean philosophy, introduced via TQC/TQM, but has not systematically deployed Lean Construction methods as in the West. In Japan, the initial focus was more on quality over production efficiency.

HOW DIFFERENT IS THE ORTHODOX JAPANESE APPROACH TO LEAN?

One of the few but most consistent studies on Lean Construction has been conducted by the Research Institute of Construction and Economy (RICE). Yamane et al. (2000) provided a concise yet comprehensive overview of the early days of Lean Construction, mentioning the Egan Report (1988) and research on TPS by European and American scholars as a strategy to overcome issues left unsolved by what the so-called Project Management (PM) methods were not able to do, particularly in terms of dealing with uncertainty and variability.

There was a sense that construction sites operated based on know-how accumulated over many years, and that would be the cornerstone for improving efficiency. They recognized that construction lagged behind manufacturing in many aspects of production systems and production management methods based on “theory”. In a footnote, they cited the Ministry of Construction’s “Construction Industry Technology Strategy (2000)”, which stated that the country had not necessarily accumulated management skills compatible with the international community, so it was necessary to improve the sophistication of management approaches.

One of the interesting points discussed by Yamane et al. (2000) was the comparison between the Last Planner System (LPS) and the Japanese-style construction management. Since the main differences pointed out by that article could be outdated, the four points were checked against the field by authors who updated their descriptions with contemporary reflections.

1. **Lookahead Planning and its associated processes.**
The Lookahead Planning resembles the Japanese *Gekkan Keikaku* (monthly planning). However, the Lean Construction way not only derives “should” from the master plan but considers the “can”, making explicit the necessary conditions in an iterative system reviewed weekly. In comparison, Japanese planning derives monthly and weekly work plans from the master plan and makes sub-processes adhere to them. However, there is no systematic procedure for constraint identification and elimination, which are carried organically.

2. **Last Planner and its associated processes.**
The Last Planner shares characteristics with the Japanese *Shūkan Keikaku* (weekly planning). The Lean way “shields” production by verifying work start conditions based on objective criteria. In comparison, the Japanese way also checks the readiness before moving a task from the monthly to the weekly work plan. The judgment, though, is heavily empirical and relies on tactic knowledge. The adherence to schedule is effective (partially due to its strict discipline) but not necessarily efficient since there is no systematic variability measurement.

3. **PPC metrics and progress lines.**
The PPC is a quantitative indicator of the process plan’s “quality” or “reliability”. It grounds the determination of investigations of the causes of planning failures and poor adherence. By comparison, Japanese sites draw *Shinchoku-sen* (progress line) on process charts that resemble the Line of Balance, updating them weekly and monthly. However, such a practice evaluates the results quantitatively but does not provide a notion of the production system’s “goodness” in terms of “healthy work allocation” and overall process reliability.

4. **Planning responsibility, collaborative kaizen studies, and daily huddles.**
By definition, the LPS promotes the empowerment of frontline workers by engaging them in co-creating the Lookahead and Commitment plans. In Japanese sites, active discussions are held with the foremen regularly in meetings equivalent to “daily huddles” to consider improvements to the production system. In the *Chōrei* (morning assemblies), the communication is mostly direct from the main contractor to the workers. But, in the so-called

"11:30 meetings" for progress and safety management alignment, foremen positively engage with operational decisions and fine-tune countermeasures to arising issues. Still, in most cases, the staff of the main contractor elaborates the process plans in the site office.

THE PARADOXICAL GAP WITH THE LEAN CONSTRUCTION COMMUNITY

Japanese building production took advantage of specific management ideas successfully implemented in manufacturing but never called itself Lean Construction. Despite sharing operational characteristics, its development occurred independently. On the other hand, Lean Construction embodied pre-digested conceptualizations from Lean Production and not directly from Japanese construction sites. Therefore, casual similarities arise from latent ties in their shared sources of inspiration rather than being the product of active exchange and collaboration.

Lean Construction has employed Japanese vocabulary to convey specific ideas, positioning them as holding a different meaning from the customary (i.e., embedding the new philosophy). As elucidated by the text mining conducted by Shigaki et al. (2021), many words that became popular because of the TPS have been utilized without translation at construction sites. The continuity over the years suggests that such a lexicon has become part of the daily vocabulary. They are now an intrinsic part of management systems. Nonetheless, there was no mention of terminology exclusive to construction. The most cited authors are Ohno (1988) and Shingo (1985), with no significant quotes from Japanese architecture or civil engineering academics.

Fig. 2 shows that the tokens "Japan" and "Toyota" appeared the most to contextualize the source of inspiration, followed by specific principles, methods, and tools in IGLC papers.

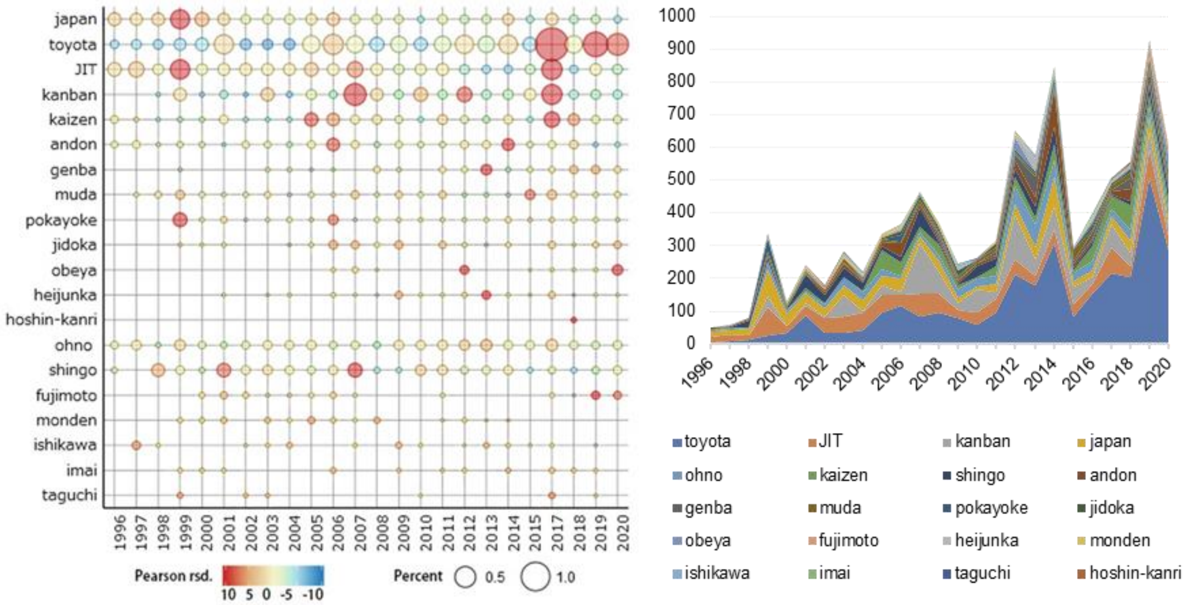

Figure 2: Japan-related keywords in IGLC conference papers (1996-2020) (Source: Shigaki et al. 2021)

The increasing number of participants in the IGLC conferences suggests that the topic is not exhausted. Adaptive in nature, Lean has merged with trending topics to respond to pressing issues such as contracting systems, digital transformation, sustainability, and well-being. It has also broadened its coverage to include more regions across the globe. However, the Japanese participation has been modest, disproportional to its expected position as the source of the TPS.

As for publications in the IGLC, considering the first authors, Japan stands at the 26th position among 50 countries, with only nine papers accounting for 0,42% of all articles (2004, 2005, 2006, 2014, 2017, 2018, 3x in 2023). Three of those papers were presented at the IGLC Conference in Lille, along with two industry day presentations, a record high engagement.

Historically, the countries that hosted more IGLC conferences have the most publications, even though it is difficult to conjecture about the industry-wide level of awareness and organization of their Lean Construction ecosystems. For instance, the US hosted the IGLC six times and is accountable for 21.7% of IGLC papers (affiliations of the first author), followed by Brazil (3x and 14.2%) and the UK (3x and 11.0%). As Osaka and Kyoto will host the IGLC 2025, one can expect growth in the exchange between Japan and the IGLC community.

The first appearance was of a graduate student during his study abroad at Penn State (counted as US), whose research had no direct relation to Japanese construction (see Sakamoto et al., 2002). The first official record is from Prof. Yoshitaka Nakagawa, who said, at that time, that "only a few contractors and house building companies are introducing this Lean Construction system" (see Nakagawa & Shimizu, 2004; Nakagawa, 2005; Nakagawa, 2006).

Then, Dr. Akira Inokuma from the Japan Federation of Construction Management Engineers Association (JCM) published the intriguing "Absence in the Provenance." He stated that "ironically, dialogue on Lean Construction has been limited in Japan, and almost gives a perception that LC is not applied in Japanese construction projects" (Inokuma et al., 2014).

After that, Prof. Koichi Murata, with an industrial engineering background, collaborated with long-standing IGLC members based in the UK, establishing the first formal bridge with the IGLC community (see Murata et al., 2017; Murata et al., 2018; Murata, 2023). In the last conference, Prof. Kaori Nagai, with substantial experience in construction R&D, debuted at an IGLC conference (see Nagai et al., 2023). She coincidently belongs to the same University as the previous professor. Nevertheless, their encounter at the conference was serendipity.

The last publication was of an expat (counted as Japan) who had previously learned Lean Construction abroad but was affiliated with Japanese institutions. The transmission pattern was the opposite of the first one. With an "outside-inside" view, the authors identified tacit manifestations of the Lean philosophy in Japanese construction (see Shigaki & Yashiro, 2023).

Table 1 indicates the co-authorship patterns of the nine papers previously mentioned in terms of "Japanese x International" and "Industry x Academia" allocations.

Table 1: Collaboration patterns of IGLC papers from authors related to Japan (1996-2023)

Pub. Year	First Author	Japan. co-authors		Intl. co-authors		Co-author's affiliation
		Academia	Industry	Academia	Industry	
2004	YN	1	1	-	-	Mid-sized GC
2005	YN	1	-	-	-	-
2006	YN	1	-	-	-	-
2014	AI	-	5	-	-	Consultants
2017	KM	1	-	3	-	U. Huddersfield (UK)
2018	KM	1	-	3	-	U. Huddersfield (UK)
2023	KM	1	-	-	-	-
2023	KN	2	2	-	-	Nihon U, Mid-sized GC, Dev.
2023	JS	2	-	-	-	U. Tokyo

A search for "Lean Construction" in the J-Stage platform (https://www.jstage.jst.go.jp) will lead to only two papers (Nakagawa, 2005; Inokuma, 2014). Both are repeat authors from the IGLC articles shortlist. To explain Lean Construction to the local audience, they both referred to the TPS. The former mentions the Last Planner System as an approach that originated in construction. The latter does not mention specific methods but has the IGLC homepage in the bibliography. The oldest record, however, could only be found in a printed source: the

Proceedings of the 15th Kenchiku Seisan Symposium organized by the Architectural Institute of Japan (AIJ) by Prof. Jun Shiino who did not publish at the IGLC (see Shiino et al., 1999). That is the only paper with "Lean" in the title since 1985.

BRIDGING THE GAP: A CATCH-BALL DIALOGUE

HOW DID JAPANESE CONSTRUCTION INFLUENCE LEAN CONSTRUCTION?

The origin of Lean Construction dates to Lauri Koskela's visit to Stanford University in the early 1990s. Despite the well-known history involving Lauri Koskela, Glenn Ballard, and Gregory Howell, there is little discussion on the role weight of Japanese construction as a source of inspiration for the development of Lean Construction.

When asked about the triggers for interest in the TPS and the American pre-digested Lean Production, Koskela said:

> *For me, there was a specific, concrete trigger: A colleague asked whether we in construction have considered simplifying operations before automating them. I found that his question was inspired by Japanese experiences and started to look for the "new production philosophy" as embodied in the TPS.*

In the preface of his doctoral thesis, Koskela (2000) acknowledged a Japanese person affiliated with a leading house manufacturing company who contributed with a case study. However, such interaction does not seem to have significantly influenced the theorization of Lean Construction. When asked about the exchange with the Japanese person, he said:

> *Such interactions played only a minor role. I had been in Japan earlier for an extended period and had made readings in Japanese culture, but I do not think these experiences were much discussed in the 1992 report.*

WHEN AND HOW DID THE JAPANESE LEARN ABOUT LEAN CONSTRUCTION?

Even among the few people acquainted with Lean Construction, the learning routes and the degree of awareness can be diverse. The testimonials below confirm such a scenario.

> ***[J1]*** *In Japanese construction, scientific management methods, such as TQC, were introduced in the 1970s. By the time I joined the company in 1992, they had become well-established and are still in use. Around 1993, the collapse of the bubble economy made corporate competition fierce. In 1995, I began researching production systems that could significantly reduce costs and improve productivity. Then, I started paying attention to TPS and learning about it from books, including materials by Fujimoto-san. I remember hearing the term "Lean" around that time. However, I did not pay much attention to Lean Construction research when considering ways of applying Toyota's methods. It was around 2009 when I learned about the Last Planner. I got very interested in it and started paying attention to Lean Construction.*

> ***[J2]*** *Coming from the construction site, I started working in software development three years ago (2021) and became interested in Agile. I wondered if this methodology could be applied in construction and began researching examples. It was when I came across the term "Lean Construction". About a year and a half ago (2022), when visiting a hospital project in Norway that utilized a workflow with certain BIM tools, the director of that software vendor taught me that Lean Construction concepts had been employed there.*

> ***[J3]*** *I'm not very familiar with it in the first place. I have a vague understanding that Lean Production has derived from TPS, which focuses on improving bottleneck processes.*

WHY HAS THERE BEEN LESS INTEREST IN LEAN CONSTRUCTION IN JAPAN?

The less interest reflects the low level of awareness, partially due to the language barrier and the difference between high-context and low-context cultures compared to the West.

> ***[J1]*** *Lean Construction is hardly known in Japan. However, just because there is less interest in Lean Construction, it does not mean that the Japanese construction industry is lagging behind in production methods (don't get me wrong). There are several possible reasons why Lean Construction has not received attention. (1) There is a tendency to value "tacit knowledge from the gemba", which has led to a gap in awareness between practitioners and researchers; (2) It is assumed that production methods that have been studied are somewhat difficult to understand and may not be suitable for practice use (if you can't*

engage practitioners in the field, no matter how good the method is, it will die without evolving); (3) There were attempts to learn directly from the TPS, but the translation from manufacturing to construction has not been successful; (4) English has been a barrier, so translation tools in recent years have been a great help.

***[J₂]** Many people just do not know the word. Additionally, there is a bias that since architecture involves creating one-of-a-kind products, it would not be possible to apply manufacturing processes directly. Consequently, only a few individuals are inclined to study the TPS. Also, Japanese people don't frequently search for information in English, so they do not come across information related to Lean Construction.*

***[J₃]** In Japan, production improvement efforts started with the Zero Defects movement, followed by QC activities, TQC, and then TQM. This approach was adopted not only in construction but in all industries. In post-war years, "Made in Japan" was synonymous with poor quality. As a national policy response, quality management began to gain importance. Organizations such as JUSE (Union of Japanese Scientists and Engineers) held QC conferences for all industries, and these activities continue to this day. However, the concept of Lean did not resonate in this country.*

WHY HAS IT BEEN HARD TO COLLABORATE WITH JAPAN SO FAR?

As part of the catch-ball process, the authors of this paper identified several difficulties in establishing deeper connections with Japan and pointed out some directions, summarized below.

***[W]** Understanding the research, business, and cultural context of construction in Japan has proven to be challenging. We need more "conduits" like the professors who already attend the IGLC conferences. There is also this language barrier, as only a few works have been published in English. We also need more research projects with set targets and budgets for collaborations with Japan. It is difficult to obtain funds, at least in the UK, focusing on Lean Construction from traditional research funders. Japanese business organizations could be more active in that regard. Due to the lack of engagement of Japan with the global Lean Construction community until now, Japan is seen as a "no Lean Construction zone" by many.*

WHAT COULD JAPANESE CONSTRUCTION LEARN FROM LEAN CONSTRUCTION?

Towards the wrap-up, the Japanese players reflected on the opportunities to take the good parts of the Lean Construction to further improve their so far tacit approach.

***[J₁]** By learning sophisticated "philosophy" and "methods" that are easy to understand for practitioners and putting them into practice. Lean Construction could be used to make explicit what is done implicitly.*

***[J₂]** Key aspects: (1) Respect for people: It is critical to have conduct guidelines for practicing it. In Japan, there is a tendency to appraise value delivery through self-sacrifice, which has hindered the ability to respect individuals. The concept of "humility", which is admired by foreigners, may intersect with this issue. (2) Logification and verbalization: Japan has struggled with formalizing and articulating systems. The ability to turn tacit knowledge into explicit knowledge is an urgent social matter. (3) Simplifying building structures and working with margins: In Japan, there is also a tendency to favor processes with "no gaps" or minimal downtime. Adopting a mindset that allows buffers could enable smoother processes and more flexibility. (4) Roles: Setting new roles with unique skills, such as coaching and facilitation, have become necessary to implement Lean. Practical examples from overseas could provide valuable insights.*

***[J₃]** I want to learn the concepts and examples of Lean Construction held overseas first. As of now, I cannot provide any definitive insights as I am not well-versed in this area.*

Finally, the authors of this paper provide their perspective on this matter.

***[W]** Japanese construction is well-known for completing projects to a high standard and adhering strictly to the schedule, which may require employing additional resources, working extended hours, or investing in more technologies. To avoid overburden (muri), the Western construction industry has been focusing on health, safety, and well-being. These aspects could be transferred into the Japanese approach. Besides, Lean Construction techniques, such as the Last Planner System, Takt Planning, and Location-Based Planning could be of interest to Japan. Lean design and engineering (beyond construction) could also be new for the Japanese context. Above all, we need to go to the gemba and see what we can offer.*

WHAT COULD THE LEAN CONSTRUCTION MOVEMENT LEARN FROM THE CURRENT JAPANESE CONSTRUCTION MANAGEMENT METHODOLOGIES?

The answer is more about put light on what exists but has not been revealed thus far.

> ***[J₁]*** *Lean Construction could add new methods, such as sound planning and execution resulting from the excellent cooperation between main and subcontractors, by (re-)interpreting Japanese Kenchiku Seisan.*

> ***[J₂]*** *Key aspects: (1) Management techniques such as "shisa-koshō (literally pointing and calling)" and the daily meetings. (2) The highly organized site operation routine for quality, safety, and hygiene management in close cooperation with the subcontractor' foremen. (3) While it may not necessarily be considered a positive aspect, Japanese companies can complete construction work quickly. On the other hand, it might require a significant number of workers and extended working hours before its completion.*

> ***[J₃]*** *Overseas companies tend to be more litigious and have documentation excesses as a defensive management approach. Consequently, the cost of construction guarantees from insurance companies is significantly. By offering "full turnkey" solutions, Japanese General Contractors take comprehensive control and spend less with those kinds of issues. Additionally, General Contractors have advanced in construction technology development, providing solutions such as "composite construction methods (fukugōka kōhō)" and "reverse construction methods (sakauchi kōhō)" that I have not heard about out there. However, due to fundamental cultural differences, it is challenging to make direct comparisons.*

Like in the prior question, the authors provide their perspective on this matter too.

> ***[W]*** *Japan seems to have implemented innovative management practices, drawing inspiration directly from the source, that is, the Toyota Production System. Rather than simply adopting techniques from a toolbox, Japanese-style management returns to the fundamental concepts that underpin these practices. Many overseas organizations, however, implement different tools without considering fundamental concepts, which can affect results. By prioritizing a deep understanding of the underlying theory and principles, overseas organizations may be able to develop a more holistic approach. Also, new management techniques from Japan can be added to the Lean Construction arsenal. Recently, for instance, a large design consultancy company in the UK introduced ji-kōtei kanketsu, which became very successful.*

DISCUSSION: LESSONS FROM ABROAD

There are two main lessons from which Japan could take advantage when organizing itself regarding Lean Construction's future directions. (1) The role of dynamic ecosystems in the birth and expansion of the Lean Construction movement; and (2) The presence of heavy-weight champions who actively developed "conduits" leaders. The importance of the Californian ecosystem can be recognized in the intertwined biographies of exponents of this subject.

The "*Festschrift honouring Dr. Glenn Ballard*" (see Koskela et al., 2022) reports the story of a "maker at heart" who gained first-hand experience as a field worker on-site and then broke through to managerial positions and gradually transitioned from industry to academia. His collaboration with Gregory Howell, Lauri Koskela, and Iris Tommelein gave him access to widen his connections and enable enriching exchanges with construction companies, industry organizations, and Universities, where he met field workers, executives, notable professors, and students, each contributing to the development and maturation of innovative ideas.

This part of the history is also found in the inspiring first-person narrative of Iris Tommelein in her "*Journey Toward Lean Construction*" storytelling (see Tommelein, 2015). Colleagues from multidisciplinary backgrounds, encouragements to "go to the gemba" as an academic, the transit between lively Universities, the field experience in a Sabbatical, and the establishment and direction of a dynamic research laboratory (PS2L) with strong ties with the industry were contributing factors to enriching the path of a champion that transmitted the knowledge to talented students who have helped conduct the paradigm shift in the AEC industry.

Moving the focus to Scandinavia, Lohne et al. (2022) narrated the "*Emergence of Lean Construction in Norway*", which, as they said, was a phenomenon occurring within a setting that is generally advantageous but also following an effort carried out on several levels. The specificities of the Norwegian context included, for instance, the early experimentation by its largest contractor (Veidekke), the formal introduction of Lean Construction in the academic curriculum, and publication by authors from industry, universities, and research institutions. The appointment of Glenn Ballard as an adjunct professor at NTNU was also emphasized.

Going to a specific case, Elving (2022) narrated "*A Decade of Lessons Learned*" at Skanska Finland, pointing out what worked and what did not work in taking academic concepts to industry. The advice from Glenn Ballard was again highlighted. In the case of experimenting with the Last Planner System implementation, he emphasized the significance of industry-level approaches and technology platforms to logistics and supply development.

Clients and asset owners have also played an important role in the Lean Construction ecosystem. In the UK, for instance, National Highways' Lean Construction agenda has driven application in their supply chain (NH, 2020). In the US, Sutter Health has been a large client organization demanding Lean Construction application, recognized by the LCI for "moving the industry forward in embracing and implementing Lean tools on capital projects (LCI, n.d.)".

Regarding the heavy-weight champions, beyond his own contributions to the Lean Construction discipline through the TFV theory, Lauri Koskela also nurtured pupils who have made remarkable contributions. To name a few, Sergio Kemmer has been a successful consultant to a range of company sizes and regions. Bhargav Dave has led a startup whose core product emerged from PhD research. Daniel Forgues and Algan Tezel have contributed from an academic position while building ties with the industry. Indeed, some champions have industry backgrounds. Sven Bertelsen (Denmark) and Dean Reed (US) are notable examples who observed and participated in the evolution of the Lean Construction movement.

It is also worth noting the successful stories from South America, personified by Prof. Carlos Formoso (Brazil) and Prof. Luis Alarcón (Chile), who not only actively promoted the Lean Construction agenda, but also taught key figures who are now spread all over the world in both academia and industry. The Southern Hemisphere could be an inspiration to the East. As a limitation, this paper does not cover many other exponents deserving acknowledgment spread in various locations. Many more could also provide insights for advancing Lean in Japan.

During Japan's rapid economic growth period, in the second half of the last century, quality issues demanded innovative solutions. Such a context relates to the project ordering system in which General Contractors control the whole process and take massive responsibility. By then, instead of applying Lean as we know it today, the idea was to merely "build things that do not turn out into problems". Because of such strong customer orientation, it turned out that the physicality of buildings and the processes required to erect them became complicated.

In that context, the solutions created to tackle those challenges had an earnest technological emphasis, developing "hard technologies" to enable the so-much-aspired rationalized construction processes and other "soft" management goals. The *fukugōka kōhō* (Shigaki & Yashiro, 2023) and *sakauchi kōhō*, strategies not widespread overseas, are expressions of their unique engineering strength, which are partially the result of well-structured R&D Institutes and excellent in-house designers. That was chronologically before the emergence of the Lean Construction movement in the West and has since developed independently. The takeaway from those experiences was the attempt to create solutions that help organize the entire business in a way that benefits the owner. Such an attitude reflects the Japanese "culture of matching".

Intriguingly, Japan has developed Lean-ish ideas as part of quality management efforts but has not formalized Lean Construction as a platform for improvement in the delivery of projects. Studying from foreign examples, a proper curriculum in architectural and civil engineering education would possibly help accelerate the process of converting tacit knowledge into know-how that could be more easily transmitted to next-generation practitioners. Currently, the AIJ has no active committee to discuss Lean Construction. Neither has the influential *Nikkenren* (Japan Federation of Construction Contractors) a working group on this topic. The next IGLC could be a trigger to move forward.

CONCLUSION

The testimonials confirmed that Japanese construction has elements of Lean ingrained in routine practices. However, they have not been deployed as formal Lean Construction methods as known in the IGLC community. Through the preliminary but engaging dialogue between Lean theorizers and Japanese construction practitioners, the paradoxical gap between them has started to be filled. The continuity of such exchange could trigger innovations that bridge and eventually unite excellent partial solutions.

As a next step, Japanese constructors have aspired to pull their engineering strength to the next level and combine it with innovative management practices, including incorporating good ones learned from overseas. That is where the role of Lean resides. Lean may help fill the gap of converting tacit knowledge into structured knowledge, increasing transparency, smoothing the transmission of know-how to business partners (externally) and young employees (internally), creating more efficient project deliveries, and turning itself into a more attractive business. They aspire to nurture talented people who "generate maximum value by creating works that amaze", powered by individual ingenuity and collective rationality.

ACKNOWLEDGMENTS

The authors would like to thank all participants for their support in this investigation.

ASSESSING SOCIAL, TECHNICAL, AND OPERATIONAL MATURITY DIMENSIONS FOR DIGITAL TRANSFORMATION IN THE CONSTRUCTION PHASE

Luara L. A. Fernandes[1], Makarand Hastak[2] and Dayana B. Costa[3]

ABSTRACT

The importance of digital transformation (DT) has risen significantly in the past few years in several industry sectors, including construction. Some potential benefits of DT in construction include improvements in productivity, efficiency, safety, quality, and collaboration. However, fully embracing DT opportunities involves committed efforts in Key Project Areas (KPAs), and identifying these areas is still challenging. Therefore, this work aims to assess social, technical, and operational maturity dimensions for digital transformation in the construction phase. These dimensions are the KPAs construction managers should focus on throughout the construction environment DT process. A questionnaire was administered to 54 construction professionals from industry and academia. Data collected was analyzed using ranking analysis from the Relative Importance Index (RII) calculation. Results revealed that the participants did not rank technical aspects as the most significant; rather, these aspects were regarded with slightly less importance than other dimensions. The balance among social, technical, and operational factors in the ranking indicates that construction professionals recognize the insufficiency of technology implementation alone for driving significant changes; instead, human resources must lead the process improvement with the support of digital technologies. These findings align with Industry 5.0 and Lean Construction concepts, reflecting some synergies between them.

KEYWORDS

Digital transformation, Construction phase, Industry 5.0, Lean construction.

INTRODUCTION

Digital transformation has become a high-priority agenda theme for organizations and governments due to its competitive advantage in many sectors, including construction (Zomer et al., 2019). According to Tilson, Lyytinen, and Sorensen (2010), digitalization is "a sociotechnical process of applying digitizing techniques to broader social and institutional contexts that render digital technologies infrastructural." It is a deep transformation of business

activities, processes, competencies, and models to embrace the changes and opportunities offered by digital technologies and their influence across society (Demirkan et al., 2016).

The emergence of Industry 4.0 in the construction industry (Construction 4.0) seeks to transform it towards digitally developed businesses (Alaoul et al., 2018). The industry definition of Industry 4.0 for construction encompasses several interdisciplinary technologies and concepts that enable the digitization, digitalization, automation, and integration of the construction process at different phases (Oesterreich & Teuteberg, 2016). González et al. (2022) presented the novel concept of Lean Construction 4.0, a Process-People-Technology Functional Model based on the idea that Lean Thinking can be the steppingstone for an effective adoption of IR 4.0 in construction. According to this approach, IR 4.0 technologies can potentially eliminate or reduce any of the seven Lean wastes identified originally by Shingo et al. (2005) and Taiichi (1988), while Lean Thinking supports eliminating waste and adding value, supporting a solid and efficient Industry 4.0 development and implementation.

In 2020, the concept of Industry 5.0 was launched to address challenges faced by environments under Industry 4.0 transformations, such as lack of resilience, insufficient attention to sustainable production approaches, and overemphasis on technology (Olah et al., 2020; Sindwani et al., 2022; Zizic et al., 2022). Industry 5.0 advocates balanced human-machine cooperation focusing on the diverse stakeholders' well-being (i.e., society, companies, human resources, and clients) (Noble et al., 2022). The application of Industry 5.0 in construction is still in its early stages.

According to Sony and Naik (2020), human-machine collaborations should be guided by the sociotechnical transformation. The sociotechnical systems approach concentrates on incorporating technology into the work system rather than focusing mainly on technology (Sackey et al., 2015). It is based on the observation that a successful technology implementation involves fully understanding the organizational context (structure, work, and workforce) (Sackey et al., 2015). While the original approach (Trist, 1981) describes a sociotechnical system as a combination of the social and technical subsystems, Vlachos et al. (2021) add the operational system, which, according to Fernandes and Costa (2024), is more suitable for construction environments.

Furthermore, incorporating digital technologies into construction environments can enhance productivity, safety, quality, and project management (Maskuriy et al., 2019). However, Joppen et al. (2019) highlight the challenges of measuring these transformations. Even though many analyses describe changes due to digital transformation, the instruments for recording them with the support of indicators are still poorly discussed (Joppen et al., 2019). Unlocking the advantages of technological advancement involves understanding how these transformed processes should be assessed and managed using assessment tools such as maturity models (Kloviene & Uosyte, 2019). In addition, to fully embrace IR 4.0 opportunities, managers should devise a strategy focused on Key Project Areas (KPAs) (Maskuriy et al., 2019). Nevertheless, identifying these KPAs remains challenging, and the existing literature still needs to explore this gap further. Considering a new sphere of knowledge, it is not possible to identify them only from the literature, and exploratory research methods, such as case study interviews (De Bruin et al., 2005), surveys, and on-site immersions, should be considered in this process.

Therefore, this work assesses social, technical, and operational maturity dimensions for digital transformation in the construction phase. These dimensions are the KPAs that need to be measured and managed throughout DT in the construction phase. This paper presents one stage of broader research in the context of a Ph.D. thesis, which aims to propose a Maturity Measurement System for an Intelligent Construction Environment, positioning the construction industry in the digital transformation path from a sociotechnical perspective. The first product of the Ph.D. work was a conceptual model for measuring the maturity of digital transformation in the construction phase (Fernandes & Costa, 2024). This model introduced 24 maturity dimensions (categorized into sociotechnical subsystems), which are the critical aspects construction managers should focus on and manage throughout the digital transformation process of the construction environment. The assessment of these dimensions is presented in this paper. The model is further presented in the Literature Review section.

This work's primary practical contribution is a preliminary proposition of measurable domain areas essential for continuous improvement, assessed in terms of importance, which directs construction projects toward an Intelligent Construction Environment. Theoretical contributions include insights into the challenges the Industry 4.0 technology-centric approach poses, potentially hindering the proper integration of these advancements into the construction sector. Additionally, the study explores the role of Industry 5.0 principles in this context and their potential synergies with Lean Construction concepts.

THE SOCIOTECHNICAL APPROACH IN THE DIGITAL TRANSFORMATION CONTEXT

A system is a social construct encompassing several relationships between elements expressed differently (Patriarca et al., 2021). Emery and Trist (1960) originally used the term "sociotechnical system" (STS) to describe systems that involve a complex interaction among humans, machines, and the environment in the work system. This approach considers that a change in one part of the system will lead to changes in other parts (Sony & Naik, 2020).

In the digital transformation context, Sony and Naik (2020) point out that, in addition to the integration of the cyber and physical domains through technology, Industry 4.0 is also a social (human-related) and technical (non-human-related) system. The sociotechnical approach unveils new opportunities for prompt development based on recognizing the importance of human work in the innovation process (Kagermann et al., 2013). According to Hirsch-Kreinsen et al. (2018), Industry 4.0, from a sociotechnical perspective, comprises the subsystems of technology, organization, and people and the interface among them. Patriarca et al. (2021) present the evolution of a sociotechnical system toward a Cyber-Socio-Technical System (CSTS). The CSTS extends to the social relations between humans and cyber artifacts and the collaboration of multiple cybernetic artifacts (Patriarca et al., 2021).

Furthermore, Vlachos et al. (2021) present a sociotechnical system as a combination of social, technical, and operational subsystems, more apparent in lean automation implementations. Fernandes and Costa (2024) designed the construction environment under digital transformation based on this three-subsystems concept, which is composed of the following elements: human resources, culture, digital technologies, work infrastructure, production processes, and performance.

DIGITAL TRANSFORMATION IN CONSTRUCTION

Digitalization is revolutionizing several construction processes, including planning, designing, constructing, operating, and maintaining structures (Ozturk, 2021). Forcael et al. (2020) point out that the pillars of Construction 4.0 are the digitalization of the construction industry and the industrialization of construction processes. According to Sawhney (2020), Construction 4.0 is a framework that is a confluence and convergence of the following areas:

- Industrial production – Prefabrication, 3D printing and assembly, and offsite manufacturing.
- Cyber-physical systems – Robots and cobots (collaborative robots) for repetitive and dangerous processes, drones for surveying and lifting, movement and positioning, and actuators.

- Digital technologies – BIM, video and laser scanning, IoT, sensors, AI and cloud computing, big data and data analytics, reality capture, blockchain, simulation, augmented reality, data standards, interoperability, and vertical and horizontal integration.

While the term Construction 4.0 straightforwardly applies the Industry 4.0 concept in the Construction Industry, Fernandes and Costa (2024) argue that digital transformation in construction environments should be driven by Industry 4.0 and Industry 5.0 principles. These authors presented the concept of an Intelligent Construction Environment as "an efficient, resilient, human-centered, and sustainable environment composed of a complex sociotechnical system that uses digital technologies as tools for continuous improvement (Fernandes & Costa, 2024). According to this study, its elements dynamically interact to achieve the following principles: Human centricity, Flexibility, Resilience, Transparency, Collaboration, Decentralization, Virtualization, Horizontal and vertical integration, Real-time capability, Sustainable management, Predictive capacity, and Interoperability.

Fernandes and Costa (2024) also presented 24 social, technical, and operational dimensions to measure the maturity of digital transformation in construction environments in the construction phase (Figure 1). These dimensions are the critical aspects construction managers should focus on and manage throughout the digital transformation process of the construction environment. The dimensions proposed are as follows:

- Social subsystem: Coordination, Sustainability, Innovation, Training, Participative decision-making, Communication, Occupational health and safety, and Promotion of formal education.
- Technical subsystem: Digital technology implementation and management, Development and maintenance of digital solutions, Collection, storage, processing, analysis, and management of massive and complex data, Data Security, Robots and cobots, Construction site layout, and Workspace.
- Operational subsystem: Complexity management, Production planning and control, Storage and logistics management, Timely prediction, Supply chain management, Quality management, Performance management, Cost reduction, and Timely action.

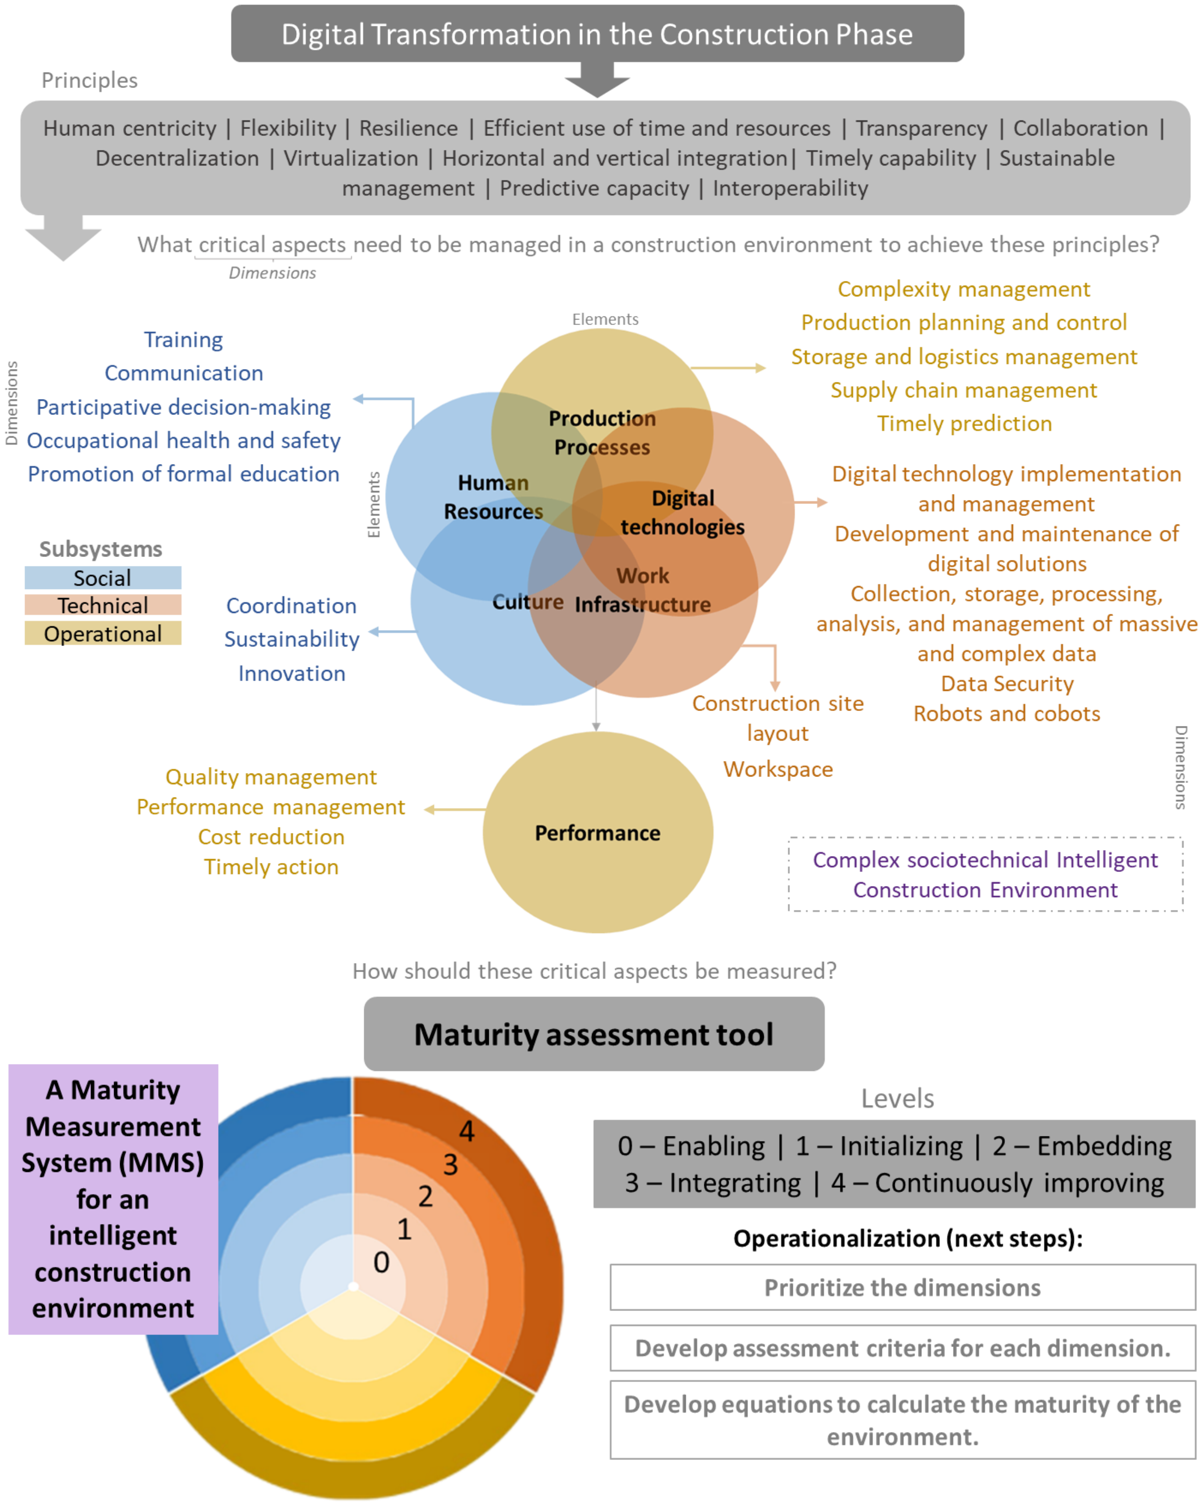

Figure 1 – The conceptual model for measuring the maturity of an Intelligent Construction Environment (Source: Fernandes and Costa, 2024).

The definition of each of these dimensions is presented in Fernandes and Costa (2024).

RESEARCH METHOD

The methodological approach adopted in the development of this study was a survey, which consists of a data collection procedure from a sample of individuals through responses to questions (Check & Schutt, 2012). The data collection instrument used was a questionnaire, and the sample was composed of construction management professionals from industry and academia. The survey aimed to assess the maturity dimensions proposed by Fernandes and Costa (2024) in terms of importance. Thus, the research team required the participants to answer the following question: "On a scale from 1-10, what weight should these dimensions have in their respective subsystems for assessing the maturity of an Intelligent Construction Environment?".

DATA COLLECTION

The study's development initially involved designing a structured questionnaire in the Google Forms platform. It consisted of 5 sections, which are the following: (a) Cover letter, including the research purposes and the definition of an Intelligent Construction Environment, and agreement terms; (b) Respondent profile, including major, occupation area, position, affiliated organization/university, and highest degree attained, (c) Social Dimensions, (d) Technical Dimensions, and (e) Operational dimensions. In the three last sections, the respondents were required to assign a weight from 1 to 10 to each dimension, according to the following degree of importance: 1-4 - Low Importance, 5-7 - High Importance, 8-10 – Essential. In addition, participants could also propose adding or removing dimensions and share notes or comments through open-ended questions. The instrument was tested with the GETEC (Research Group in Construction Technology and Management) research group on January 26, 2023. The pilot application involved 15 people, including 3 Ph.Ds., 3 MSCs, 1 Civil Engineer, and 8 Undergraduate Students (Civil and Electrical Eng.), and it was aimed at evaluating the understanding of the questions and the response time.

Then, the questionnaire was sent in English and Portuguese by e-mail to a list of 50 potential respondents from Industry and Academia. Then, after two weeks, the questionnaire was disseminated through LinkedIn, with the aim of engaging additional relevant members not initially included in the email list and to serve as a reminder for those who had received the email but did not respond. The intended participants were professionals in civil engineering and architecture from industry and academia. It was initially shared on August 4th, 2023, and remained collecting responses until September 1st, 2023.

A total of 55 responses were obtained - 43 from the Portuguese (Brazilian respondents) and 12 from the English form (Respondents from Denmark, India, Chile, Colombia, Portugal, South Africa, and the United States), of which 54 were considered valid because one was identified as a duplicate. Eight of the 54 respondents were not initially included in the email list.

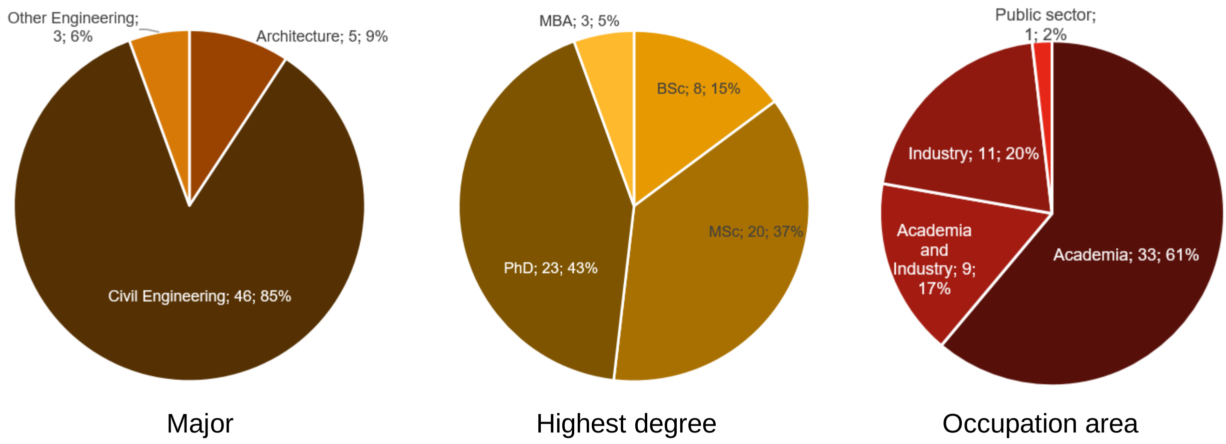

Figure 2 – Characterization of the respondents

DATA ANALYSIS

Data analysis first involved the calculation of Cronbach's alpha, denoted as Cα, a reliability coefficient. It was developed by Lee Cronbach in 1951 to measure the internal consistency of a test or scale (Tavakol & Denik, 2011). Internal consistency refers to the degree to which all items in a test measure the same concept, indicating the interconnectedness of test items, while reliability quantifies the extent of measurement error in the test (Tavakol & Denik, 2011). Cronbach's alpha is mathematically defined as the adjusted proportion of total variance of item scores explained by the sum of covariances between item scores, ranging from 0 to 1 when all covariance elements are non-negative (Heo et al., 2015). A higher Cronbach's alpha (Cα), approaching 1, indicates greater reliability. The following reliability scale (George & Mallery, 2003) was adopted in this work:

$\alpha \geq 0.9$ Excellent

$0.9 > \alpha \geq 0.8$ Good

$0.8 > \alpha \geq 0.7$ Acceptable

$0.7 > \alpha \geq 0.6$ Questionable

$0.6 > \alpha \geq 0.5$ Poor

$0.5 > \alpha$ Unacceptable

The Cronbach's alpha (Cα) was calculated in the SPSS software, resulting in a value of 0.901, which indicates excellent reliability.

Subsequently, data were analyzed using ranking analysis from the Relative Importance Index (RII) calculation. It is a non-parametric technique for analyzing structured questionnaire responses (Chung et al., 2021). The RII ranges from 0 to 1, enabling the identification of the most influential factors within a given set (Watfa et al., 2022). It has been widely employed in assessments of construction-related research and technology adoption drivers (Watfa et al., 2022). The dimensions' RIIs were calculated using the following equation:

$$\text{Relative Importance Index (RII)} = \frac{\sum W}{A \times N}$$

Where:

W = the weight assigned by the respondents to each dimension.

A = the highest weight that could be assigned.

N = the total number of respondents.

The data were converted to a Likert scale (1-5) to simplify the calculation process. The importance scale adopted to analyze the RIIs was the following (Chung et al., 2021):

High ($0.8 \leq RII \leq 1.0$),

High-Medium ($0.6 \leq RII < 0.8$),

Medium ($0.4 \leq RII < 0.8$),

Medium ($0.2 \leq RII < 0.4$),

Low ($0 \leq RII < 0.2$).

The findings obtained are presented in the next section.

FINDINGS

Table 1 summarizes the list of dimensions, with the respective subsystem, percentage of answers in each level of importance, the correspondent RII, and rank. The dimensions' RII values ranged from 0.652 to 0.956, classifying all dimensions with a high (87,5%) or high-medium (12,5%) importance level. The dimension "Communication" was ranked as the most important, followed by "Training" and "Production Planning and Control." These three dimensions were the only ones with an RII exceeding 0.9. Notably, none of these dimensions are technical, suggesting that the respondents do not prioritize technical aspects as the most crucial factors, indicating an alignment with Industry 5.0 principles.

Table 1 – Ranked dimensions.

Dimension	Subsystem	% of answers in each level of importance			RII	Rank
		(1-4)	(5-7)	(8-10)		
Communication	Social	0.00%	1.85%	98.15%	0.956	1
Training	Social	0.00%	9.26%	90.74%	0.933	2
Production planning and control	Operational	0.00%	14.81%	85.19%	0.933	2
Digital technology implementation and management	Technical	0.00%	16.67%	83.33%	0.896	4
Data Security	Technical	1.85%	20.37%	77.78%	0.896	4
Quality management	Operational	0.00%	16.67%	83.33%	0.896	4
Workspace	Technical	3.70%	22.22%	74.07%	0.881	7
Performance management	Operational	1.85%	16.67%	81.48%	0.881	7
Innovation	Social	0.00%	24.07%	75.93%	0.874	9
Timely action	Operational	1.85%	18.52%	79.63%	0.867	10
Supply chain management	Operational	5.56%	14.81%	79.63%	0.863	11
Development and maintenance of digital solutions	Technical	0.00%	37.04%	62.96%	0.859	12
Storage and logistics management	Operational	3.70%	22.22%	74.07%	0.859	12
Timely prediction	Operational	3.70%	27.78%	68.52%	0.856	14
Occupational health and safety	Social	3.70%	27.78%	68.52%	0.852	15
Collection, storage, processing, analysis, and management of massive and complex data	Technical	1.85%	29.63%	68.52%	0.852	15
Cost reduction	Operational	3.70%	27.78%	68.52%	0.844	17
Coordination	Social	3.70%	33.33%	62.96%	0.837	18
Construction site layout	Technical	3.70%	38.89%	57.41%	0.83	19
Participative decision-making	Social	5.56%	33.33%	61.11%	0.826	20
Sustainability	Social	5.56%	29.63%	64.81%	0.822	21
Complexity management	Operational	7.41%	40.74%	51.85%	0.785	22
Promotion of formal education	Social	11.11%	42.59%	46.30%	0.774	23
Robots and cobots	Technical	20.37%	57.41%	22.22%	0.652	24

Following them, the dimensions “Digital technology implementation and management,” “Data Security,” and “Quality management” share the fourth position. This alignment suggests that managers recognize the significance of protecting data, which encompasses preventing unauthorized access, using and disclosing stored information, and ensuring data privacy. Managing this aspect is crucial, especially considering that it is one of the foremost concerns associated with the progression of digital technologies in workspaces.

It is worth highlighting that among the top 9 dimensions, there are three of each subsystem (social, technical, and operational). Even if a "hypothetical" RII is calculated for the subsystems, based on the respondents' average weights assigned to dimensions within each subsystem, similar values are found among them: 0.830, 0.822, and 0.837 for the social, technical, and operational subsystems, respectively. This symmetry suggests that equal importance is given to social, technical, and operational aspects of the digital transformation process. It implies a recognition that effective management and successful outcomes in this context require a holistic consideration of not only technological factors but also social and operational features.

Nevertheless, the dimension "Robots and cobots" was ranked as the least important, followed by "Promotion of formal education" and "Complexity management." These were the only dimensions with an RII lower than 0.8. The lower RII was attributed to "Robots and cobots," which may be related to the construction sector's resistance to the replacement of human labor by technologies in production, as presented in Fernandes and Costa (2024), coupled with concerns about the potential financial impacts associated with such changes. Regarding the "Promotion of formal education," one respondent emphasized that the education dimension should prioritize pursuing learning opportunities over attaining a degree, considering the latter is not necessarily essential. Several respondents argued about the meaning of "Complexity management," which potentially influenced its assigned weight and contributed to the low RII of this dimension.

In response to open-ended questions, participants provided various additional comments. In the **social subsystem section**, the main suggestions involved the inclusion of dimensions related to mental health, strategy, transparency, and governance. It was also proposed addressing elements such as cultivating a culture of exchanging experiences among employees, establishing a non-judgmental environment, and relocating sustainability and participative decision-making from the operational (construction site) to the organizational level, suggesting that the latter two aspects should be strategically addressed at a broader organizational scale.

In the **technical subsystem section**, some respondents suggested that layout and workspace should be addressed as a single dimension, while others suggested a construction site dimension including all these aspects. Others recommended repositioning social dimensions, including occupational health and safety and communication, within the technical subsystem to align these aspects more closely with the technology and workspace dynamics. One participant suggested ensuring the accessibility of digital tools for workers across all hierarchical levels.

In the **operational section**, most comments were related to the dimensions "Cost reduction" and "Complexity management." Respondents argued that the emphasis should not be on cost reduction but on effective cost management, acknowledging that digital transformation may demand initial short-term increases. Regarding "Complexity management," several participants argued the meaning and purpose of this dimension, which implies that complexity studies in construction are still not properly disseminated, and the term is still not familiar among both industry and academic professionals. However, other respondents suggested that all the other dimensions already cover its aspects. One respondent emphasized that the most significant opportunities for improvement within the operational subsystem lie in this dimension, as traditional approaches already address time, cost, schedule, and quality concerns. Moreover, some participants suggested consolidating "Timely prediction" and "Timely action" into a single dimension, arguing the interdependence of these aspects.

DISCUSSION

In the past few years, the upsurge and fast dissemination of Industry 4.0 concepts and technologies have triggered several debates regarding applying these novelties in construction. It is already a consensus that this industry is behind in adopting these features, which can be attributed partly to its inherent characteristics, artisanal nature, heavy reliance on human labor, and the intrinsic complexity of its production environments. However, the IR 4.0 excessive focus on technology is also an obstacle to integrating these advancements into the construction sector. Fernandes and Costa (2024) argued in their study that digital transformation in construction must be driven by IR 4.0 and IR 5.0 principles, and the findings of this survey align with this perspective.

The results of this study revealed that the participants did not prioritize technical aspects. Instead, these aspects were regarded with slightly less importance than other dimensions. More specifically, none of the top three ranked dimensions (the only ones with an RII higher than 0.9) were technology-related; the first two were social dimensions related to human resources, while the third was an operational dimension concerning the production process element. Moreover, the balance among social, technical, and operational aspects in the rank suggests that construction professionals recognize that technology implementation by itself is not enough to promote significant changes; instead, human resources must lead the process improvement with the support of digital technologies.

Part of this awareness can be attributed to the construction industry's extensive journey in studying and implementing the principles of the lean production philosophy, which emphasizes people engagement, learning, and leadership, from shop-floor workers to managers, in process improvement. In fact, Lean Construction and Industry 5.0 share core values. For Mladineo et al. (2021), Lean management can be seen as an Industry 5.0 enabler. According to Faisal et al. (2024), combining these concepts may enable a cost-effective, sustainable, and efficient production system that enhances worker capabilities by optimizing productivity and minimizing waste.

The synergies between Lean management and Industry 5.0 principles (human centricity, resilience, and sustainability) have been individually explored in some studies. Solaimani and Sedighi (2020) identified that lean construction positively impacts all three pillars of sustainability in construction projects. Hamerski et al. (2023) pointed out that the Last Planner System, despite some limitations, can contribute to a resilience performance in construction. Mladineo et al. (2021) showed that most key success factors of Lean management and Lean tools implementations in SMEs are people-oriented, reflecting the human-centric approach to organizational and process improvement, as required by Industry 5.0. Nevertheless, these synergies have not been studied directly and holistically yet, which suggests an interesting gap to be explored in future works.

CONCLUSION

This work aimed to assess social, technical, and operational maturity dimensions for digital transformation in the construction phase. For that, it presented the results of a survey questionnaire administered to 54 construction professionals from both industry and academia. Data analysis involved ranking the dimensions by calculating their Relative Importance Index (RII) from the weights assigned by the respondents. Results show that technical dimensions were not ranked as the central ones, and the outcomes indicate an equilibrium among the importance of social, technical, and operational factors for digital transformation in the construction phase. Findings align with Industry 5.0 and Lean Construction concepts, indicating synergies among them. Although these synergies have been individually explored in some studies, they have not been studied directly and holistically yet, which suggests an interesting gap to be explored in future works.

This work is one of the stages in the development of a Ph.D. thesis, which aims to propose a Maturity Measurement System for an Intelligent Construction Environment. The findings presented in this paper support the assignment of weights and refinement of maturity measurement dimensions, which is the initial step in transforming the proposed conceptual model (Figure 1) into a practical tool—the Maturity Measurement System (MMS). Future steps involve (a) the proposition and validation of assessment criteria and equations to measure the maturity in each dimension, subsystem, and overall environment and (b) the application, test, and validation of the MMS, with subsequent guidelines for implementation.

A CRITICAL ANALYSIS OF CHOOSING BY ADVANTAGES IMPLEMENTATION IN THE TENDERING PROCEDURE BASED ON EU DIRECTIVE AND GERMAN LEGISLATION

Annett Schöttle[1] and Fabian Behme[2]

ABSTRACT

The Choosing by Advantages (CBA) Tabular method is a decision-making method that differentiates between alternatives based on the importance of advantages. By doing so, cost-related factors are excluded from the table to better understand the value of each alternative. After evaluating the value, the cost/price of each alternative is analyzed in relation to the value. This is a crucial rule to avoid overestimating cost/price and underestimating the value of an alternative. In the public tendering procedure, price is usually the only factor or the main factor used to decide between proposals. As other authors have already pointed out, this leads to speculative bidder behavior that might be rewarded. Using CBA requires a change in thinking, but it will be beneficial in truly understanding the differences between proposals. Therefore, this paper examines the use of CBA in the tendering procedure based on EU Directives and German legislation. It was found that it is possible to implement CBA in the current tendering procedure without violating the principles of CBA. However, the adjustment needed to apply CBA within the current regulations clearly goes against what CBA intends. Therefore, we suggest changing the current reactive tendering procedure to an active decision-making process. This paper does not provide a final answer but aims to open the discussion.

Choosing by Advantages (CBA), legislation, public, tendering.

INTRODUCTION

Can a tendering procedure for large projects be fair based on price alone? In many projects, there is a tendency to prioritize the lowest price, or if other factors are considered, the price is given significantly more weight. This makes it difficult to understand the differences between proposals and creates room for speculation to win bids. Rosenfeld (2014) refers to these unrealistically low tender-winning prices as "suicide tendering." So, what happens when someone is contracted under these conditions? Over the years, numerous authors have already pointed out that competition based solely on price often leads to disputes and claims during project execution, creating an unhealthy project organization where the project ultimately suffers (e.g., BMVI, 2015; Elfving, 2005; Eriksson & Laan, 2007; Rosenfeld, 2014; Rooke, 2014; Schöttle & Gehbauer, 2013). However, public tendering has not undergone significant changes yet; the transactional approach still dominates the public system and is based on a

misguided focus. Instead of focusing on project requirements and needs, the emphasis shifts to monetary transactions. Each tender partially sets the tone for the project because it represents the initial interaction between the owner and the contracted parties (Schöttle, 2022). The parties' behavior during the tendering procedure will ultimately impact the project execution. So, how can we improve the tendering procedure?

We believe that a tendering procedure based on a fair evaluation of proposals is essential, meaning an established method such as Choosing by Advantages (CBA) needs to be applied. The benefits of CBA in the tendering procedure were first mentioned by Schöttle et al. (2017). They explained that traditional methods, such as weighted sum, have two major issues. First, by mixing value with price/cost, they open the door for speculation. Second, it becomes difficult to differentiate between proposals when factors are the primary focus. Suhr (1999) refers to this as unanchored judgment and highlights the danger that arises from overestimating insignificant facts and underestimating significant ones. Both issues were further discussed by Schöttle and Arroyo (2017). They illustrated the magnitude of the price impact compared to other information and how irrelevant information influences decision-making.

We acknowledge that this is only one aspect of the overall procedure. However, this paper aims to enhance the evaluation of proposals, improve the differentiation between them, and select the best opportunity for the project. Therefore, the research question is: How can CBA be applied in the public tendering procedure in Germany?

With this in mind, we are not focusing on a specific delivery system. The proposed approach can be implemented in both traditional delivery settings and more collaborative approaches. Of course, a more collaborative approach already includes a different mindset as it involves selecting partners rather than just contractors. Implementing CBA in a traditional tendering procedure, however, offers owners a chance to better understand their expectations and the value at stake. We argue that this will change the owner's attitude toward task and risk transfer. Therefore, based on the EU Directive, this paper will demonstrate if and how CBA can be applied in the German public tendering procedure without violating the method. This will not only provide German public owners with a guideline but also offer guidance to other EU members and countries worldwide facing similar challenges.

Consequently, we will first introduce CBA and the prior anchoring procedure proposed by Suhr (1999). Second, we will explain the EU Directive and German legislation as the foundation for the tendering procedure. Then, we will outline the research method, discuss the findings from the focus groups, and conclude.

CHOOSING BY ADVANTAGES TABULAR METHOD WITH THE PRIOR ANCHORING PROCESS (PAP)

CBA is a decision-making system that compares alternatives by analyzing the importance of the advantages (Suhr 1999). The system is based on the following four principles: (1) decision-makers must learn and skillfully use sound decision-making methods; (2) decisions must be based on the importance of the advantage; (3) decisions must be anchored to the relevant facts, and (4) different types of decisions call for different sound methods of decision-making.

The comparison of advantages and the magnitude of the difference between them helps the decision-maker to see and understand the real differences between the alternatives. Differentiation is based solely on value, meaning price is not considered in the initial assessment. The price of each alternative will be analyzed in the final step by showing the relationship in a diagram. In CBA, it is a fundamental rule not to mix price with value, as cost-related data is seen as a message and medium of exchange (Suhr 1999). Once the money is spent, it cannot be spent again. Therefore, it is crucial to have a clear understanding of how money is being spent, especially if it is taxpayer money. In CBA, the ultimate question is whether decision-makers want to spend the proposed money on a specific value (importance of advantages [IoA]). This allows the decision-maker to understand and reflect on the trade-off. However, separating price from value and viewing price as a constraint is often one of the most challenging aspects of learning CBA (Arroyo et al. 2019), as commonly used scoring methods mix cost-related data with value to generate an apparently objective number.

For a public tendering procedure, Suhr (1999) introduced the prior anchoring process (PAP) because public authorities must transparently publish how proposals will be evaluated before the request for proposals. The prior anchoring process is an add-on to the CBA Tabular method and must be included in the tendering documents to evaluate the proposals using the Tabular method (see Figure 1). The PAP consists of the five steps (Suhr, 1999):

1. Define the factors.
2. Define the must and want-to-have criteria for each factor.
3. Estimate the expected range of attributes for each factor.
4. Define the expected range of advantages for each factor by defining the worst acceptable (WA) attribute, the worst expected (WE) attribute, and the best expected (BE) attribute as anchors for identifying future advantages. Select the least-preferred attribute, either WA or WE, or both if they are the same, and calculate the anchor-statement advantage (ASA), which is the difference between the least-preferred attribute and the BE.
5. Decide the importance of the expected advantages by choosing the paramount advantage (PA) from the ASA. Then, assign the importance weight of each ASA compared to the PA, and for each factor, create either a preference curve for qualitative data or a preference chart for qualitative data.

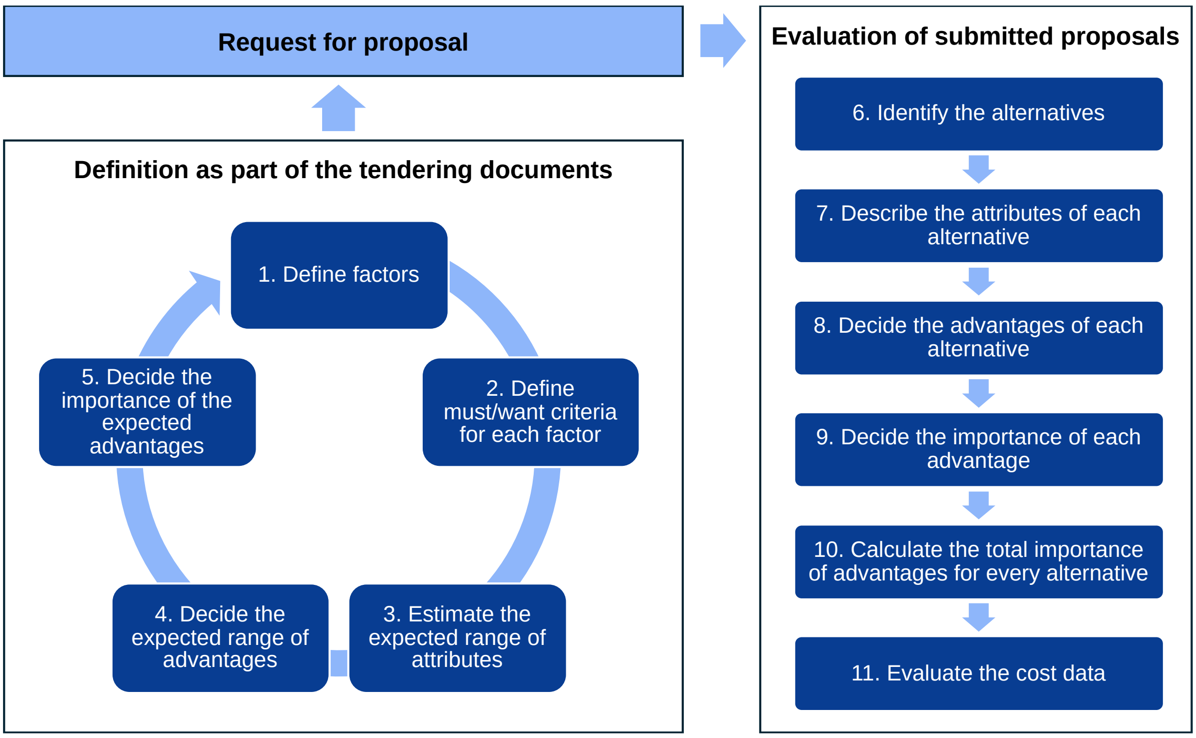

Figure 1: Process steps of CBA in the tendering procedure

Compared to Suhr (1999), Schöttle et al. (2017) introduced the minimum requirement (MR) as the attribute that must be achieved and defined ASA as the difference between BE and MR. However, we will not discuss whether WA, WE, or MR should be defined, as ultimately, they serve the same purpose. They help determine the ASA and identify the preference curve/chart.

While the PAP requires significant effort to develop, Suhr (1999) proposed that, if the law suffices, the RFP should simply state that CBA will be used to evaluate the proposals and to avoid favoritism, the proposal should be analyzed anonymously so that the bidder cannot be identified. This is feasible when there is no contact between the bidder and the judge during the tendering procedure. However, if a competition phase is included in the tendering procedure, it becomes difficult to avoid identifying bidders with their proposals, as both sides interact. This is where the PAP becomes necessary. Another option proposed by Suhr (1999) is to change the legal process, as the current assessment of the proposal is based on unanchored judgment. In this regard, Suhr (1999) points out that "factor weight and attribute ratings are unanchored judgment, and [...] that selecting a contractor based on unanchored judgment is legally unacceptable" (p. 225). Consequently, he argues that using a factor weight method in a legal procedure should be prohibited. However, using a PAP in the tendering procedure means that the price proposal and the proposal containing the technical and social aspects, referred to as the value proposal, must be submitted separately but simultaneously. The price proposal will be opened after evaluating the value proposals to overcome price bias.

Nevertheless, Suhr (1999) states in his book that it would be preferable to use CBA as simply as possible, and thus, not everything needs to be defined in advance. However, different countries have different rules and regulations, and what works in one country may not work in another. However, his book lacks evidence of whether CBA works within a public tendering procedure in a specific country or if the law needs to be adjusted to apply CBA effectively.

EU DIRECTIVE AND GERMAN LEGISLATION

In the European Union, the requirements for award criteria in public procurement law are primarily based on Directive 2014/24/EU, issued on 26 February 2014. Directives are not directly applicable but need to be transposed into national law by member states. Individual member states have the autonomy to determine how they implement these directives in practice. Since EU Directives are framework legislation, member states are obligated to implement them in a timely and proper manner. It can be assumed that the legal situation within the EU is generally harmonized. Therefore, the following statements apply to all EU member states.

"MOST ECONOMICALLY ADVANTAGEOUS TENDER" AND MINIMUM WEIGHTING OF PRICE

Article 67 of Directive 2014/24/EU provides the framework for national procurement regulations to design award criteria in a public procurement procedure. This European Directive allows contracting authorities considerable freedom by expressly permitting the inclusion of various factors such as quality, technical merit, aesthetics, expediency, organization, environmental characteristics, innovation, qualifications of the personnel entrusted with execution, and delivery or execution time as award criteria. However, a public contract must always be awarded based on the criterion of the "most economically advantageous tender" (Article 67, Paragraph 1, Directive 2014/24/EU). This limits the freedom of contracting authorities to include non-monetary, qualitative evaluation aspects in that these can only be factored into the procurement decision as part of a price-performance ratio. The price—or the costs, as Article 67 of the 2014/24/EU Directive also explicitly allows costs to be used instead of price—must be considered when evaluating tenders. However, there is no stipulation for a minimum weighting of the price, at least according to German jurisprudence. In fact, the Federal Court of Justice has clarified that qualitative award criteria should generally receive more weight the less the requested asset represents a standardized service customary in the market. An excessively one-sided focus on price carries the risk of award decisions that ultimately prove to be uneconomical because they fail to account for qualitative differences in the service (BGH X ZB 3/17, p. 16, para. 35).

The contracting authority is, therefore, mainly free to determine the relative weighting of the individual award criteria relative to each other, as the weighting of the selected award and sub-criteria interact with each other and significantly influence the award objective pursued. For an award—for example, for a bridge—the contracting authority will receive significantly different tenders with a weighting of 30 % price and 70 % quality than, for example, for an award with a weighting of 50 % price and 50 % quality.

Relative weighting only finds its limits in the prohibition of arbitrariness and discrimination. For example, in cases where an excessively marginal weighting of an individual award factor leads to a distortion of competition or unequal treatment of individual bidders. According to German jurisprudence, this is only the case "if qualitative evaluation criteria individually or as a whole are given a weighting that cannot be objectively justified and therefore suggests that the criteria have been designed in such a way that only one or individual companies have realistic prospects of being awarded the contract, while other bidders would have no chance from the outset despite (...) objectively given suitability." (BGH, X ZB 3/17, para. 38).

With the relative weighting of the award criteria, the contracting authority believes it ultimately makes its priorities clear to the bidders. It is an assumption that weighting factors are a powerful tool for achieving the award objective. However, this contains two major mistakes. First, assigning a numerical weight does not determine the method's objective, and second, the importance of a factor cannot be accurately represented by a single numerical value; rather, it is an evaluation based on an assumption (Suhr, 1999).

FURTHER REQUIREMENTS FOR THE INCLUSION OF NON-MONETARY CRITERIA

Link to the subject matter of the public contract (Article 67 (2) and (3) Directive 2014/24/EU)

A prerequisite for the admissibility of an award criterion is that it must be linked to the subject matter of the public contract, as stated in Articles 67 (2) and (3) of Directive 2014/24/EU. According to Article 67 (3) of the Directive, this link is established if the criterion relates in any respect and at any stage of the life cycle to the works, supplies, or services to be provided under the contract. This may concern, for example, the specific process of production or provision of works—or a specific process related to another stage of their life cycle. The specific criterion does not have to be part of the material substance of the subject matter of the contract. Thus, European Directive law provides extensive possibilities for including qualitative, non-monetary aspects in the evaluation.

No unrestricted freedom of choice (Article 67 (4) Directive 2014/24/EU)

According to European Directive law, an award criterion must not grant the contracting authority unrestricted freedom of choice. Therefore, the chosen award criterion must support the possibility of effective competition and be accompanied by specifications that enable an adequate review of the tenderers' information to assess how well the tenders meet the award criteria. Consequently, award criteria must ensure an objectifiable and verifiable decision-making process to prevent arbitrary decisions. However, this does not preclude subjective aspects—such as the aesthetics of a building—from consideration, provided certain conditions are met. For instance, multi-member evaluation committees should be established for such criteria to deter arbitrariness, and these may be contracted externally. For transparency reasons, the complete evaluation matrix, including the planned evaluation process, should be publicized beforehand. During the evaluation process itself, the criteria used to award points should be meticulously documented. Therefore, it is not advisable to base the evaluation of individual award criteria solely on oral statements made by bidders during a presentation meeting (Braun, 2021).

Weighting and specification in the procurement documents (Article 67 (5) Directive 2014/24/EU)

Article 67 (5) of Directive 2014/24/EU mandates that the contracting authority must weigh the individual criteria and present the intended weighting in the procurement documents. This obligation applies not only to the overall weighting but also to the respective sub-criteria. Only under very strict conditions may the contracting authority deviate from the principle that weighting rules for sub-criteria must be published in advance and cannot be introduced subsequently (ECJ, C-677/15P, para. 41 et seq.). The requirements for sub-criteria, particularly their substantive specification, are closely linked to the tender specifications. Therefore, an abstract description of the required depth of content cannot be expressed in abstract terms; it depends on the individual case.

Compliance with the general principles of Community law

In addition to the requirements of European Directive law, award criteria must also comply with the general principles of Community law. The transparency requirement is especially pertinent here. The requirement of transparency under public procurement law means that the award criteria provided by the contracting authority must be sufficiently specific and comprehensible in terms of content. As "quality" is not a self-explanatory criterion, the contracting authority is required to describe the qualitative requirements of the procurement object as precisely as possible and establish corresponding sub-criteria. Vague terms, such as "best possible fulfillment of requirements," may constitute a breach of the transparency requirement, as they hinder the genuine comparability of tenders.

A Real-life Example of Current Practices

Real-life example for a relative evaluation method (simplified): The tendering process was for external project supervision services for the megaproject second core line of the city train (2.SBSS) in Munich. The heart of the route is a 7-km-long tunnel connecting Munich Main Station, Marienhof Station, and Munich East Station. The route intersects several lines of Munich's subway network, with platforms to be constructed between 40 m and 16 m below ground.

Framework for the tender:

1. The tender with the lowest price receives 80 points. Bids exceeding 1.5 times the value of the lowest bid price receive 0 points. Points for other bids are linearly interpolated between the lowest bid price and 1.5 times that value.
2. Up to 20 points are available for the written and oral elaboration of the concept regarding the quality of the personnel and the software tools to be used.

Table 1 shows that bidder 1 reached 85 out of the maximum of 100 points and was awarded the contract.

Table 1: Result of the real-life tendering procedure

Bidder	Total Price (fictional)	Price Points	Quality Points	Total Points
1	40 €	80	5	85
2	50 €	40	10	50
3	60 €	0	20	20

This simplified example illustrates that within the specified legal framework, it is feasible to establish the legally required price-performance ratio by simply converting price and quality into evaluation points and determining “the most economically advantageous tender.” In this scenario, a relative evaluation method focused on the criterion “total price” was employed. Nevertheless, the setup of this tender clearly indicates that the decision was predominantly price-driven and that other factors had minimal influence. Moreover, this example starkly demonstrates that our judgments are based on scoring factors that do not provide a clear understanding of the differences between the proposals or their significance. This is precisely what Suhr (1999) criticizes as unsound. Thus, the authors will explore how CBA might be applied and its potential benefits for future tender processes.

RESEARCH METHOD

This paper aims to understand how CBA can be applied based on the EU Directive in the German public tendering procedure without violating the second and third CBA principles specifically. The research question is: How can CBA be applied in the public tendering procedure in Germany? This qualitative research utilized two focus groups to collect data from experts through discussion (Gray, 2009; Morgan & Krueger, 1993). The first group included contractual experts focusing on the EU Directive and German legislation, while the second group comprised three CBA experts (including the first author) to discuss whether the outcomes of the first group violated the second and third CBA principles.

In addition to the two authors (a CBA expert and a contract manager), the first focus group included an architect, a lawyer from the DB legal department, and a second contract manager from DB InfraGo. Additionally, a project manager shared his thoughts with the authors before the focus group, as he could not participate. During the first focus group, two significant questions were addressed:

- Can we apply the CBA Tabular method with the PAP proposed by Suhr (1999) in Germany?
- Is the diagram showing the price versus the IoA sufficient, or do we need to present the relation in a numerical ratio or weighted sum based on the EU Directive and German legislation?

Before discussing the questions, the participants were introduced to CBA. During the discussion, a simplified example was used to illustrate the table and diagram to facilitate a shared understanding. In the second focus group, the results from the first group were reviewed to determine if any aspect of the procedure violated the CBA principles or the intended approach.

DISCUSSION

In general, there are two options for implementing a method into the public tendering process: either the regulations concerning the tendering procedure need to be changed, thus altering the law, or the method needs to be adapted to comply with the second and third CBA principles. We will now discuss the questions from the two focus groups to determine how to apply CBA in the German public tendering procedure.

CAN WE APPLY THE CBA TABULAR METHOD WITH THE PAP PROPOSED BY SUHR (1999) IN GERMANY?

As the tendering procedure requires that the assessment method for proposals be published, the tabular method needs a more precise definition upfront. Suhr (1999) proposed that the CBA tabular method should be adjusted by integrating the PAP to help bidders understand how their proposals will be evaluated. During the discussion, the question of whether defining WA, WE, and BE is sufficient arose. The group concluded that defining WA, WE, and BE and the resulting ASA alone is challenging and agreed with Suhr (1999) that the preference curve/chart also needs to be defined. They argued that there is too much uncertainty about how the evaluation tends to be if we assume non-linearity. Since preferences are usually not linear (Suhr, 1999), the preference curve/chart for each factor must be clearly defined in the tendering procedure. This should not result in significant efforts to discuss mathematical functions. A set of curves/charts should be defined in advance so the owner team can select the one that best represents the relationship between attributes, advantages, and the IoA.

The exact number of curves/charts the set should contain is not specified and requires further research. However, it must be considered that Suhr (1999) states that preference curves are only for quantitative data and qualitative data must be represented using a preference chart, but it is unclear how detailed the chart for qualitative data must be. Further testing might also be necessary to determine whether qualitative data can be represented by a preference curve and if the scale of attributes can be defined in detail using the x-axis. Nevertheless, defining the preference chart will require more effort than defining the preference curve for quantitative data.

Another point of discussion was the definition of the criteria. According to Article 67 (4) of Directive 2014/24/EU, the criteria must be precisely defined to comply with the requirement to prevent unrestricted freedom of choice. For example, criteria such as "the less uncertain the construction schedule, the better" or "the higher the technical experience, the better" would be too vague and allow too much room for interpretation. Without further specification, these criteria would violate the prohibition of arbitrary freedom of choice and the principle of transparency. Therefore, it can be stated that the degree of detail and, therefore, the effort to set up a PAP is high.

Is the Diagram Showing the Price vs. the IoA sufficient, or Do We Need to Present the Relation in a Numerical Ratio or Weighted Sum Based on the EU Directive and German Legislation?

As noted, the public tendering procedure must represent a relationship between price and value. However, the specifics of how this relationship should be presented are not detailed in the EU Directive or German legislation. Under German case law, it is not necessary to assess price and quality criteria using the same method. In practice, the degree of fulfillment of a factor is commonly used for assessment. The contracting authority has considerable leeway in relating price and value. A standard of comparison must be established—for example, by converting the tender price into price points. Both absolute and relative evaluation methods are allowed. According to German case law, the price conversion formula can only be challenged under public procurement law if it is incompatible with the principle of fair award competition (BGH X ZB 3/17). The contracting authority has a broad margin of discretion. Therefore, the authors conclude that using CBA in a public procurement process is feasible under current legislation. Indeed, the owner is free to determine the weight of the price. In practice, public owners interpret the relationship as a ratio or weighted sum, but creating a ratio or weighted sum based on the IoA vs. price contradicts the third CBA principle that decisions must be anchored in relevant facts. In CBA, cost-related data is not mixed with value to produce a number as other scoring methods do.

Nevertheless, neither the EU Directive nor German legislation restricts using the IoA vs. price diagram to represent the proposals. The conflict with interpreting the diagram arises when considering how a public owner can justify selecting a proposal that has a higher IoA but also a higher price (see Figure 2, point A vs. point B). This is a tricky part. Therefore, the public owner may need to establish predefined rules on how to handle a trade-off in terms of IoA and price, for example, defining that a higher IoA could justify a specific price or specific price range.

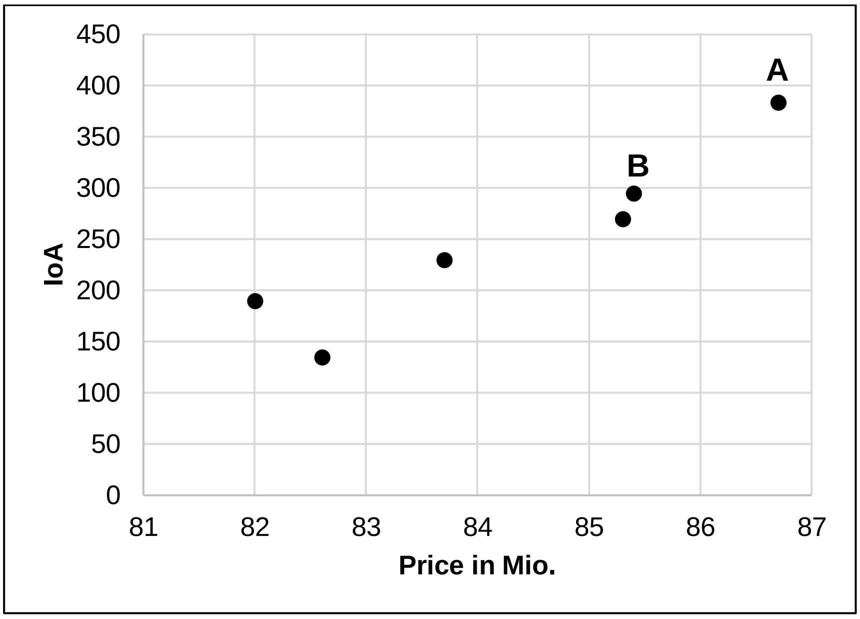

Figure 2: Example of the Importance of Advantages (IoA) vs. price diagram

DOES CBA GET VIOLATED BY THE CURRENT REGULATIONS?

As explained in the previous section, CBA is possible in a public procurement process under restrictions. However, does this violate the positive effects of CBA?

The current practice in the tendering procedure involves following the law and puts the decision-makers in a position where they are not truly making decisions. The decision-maker assists with the procedure rather than taking ownership. Making a decision is an investigation. But how can we investigate by defining everything upfront? Applying CBA in tendering procedures results in an endless number of rules that need to be set for every possible outcome. This makes CBA burdensome and almost impossible to implement in complex situations. CBA requires ownership and a mindset of investigating the differences and the importance of the differences represented in the IoA (second and third CBA principle). However, the high degree of upfront definition makes it difficult to see the benefit of the application. The current practice focuses on the procedure itself rather than the decision itself, and this needs to change for successful CBA implementation. This raises the question of whether the law can cover everything. Obviously, it cannot. So, what should be the focus? Should we prioritize fulfilling the procedure or invest in involving people who can address the needs and constraints together? Should we deflect or instead train people and establish processes to make effective decisions in the tendering procedure for the project’s success?

Another issue ignored by current practice is how to deal with new or unexpected information. Especially in megaprojects, where a tendering procedure can take months or even a year, new information is generated, and the tender documents quickly become outdated before the tender is awarded. This poses a dilemma for every project. Thus, we cannot freeze our information status, but we do freeze the tendering process, or we already know which claims to address. So, why can’t we act accordingly?

The tendering procedure is reactive. It does not provide the opportunity to correct mistakes as soon as the tendering document is published. For public owners, this means they must adhere to known practices. This is primarily due to political constraints and the fear of making a mistake. There is always the risk of project delays because bidders may have a claim against the tendering procedure. Nevertheless, there are good examples where public owners successfully changed the tendering procedure. For instance, the University of California San Francisco changed its scoring method during the evaluation process of a project, and even the non-winning bidder teams found the new procedure fair (Schöttle, 2022). Consequently, we need to change our mindset and understand tendering as a proactive decision-making process.

FINAL REMARK

There are only two options here: (1) Everything needs to be defined in such detail that decision-makers might avoid the use of CBA in a complex decision, although it is the right thing to do, or (2) the law needs to change to put the decision-maker in a position to really decide and not follow instructions no matter what. Understandably, favoritism and corruption must be stopped. However, in the current system, the tendering process can be manipulated to generate favoritism. Right now, people are not taking responsibility for their decisions as they frame them according to the law. Thus, the question is: What problem are we trying to solve here? No method alone can do so, as humans will find a creative way to circumvent it. The tendering procedure is a human-made artifact. What needs to happen is that a board of decision-makers with different perspectives should be empowered to make decisions. They should act as a court of law (see Koskela et al., 2018).

Therefore, the problem of favoritism and corruption cannot be solved by a rule; it can be minimized by making decisions as a group. The issue needs to be reframed, and with this paper, we invite you to start a discussion about how we select partners in the tendering procedure.

CONCLUSIONS

After providing a brief overview of the legal framework for awarding in the EU, the authors believe that CBA can be incorporated into public procurement procedures—even within the existing public procurement legislation framework. Therefore, the research question of whether and how CBA can be applied in the public tendering procedure in Germany can be answered by utilizing the PAP. This approach will not violate CBA principles. However, the adjustment required to apply CBA within the current regulations will discourage owners from using it, which goes against the intentions of the CBA. Public authorities must recognize that the current practice is reactive, subjective, unfair, and does not foster ownership. We need to shift our perspective and view the law as a means rather than an end goal that must be achieved. Therefore, we invite owners to engage in discussions regarding current practices and the implementation of CBA in the tendering procedure.

In addition to discussions, further research is necessary as this study has limitations in its theoretical approach. Data should be collected through experiments or applications to validate the theoretical findings. This should be the next step for future research.

ACKNOWLEDGMENTS

We would like to express our gratitude to the focus group participants for taking the time to discuss the questions with us.

ISO 18404: A MODEL FOR LEAN TRANSFORMATION IN AN ALLIANCE

Paul J. Ebbs[1] and Steven A. Ward[2]

ABSTRACT

The literature and case studies reporting lean transformation in the construction/infrastructure sector are rare. This study's objective is to examine whether the Lean Standard, ISO 18404 provides a useful model for lean transformation. By Case Study and Participatory Action Research, the deployment of ISO 18404 and certification journey of a UK highway alliance (the Alliance) is reported, structured around four Themes for lean transformation. Findings are supported by the latest literature along with a quantitative and qualitative survey with those involved in 18404 deployment (n=35/58). The survey data was thematically analysed and is largely articulated through the four Themes for lean transformation. Whilst ISO 18404 is imperfect, it remains that ISO 18404 provides a useful model for lean transformation and can assist with embedding a culture of sustainable continuous improvement in an Alliance.

KEYWORDS

ISO 18404, Alliancing, Lean Transformation, Lean Leadership, Continuous Improvement

INTRODUCTION & BACKGROUND

This paper follows Ward and Caklais' (2019) case study that piloted the deployment of ISO 18404 to support organisational lean transformation in a UK housebuilder, Gilbert & Goode (G&G), and papers reporting the development of a Lean Project Delivery System for a UK Client Organisation (Pasquire and Ebbs, 2017; Ebbs and Pasquire, 2018; and Ebbs et al. 2018).

ISO 18404 is an international standard for lean and is proposed as a model for lean transformation (Ward & Caklais, 2019) and organisational improvement (Oudrhiri et al., 2022). When used together with the Royal Statistical Society's (RSS) sector scheme alongside ISO 9001, it provides a Lean Management System Standard that aligns the achievement of an organisations' strategic objectives with its lean architecture (Key Personnel and Tools) and requires demonstrable continuous improvement. ISO 18404 is sector agnostic and only abstractly prescribes how to deploy lean by focusing on aligning an organisations' strategy, architecture, and improvement activities through a series of Lean Competencies and ISO Clauses. For more on 18404 see Ward & Caklais (2019); Ward (2019) and BS ISO 18404:2015. Since Ward and Caklais' (2019) paper, Balfour Beatty Highways UK have been certified to ISO 18404 and have maintained their certification with annual British Standards Institute (BSI) Audits. In 2023, the BSI Auditor noted Balfour Beatty's Lean Management System was continuing to improve. However, in parallel, the ISO 18404 certification for pilot organisation G&G was not maintained. This was principally attributed to a change in Managing Director and many of the ISO 18404 Key Personnel (Lean Leaders and Practitioners) leaving the organisation, noting the previous Managing Director was a Royal Statistical Society certified ISO 18404 Lean Leader who personally delivered lean training to over 100 people (Ward, 2019).

[2] Managing Director, Lean Construct Ltd., UK, steve@leanconstruct.co.uk, orcid.org/0000-0002-5291-7246

In 2019, the researchers were direct employees of a Global Engineering Firm who were tendering for a UK highway alliance framework (the Alliance). This was being procured through an NEC4 Alliance Contract to deliver c.£1.5bn-£3bn. of infrastructure upgrades to the UK's Strategic Road Network. The bid required those tendering to make appropriate tender commitments – ISO 18404 became one of these. The Alliance was commissioned in May 2020 and by March 2025 it will have substantially delivered several development projects and three programmes of work that are key to the Client's Roads Investment (2020-2025) Delivery Plan.

The research focus is on the deployment of ISO 18404 and rests on a single case study (a UK highway alliance) using the four Themes identified by Ward and Caklais (2019) to start framing and reporting the primary and tertiary data collected. The 4 Themes are:

1. Organisational Structure – supportive business model required
2. Roadmaps & Lean Concepts – need dual clarity before the critical mass will adopt lean
3. Leadership – senior leadership participation required and philosophy comes before tools
4. Change by Force – moving to clients specifying lean, training and use of the principles

The literature review below is followed by a summary of the primary case study data before exploring 18404 deployment methods through specific case study examples.

LITERATURE REVIEW

Ward and Caklais (2019) previously explored the question of whether the 18404 standard could assist lean construction transformations and carried out a literature review using the search terms "ISO 18404" and "transformation" on the IGLC website and on Google. 79 papers were identified and 15 found relevant. They found the four key Themes of interest noted above across the 15 papers. Five years have passed so this literature review was updated through Scopus using key words "Lean Transformation (+ Infrastructure +/or Construction)" and "ISO 18404".

New IGLC Papers

Peltokorpi et al. (2021) provided a view on construction sector transformation and identify five broken sub-systems: a) Products; b) Processes; c) Information and Digitalization; d) Value Creation; and e) Business Models. They observe that a systemic approach is essential for sustainable improvement and that all five sub-systems need to be simultaneously addressed. This partially aligns with the four Themes; however, these focus primarily on organisational transformation whereas Peltokorpi et al. (2021) examine the sector as a whole.

Other papers

Ward (2019) presented more information about the original certification pilot Gilbert & Goode in the final project report for the Construction Industry Training Board. It provides more detail about the initial pilot rather than any additional insights to report here. Antony et al. (2023) focused on a cross sector survey of Lean Six Sigma Blackbelts to explore the applicability of ISO 18404 to smaller enterprises. They conclude that the standard needs revision. They also provide critique in Antony et al. (2021) where a range of cross sector Lean Six Sigma Experts were interviewed as to the pros and cons of 18404. They concluded the standard is "not fit for purpose". Oudrhiri et al. (2022) rebutted Antony et al. (2021) with an in-depth explanation of how 18404 works in practice, noting the Antony et al. (2021) work was based on significant general experience with lean six sigma, but no specific experience with the application of 18404. Oudrhiri et al. (2022) provide explanations and information regarding how the standard works in practice by people familiar with its application. Related to the requirement for the systemic change called for by Peltokorpi et al. (2021), Ward and Mossman (2023) explored the business case for Integrated Project Delivery (IPD). They carried out a benchmarking study of project performance and noted that Project Alliancing represents a system change and positive shift in performance but does not focus on lean. When lean processes and leadership are built onto Alliancing a further significant shift in performance is gained as shown in Figure 1.

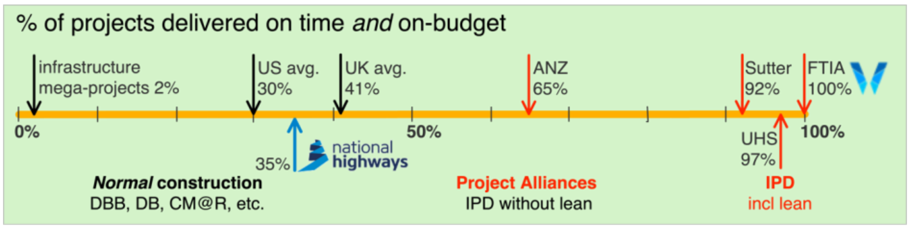

Figure 1: Percentage of projects on time and on budget or better (Ward & Mossman, 2023)

RESEARCH METHODOLOGY

The methodology was a single Case Study (Fellows and Liu, 2003; Yin 2018). Data were collected from many primary and tertiary sources including lean strategy development and review workshops, lean workshops, 18404 management reviews, leadership team meetings, internal and external 18404 and Highways Excellence Lean Maturity Assessment (HELMA) audits, contract documents and annexes, diary notes, interviews, observations and a survey of the ISO 18404 Lean Practitioner/Leader Candidates and Sponsors. Data were analysed and framed using content/thematic analysis techniques advocated by Braun & Clarke (2006) and Boyatzis (1998) employing a sliding 7-point numerical scale (Nunnally, 1978).

Survey Data

A survey was conducted with those who were 'involved' in 18404 deployment (n=58) rather than the approach taken to review the standard by Antony et al. (2023) where the respondents who reviewed 18404 had little practical knowledge of it. 'Involved' meant they had either gone through the RSS approved training, were pursuing individual certification or were one of the 18404 Sponsors. Approximately 10% had left or were leaving the Alliance. The response rate was 60% (n=35/58) with the distribution of respondents aligned to respondents' roles as shown on Table 3. There were four questions. Questions 1 & 2 were quantitative with the average response shown below. Questions 3 & 4 were qualitative with the analysis in and after Table 2.

1. As an individual, what value have you got from involvement in ISO 18404 to date where 1 = no value and 7 = high value? Average was 5.89
2. How effective is ISO 18404 as a model for Organisational Lean Transformation and Business Improvement where 1 = not effective and 7 = very effective? Average was 6.0
3. Please state your key thoughts on ISO 18404 as an approach to embed a culture of sustainable continuous improvement in an organisation.
4. Please state your key thoughts how 18404 has or has not impacted lean culture, production and/or benefits realisation such as efficiencies or any of the Six Outcomes.

Table 1 replicates Ward's (2015) Critical Success Factors (CSFs) for lean interventions. The CSF references in the left column of Table 1 are mapped to the sub-themes of right column in Table 2 to show the correlation between the results of the thematic survey analysis with Ward's (2015) CSFs. Table 2 also outlines additional insights not found by Ward and Caklais (2019). Many examples of CSFs correlating to the four Themes exist. For example, Theme one in Table 2 'Org Structure' relates to the Alliance Model which correlates to the CSFs 'no blame culture' (23) and 'long term relationship or work stream required' (19) in Table 1. Table 2 shows the broad distribution of 221 mentions (taken from 126 statements) relative to Ward and Caklais'(2019) four Themes. Most statements typically fell into several Sub-Themes. The analysis was conducted using a simple tally chart to capture the no. of mentions of each Sub-Theme.

Table 1: CSFs Significant Hypotheses (after Ward, 2015)

CSF Reference #	Critical Success Factor (CSF)	Confidence Level
21	The facilitator is critical to success	>99%
18	More than one tool required for success	>99%
10	Management must stay focused on efforts to improve	>99%
17	Relevant data is available or is created	>99%
11	Lean training is required	>99%
14	Staff time out required to focus on improvements	>99%
2	Buy-in from improvement team required	>99%
19	Long term client relationship or work stream required	>95%
8	Lean capability in management required	>95%
23	No blame culture required	>95%
3	Senior management buy-in required	>90%
9	Direct senior management involvement required	>90%
13	Closing actions by improvement team required	>90%

Table 2: Thematic Analysis of Survey Responses (n=35) Mapped to Ward's CSFs

#	Theme	Sub-Theme	No. of Mentions	Ward's (2015) CSF Reference #
1	'Org Structure'	Alliance Model	2	23, 19
2	'Roadmaps & Clarity of Concepts' (n=39)	18404 provides a model/structure/consistency	22	N/A
		Adaptation of lean tools and techniques req'd	9	21, 18, 11
		18404 aligns with org strategy	8	17
3	(Lean) 'Leadership' (& Culture & Community) (n=55)	Mindset and culture change	25	10, 2, 23, 3, 9
		Lean leadership and sponsorship	16	10, 8, 23, 3, 9
		Sense of lean community	14	21, 18, 11, 14, 2, 8, 23, 3, 9, 13
4	'Change by Force' Conditions)	(External Market	0	N/A
4 a	Lean as Business as Usual (BAU) (n=98)	Better lean knowledge, tools and competency	41	21, 18, 17, 11, 14, 2, 8, 23, 3, 9
		Realisation of benefits and outcomes	38	10, 17, 11, 14, 19, 23, 13
		Focused lean training & team capability	13	21, 18, 17, 11, 14, 2, 8, 23, 3, 9, 13
		Availability & use of lean support	6	21, 11, 2, 8, 3, 9
5	ISO 18404:2015 Standard (n=22)	Positive view of 18404	14	N/A
		Maturity of 18404 standard	5	N/A
		Certification benefits	2	N/A
		Negative/indifferent view of 18404	1	N/A
6	Concerns	Organisation Change Challenges & Portfolio process & evidence collection	6	N/A

REFLECTION ON SURVEY THEMES & DATA COLLECTED

Ward's CSFs in Table 1 were correlated to the survey analysis in Table 2 as one could argue that a lean transformation is a series of interventions, and the CSFs are appropriate to both. Below is some discussion around the qualitative data supporting Table 2's Themes and Sub-Themes with the number of mentions from Table 2 denoted in the brackets after each heading. Table 3 outlines the distribution of survey responses from the demographics of those 'involved' in 18404 deployment. These are known as 'Key Personnel' in ISO 18404:2015.

Table 3: Demographics of ISO 18404 Key Personnel (N=48) and Survey Responses (N=35)

# 18404 Trained	Role	Survey Responses
2	Sponsor (Alliance/Programme Leadership Team)	7
4	Sub-Programme Leadership	6
7	Construction Manager/Director	4
4	Site Agent	3
8	Design Manager/Lead	1
3	Supply Partner Manager	2
2	Planner	2
13	Production Hub (Back Office)	8
5	Lean Coach	4

THEME 1: ORGANISATIONAL STRUCTURE (N=2)

A single reference to 'Org Structure' was made by a Planner who thought "18404 has added to the collaborative approach of the Alliance and team members feel reassured working slightly out of their normal routines (e.g., a less commercial mindset)". There was another positive reference about the Alliance by a Sponsor. The Alliance is an Enterprise Model built around Infrastructure Client Group (2017) Project 13 concepts which has helped develop long term relationships, inform the development of the Vision, Mission, and Six Outcomes in Figure 2, and encourage role modelling 'Trust' as one of the Alliance's Six Behaviours. The Alliance model supports Ward's (2015) 'no blame culture' and 'long term relationships or workstreams' CSFs and Ward and Mossman's (2023) move towards IPD. The scarcity of comments relating to org structure suggests that Alliancing is conducive to lean transformation and ISO 18404.

THEME 2: ROADMAPS FOR LEAN AND CLARIFICATION OF CONCEPTS (N=39)

This was broken down into three broad areas and was alluded to in some format by every demographic in Table 3 except for the Planners.

The structure, framework, and consistency of ISO 18404 (n=22)

30% of this Sub-Theme's references were from the Sponsors or Programme Leadership and the remaining were spread across the other demographics. One of the Lean Coaches referred to 18404 as a "powerful transformational model".

Adaptation of lean tools and techniques (n=9)

References were made to the agnostic nature of 18404 and the need to interpret it relative to infrastructure and job roles. Additionally, as the 18404 course was specifically tailored to lean in the construction sector, there were several remarks about how the ideas and tools taught had changed the Alliance's approach to delivery. Some statements argued the 18404 competencies were catalysts for change – like Deutschman's (2007) conundrum of 'Change or Die'.

Alignment of lean strategy with organisation strategy (n=8)

Whilst there was not an abundance of statements specifically regarding strategy alignment there were many mentions related to how 18404 was supporting the realisation of benefits and outcomes (n=38). This infers that 18404 is beginning to impact strategic goals. The Hoshin Plan discussed in the Case Study was designed to support realisation of all Alliance Outcomes.

THEME 3: LEAN LEADERSHIP, CULTURE & COMMUNITY (N=55)

Ward and Caklais' (2019) Theme of 'Leadership' was expanded to reflect the statements.

Mindset & Culture Change (n=25)

The difficulties getting buy-in to a lean culture and the impact of 18404 to "win over" mid-senior level leadership and embed large scale change was recognised.

Lean Leadership & Sponsorship (n=16)

The Leadership engagement and the Sponsor role helped generate lean deployment momentum.

Community of Practice & Cohort Selection (n=14)

The positive impact of the diverse selection of Key Personnel trained (including leadership) along with the lean coaching availability and support structure was as another important factor.

CHANGE BY FORCE (N=0)

There were no comments related to change by force. However, the specific requirements for lean contained in the Contract Annex (G) which included a requirement for annual Highways Excellence Lean Maturity Assessments (HELMA) audits (National Highways, 2024), combined with a tender commitment 'to lead the Alliance to ISO 18404 Accreditation' provided external force. HELMA 'forced' the Alliance to collect appropriate evidence albeit from a 'show us your best homework' lens. The Alliance scored 1.7/4 in 2021 and jumped 35% year on year to 3.1/4 in 2023. The moderators noted "since the 2022 HELMA the Alliance have put considerable effort into expanding their lean deployment and building sustainable capability using ISO 18404 as the main method. This has delivered considerable success and there has been a real step change in performance and capability." Furthermore, the BSI ISO 18404 Stage 1 and 2 Audits in February and March 2024 did 'force' many good practices such as the release of the Alliance Policy (combined quality & lean), establishing the Lean Deployment Plan and Dashboard, and helping structure lean deployment vs. an ad hoc lean intervention approach.

LEAN AS BUSINESS AS USUAL (BAU) (N=98)

An underlying theme that emerged in 2023 through the Sponsor sessions, discussions, and strategy updates was that lean was no longer a "buzz word" (Crisp, 2023) and was now part of the Alliance DNA (Slater & Grimm, 2023). The Alliance 2023-2025 Strategy and Production Delivery Plan were published in July '23 with 27 implicit and 7 explicit references to lean. The high proportion of mentions relative to lean as Business as Usual (98/221), suggests the people and lean competency development approach played a significant factor in normalising lean. As reported by the respondents: "this is the way we deliver projects in the Alliance… [lean] supports us realising our Six Outcomes… the [lean] benefits are felt right across the Alliance".

THE CASE STUDY – OVERVIEW, RESULTS & DISCUSSION

The case study examines a UK Framework Alliance with six partner organisations who provided programme management, digitally enabled design, and on-site assembly services for highway upgrades. The Alliance then pre-procured a supplier network, to deliver enhancements to positively impact safety, environment, congestion, and asset condition using the Six Outcomes in Figure 2 as shared goals to support the vision and mission.

Figure 2: Alliance Vision, Mission and Outcomes

The Alliance NEC4 contract model is IPDish (Ward & Mossman, 2023) with a single approach to shared risk and reward. The Alliance model supports Table 2's Theme 1 requirement for the right 'Organisational Structure' and Theme 4's 'Change by Force' for lean transformation.

Lean requirements were specified in the Contract Annex (G) and included requirements such as lean leadership, learning and sharing current best practices and adopting key lean tools such as the Last Planner System (LPS) - known as Collaborative Planning in the UK, Visual Management, and lean maturity assessments. Fundamentally, Annex G required a coherent lean strategy and deployment plan to support realising Client Safety, Customer and Delivery imperatives. The client moderated and scored lean deployment through annual HELMA audits (Highways England, 2020; National Highways, 2024) which have been in use since 2009 (Williams, 2023). HELMA was initially reported by Drysdale (2013) under the guise of HALMAT (Highways Agency Lean Maturity Assessment Tool) and alluded to by Nesensohn (2014) in his Lean Construction Maturity Model. Annex G also supports Theme 2's 'Roadmaps & Clarity of Concepts' and Theme 3's 'Leadership' requirements for a lean transformation.

Since inception and throughout the life of the Alliance, a complex set of challenges were faced, including COVID-19 impacts, changing standards and technologies, and changing Government requirements, all of which impacted scope and increased the number and complexity of projects. With respect to lean deployment the biggest initial challenge was to increase lean support capacity and the lean capability of leadership, individuals, and teams. The biggest challenge not overcome was to establish a physical Big Room environment 3 years into the Alliance (Ward & Mossman, 2023) – this was largely due to mobilising in a pandemic, and the dispersed nature of teams and individuals across the framework in the UK, Europe, and India. The countermeasure was pulse-based co-location combined with Big Room workshops as required and digital solutions such as Dashboards and 'Home Visual Board' to visualise performance (Szyperski et al., 2023).

Researchers Background, Experience and Roles

The Researchers (A & B) are Certified ISO 18404 Lean Experts. 'A' became certified as a Lean Expert in 2024 and 'B' in 2017. The 18404 Lean Expert qualification is like that of a Fellow within a Chartered Organisation and requires assessing every three years with evidence no more than five years old. 'A' and 'B's' lean experience totals c.40 years and construction experience c.70 years. 'A' instigated ISO 18404 in the Alliance acting as an internal Lean Coach and chaired the Lean Production Steering Committee. 'B' provided external ISO 18404 expertise during the initial bid and after 18404 Business Case approval, having supported two companies through 18404 Certification. The Lean Production Steering Committee had representation from across the Alliance and 113 years of lean experience when established in September 2022.

ISO 18404

The Business Case for ISO 18404 was approved by the Alliance Board in November 2022. The funding was primarily to support c.40 Key Personnel participate in an Approved RSS 18404 Lean Practitioner Course, develop their lean portfolios, and attend their external assessment. A relatively smaller funding envelope supported the auditing and certification process by BSI (British Standards Institute), 24 months of external 18404 coaching for the Lean Production Steering Committee and support for Ward and Mossman's (2023) IPD study.

For organisational certification to ISO 18404:2015 the link between day-to-day lean improvements and strategic objectives' realisation must be demonstrated. This broadly focuses effort on two areas:

- Individual Lean Competencies according to Tables B1 & B2 in the standard which require people to demonstrate application of a mixture of soft and hard competencies.
- Organisation conformance to Clauses 4 – 6 normative to ISO 9001:2015 to demonstrate alignment across strategy, architecture, and (quantified) continuous improvement.

ISO 18404 Strategy & Hoshin Planning

The Lean Production Steering Committee was responsible for co-creating, revising, and coordinating the deployment of the Alliance Lean Strategy through regular meetings and workshops to support deployment of the wider Alliance Strategy & Production Delivery Plan.

The purpose (why) of the Lean Strategy was "to embed a culture of sustainable continuous improvement by March 2025". The original breakthrough goals (what's) were to:

1. Achieve ISO 18404 Accreditation by March 2024
2. Ensure 80% of people approved to work on the Alliance were at a level of lean competency appropriate to their role by March 2025
3. Achieve 5% efficiency savings through Lean Improvement Projects by March 2025

The 3 what's were revised in February 2024 to reflect an updated Alliance Strategy to include:

4. Improving LEI (Lookahead Execution Index) from 44% to 70% by March 2025
5. Effectively measure RfT (Right first Time) Quality by March 2025

The breakthrough goals (what's), were originally to be realised through 14 initiatives (how's) which are summarised under three headings:

1. Developing lean competency through training, coaching and the application of lean
2. Excelling at core lean tools such as the LPS, VM, and Direct Work Observations
3. Sharing and embedding current best practices and lesson learned

ISO 18404:2015 requires demonstrating the link between organisational strategic goals and continuous improvement so the Lean Strategy was revised to reflect a leadership focus on Right first Time. Countless debates occurred on how to measure this which resulted in an even more focused approach to a full LPS adoption and the introduction of a new 'snag free PPC' metric TRiFT (Tasks Right First Time) to screen weekly promises for rework and capture reasons why. The original 14 how's were not all discrete initiatives or interventions. Some did not progress as initially anticipated. They increased to 16 in Feb 2024 when the Lean Strategy was updated to reflect current state lean deployment - less relevant how's were removed and new ones added.

ISO 18404 ARCHITECTURE (KEY PERSONNEL, REVIEWS & TOOLS)

The Steering Committee co-created the ISO 18404 architecture and largely codified this as the Alliance Lean Production System. This was a combination of the most relevant of 16 How's in the Lean Strategy plus any emergent best practices such as ELMO (Enough Let's Move On). The lean system was rolled out in the pre-assembly (design) and assembly (construction) phases of all programmes and projects to develop people, excel at core lean tools and realise benefits. A snapshot of the Deployment Plan is in Figure 4. Elmo emoji denotes his deployment date.

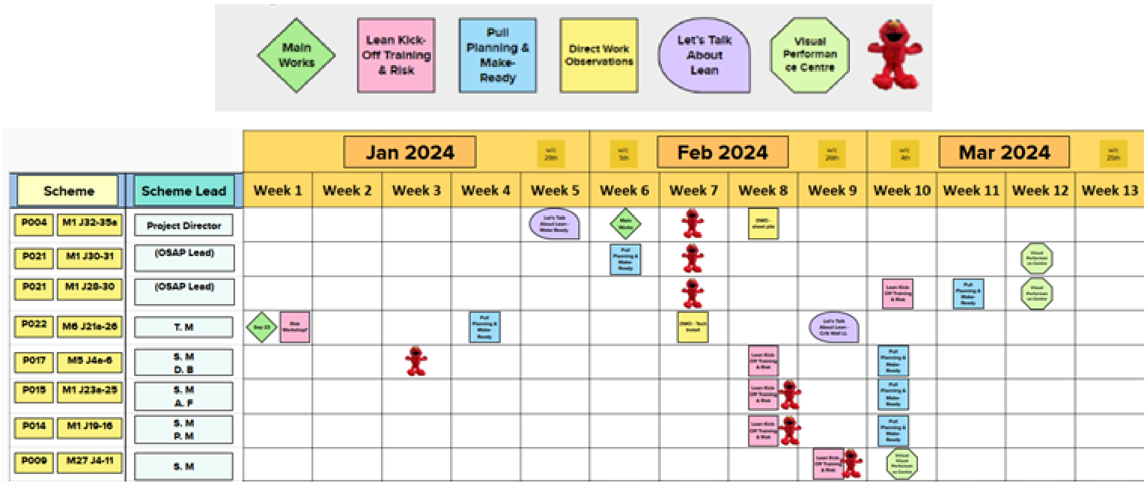

Figure 4: Alliance Lean Production System (ALPS) Deployment Plan (sample of projects)

The ISO 18404:2015 standard requires an appropriate level of Key Personnel to deploy an organisations lean management system (architecture) in pursuit of strategic objectives. A 5-level lean training and coaching programme was developed and deployed. Levels 3-5 were to ISO 18404:2015 Tables B1 & B2 competency requirements whilst levels 1 & 2 were tailored for lean awareness and day-to-day application. 48 people completed the ISO 18404 training over 12 months in 4 Cohorts with 1 Lean Expert, 3 Lean Leaders and 2 Lean Practitioners certified by March 2024. 26 of the remaining candidates committed to be assessed as ISO 18404 Lean Practitioners (Level 3) by December '24 upon completion of their portfolio of evidence.

18404 Practitioner portfolios were focused on delivering improvement projects and/or deploying core tools and techniques as defined in the strategy. The 18404 Key Personnel were all thoughtfully selected mid-senior level leadership as listed in Table 3. Pull vs. Push was the final factor in selection. The Key Personnel championed lean deployment at local levels to identify and support improvement activities within their programmes and projects to directly improve performance by seeking out and resolving problems collaboratively, making people feel safe to highlight, prevent and learn from mistakes and prevent reoccurrences. The result of this top-down approach to lean deployment was demonstrated in Table 2 where 'Lean Leadership, Culture & Community' and 'Lean as Business as Usual' featured heavily.

The biggest challenge developing the 18404 Key Personnel was the preparation of portfolios. Course feedback of 92% averaged across the cohorts, however, portfolio progress was slow. One of the original 'how's' in the strategy was to certify 20 18404 Key Personnel by March 2024 but by July 2023 it was clear that a countermeasure was required if this was to be achieved. From December 2023, a Sponsor role for the 18404 Candidates was introduced by distributing Candidates across the Alliance Leadership Team. The Managing Director personally sponsored three 18404 Lean Practitioners. In hindsight, this was a top-down strategic approach to sustainable lean deployment. In parallel, monthly 'Portfolio Coaching Clinics' were held to coach people through the competencies and develop action plans to demonstrate the application of 18404 competencies to their role. The Alliance's 18404 architecture was further supported through a Lean Comms Plan shown in Figure 5 using various mediums such as networking and knowledge-sharing events such as 'Let's Talk About Lean' monthly webinars and annual 7ogether conferences, internal bi-annual Connec7 magazines (SMP Alliance, 2023a, 2023b), and LinkedIn posts that spread the understanding of new initiatives and applications of lean.

	Monthly	Quarterly	Annually
Touchpoints	Single Slide Update	10mins Strategy Update	
Let's Talk About Lean		Current Best Practice Share	
Digest	Strategy and/or scheme deployment article		
Connec7 Magazine			4 Page Lean 7imes bi-annually
Events	Supply Network F2F, 7ogether, International Group for Lean Construction (IGLC), NH Lean Practitioner, Highways UK		
LinkedIn	Approx bi-weekly - all of the above e.g., 18404 kick-off, Make-Ready Post, Pull Planning, Training & Coaching		

Figure 5: Lean Comms Plan

Additionally, 18404:2015 normative to ISO 9001 requires internal audits and management reviews. Monthly Leadership Governance and Project Performance Reviews through ALPS Dashboards and quarterly site visits helped demonstrate compliance and identify opportunities.

Organisational Certification requires independent two stage auditing of the Alliance Lean Production System (ALPS), processes, and software normative to ISO 9001. These were defined by the Alliance in Hoshin Plans but recorded formally in Alliance Integrated Management System documentation. In February 2024, the auditor noted zero non-conformances at Stage 1 and during the wrap up the Alliance Managing Director noted "we are embedding lean as 'the' thing not 'a' thing we do to help us achieve our vision, mission and outcomes (strategy), lean is now part of our DNA and next time we start an Alliance it has got to be from day one, we are now setting a new benchmark for infrastructure performance, every project before us overran". The Auditor noted it was his third organisation to audit 18404, but he also provided consultancy for another organisation. He noted the systems were "as good or even better than he had seen before". During the March 2024 Stage 2 Audit the Auditor met with multiple project teams to understand their role in lean deployment to see the results of 18404 deployment. A common theme was how shared understanding (Pasquire, 2012), and detailed knowledge of how to do the work (Spear & Bowen, 1999) significantly improved when using the Alliance Lean Production System. Highlights were one project delivered four weeks early (approx. 10%) which was unprecedented in highways and another project delivered five Emergency Areas (extra safety laybys) within the same time originally allowed to complete three, or a 66% productivity improvement. No non-conformances were found by the BSI and the Alliance was recommended for certification to ISO 18404 by the Auditor in March '24.

CONCLUSIONS

Systemic change is required to enable sustainable lean improvement. Bolting lean onto a broken system only yields superficial results. The focus here is effective lean construction transformation (systemic change) and whether ISO 18404 is helpful in this regard. Project and Framework Alliancing represent a system change and ISO 18404 also contributes to this by providing a repeatable business strategy for effectively deploying lean that is properly linked with project delivery needs. In the case study presented, Ward & Caklais' four Themes are clearly present and the additional theme of Lean as Business as Usual together with the positive quantitative survey responses to Questions 1 & 2 provide evidence of sustainable improvement.

ACKNOWLEDGMENTS

We thank all those directly 'involved' in 18404 deployment in the Alliance helping embed a culture of sustainable continuous improvement and everyone else for buying into the culture. The authors also want to thank Robert Hales for his vision and leadership to build a team at WSP in 2019 focused on embedding ISO 18404 into the infrastructure/construction sector.

INSTITUTE FOR LEAN CONSTRUCTION EXCELLENCE LEAN MATURITY MODEL (ILMM) – A LEAN MATURITY MODEL FOR INDIAN CONSTRUCTION

Kalyan Vaidyanathan[1], Marimuthu Kannimuthu[2] and Koshy Varghese[3]

ABSTRACT

In the construction industry, sustained implementation of lean practices is vital for enhancing efficiency and outcomes for projects and organisations. Having a maturity model is one way to assess sustained implementation. This paper identifies the need and describes a comprehensive maturity model framework to gauge and improve project and organisational lean maturity in the Indian construction context – Institute for Lean Construction Excellence Lean Maturity Model (ILMM). The model introduces a distinctive 4x3 matrix, with four levels – Bronze, Silver, Gold, and Platinum – each further divided into three sublevels – Low, Medium, and High. The assessment is done on five dimensions – top management support, process, people & partners, methods & tools, and technology. Field data collection has been done on two projects to see if data on the proposed assessment dimensions can be gathered and an appropriate rating provided to the project along with guidelines on how to improve the maturity.

This research advances lean construction practices by providing a practical framework for continuous improvement and organisational excellence tailored to local construction contexts. In the next phase, the authors plan to do a more elaborate assessment across a broader range of projects and modify the ILMM framework as needed based on their experience.

KEYWORDS

Lean Construction, Lean Maturity Model, Lean Culture, Continuous Improvement, Assessment Framework.

INTRODUCTION

In the dynamic world of construction, variability is constant. Lean construction aims to minimise waste and maximise value, offering a toolkit of methods and tools developed over nearly three decades. Technology, particularly in project information management, has also evolved, providing digitisation as a means to reduce waste. As a result, organisations undertaking lean transformation now have various options, but the specific approach depends on individual projects or organisations. As projects and organisations progress in their lean adoption journey, guided by their awareness and experience, they face challenges in understanding how to sustain implementation and ensure continuous improvement. This

observation and feedback are particularly notable in the Indian construction industry, which has embraced lean construction practices and technology solutions over the past decade. This paper addresses this critical gap by proposing a maturity model for projects and/or organisations as a means to sustain their lean adoption initiatives.

India has seen significant investment in real estate and infrastructure for the past decade, and this trend is expected to continue (*Infrastructure Development in India: Market Size, Investments, Govt Initiatives | IBEF*, n.d.). As the industry grows, the industry is evolving in its professionalism and is seeing varying levels of adoption of processes like lean construction and technology, including building information modelling (BIM), digitisation of various processes, etc., for the past decade or so (Giridhar et al., 2018; Kalyan et al., 2018; Karanjawala & Baretto, 2018; Ravi et al., 2018; Vaidyanathan et al., 2016). However, our research and interactions with the industry indicate that while there are pockets of adoption and understanding of individual tools and technologies, there has not been a planned, organic, and transformative change that has been effected in any organisation. On the contrary, after a decade of adopting lean construction practices in the country by a few organisations, there is a sense of saturation. The authors realise that as the adoption of lean construction practices grows, so must the tools to assess the level of adoption, provide a roadmap to deepen the adoption and offer an actionable direction to improve the adoption. There is a conspicuous absence of any applicable framework that can benchmark the level of adoption tailored to local intricacies. The proposed maturity model bridges this gap for the Indian construction industry.

The rest of the paper is organised as follows. The next section provides a literature review of available maturity models and a comparison of their strengths and applicability. The third section describes the need for a maturity model identified for the stakeholders in the local Indian construction industry. The fourth section describes the ILMM framework and describes the assessment framework. The fifth section describes the pilot assessment studies done on two projects using the ILMM framework. The last section provides some conclusions and a way forward for the ILMM framework.

LITERATURE REVIEW

A literature review of both available lean maturity models has been done. That helped identify the strengths of each of the models and the motivations behind their evolution. That review coupled with the need in the industry, helped the authors create a maturity model framework that addresses the needs of the local industry while taking into account some of the best practices in the existing models (

Table 1). This literature review is divided into six prominent frameworks across Lean Construction and broader organisational excellence, as outlined below.

LEAN CONSTRUCTION MATURITY MODEL FRAMEWORKS:

LESAT

The MIT - Lean Evaluation of Systems and Tactics (LESAT) helps analyse project outcomes through stakeholder interviews and robust data analysis. It utilises Lean performance indicators (LPIs) to evaluate the impact of Lean practices on project goals. Its four levels – Fragmented, Emerging, Integrated, Continuous Improvement – are based on objective data, revealing valuable insights into project performance. However, LESAT's data-driven nature requires significant resources and time, making it less suitable for quick assessments. Additionally, its project-centric focus might neglect the bigger picture of organisational transformation (Massachusetts Institute of Technology, 2012).

HELMA

The Highways England Lean Maturity Assessment Toolkit (HELMA) was developed for infrastructure projects in the UK. HELMA employs a gap analysis approach, comparing your current state with established best practices. Its five levels – Basic, Emerging, Intermediate, Advanced, and Leading – pinpoint areas for improvement and offer resources specifically designed for infrastructure projects. HELMA has been successfully used in this domain, but it might not translate well to other sectors, and its detailed scoring system can be daunting for newcomers (Highways England, 2018).

LCMR

The Lean Construction Maturity Rating (LCMR) offers a Framework for the Progressive Evaluation of Lean Construction Maturity Using a Multi-Dimensional Matrix (FPE-LCMM). Its spider radar charts and bar graphs provide a holistic and dynamic view. It analyses both project-specific and organizational-level factors, guiding you through three strategic stages: Initiation, Integration, and Optimization. While its intricate calculations require expert guidance, the FPE-LCMM provides a comprehensive picture of your lean maturity journey (Sainath et al., 2018).

Nesensohn LCMM

The Nesensohn Lean Construction Maturity Model (LCMM) is a guided step-by-step methodology to help assess the lean implementation path for organisations. This framework focuses on adopting specific tools and techniques, offering a self-assessment questionnaire with four defined levels: Awareness, Initiation, Integration, and Continuous Improvement. Post-assessment provides clear action plans towards mastering key lean practices. However, Nesensohn LCMM's framework and assessment methodology pressed the need for generalisation of the emergent elements of Lean Construction maturity as well as the 11 Key Attributes articulated in the LCMM, which can be confirmed or disconfirmed through further empirical evidence (Claus Nesensohn et al., 2016). Hence, it proves challenging to adapt these concepts to the Indian context, especially considering that the Indian industry is still in the nascent stage of embracing professionalism and incorporating tools and technologies. This underscores the importance of studying the key attributes applicable to Indian contexts, a necessity that must be verified with industry practitioners.

LCI Lean Maturity Model

The LCI Lean Construction Institute Lean Maturity model is an established framework that utilises a familiar self-assessment survey with five levels: Beginner, Aware, Focused, Advanced, and Lean Enterprise. Its binary scoring system offers a baseline for benchmarking and comparing your progress with others. While the LCI model's widespread recognition makes it a valuable tool, its rigidity might not capture the nuances of incremental progress within each level (*Organization Lean Assessment | Lean Construction Institute*, n.d.).

ISO 18404

The ISO 18404 standard offers a comprehensive framework for defining competencies in Six Sigma, Lean, and "Lean & Six Sigma," ensuring clarity and alignment. Structured guidelines and clear definitions facilitate effective implementation. At the same time, its complexity and resource-intensive nature may pose challenges for smaller organisations, potentially limiting inclusivity and hindering complete understanding and implementation (International Organization for Standardization, 2015). Antony et al., (2021) uncovered that the current standard requires improvement to align with industry needs. So, it underscores the importance of consulting industry experts to establish the appropriate dimensions, assessment levels, and criteria for standardizing lean maturity assessments across projects and organisations.

Table 1: Comparison of Lean Maturity Models

Framework	Focus	Methodology	Scoring	Strengths	Weaknesses
LESAT	Project-based assessment for enterprise	Stakeholder interviews and data analysis	Lean performance indicators (LPIs) mapped to maturity levels	Rigorous and data-driven focus on outcomes	High resource requirement, not ideal for quick assessments
HELMA	Infrastructure project context	Gap analysis between current state and desired state	Scoring based on specific criteria for each maturity level	Tailored for infrastructure projects, clear action plans	Not suitable for other sectors, complexity in scoring
LCMR	Multi-dimensional evaluation	Weighted factor model based on spider radar and bar charts	Lean scores mapped to maturity progression curve	Holistic and dynamic, considers project and organisational levels	Requires complex calculations and expertise
LCMM	Organisation-wide lean evaluation	Self-assessment questionnaire with scoring based on adoption levels	Scoring across four levels: Awareness, Initiation, Integration, and Continuous Improvement	Practical and easy to use, suitable for beginners	Limited scope, focuses mainly on 11 key cultural attributes
LCI-LMM	Organisational level assessment	Self-assessment survey with weighted scoring	Five levels: Beginner, Aware, Focused, Advanced, and Lean Enterprise.	Widely used and recognised, suitable for benchmarking	Limited flexibility, binary scoring system
ISO 18404	Organisational & Individual level assessment	Assessment based on personnel and process documentation	Green, Black, and Master Black belts	Structured guidelines to facilitate effective implementation, enhancing education, training, and experience levels for personnel	It is too complex for the Indian context and does not cover technology and other aspects.

POINT OF DEPARTURE

The literature review of various maturity models reveals that each model has its strengths and has been developed for the context in which it has been developed. Applying the model beyond the context and assumptions to which it has been developed will not yield the desired results. In fact, models likely cannot be developed in a very widely applicable framework for it to be effective. Beyond that first point of realisation, the authors realised that there is a need to document the context in which we are trying to develop a maturity model. Based on the authors' experience in trying to drive lean construction practices in the Indian construction industry over the past nearly fifteen years, the following have been observed:

- Projects or organisations adopt one or more of the processes of the basic lean toolset – Last Planner System™, Value Stream Mapping, Work Sampling, and 5S.
- Adoption set and level of adoption is dependent on the team and organisation.
- Some or most organisations have or are adopting digitisation technology solutions for project collaboration and control, 3D BIM modelling, etc.
- While motivated organisations continue to adopt some combination of the methods and tools and technology solutions, they are unable to proceed to the next level of transformation, leading them to reach a level of saturation.
- Projects and/or organisations are also unable to benchmark themselves with respect to each other to motivate themselves to go to the next level.

Based on the above observations, the authors posit that any maturity model developed for the Indian construction context has to incorporate the following into the framework.

1. Be applicable to the local industry context.
2. Provide flexibility to let organisations decide whether lean adoption should be project-based, organization-based, or hybrid.
3. Provide the ability for teams to make relative comparisons.
4. Data collection and assessment methodology has to be simple, practical, and something that can be easily taught to other assessors.
5. Be objective so the results are unbiased and process, not people-dependent.
6. Be somewhat prescriptive to give organisations a guided roadmap to driving lean transformation over time in a structured fashion.

The proposed model incrementally becomes more comprehensive, allowing objective data collection and evaluation and allowing the adoption to be project- and/or organization-based. However, it has to evolve to meet the above needs with the methodology described below.

RESEARCH METHODOLOGY

From the research method perspective, we are still in an exploratory stage of developing the Lean maturity model. Based on testing the outcomes from this exploratory stage, more rigorous research will be utilized to develop/ refine the ILMM. For developing the Lean Maturity Model for the construction industry in the Indian context involves an evolution from what we learned about the development of the LCMR model. Applied qualitative research methods instrumented for synthesising best practices from literature, conducting brainstorming sessions, presenting to stakeholders at conferences, and conducting pilot studies to develop the framework. This section outlines the systematic process of refining and validating the framework components.

FRAMEWORK EVOLUTION

The core framework for the maturity model evolved from adapting and adopting the best practices from the existing models reviewed and ideating the rest of the framework based on the needs identified as described above. So, while the foundation of our research was laid through the extensive literature review focusing on maturity models within the field of construction and across other industries, the basic tenets of the framework were evolved through collaborative discussion and ideation between the authors.

BRAINSTORMING SESSIONS

Once the basic framework of the model was in place, the authors conducted several unstructured brainstorming sessions with academic researchers and industry professionals. These collaborative discussions aimed to get feedback on the model proposed from industry professionals on its applicability, adoptability by the industry, ease of assessment and other criteria discussed above. The same with academic researchers aimed to question the assumptions that the authors had built into the model, modify the criteria for assessment, and provide a certain level of academic rigor to the proposed approach for periodic and continuous evaluation to get the desired outcomes. All of the conversations also sought to understand and brainstorm the model's applicability to the Indian construction context and any potential limitations to its adoption by the industry. The model presented in the next section results from that iterative dialogue and exchange of insights.

PRESENTATION AND FEEDBACK

Once the model was finalised through the brainstorming sessions above, the proposed model was presented to a wider set of stakeholders at multiple forums. These included the Indian Lean Construction Conference (ILCC) in 2022 and 2023. These presentations served as platforms to solicit feedback from a diverse audience comprising researchers, practitioners, and stakeholders. The input received during these sessions helped refine the model and validate its relevance and effectiveness in addressing industry challenges.

PILOT STUDIES

To validate the practical utility of the developed model, an initial pilot study has been conducted across two construction projects in India. These studies aimed to assess the model's ability to measure the current status of lean maturity within projects and/or organisations and provide actionable insights for improvement to the next level of maturity. More importantly, the project teams accepted the assessment methodology as a benchmark of where they stand and guidance on where they need to go.

In summary, our research methodology integrated theoretical insights, collaborative engagement, stakeholder feedback, and empirical validation to develop ILMM tailored to the specific needs and dynamics of the Indian construction industry. This iterative and inclusive approach ensured the creation of a model that is not only theoretically sound but also practical and actionable in driving organisational transformation. The authors are aware that the model is evolving and will evolve as more assessments are done, but they believe that the current version is ready for industry-wide deployment.

PROPOSED FRAMEWORK

The Institute for Lean Construction Excellence Lean Maturity Model (ILMM) consists of twelve levels as described below and summarised in

Table 2 graphically depicted in Figure 1 below. The assessment methodology to determine the level at which each project and/or organisation encompasses a modified Plan-Do-Check-Act (PDCA) approach is described below.

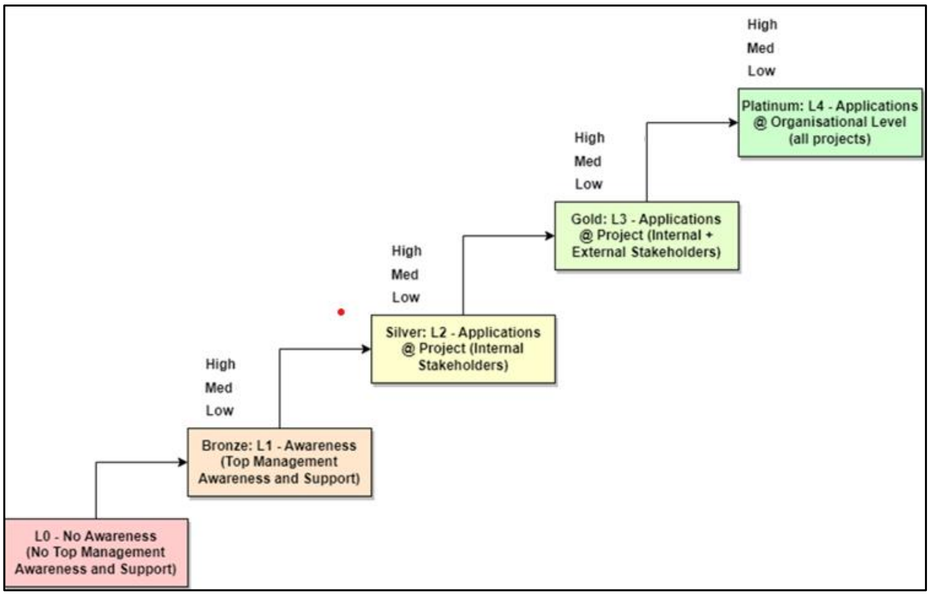

Figure 1: ILCE Lean Maturity Model (ILMM)

ILMM consists of four levels of maturity. Each level provides a significant leap in lean adoption from the previous level. Within each level, the model allows sub-categorization of 3 sub-levels: Low (L), Medium (M), or High (H). These sub-categorizations allow for the measurement of incremental improvement within the maturity level in a relatively smaller time horizon, allowing projects and/or organisations to grow organically to the next level. The four major levels of maturity and their sub-levels are summarised in the table and described briefly below:

7. **L0: NO Awareness**: This level indicates a general lack of awareness and support of lean practices at all levels of the organisation, including the top management. There is no concrete evidence of Lean initiatives in the project and/or organisation at this stage.
8. **L1 – Bronze**: At this level, there is Top Management Awareness of lean, and they commit resources in the form of a lean champion to drive the awareness within the various department heads with increasing adoption among them as they move from Low, Medium, and High as described in the table below.
9. **L2 – Silver**: At this level, lean adoption is done with internal stakeholders of the organisation at the project level driven by a corporate strategy. As the project teams move from Low, Medium, and High, there is an increasing level of adoption among the internal stakeholders, as described in the table below.
10. **L3 – Gold**: At this level, lean adoption is again extended to external stakeholders, driven by a corporate strategy. As project teams move from Low, Medium, and High, there is an increasing level of adoption among the external stakeholders driven by the project team, as described in the table below.
11. **L4 – Platinum**: At this level, lean adoption is happening at the portfolio or business unit level with increasing levels of adoption as described in Table 2 below.

Table 2: ILCE Lean Maturity Model

Maturity Level	Low	Medium	High
L0: No Awareness	Not Applicable	Not Applicable	Not Applicable
L1 – Bronze: Basic Awareness at Top Management Level	**Bronze – Low** No concrete evidence, but there is a Top management awareness	**Bronze – Medium** Top management and a FEW HODs attended Lean Awareness Sessions Part-time Lean champion to drive initiatives	**Bronze – High** Top management and ALL HODs attended Lean Awareness Sessions Full-time Lean champion to drive initiatives
L2 – Silver: Lean Application at Project Level with Internal Stakeholders	**Silver – Low** Corporate Strategy to adopt Lean practices Education and Training to a FEW Internal stakeholders Setting Operational targets for ONE internal department to adopt basic lean tools	**Silver – Medium** Execution of basic lean tool adoption in ONE internal department Education and Training to ALL Internal stakeholders Setting Operational targets for the adoption of basic lean tools with ALL internal departments	**Silver – High** Execution of basic lean tool adoption in ALL internal departments Continual Education and Training to ALL Internal stakeholders
L3 – Gold: Lean Application at Project Level with Internal and External Stakeholders	**Gold – Low** Corporate Strategy to adopt Lean practices to the next level Education and Training to a FEW External stakeholders Setting Operational targets for ONE External department to adopt basic lean tools	**Gold – Medium** Execution of basic lean tool adoption in ONE External department Education and Training to ALL External stakeholders Setting Operational targets for ALL Internal departments to adopt basic lean tools	**Gold – High** Execution of basic lean tool adoption in ALL External departments Continual Education and Training to ALL External stakeholders
L4 – Platinum: Lean Application at Portfolio and Organization Level	**Platinum – Low** Corporate Strategy to adopt Lean practices to the next level At least 20% of the projects at Gold - High	**Platinum – Medium** At least 40% of the projects at Gold-High	**Platinum – High** At least 80% of the projects at Gold-High

It is assumed that broadly, a project team will take around 2 to 2 ½ years to go from one maturity level to another, and they will move from one sub-level to another to another during that period. The lean strategy document that each project team will write provides the flexibility that the team(s) and organisation (s) need to adopt their path to lean transformation. Each could adopt a strategy depending on whether their internal organisational structure is de-centralized (project-based) or, centralised (shared functions), or a hybrid between the two. But within each strategy document, the ILMM model expects that they cover their strategy to adopt lean along five dimensions as discussed below:

1. *Top Management Support:* Based on the author's experience, pursuing lean initiatives without top management support and, consequently, a lack of resources is challenging.

Hence, the authors strongly believe this needs to be aligned before any project team or organisation takes any lean initiatives.

2. *Process*: Understanding and documenting processes is another principle aspect of lean. Documenting processes help identify waste and create pathways for continuous improvement. It also helps benchmark where a project (or organisation) stands on a process and helps them realise how and what to improve and the potential benefits gained through any interventions.
3. *People & Partners*: The authors' experience driving lean awareness and adoption in the Indian construction industry has made them intimately realise that a lot of the success of lean adoption happens after people and teams realise that it is the culture that needs to be changed and transformed – the culture of accountability, trust and transparency among stakeholders (both within and outside organisation), proactive information sharing, and putting project's needs above organisational constraints (sometimes) are critical for the long-term success of lean initiatives. This cultural transformation is critical for the sustained implementation of lean initiatives.
4. *Methods & Tools*: The lean construction research community has created or adopted several lean methods and tools over the past nearly thirty years. But the authors' believe the basic lean toolset is – Last Planner System™ (LPS), Value Stream Mapping, 5S, and Work Sampling. The authors recommend adopting these in the initial phase of lean adoption. The other methods and tools can be adopted organically as understanding and maturity grow. However, the basic tools are necessary to realise the benefits of lean adoption.
5. *Technology*: Technology has always served the purpose of improving productivity and eliminating wasteful processes, including data entry duplication and simplifying project information sharing, collaboration, and control. The authors' believe that adopting technology solutions with a lean mindset of productivity improvement and waste elimination is a better roadmap for technology adoption that makes them more sustainable.

Each level within the ILMM framework is associated with specific criteria along each of the five dimensions outlined above. By providing flexibility but governing it through fixed parameters, the authors believe they can give organisations the flexibility to adopt their own path but, at the overall industry level, provide some level of uniformity during the maturity assessment. That uniformity is critical to allow project teams and organisations to benchmark themselves and figure out how they measure up against the industry. The sub-categorization allows teams to make incremental progress without waiting for long periods and is expected to provide intrinsic motivation.

The assessment of project teams to benchmark them to a certain level of maturity is done through a survey. The assessment methodology is a modified PDCA methodology as outlined below:

- *Plan – Assessment Readiness:* Herein, the project teams and assessors agree to the basics and logistics of the assessment, allowing project teams to prepare the evidence.
- *Do – Assessment*: This is the actual onsite assessment done by the assessors. It is an in-person assessment with the assessors interviewing all the project departments, including the project team members. The assessors are expected to talk not only to the leaders in the functions but also to the supervisors, last planners, storekeepers, engineering document coordinators, billing engineers, etc. Individual interviews and surveys are done with each of the departments. Actual site walk-throughs are to be done by the assessors to gather information through visual inspection in addition to documentary evidence.
- *Check – Reporting & Assessment Action Plan*: Post the onsite visit, the assessors are expected to write a report documenting the current as-is of each department,

highlighting their strengths, the evidence gathered, etc. Based on this, the assessors benchmark the team to a certain maturity level and justify the same based on the evidence collected and gaps identified. The authors are working on a standard template report and are in the early stages of the same. The pilot studies (see below) show how it has evolved as of date.

- *Act – Implement Improvement Action Plan*: This is the implementation phase wherein the project teams implement the recommendations given by the assessors over time, document improvements and advance to the next level of maturity.

The actual assessment is done as a survey. The authors have developed standardised questions for each maturity level (and sub-level) along the five dimensions outlined above. The assessment is expected to take two working days, with the assessors visiting the project teams onsite. The responses to the assessment survey are the evidence that the team provides. The evidence is expected to be documentary evidence (like a certification for having attended a training course, a VSM document, etc.), a visible manifestation of a lean process (for example, a site store organised keeping 5S principles in mind or a Big Room wherein the teams have displayed their lookahead constraints, weekly work plans, PPC etc.) or an interview with individuals of the project teams (for example, What is waste, what is value etc.). The authors have developed an expected set of answers to each survey question. The survey and the expected answers provide some standardisation and objective assessment to the maturity assessment process. As outlined above, the post-assessment report benchmarks the project at a certain level of maturity. It provides actionable recommendations for the team to reach the next sub-level(s) or major maturity level. Finally, with the intent to scale, the authors recommend that the project teams do quarterly self-assessments to ensure that they are making incremental progress and have external assessors do an annual assessment to ensure that major progress is assessed and benchmarked. The next section shows how the methodology was applied on two project sites as a pilot study.

PILOT STUDY

Project: Cement Grinding Unit

The first pilot study was done on a Cement Grinding Unit project. The assessment was done with the main civil contractor whose contractual value in the project is Rs. 85 Crores. The project duration is about 30 months and the site had been functioning for about 18 months when the assessment was done. The project exhibits several strengths in its lean implementation, including robust top management support from the site and head office. There are limited yet documented process maps and no evidence of initial lean awareness training for 25% of the project team members. The site shows a strong adoption of 5S across several departments, including stores, quality, safety, time office, etc. The team has implemented LPS in the critical facilities of the project but not across all the facilities in the contractor's scope. The contractor has also implemented a web-enabled ERP system for data management across some functions, including accounting, finance, and HR.

Based on the outcome of the assessment, the authors, as assessors, have marked the project at a *Bronze – Medium* level of maturity. The recommendations to get to the next level of maturity include filling the gaps and completing some of the incomplete implementations of lean processes. Although the detailed action report is not in the scope of this paper, the main recommendations include items like exhaustive documentation of processes, thorough implementation of LPS, comprehensive lean training for the rest of the project teams, and adoption of other basic lean tools. To get the project team to further their maturity level, they also need to evaluate their technology strategy and deepen the complementary nature of technology and process. Finally, the organisation must develop a lean strategy document outlining how to operationalise their lean adoption (and hence maturity) through the project and/or organisation.

Project: Underground Metro Construction

The second pilot study was done on an Underground Metro construction project. The assessment was done with the main EPC contractor whose contractual value in the project is Rs. 1,526 Crores. The project duration is about 42 months and the site had been functioning for about 24 months when the assessment was done. From the assessment, it is evident that the project enjoys robust top management support both from the HO and site offices. The team has spent significant effort documenting processes in certain departments like Planning and QA/QC. All the site office personnel had undergone lean training as part of their corporate learning & development process. On an as-needed basis, the team has adopted LPS and constraint identification. At least in the stores, the team had adopted sophisticated technology solutions to monitor and manage material consumption and avoid pilferage. There were dedicated lean champions at the HO level who constantly ideated and drove lean initiatives across various project sites (including this one).

Based on the outcome of the assessment, the authors, as assessors, have marked the project at a *Bronze – Medium* level of maturity. The recommendations include comprehensive lean training for all the field project team members, a more rigorous and continuous adoption of LPS, the basic adoption of other basic lean methods and tools, and the extension of the documentation of processes to the other departments. Although the detailed action report is not in the scope of this paper, the main recommendations to get the project team to further their maturity level included the comments discussed above. Here, the assessors also recommend that the organisation develop a lean strategy document that outlines how they plan to operationalise their lean adoption and complementary digitisation strategy evolution (and hence maturity) through the project and/or organisation.

CONCLUSIONS

In conclusion, the authors have presented a maturity model that addresses the needs for the Indian construction industry. The model is currently the first version of the maturity model, and the authors believe that the model will evolve as more assessments are done. It should be noted that both the pilot project sites were done with organisations that had been practising lean in various forms for the past few years and had reached a sort of saturation point. The outcome of the assessment report has been presented to the project teams and organisations. The objective is to give organisations a concrete set of actions to implement and a guideline for adopting and growing their lean adoption to the next level.

One of the limitations of the current model and pilot studies is that it is not clear how the model will perform on a portfolio of projects within the same organisation and how the outcomes will interplay when assessment is done on various projects within the same organisation. The authors are aiming to address this in their next phase of research and potentially modify the maturity model based on the learning that comes out of that study. In the next phase, the authors are also looking to run pilot studies on projects and organisations that have not started on their lean transformation journey. Finally, the authors are looking to do a second assessment on the existing project sites and see if the maturity levels do advance (assuming the project teams did implement the recommendations from the current assessment) and if that increase in maturity levels translates to measurable improvement in project performance.

ACKNOWLEDGMENTS

The authors thank the ILCE Board of Directors, Lean practitioners, & Academic researchers for providing feedback for this work. The authors also wish to thank the pilot project teams and their respective parent organisations for providing access to their lean implementation for the pilot studies.

LEAN CONSTRUCTION 4.0 AND SOCIETY 5.0, HOW CLOSE ARE THEY?

Eric Forcael[1]

ABSTRACT

The rapid advent of technological progress has triggered many industries to modify how they perform their tasks. The construction industry has not been immune to this reality. In this sense, Lean Construction 4.0 was recently born from the fusion of Lean principles and Construction 4.0. Similarly, concepts such as Industry 5.0 and Society 5.0 have also emerged in recent years, intending to put human beings at the center of companies' work. Thus, this article addresses how close Lean Construction 4.0 and Society 5.0 are. After analyzing both approaches, it is feasible to say that the relationship between both views is sensitively close, specifically under a human-centered approach and, therefore, it cannot be ignored as a process that also deals with the transformation of society through technology.

KEYWORDS

Lean Construction 4.0, Society 5.0, Human-centered approach, People-Process-Technology.

INTRODUCTION

According to Hamzeh *et al.* (2021) and González *et al.* (2023), Lean Construction 4.0 can be defined as the necessary combination of Lean principles and the implementation of technologies that make up Industry 4.0 in the construction industry, also known as Construction 4.0. In this sense, Lean Construction is inspired by the postulates originally proposed by Lauri Koskela (1992), aimed to meet customer needs better while using less of everything, based on production management principles, and resulting in a new project delivery system that can be applied to any construction but particularly suited for complex, uncertain, and quick projects (Aziz & Hafez, 2013; Howell, 1999). Similarly, based on Industry 4.0, the concept of Construction 4.0 was born, essentially made up of the digitization of the construction industry and industrialization of construction processes (Forcael *et al.*, 2020), and characterized by robotics, Internet of Things, digital twins, 4D printing, cloud augmented and virtual reality, blockchain, artificial intelligence, machine learning, and deep learning (Baduge *et al.*, 2022).

On the other hand, Society 5.0 is a model to spread to industry and the general public how governments envision a society in the future, based on a people-centric society founded on merging cyberspace and physical space (Deguchi *et al.*, 2020) to balance economic advancement with the solution of social problems (Huang *et al.*, 2022). In other words, Society 5.0 states a system of systems connected to mitigate both local and global major social problems (productivity, competitiveness, networking, and well-being), focused on humans to balance the growth of Big Data, Internet of Things, and Artificial Intelligence, and maximize human use of the current and future technological transformation and digitization (Narvaez Rojas *et al.*, 2021).

[1] Professor, College of Engineering, Architecture and Design, Universidad San Sebastián, Concepción, Chile, eric.forcael@uss.cl, orcid.org/0000-0002-3036-4329

Thus, on the one hand, a new perspective arises that connects Lean Construction with the technologies of Construction 4.0, while another perspective known as Society 5.0 seeks to put people at the center in the face of deploying those technologies typical of Industry 4.0. This paper tries to answer the question of how close both views are. Regarding the rules of exclusion or inclusion of dimensions for the critical and comparative analysis between Lean Construction 4.0 and Society 5.0, the main criterion was to consider some of the most cited bibliographical sources related to both topics, accordingly included in the present research.

LEAN CONSTRUCTION 4.0

LEAN CONSTRUCTION

According to Koskela *et al.* (2019), from an epistemological point of view, there can be two interpretations of Lean Construction: a Platonic one that considers a static body of knowledge applied to practical situations or an Aristotelian one that contemplates a dynamic body of knowledge that is born from discoveries that come from practical situations. As a consequence of this reflection, Lean Construction could be defined as a combination of a circumstantial production model arising from trying to solve specific issues in the construction industry by implementing generic lean production principles, tools, and methods from the automobile manufacturing industry (Koskela, 2020).

In this sense, authors such as Womack & Jones (2003) and Pessôa & Trabasso (2017) have established that the Lean principles correspond to specifying value, identifying the stream value, guaranteeing the flow, pulling the value, and seeking perfection. According to Aziz & Hafez (2013), lean thinking can be summarized into eleven principles: reduce the share of non-value-adding activities (waste); reduce variability; minimize the number of steps, parts, and linkages; increase process transparency; focus control on the complete process; balance flow improvement with conversion improvement, to mention a few (Koskela, 1992), while the Construction Industry Institute (Ballard *et al.*, 2007) considers fourteen principles organized in four categories (4P of the lean way): Philosophy, Process, People and Partners, and Problem-Solving, including decisions based on long-term philosophy even over short-term financial objectives, developing extraordinary work teams committed to the enterprise philosophy, going through a company that learns from deep and continuous cogitation and improvement.

On the other hand, from a lean perspective, Dave *et al.* (2008) state that people, process, and technology —essential aspects of Lean Construction— can be summarized as a) People: the core driving force behind the process and technology, where a poorly implemented information system may jeopardize to reach a higher efficiency; b) Process: a task-based approach where variability is inherent within the processes and wastes have to be eliminated or reduced; c) Technology: including information and communication technology (ICT) systems such as CAD, estimating, scheduling and productivity software, 3D modeling, and BIM, among other tools. Accordingly, the TFV theory establishes that Transformation (T), Flow (F), and Value (V) influence People, Processes, and Information Systems (Dave *et al.*, 2008; Koskela, 2000), including the problem-solving ambit from the 4P of the lean way (Ballard *et al.*, 2007).

Thus, the last 30 years have brought with them a series of advances in rethinking the construction industry based on technology, processes, and people interaction, integrating partnering practices, databases, new construction methods, new financial and cost models, and quality management practices, helping practitioners to think about construction as a manufacturing process (Tzortzopoulos *et al.*, 2020).

CONSTRUCTION 4.0

During this first quarter of the 21st Century, significant technological and scientific progress has been evidenced in terms of Industry 4.0, which mainly focuses on computer and cyber-physical systems (Boyes *et al.*, 2018). On the other hand, the construction industry has also taken advantage of these advances, converging in what is known as Construction 4.0, a term first mentioned in 2016 by Roland Berger, which emphasizes that the digitization of the construction industry, encompassing digital data, automation, connectivity, and digital access (Roland Berger, 2016). Accordingly, Sawhney *et al.* (2020) establish that Construction 4.0 is a framework where industrial production and construction, cyber-physical systems, and digital technologies occur. Forcael *et al.* (2020) mention some technologies of Construction 4.0, such as BIM, drones, virtual and augmented reality, new materials, cloud-based project management, blockchain and cybersecurity, artificial intelligence, Big data, laser scanners, robotics and automation, wearable sensors, Internet of Things, actuators, additive manufacturing, offsite and on-site construction; technologies that may help define Construction 4.0 as the industrialization of the construction processes and digitalization of the construction industry.

Recent investigations also establish that Construction 4.0 has diverse variants focused on the broader ambit of the asset/product/property of the realm of construction and going beyond the general concepts of Industry 4.0, including but not limited to lean construction, digital building ecosystems, Internet of Things, and smart cities (Siriwardhana & Moehler, 2023). Similarly, according to Muñoz-La Rivera *et al.* (2021), Construction 4.0 can be categorized into (a) Automation (to integrate digital end-to-end engineering based on technologies to automate the physical manufacturing environment), (b) Simulations and Modelling (implements to design, build, and operate infrastructures and buildings through simulation and modeling), and (c) Digitalization and Virtualization (implements for products and industrial processes, digitally and virtually). In other words, Construction 4.0 is an extension of Industry 4.0 that focuses specifically on the construction industry, emphasizing automation, dematerialization of buildings (usually linked to “smart” homes), and the interdisciplinary nature of new construction (Forcael *et al.*, 2020).

LEAN CONSTRUCTION 4.0 FUNDAMENTALS

Essentially, the concept of Lean Construction 4.0 is a framework that integrates the principles of Lean Construction and the technologies associated with Industry 4.0 (Hatoum & Nassereddine, 2023). Accordingly, Hamzeh *et al.* (2021) suggest that Lean Construction has to seize the changes triggered by Industry 4.0 while keeping the people-processes-technology in the center, where a turnaround to Lean Construction 4.0 requires focusing on the combined benefits between digital/smart technologies and production management theory. On the other hand, based on the three crucial aspects of Lean Construction: people, process, and technology (Dave *et al.*, 2008; Koskela, 2000), there is an inherent connection between technology and Industry 4.0, or even more specifically, Construction 4.0. Nevertheless, given that Lean Construction 4.0 focuses on integrating ICT into the construction industry, it will not be easy to transform the current construction business model if all construction participants do not incorporate innovative technologies and techniques (Musa *et al.*, 2023).

Notwithstanding the relevance of the previously emphasized relationship between Lean principles and Construction 4.0, it is crucial to consider the power of people as the foundations needed to successfully attain the Lean Construction 4.0 vision of the Architecture, Engineering, and Construction (AEC) Industry (Hatoum & Nassereddine, 2023). In other words, since the resistance of a chain is given by the resistance of its weakest link, it is not possible to talk about process and technology leaving people behind, especially when one expects to have a robust chain made of people-process-technology.

In terms of applications, despite the incipient nature of the concept, some initiatives of Lean Construction 4.0 are already evidenced, such as the feasibility of implementing it in multi-family projects to improve the decision-making experience using digital twins of building works (Lara Ramirez *et al.*, 2022). Another example concerns evaluating the usability of a cloud-based tool called LeanBuild after the design stage and assessing the exhaustiveness of the software design flow, showing that considering data privacy and security, modules for designing and tracking offsite construction, sustainability tools, and artificial intelligence enhance its use and bring more value to end-users (Musa *et al.*, 2023).

In summary, Lean Construction 4.0 can be graphically represented through Figure 1, adapted from González *et al.* (2023) and Forcael *et al.* (2020).

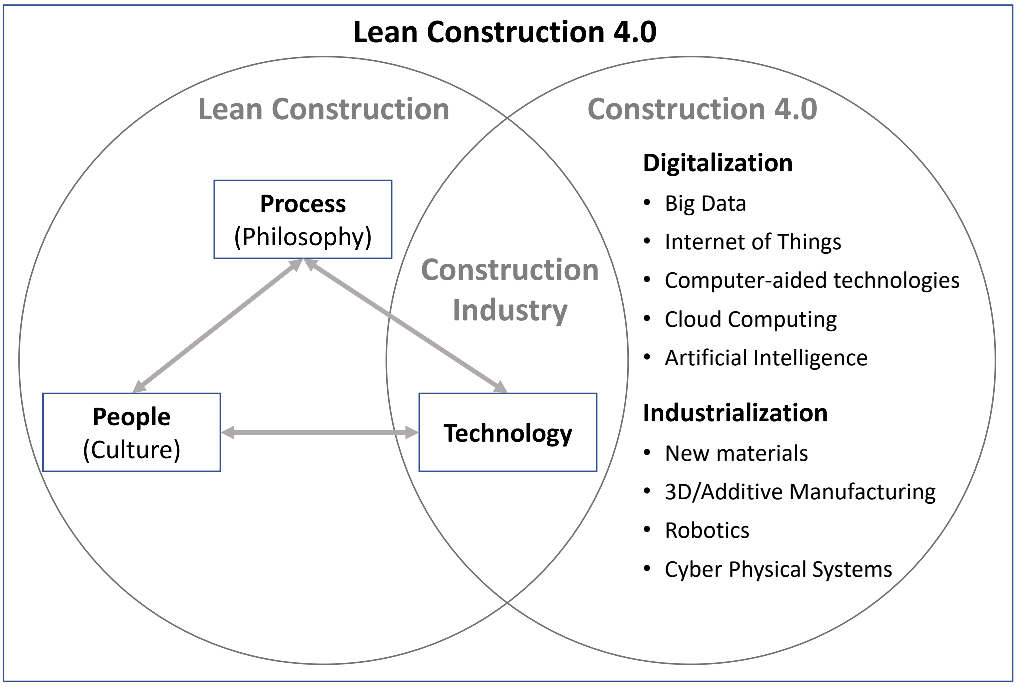

Figure 1: Lean Construction 4.0 (adapted from González *et al.* (2023) and Forcael *et al.* (2020))

SOCIETY 5.0

The term "Society 5.0" was proposed in January 2016 by the Japanese government as part of the 2016-2020 Fifth Basic Plan for Science and Technology, aimed at merging the physical space (real world) and cyberspace by fully leveraging ICT, based on a "super smart society" that brings wealth to the people (Council for Science Technology and Innovation Cabinet Office Government of Japan, 2015). From a chronological point of view, Society 1.0 corresponds to the hunter-gatherer human, Society 2.0 is related to the agrarian human, Society 3.0 is centered on an industrial human, Society 4.0 regards an information-based human, and finally, it is found to a superintelligent society known as Society 5.0 (Deguchi *et al.*, 2020).

According to Narvaez-Rojas *et al.* (2021), Society 5.0, as a Japanese concept for a "superintelligent society," is focused on human beings at the core of transformations, economic growth, technological development, and sustainability, allowing for the development of sustainable technology without restricting prosperity. In other words, Society 5.0 consists of finding solutions for the current society's obstacles based on a modern super-smart society, where people may benefit from a high-quality and enjoyable life by amalgamating cyberspace and physical space through fully utilizing ICT (Huang *et al.*, 2022).

Also, taking into account the relevance of placing the human being at the center of the work of every company, Industry 5.0 came up as a vision from a technological Industry 4.0 to an industry centered on people and the workers' well-being but keeping up productive performance (Alves *et al.*, 2023). Comparatively speaking, Industry 5.0 was launched by the European Commission looking for a sustainable, human-centric, and resilient European industry, while Japan suggested Society 5.0 to equilibrate economic progress and social issues solutions within the Japanese society (Huang *et al.*, 2022).

Thus, Society 5.0 should be sustainable and resilient against threats and unpredictable and uncertain conditions, ensuring people's safety, security, and well-being (Council for Science Technology and Innovation Cabinet Office Government of Japan, 2021). This vision toward a people-centric society, which looks to merge cyberspace with physical space, based on a knowledge-intensive and data-driven society, can be schematically summarized in Figure 2.

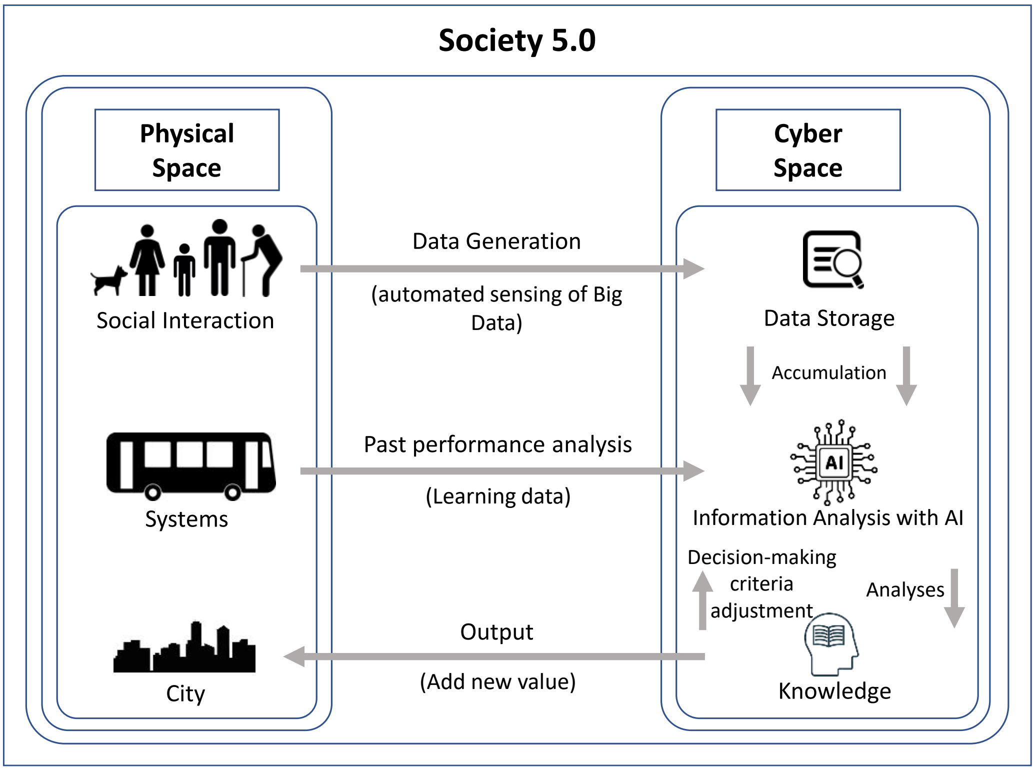

Figure 2: Society 5.0 (adapted from Deguchi *et al.* (2020))

RELATIONSHIP BETWEEN LEAN CONSTRUCTION 4.0 AND SOCIETY 5.0

Based on all of the above, it will be increasingly necessary to consider those aspects behind the technologies associated with Lean Construction 4.0 and Society 5.0, such as digital manufacturing, Internet of Things, cybersecurity, artificial intelligence, big data, cyber-physical systems, maker culture, among others, but also those topics related to professional ethics, environmental and social sustainability, decision-making under challenging situations, and the promotion of creative problem solving, thereby focusing on people. To achieve this, it would be good, for example, to look back to the model of the ancient engineers, who built fortifications and ports, channeled rivers, designed machines, and traveled to discover the world to successfully face and solve the increasingly demanding needs of a society that was becoming increasingly globalized (Cámara & Revuelta, 2016).

Tomorrow then involves implementing the technologies behind Lean Construction 4.0 but properly managing humanity's most precious resource, people; also worrying about their comprehensive training, including professionals not only from the AEC but also talent from diverse fields of knowledge: philosophers, sociologists, linguists, biologists, economists, jurists, scientists from various areas and even politicians. All of this, along with a more accentuated role of people, will provide the flexibility, plurality of approaches, and dynamism necessary to face the dizzying technological changes that the future holds for the construction industry.

In this way, it is interesting to consider how Lean Construction 4.0 principles and Society 5.0 are connected, as schematically shown in Figure 3 and discussed in the following section.

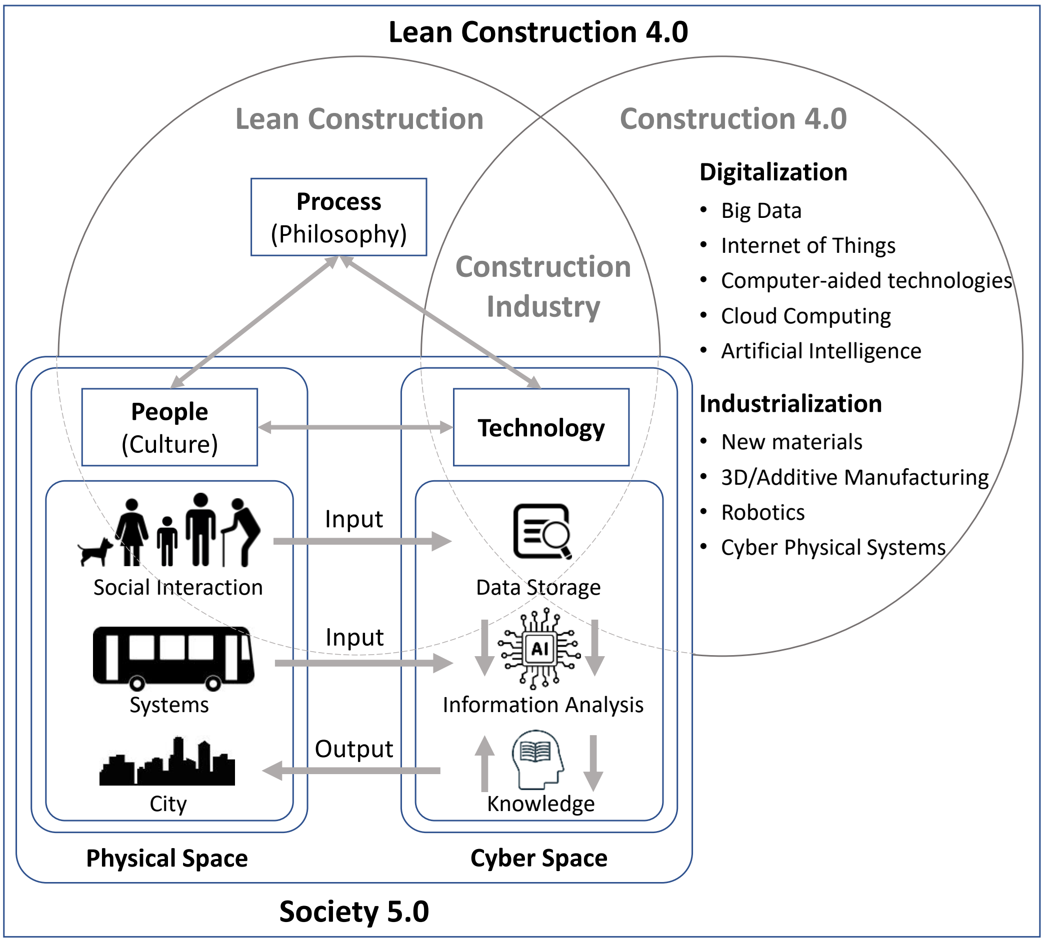

Figure 3: Lean Construction 4.0 and Society 5.0.

DISCUSSION

NEW CHALLENGES FOR A LEAN CONSTRUCTION 4.0 BASED ON SOCIETY' NEEDS

Due to the extensive scientific-technological growth, construction professionals could easily take on the legacy of the ancient engineers, characterized by their ability to face the most varied intellectual, productive, and even artistic challenges, always considering the technical aspects of their tasks but without leaving behind the human perspective in their performance (Cámara & Revuelta, 2016), capable of learning and reinventing themselves throughout life, with global projection and vocation, aware of the challenges of working with professionals from other countries and cultures, to deal with the challenges for sustainable growth of society.

These construction professionals, with solid technical and technological knowledge, are called to build a new humanism for the 21st Century (Bokova, 2014), given that they occupy positions of responsibility in all areas of the construction industry; therefore, with the ability to make decisions based on the Lean Construction 4.0 view but in total harmony with Society 5.0.

In this sense, this new approach of Lean Construction 4.0 must also be involved in the decision-making processes that affect society since the construction industry is linked primarily to technical or technological problems and overlooks its impact outside its immediate operational environment. In developing any construction project, considering environmental and social aspects is essential to the change and must be motivated by academia and industry.

It is for all these reasons that the path to the future requires a construction industry better prepared to continue developing and guiding the technological advances that are rewriting the present and that include the development of supermaterials, global communication networks, the widespread use of nanotechnology, and the exponential growth of artificial intelligence, among others. New Lean Construction 4.0 development schemes are necessary to combine the fundamentals of construction and new technological challenges, becoming more stable, specialized, and dynamic, thus aligning the performance of the construction industry with the needs of this new paradigm of Society 5.0.

The construction industry of the future must be able to learn along its way and adapt to today's rapid technological changes, continually preparing to reinvent its professional work, assuming the possibility that certain construction areas or constructive processes will disappear —the disuse of formworks with the advent of 3D concrete printing methods (Forcael *et al.*, 2021), or drones replacing people in the structural inspection of bridges (Jeong *et al.*, 2020) —, bringing the challenge of defining and linking to new business sectors.

PREPARING THE CONSTRUCTION INDUSTRY FOR THIS NEW PARADIGM THAT COMBINES LEAN CONSTRUCTION 4.0 AND SOCIETY 5.0

The ability to learn and adapt during the life of a company is a crucial competence for its survival, where conventional practices in the construction industry will require to be redesigned to adapt to the new changes brought by Industry 4.0 and boost growth successfully (Alaloul *et al.,* 2020). In this sense, taking into account that technological revolutions occur without pause and that these will affect the role of any company in society, learning to learn and adapt over time is increasingly necessary. This adaptative skill must be actively promoted within the construction industry through strategies that include increasing collaboration between academia and industry (Falcone *et al.*, 2019), establishing research and training collaborations between higher education institutions and local communities, developing continuing training programs for construction professionals, and creating mechanisms for the increment of significant learning in diverse contexts (cultural, social, technological).

Thus, the solution to different social challenges and the adaptation to the radical changes that are coming will require a more complex construction industry, which transcends traditional practices, including aspects such as the ability to implement and work in multidisciplinary and international teams, an interest in delving into cultural, social, political, and historical aspects, as a complement to purely scientific-technological ones, and a basis for mutual understanding between countries and cultures, and awareness of globalization as a fundamental key towards the new perspective of Lean Construction 4.0 and Society 5.0, which improves social cohesion and access to opportunities.

On the other hand, an adequate adaptation of the construction industry is necessary to solve the needs demanded by Lean Construction 4.0 in a dynamic and personalized way based on greater legislative dynamism and simplifying procedures and bureaucracies focused on data, moving towards human-centered systems. In this sense, it is also crucial that the construction industry assumes the role of accompanying its workers to turn them into the leaders of the future, with adequate training in aspects related to personal and professional growth, the management of technological, economic, and human resources, further promoting graduate training in construction. In other words, the industrial revolutions in which society is involved demand the attention of organizations to develop and train human resources for the future growth of the nations (Man, 2020). Lean Construction 4.0 and Society 5.0 cannot be absent in this challenge.

Finally, in terms of competitiveness in the era of Industry 4.0 and Society 5.0, it will be required to count on sensitive human resources who are fervent to find opportunities and dare to produce changes to stay in the game against competitors (Ellitan, 2020).

MERGING OF LEAN CONSTRUCTION 4.0 AND SOCIETY 5.0

As known, Industry 4.0 was defined more than ten years ago, mainly driven by a comprehensive set of interconnected innovative technologies (intelligent factories, artificial intelligence, rapid prototyping, additive manufacturing, big data, cloud computing, and robotics, among others), moving from the third to a cyber-systems-based industrial revolution (Kagermann *et al.*, 2011). Although the topics belonging to Industry 4.0 have been a matter of permanent interest, the number "5.0" has been more related to research and development of processes, products, and systems performed as "4.0 Technologies," which have been moving towards Society 5.0 (Cabinet Office of the Government of Japan, 2024). Consequently, "Industry 5.0" has been born as the effect of implementing the technologies from Industry 4.0 and their diverse derivations into the "Society 5.0" approach (Gürdür Broo *et al.*, 2022; Habash, 2022).

Thus, "5.0" will be significant in the future construction industry since its fundamental mission is to generate and apply innovative knowledge in traditional construction. In this sense, if society moves towards Industry 4.0, the construction industry must advance even faster, not only thinking about current challenges but also implementing new technological advances that allow it to reach the productivity levels of other industries. Consequently, Lean Construction 4.0 and Society 5.0 should converge on systems and methodologies beyond conventional construction's current and already obsolete models.

Ethical and Social Aspects Behind Lean Construction 4.0 and Society 5.0

As the construction industry is considered unethical, including but not limited to nepotism, interest conflicts, bribes, or contract awarding for political reasons (Owusu *et al.*, 2019), there is a challenge to meet the conduct codes and avoid corrupt practices within the construction industry (Amoah & Steyn, 2023). Therefore, based on the people-process-technology triad, it becomes essential to motivate the construction industry to be ethical when developing construction projects, going beyond the purely procedural or technological aspects (process-technology) and considering the harmful effects of unethical practices on the social fabric (people). In this sense, the construction industry must encourage reliable and committed behavior in its professionals to work under high ethical standards, understand the social responsibility of their actions, and incorporate an attitude of service towards people in each constructive project they carry out (Forcael *et al.*, 2013; Rupnow *et al.*, 2018).

In this sense, it becomes very relevant to understand the construction industry as a social activity that must reach the highest ethical standards. This principle implies that the construction industry must realize that it does not only work with equipment and machinery but also with people fundamentally. Therefore, it has to be prepared to face its work's potential ethical and social impacts. Consequently, the merging of Lean Construction 4.0 and Society 5.0 will require each construction project throughout its entire life cycle to contemplate the study of the social effects and ethical challenges present in the industry. Fortunately, professional ethics and social responsibility have been systematically incorporated into the construction industry.

Despite the previous facts and the complex societal and technological challenges that are coming, this industry's future is promising and full of opportunities, where the accomplishment of the highest ethical standards by the construction industry will be more effortless after materializing a mutually beneficial merging of Lean Construction 4.0 and Society 5.0.

A reframing view of Lean Construction 4.0 and Society 5.0

The rapid and constant transformations in the construction industry will demand less dogmatism, open-mindedness, dynamism, foresight, the ability to adapt to vertiginous changes, and the capability to face new scenarios with humbleness. This new perspective will give the modern construction industry —which will successfully implement technological advances in its work—, a relevant role in reshaping society towards a less threatening future based on the quality of life through technology.

From this perspective, a Lean Construction 4.0 vision without strong moral and scientific postulates that put society at the center is doomed. The traditional ways of the construction industry will no longer be a rigid dogma; they must be adjusted to include the contemporary and ongoing technological revolutions from Industry 4.0, primarily related to the Construction 4.0 technologies, but without ignoring the human factor. However, disruptive technologies, such as artificial intelligence or humanoid robots, may bring uncertainty to people due to the recurrent fear that machines will replace humans sooner or later. Therefore, a Lean Construction 4.0 vision that strongly emphasizes the role of people by merging with the Society 5.0 approach will play a fundamental role in the modern construction industry.

Thus, the vision of a construction industry that strives to incorporate technology and innovation into its processes to bring comfort, well-being, and economic growth without harming the environment and respecting people is more significant than ever.

IMPLICATIONS FOR LEAN PRACTITIONERS

Below are some recommended practices for Lean practitioners that can help jointly implement Lean Construction 4.0 and Society 5.0, as a way to impact society through this integration:

It is unnecessary to look for intricate definitions of these two concepts. Lean Construction 4.0 combines Lean principles and technologies from Construction 4.0, while Society 5.0 is essentially a model to publicly spread how governments envision a future based on a human-centered view that balances new technologies and solutions to social problems.

After the discussion, there might be the feeling that using ICT is the end goal, but it is not. Although supporting effective practices via software raises the value of technological outputs rapidly, "waiting for Superman" is a recurrent problem of technology —the next iteration or version will be the response—. However, the reality is that today's generation has more software than ever, and productivity remains at a standstill. The solution is not technology itself but people driving technology to improve society.

Construction professionals must strengthen their ability to face broader intellectual, constructive, technological, social, and cultural demands without leaving behind the people-centric view. They must be capable of learning and reinventing themselves throughout life, with a worldwide vision for working with people from other countries and cultures through making decisions based on the Lean Construction 4.0 principles and Society 5.0.

The construction industry must actively promote learning to learn and adapt faster than ever, including research and training collaborations with higher education institutions. This action will increase significant learning in diverse contexts (cultural, social, technological, political, and historical), facilitating access to opportunities and cultivating social cohesion.

Construction has to solve the needs demanded by Lean Construction 4.0 in a flexible way challenged by greater legislative vigor and streamlining procedures and bureaucracy, moving on the road to people-centric systems through leaders with appropriate training in aspects related to personal and professional growth, the management of financial, technological, and human resources, based on sensitive people who are fervent to dare to produce changes.

Finally, merging Lean Construction 4.0 and Society 5.0 will require each construction project's development to contemplate studying the industry's social effects and ethical challenges throughout its life cycle.

CONCLUSIONS

The present research was focused on the merging of Lean Construction and Society 5.0, based on the construction industry's role in using new technologies to face increasingly complex construction projects and their impact on people. In this context, the construction industry needs to be closely connected with people looking to impact society by using technology and information analyses that provide a quality life for all.

This new perspective requires highlighting the relevance of counting on an updated construction industry capable of gathering the best technological aspects from Construction 4.0, including how the incorporation and implementation of technology into constructive processes emphasize the privileged position of human beings and ethical principles as crucial elements of the modern construction industry. To put it differently, new ways of envisioning a construction sector that considers the best of technological advances and people's perspectives but takes into account multiple social contexts and interactions today.

Finally, the current Society 5.0 approach, based on social interaction with systems that generate valuable data to be analyzed by different means (e.g., AI), has to merge into a new technological vision that leverages the best of the Lean Construction 4.0 emphasizing the need for linking the physical and digital worlds and the relevance of human's role in technology utilization (González *et al.*, 2023). Thus, after analyzing both views, while Lean Construction 4.0 needs to develop its processes through technology and considering people, and Society 5.0 searches for the better use of technology to improve the human's physical world, it is feasible to say that the relationship between both paradigms is sensitively close, specifically under a human-centered approach and, therefore, it cannot be ignored as a process that also deals with the transformation of society through technology, a phenomenon that the human race has been facing from its origins but today more than ever.

LEAN CONSTRUCTION ENTERPRISE MANAGEMENT: THE VALUE AND POTENTIAL OF THE MERIT GAME SIMULATION

Matt Stevens[1] and Mani Poshdar[2]

ABSTRACT

A Lean Enterprise Construction-aligned learning game is an opportunity to meet the industry's needs and wants. Competitive Simulation can offer such an alignment by using an online system as a medium to instruct. Learning three critical components: vocabulary, concepts, and processes, as well as game-based learning, allows students to acquire knowledge and skills through an interactive and entertaining learning experience to achieve the purpose of real-time teaching. As a result, many educators have adopted gamification in various disciplines in the tertiary sector to enhance learning and teaching. This paper will discuss applying the MERIT game to Lean Construction Learning through a case study within a leading Australian university. The case study incorporates the Merit Game and relevant organisational management content into an undergraduate construction management program. Its focus is Lean Enterprise principles and concepts. Overall, students reported a positive learning experience with higher-order learning outcomes while identifying good practices incorporated into future delivery programs. The case study findings will inform academics and training professionals about the potential of the MERIT game, if tailored, for teaching Lean Construction at the enterprise level.

KEYWORDS

Gamification, Online Simulation, Project Management, Construction Portfolio Management

INTRODUCTION

Introducing Lean Construction (LC) through an online game with peer competition offers a robust approach to educating emerging professionals. Effective learning games motivate students to apply principles that expose them to the content and enhance their situational thinking. The adoption of gamification in higher education has become commonplace, with an increasing number of educators embracing it across various subjects to enhance student engagement and performance (Gómez-Carrasco et al., 2019; Swacha, 2021). Nevertheless, the incorporation of gamification into Lean Construction education and its community remains a developing area.

One of the seminal works in the Lean movement was Womack and Jones' (1996) book, "*Lean Thinking: Banish waste and create wealth in your corporation*." This publication signalled the critical nature of enterprises in minimising waste and producing higher value.

Lean Construction Enterprise (LCE) dynamics are primary lessons in the MERIT Game experience. According to Tsigskas (2022), knowledge capture about LCE should be:

- Production and administration processes driven solely by complementarity of activities to increase profit.
- Flow of work, material, information, and cash through digitisation.
- Adaptation strategies and methods to changing market conditions.

These three understandings provide the learner with a starting point to build upon. They can progress their mastery to more nuanced and powerful ideas that scaffold from these foundations.

MERIT GAME AND EQUIPPING STUDENTS WITH PRACTICAL SKILLS

There is a small but significant threat to tertiary education if relevant skills are not reliably captured by their graduates. Business Insider (2024) reports that 37% made progress in skills-based hiring, including Walmart, Apple, and Target, and 45%, took college requirements out of job postings such as Bank of America, Amazon, and Lockheed Martin. Still, they failed to institute actual changes in their formal process and hiring documentation. However, it may be an emerging signal from the market about the value and hunger for relevant skills.

Recognising the importance of equipping students with practical skills, one construction management program (WSU 2020) has integrated the MERIT game into its curriculum. This game-based approach aligns with the evolving needs of the construction industry and offers students hands-on experience in managing project portfolios. By bridging the gap between theoretical knowledge and practical application, the program aims to prepare students for the dynamic challenges of the construction sector. Additionally, the MERIT game addresses challenges in direct labour management. This feature resonates with the prevailing market reality that approximately ¾ of construction firms are characterized as non-subcontract yet labour-intensive entities (Stevens and Smolders 2023a).

PROJECT PORTFOLIO DYNAMICS

Modern construction projects' larger size and increased complexity have catalysed the development of improved leadership and management training methods for leaders and managers – matriculating or working (Ahmed et al. 2014). Educational games such as MERIT simulate the intricacies and interdependencies in real-world project management, making it an excellent platform for conveying complex concepts and promoting deeper understanding. The MERIT game's foundational work is manifested in Modern Construction Management (Harris et al., 2021) and its seven editions, first published in 1983. The book focused on construction organisational leadership and the many simultaneous projects that are ongoing at any one time. The MERIT game was published, and its first competition was held in 1989.

Constructing a project is a linear one-off process in which every mistake affects two or more tasks downstream – early mistakes are especially pernicious. A contractor's business involves managing several critical paths and their myriad of tasks to produce cash flow, profit and a good reputation. Risk is well-managed when a company is sensitive to incorrect or tardy task executions (Stevens and Smolders 2023)

Building upon the educational benefits of gamification, particularly demonstrated through the MERIT game, it is essential to explore the broader dynamics of project management, specifically focusing on Project Portfolio Management (PPM). By integrating game-based learning experiences like the MERIT game with discussions on PPM, students can understand the complexities and challenges involved in managing multiple projects within an organisational context.

The MERIT game effectively simulates the challenges and opportunities inherent in PPM, a strategic framework integral to effective project management that aligns multiple projects with an organisation's broader strategic objectives (Project Management Institute, 2000). Effective PPM needs a structured process, including risk assessment, estimated profitability and an overall strategic fit to the corporate goals (Bilgin et al., 2023). PPM focuses on dovetailing projects into a time and resource demand framework unique to the constructor and requires a vastly different approach than project management (Oltman, 2008).

As an example, the staffing of projects is not primarily for the site manager to decide but typically a home office executive who balances all the current project's demands. The Lean project production practice of Percent Plan Complete, as described by Stevens (2015), may not align with realism. For educators, a solid grasp of PPM is essential for students in the construction industry, where managing multiple interrelated projects as a Project Manager or as a Managing Director is a certainty.

PPM's strength lies in its ability to handle the uncertainties and complexities often encountered in projects. It offers a flexible approach that can adapt to changes and unforeseen challenges, ensuring project success (Cooper et al., 2000). One significant advantage of PPM is its approach to understanding and managing the interconnections between different projects. Managing these connections in environments where projects are closely linked regarding resources and goals is vital for resource efficiency, avoiding delays and cost overruns (Engwall & Jerbrant, 2003).

Moreover, PPM significantly contributes to enhancing project success rates. Effective PPM involves regular portfolio reviews, strict schedule adherence, and a readiness to allocate additional resources when necessary, resulting in more successful project outcomes (Unger et al., 2012). Furthermore, effective PPM helps mitigate counterproductive practices such as overburdening teams and thinly stretching financial resources across numerous projects, which can lead to poor quality and project failure. Instead, PPM advocates for a balanced distribution of resources, ensuring that each project receives the necessary support to thrive (Levine, 2005). Additionally, PPM aligns projects with the organisation's long-term goals. Organisations can direct their efforts towards achieving broader objectives by selecting and prioritising projects based on their strategic value (Archer & Ghasemzadeh, 1999). Thus, PPM offers numerous advantages for organisations seeking to optimise project outcomes and align them with overall strategic goals. Its application provides a comprehensive framework for addressing uncertainties, managing interdependencies, improving success rates, ensuring balanced resource allocation, and aligning projects with strategic objectives.

This paper utilises the Introduction, Methods, Results, and Discussion (IMRAD) framework to examine opportunities and assert reasoned directions for the effective use of gamification in construction management teaching and learning.

METHOD

This research employed a case study approach, utilising the MERIT Game online simulation within an elective subject, Construction Business Management, at Western Sydney University (WSU). The researchers utilised this simulation to collect and analyse data, including direct observations. The study collected data from the most recent two years of weekly competition results, as well as post-competition student reflection papers.

THE MERIT GAME STRUCTURE AND PROCESS

The MERIT game places each student as a board member for a publicly held and prime construction contractor employing direct labour. The simulation encompasses six specialised management areas.: a) Financial b) Overhead c) Estimating d) Bidding e) Personnel and f) Construction. Typically, teams are comprised of 4 students and self-regulate.

Three- to six-person groups are created at the start of the subject – some self-form, while unattached students are assigned. It is recommended that each student be assigned responsibility for two of the six areas – finance, overhead, estimating, bidding, personnel, and construction. This is an intended overlap to prompt members' decision-making and interaction. Each member is encouraged to add their perspectives in the decision-making process for unassigned areas.

From the first to the fourth week of the semester, the instructor narrates the purpose (the "why"), vocabulary, concepts, and preferred process for successfully engaging the game. The teaching intent is to encourage new approaches or, at minimum, iterative improvements to engage the game successfully.

A 20-question assessment is given to individual students. Afterwards, groups are expected to enter their decisions in a 2-week trialling period for students to familiarise themselves with the program. Each class period is spent with two to three groups entering their decisions into the program while sharing their screen with all attendees. Subsequently, an 8-period competition follows. Teams who earn at or above 2,000 points receive full marks, and those scoring less are given a prorated score. After the trialling period, another more detailed online quiz is given. It is equal to the first but demands more mastery for a passing mark. This serves indirectly as a self-check for student preparation before the competition starts.

The simulation starts in the fifth period after the previous board exits. This means the flow of work and follow-on outcomes are somewhat uncontrollable for the student groups. Previous decisions affect the current opportunities. This downstream ripple effect is realistic for the industry. For each period, an analysis of the results has to be conducted. This limits planning options and informs the students of the stubborn linkage between earlier decisions, current outcomes, and future possible actions. The previous board effect (and their decisions) shows one dimension of uncontrollable factors present in construction. In this way, projects can be viewed as income-expense flows and critical path management challenges.

A reflection paper is required from all student groups as their final assessment. Four areas of inquiry are expected to be answered:

1. Individual student's expectations
2. Previous Assessments' Value and Lessons Learnt Individually and as a Team
3. Strategies and Decision-Making in Each Period
4. Reflection and Conclusions
    a) What were the challenges of working individually and as a group?
    b) What skills did you and your group acquire or strengthen?
    c) What were your individual and group lessons learnt
    d) What are your group's suggestions for future participants?

There is an intended overlap of each query's content disclosure. The researchers have found that prompting answers in the template encourages expansive and complete reflection. So, a template is provided so teams will answer the core questions and ponder "what if" and lessons learnt.

THE MERIT GAME SCORING

The MERIT Game total scoring is multifactor. Based on ten metrics, groups decrease or increase their starting 1000 points after weekly decisions. See Figure 1. The emphasis is on a balanced approach to the construction of work. Construction PPM has little room to focus on a single or a few outcomes. In the opinion of the MERIT game creators, this will lead to a deterioration of the firm's viability. Additionally, the weighted approach of the outputs guides the boards of directors to be more sensitive to transcendent results, such as client satisfaction and less so, such as operating to turnover. Of course, financial stresses will show seminal importance as the subject company is restricted in tendering and bidding options.

Performance Indicators

Period	Total	Turnover	Gross Profit to Turnover	Operating Profit to Turnover	Company Value	Capital Employed	Contract Completion	Forward Workload	Forward Margin	Share Price	Client Satisfaction
4	1000	80	75	60	120	100	120	80	120	120	125

Figure 1. Assessment Report of Individual Components Showing the Starting Point Total

Construction contracting involves early collection and confirmation of information for each project built. Excellent pre-project planning is contingent on this (Stevens et al. 2023). Effective PPM requires capturing, analysing, and distilling project and organisational data into actions. There are over three dozen reports to view and digest. See Figure 2.

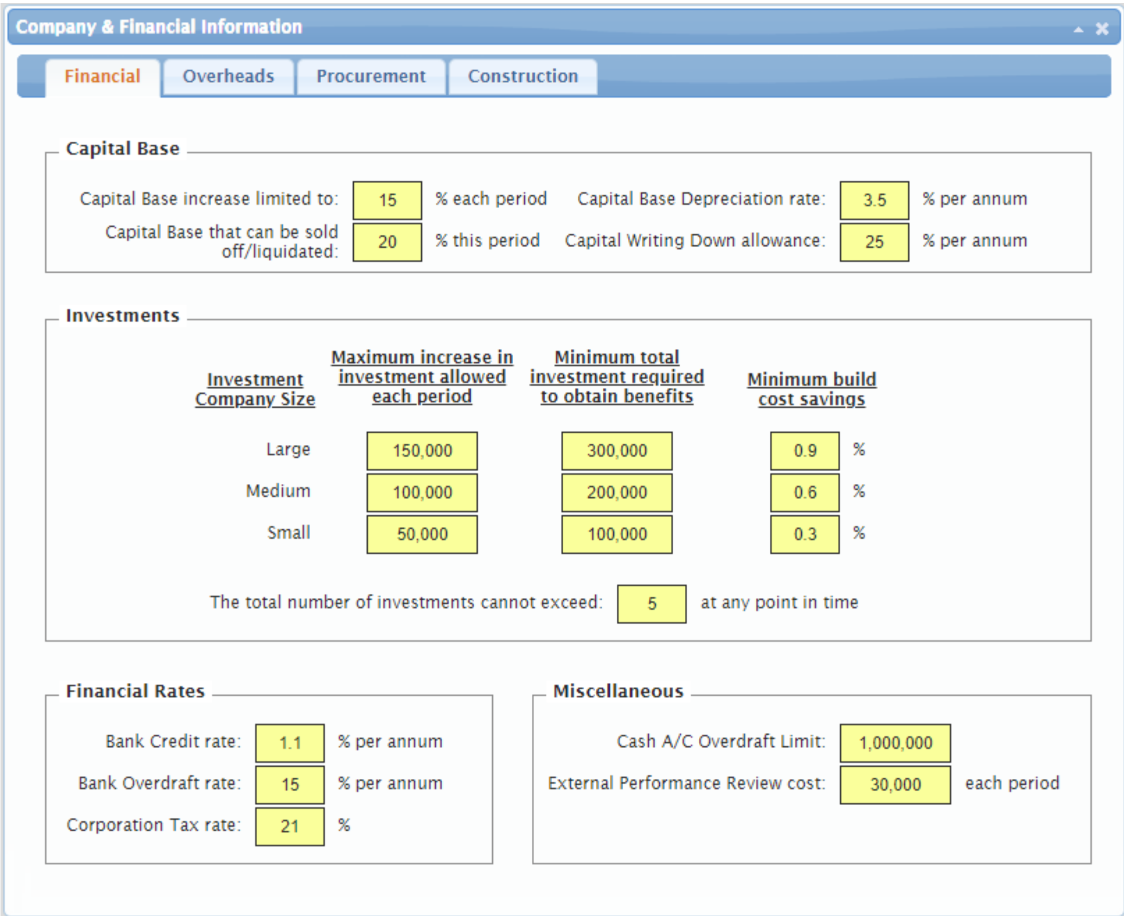

Figure 2. One Example of the More than Three Dozen Reports and Ratio Guidelines

Lean Construction Application

At the start of the semester, we propose that students capture key concepts and reorient their thinking by applying Lean Concepts to the dynamics of construction contracting PPM. Indeed, the basics will start the process of rethinking productivity in construction contracting. This change is relatively minor to the subject's content.

1. Lean Thinking versus Muda. One role of Lean leadership is teaching people how to see waste. Lean philosophy makes it a priority for stakeholders to suggest methods to convert waste into value.
    a. Type 1 Muda - Necessary but, non-value-creating practices, such as client meetings (where project results are physically evident and outstanding issues can be documented without interpersonal contact) or multiparty approval (practised in a bureaucracy).
    b. Type 2 Muda - Non-value creating and unnecessary, such as amenities (supports operations and does not directly produce work), and marketing activities (completed work done well is the best sales practice)
2. Value - Value creation can be defined as results sought by clients in which they will pay per an income schedule. Certainly, after several projects, those contractors that have consistently met safety, quality, cost and schedule demands can tender and win at a higher proposed price than the average competitor.
3. The Value Stream - In Value Streaming, many project tasks are interrelated and ordered, and when executed well, they positively affect safety, quality, cost, and schedule. Of course, clients may add environmental, economic, and social metrics to their requirements.
    a. Many steps will be found to create value unambiguously.
    b. Other steps will be found not to create value but are necessary due to current technology and production assets – Type 1 Muda
    c. On an average project, it has been found that several steps create no value and are immediately avoidable – Type 2 Muda

It is critical to explain to students that three tasks are involved in Value Streaming

- Problem-solving Task – taking information and designing an action involving a product.
- Information management Task – collection and confirmation of project facts distilled into planning through detailed scheduling to delivery.
- Transformation Task – product and labour to install the specified item on the job.

Identifying the entire value stream for each action/installation means a team understands and can improve. What is not understood cannot be improved.

4. Flow - Flow must be a priority focus by the team in construction. The demand of resources for the work available is synchronised (Single Piece Flow) Using "chaku chaku" or "load load," one worker or manager takes a task from the information gathering stage to completion as practicable—the opposite of batch and queue.
5. Pull - a formalised trigger of work ready to install determines the short-term allocation of resources for a specific task – in construction, it may be a building floor or infrastructure area.
6. Perfection - The improvement journey is inefficient and frustrating if you find "just good enough" rather than perfection. The constant striving to reach a process error and defect-free state motivates employees steadily and specifically.

Table 1: Proposed Conversion of the MERIT Game Vocabulary and Concepts to Align with Lean Construction

MERIT Game Concept	Explanation	Lean Construction Concept
Hiring and Layoffs of Managers and Workers Increase Costs.	Forecast resource demand for the current and future demand across the portfolio of projects to increase utilisation and lessen waste and resulting crises. This includes co-locating cells of production. In construction contracting, equipment shops next to tendering and PM departments cause people to communicate face-to-face, which lessens conflict and increases social and business interaction.	"Heijunka" or Levelled Workload
Governing Structure – Executive Structure Allocates Resources Among Projects	This is a critical component of portfolio management, a strategic planning tool that requires executive management to select three to five objectives – all others are deselected (Juran 1995).	"Hoshin Kanri" or Executive Level Resource Allocation
Redundant Systems and Double-Checking Keep Errors Minimised	Mistake-proofing and Trouble-blocking methods limit or eliminate potential rework and crises. (Tommelain 2008). A customised spreadsheet is recommended for students to minimise math and calculator mistakes. See Figure 3.	"Poka-yoke" ("Baka Yoke") or mistake-proofing
Construction Decision-Making	Construction Contractor must set the production rate (cycle time) to exceed customer demand due to the industry's many uncontrollable factors causing unforeseen delays. It is a core principle of LC. Meeting Takt Time assures that the project fulfils all functional requirements within the set time, positively influencing cost and quality. It must be planned and verified by a structured process, managerially driven from the tender stage and pre-mobilization planning to practical completion	"Takt Time" or Customer Required Delivery Time
Supporting Spreadsheet	The pre-programmed spreadsheet represents a simple ITC application to assist teams with rapidly calculating critical numbers. This supplants a hand calculator approach and frees up more time for iterating improvement ideas.	LC's 8th principle, "Use only reliable, thoroughly tested technology that serves your people and process"
13 Class Sessions of Trialling and Competition	The instructor selects two student teams each class session during the last 12 weeks (each team is present watching and listening) Review the previous week's decisions and results Points out key insights and suggests ideas for improvement	Kaizen

At first, students may not appreciate the structure and decision-making process needed to succeed in the MERIT game. The game produces over three dozen metrics that indicate critical strategic and operational direction from the previous period. Many indicate a strengthening, static or weakening company position. Measures such as utilisation percentage, on-site cost per worker, and estimating confidence alert the teams of deficiency or perfect optimisation. This consistent reality that collecting and confirming a myriad of information items affects the next period's decision-making is a realistic pressure. See Figure 3.

Job #	Estimating Confidence	Current Total Site Cost	Current Per Person Site Cost	Overstaff Limit	Period 4 Labour Needed	Period 5 Labour Needed	Period 6 Labour Needed	Period 7 Labour Needed	Period 8 Labour Needed	Period 9 Labour Needed	Cost Based on Current Performance	Lay Off	Billing Projected	Cash Needed Next Period
3	Extremely High	657,138	10,268	45.00%	64	64					657,138		$3,587,908	$3,493,581
10	Extremely High	74,890	14,978	35.00%	5	9					134,802		$840,835	$456,896
12	Extremely High	175,034	17,503	25.00%	10	15					175,034		$1,590,390	$1,039,471
19	Extremely High	0	#DIV/0!	45.00%	0	42					#DIV/0!		#DIV/0!	$0
20	Extremely High	0	#DIV/0!	45.00%	0	81					#DIV/0!		#DIV/0!	$0

Figure 3. Spreadsheet Critical to Organising Inputs and Calculating Outputs

DISCUSSION

Trends in construction education point to emerging opportunities and threats. Employers appear to be starting to embrace skill-based hiring criteria. Students with general management degrees without an understanding of current issues may be losing their perceived value to contractors. The largest employers from several industries are signalling dissatisfaction with graduates.

PPM is a reality for construction contractors and their managing directors. Teaching this skill will often serve future corporate leaders and their project managers. Since most contractors, including specialist contractors, manage labour directly to complete projects, the scopes they agree on are a fraction of the total project size, so PMs manage multiple jobs.

Construction contracting is a VUCA business, i.e., volatile, uncertain, complex and ambiguous, a phrase and concept created by Bennis and Nanus (1986). There is a critical need to use a proven system to attain alignment of the many contractor functions. Lean Construction has proven to beneficially guide the dozens of decisions that need to be made that affect safety, quality, cost, and schedule. Said differently, there is more certainty and speed when all decisions dovetail efficiently. It is vital since poor decisions negatively impact follow-up tasks.

In construction contracting, factorials show us the complexity dimension from an increased number of projects, i.e., this leads to a disproportionately more significant number of possible combinations and, thus, risk event probabilities. Each project varies under the conditions it is built, such as client expectations, design uniqueness, material required, contract terms, and site conditions; therefore, it contains many new variables. Additionally, multiple projects have different work-in-process percentages, undocumented promises, dozens of interrelated tasks and differing specifications. This PPM challenge is significant. So, comparing two portfolios – a) four projects to b) eight projects, i.e., possible combinations are written as n! so,

a. 4! projects means that there are 24 interconnections, i.e. 1x2x3x4
b. 8! projects translate into 40,320 interconnections, i.e. 1x2x3x4x5x6x7x8

Projects demand shared resources such as craftworkers, project managers, site supervisors, cash, and equipment. However, people are the "wild card" in the construction business. Project managers and site supervisors are unique, and when they interact with others, the predictability of positive results decreases. So, if an executive can keep the variability in people (employees, clients, and stakeholders) less, the probability of risk events manifesting is lower. Contrast this to manufacturing; for example, if a company has produced 100,000 of a product, making one more is less costly and risky than creating the first one. No other industry is exposed to this factorial dynamic. Thus, error rates trend higher than others, meaning mistake-proofing has value in reducing rework and its disproportional cost.

Presently, Information and Communication Technology (ICT) is a default option for universities' education challenges. The MERIT game can be viewed as a mature educational product. It reflects LC's 8th principle, "Use only reliable, thoroughly tested technology that serves your people and process". It has been on the market for over 30 years and is based on a textbook in its seventh edition. Refreshing its content, structure, and process will extend its useful life. This paper suggests that the Lean Construction approach can be embedded as an electronic game to further construction management education.

For the continued relevance of construction management graduates, their programs should continue to evolve in content and delivery. The MERIT Game reflects the industry's realities, especially those subcontractors comprising ¾ of the industry and main contractors constructing smaller projects.

CONCLUSIONS

The Lean Enterprise approach to construction contracting is efficient for achieving high scores in the MERIT Game, thus a beginning competent understanding of PPM dynamics. Increasing project complexity and size continue to challenge constructors. Lean Construction is a proven answer.

The researchers envision changing labels and instructions for the present MERIT game to become a useful Lean Construction teaching tool for the Community. This would be a second product that the game creators should consider. It would involve less time and expense than a bespoke one. Lean thinking is a mainstream and valuable approach to raising value and eliminating waste.

Based on the researchers' career experience and observations, PPM is not consistently taught in universities' construction management curricula. This is a misalignment with industry realities. Many graduates will become project managers who lead more than one site at a time. A smaller percentage will become construction company owners. PPM mastery is the challenge. There is little reason for educators not to confront this reality. The good news is that a ready application exists to start from. Iterative improvement can be pursued quickly.

"Business as Usual" is not acceptable in construction education, given the significant project complexity and size increases. Educators must match this rising intensity. If not, contractors may be likely to discount the value of graduates and hire more under-21 recruits with good mental, emotional, and spiritual composition and train them in needed skills. Said differently, utilising new ways of educating while covering critical gaps should keep pace with industry demands.

THE REPAIR-CO GAME: A ROADMAP TO DEMONSTRATE THE IMPORTANCE OF PROBLEM-SOLVING CAPABILITIES OF LEAN TOOLS

Ragavi Prabaharan,[1] Ganesh Devkar[2], Zofia K. Rybkowski[3] and Marimuthu Kannimuthu[4]

ABSTRACT

Lean Construction facilitators use the Repair-Co Game to introduce new stakeholders to the need for Lean. The game heightens participant awareness of the futility of impulsive finger-pointing to individual workers when an existing management system may instead be principally responsible for a company's inability to reach its expressed goals. Although this current gaming approach has been shown to be effective, the authors of this paper observed that the Repair-Co Game can also be expanded to introduce players to the usefulness of Lean tools that can identify root causes and effective countermeasures. These tools include the Ishikawa Fishbone Diagram, Pareto Chart, 5 Whys Root Cause Analysis, Big Room Meetings, and Collective Kaizen, which are implemented during Big Room meetings. This expanded version of the Repair-Co Simulation has been tested with 35 graduate students at Texas A&M University, 45 students at CEPT University, and 33 members of the URC construction company. Despite the different locations of the test grounds and make-up of players, results from initial experimental sessions have been shown to be remarkably similar in some ways but also different in others, demonstrating the important nuances of an individual context. Qualitative feedback from participants demonstrate the potential of the game in helping participants solve problems at their root cause.

INTRODUCTION

In contrast to manufacturing, the construction industry is widely recognized for its fragmentation, silo-ization of OAEC[5] (Owner, Architecture, Engineering, and Construction)

[3] Associate Professor, Department of Construction Science, Texas A&M University, College Station, TX, USA, o: (979) 845-4354, zrybkowski@tamu.edu, orcid.org/0000-0002-0683-5004

[4] Technical Secretary, Institute for Lean Construction Excellence (ILCE), India, +9173050 40838, technical.Secretary1@ilce.in, orcid.org/0000-0002-8158-1868

[5] This paper uses the acronym OAEC to signify Owner – Architect – Engineer – Constructor, where the Owner is placed in the primary position to remind other stakeholders that fulfilling the Owner's conditions of satisfaction is paramount in Lean.

stakeholders and high levels of variability. Prabaharan and Shanmugapriya (2022) investigated barriers to adopting Lean in Indian construction industries. They discovered that one of the critical barriers to the implementation of Lean is the "perceived complexity of learning and implementing Lean concepts" (p. 11). Furthermore, similar findings can be found throughout the literature, indicating that a "lack of knowledge and understanding of Lean principles and the intricacy of Lean philosophy and terminology" persists as a potential hindrance to the incorporation of Lean practices within the construction industry (Demirkesen et al. 2019, p. 7-8).

Lean simulation games serve as highly reliable training tools to help professionals learn Lean concepts through hands-on experiences. Lean games help bridge the gap between a concept and its application (Bhatnagar and Devkar 2021). Lean simulation games serve a pivotal role in helping OAEC professionals to dispel misconceptions and enhance their understanding of Lean concepts (Rybkowski et al. 2021). Lean simulation games are regarded as an influential way to teach Lean concepts clearly and effectively (Hamzeh et al. 2017; Rybkowski et al. 2018). Over the past decade, there has been a steady rise in the adoption of Lean simulation games within the OAEC industry (Bhatnagar et al. 2022). As firms progress in their Lean initiatives, they can incorporate a training program with simulation games targeted to address specific Lean processes and tools. For Lean training workshops, especially those catering to working professionals, specific Lean simulation games must be designed and tested to ensure that they are effective in communicating desired objectives.

This research paper reports on results from implementing the Repair-Co Game in three different locations with different populations,[6] namely: (i) graduate students of construction engineering and management at CEPT University in Ahmedabad, India, (ii) graduate students of construction science at Texas A&M University in College Station, Texas, USA, and (iii) URC Construction[7] practitioners, including craftworkers, and licensed engineers and architects in Chennai, India. Because so much of Lean arguably reflects common sense, students may initially question the need for Lean principles at the beginning of a course on Lean. Therefore, it is helpful to share evidence of the poor performance of the OAEC sector, but also how Lean has been shown to help (McKinsey 2017). Prior to the rounds of play described in this paper, the Repair-Co Game had already been facilitated in its original incarnation in numerous settings and in various locations. However, results from the Repair-Co Game have not been published in peer-reviewed literature in either its (a) original or (b) extended versions, which offers additional lessons. The intent of this paper is to fill this gap.

LITERATURE REVIEW

PART I: THE GENESIS OF THE REPAIR-CO GAME

The Repair-Co Game is popularly used in the classroom and professional training programs to open the minds of students and professionals about the challenges the construction industry faces, and the need for a better approach such as Lean. This simulation game is relatively simple to administer in diverse settings thanks to limited physical demands. The authors of this paper have used the Repair-Co Game in the classroom setting for several years. The version played is based on a PowerPoint™ instructional guide prepared and openly shared by Alan Mossman (2020). In this guide, Mossman credits John Seddon, Vanguard Consulting, UK, for inspiring the game (Seddon n.d.). The authors of this paper searched for the roots of this game and discovered that the stated mission of the consulting firm echoes the spirit of the Repair-Co Game. The website title, "Bursting bureaucracy in home repairs," provided contextual

[6] Readers may wish to contact the authors of this paper to learn specifics about facilitation of Repair-Co in multiple settings.
[7] URC Construction is a general contractor headquartered in Erode, India, specializing in infrastructure construction with approximately 2,000 employees.

information about the Repair-Co Game. A 20-minute podcast by Seddon (2020) was transcribed by the authors to understand the genesis of the Repair-Co Game. In his podcast, John Seddon argues that "95% of the influences on performance are in the system, and only 5% are due to the people who actually serve customers" (Seddon 2020). This is the fundamental message conveyed by the Repair-Co Game. To illustrate his point, Seddon used the example of a repair person who is called to fix washing machines. He chose repair companies as examples of service organizations because most people can readily relate to them (Seddon 2020).

Mossman developed the Repair-Co Game from Seddon's exercise. The game starts with a narrative about a Repair-Company's call centre that receives service requests from customers. The call centre personnel notifies a repairperson who is then dispatched throughout a specified geographic area according to logistics established by the call centre. The repairperson travels the route dictated by the logistics map. The repairperson's sequence of daily activities is informed by individuals such as the call centre receptionist, logistics personnel, and a manager. Mossman's graphics support Seddon's vision that helps players focus on the facts of the narrative (Figure 1).

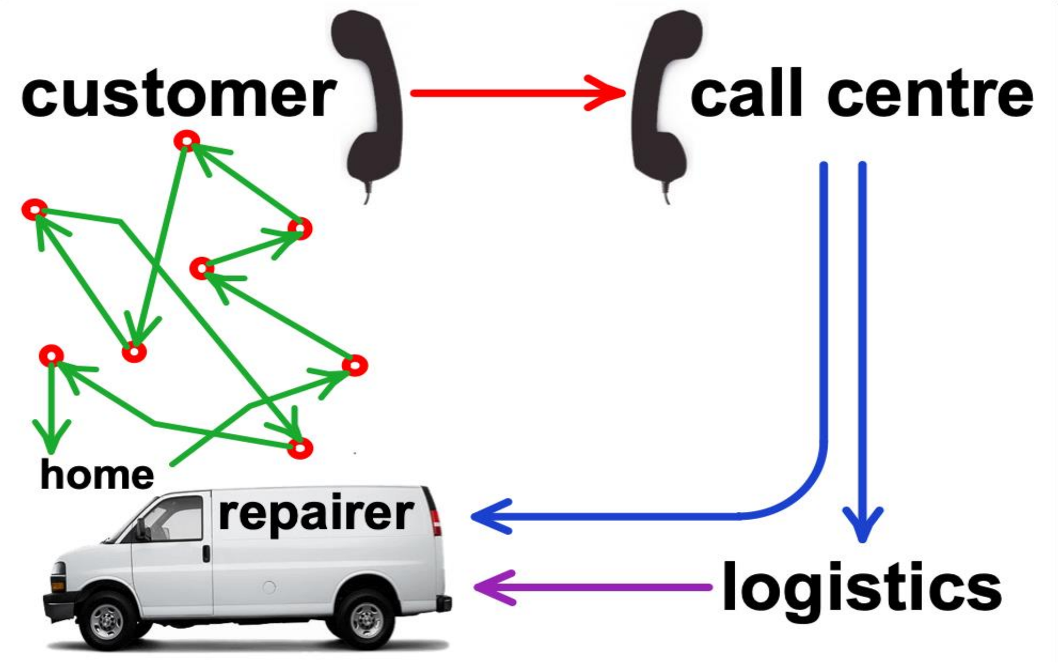

Figure 1: Repair-Co Game setup.
Graphic reprinted from Mossman (2020), with permission.

Once a facilitator describes the scenario, participants are shown the diagram in Figure 2 and asked the following questions: According to the manager's weekly schedule, how many daily repair visits are expected during a typical workweek? (e.g. 8). How many visits, on average, are actually made each day during a typical week? (e.g. 5.5). Once participants openly respond to these two questions, they are invited to individually, and then collectively in a group, brainstorm possible reasons the repairperson's schedule varies. The facilitator projects an Excel spreadsheet onto a wall for all to see; a hand-drawn table on a whiteboard or flip chart also works. In the left-hand column, the facilitator lists each brainstormed response separately. While the group is asked to collectively share at least ten possible reasons for the variability, a large and/or highly engaged group may generate quite a few more. With brainstorming complete, the facilitator writes "repairperson" in the heading of the column to the immediate right of the potential "reasons" column and "system" atop the farthest right-hand column. The facilitator then directs participant attention to the table and then asks: "What is the main cause of the variation? Is it primarily the fault of the repairperson or the system?" After moving down the list and marking participant responses, the facilitator then asks: "Yet where is the blame often placed?" While some variation is arguably due to the person or both the person and the system, most reasons for varied performance are discovered to be outside the control of the repairperson and are instead due to a fault of the system. In the Seddon version of the Repair-Co Game, the game stops here. The original intent is to give participants an "aha" realization that it is often not the individual alone who is the main culprit. In other words, the game convincingly demonstrates that it is often the *system* that first and foremost needs to be fixed with the help of those performing the work.

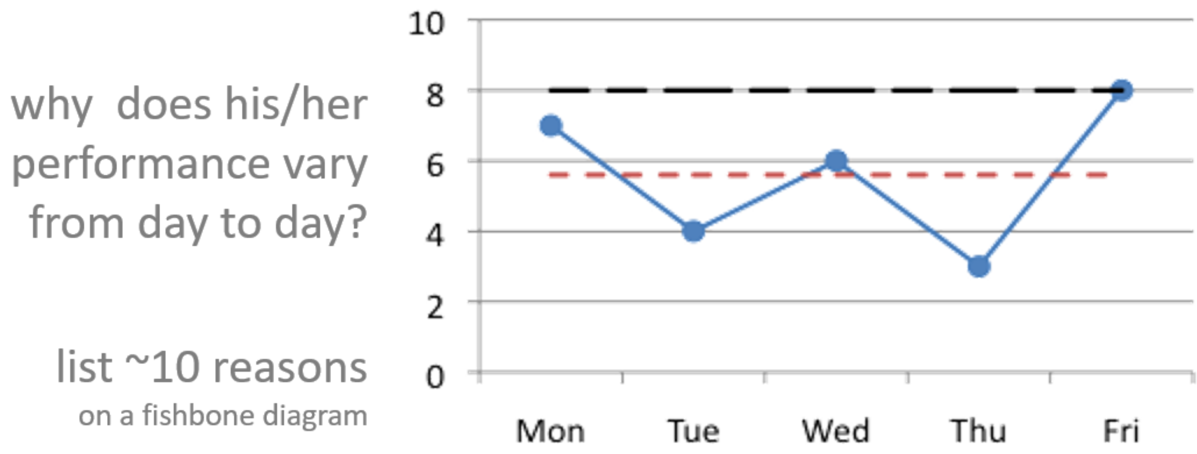

Figure 2: Performance characteristics of the repair person during a typical workweek. The graphic is reprinted from Mossman (2020) with permission.

Individuals can be myopic. One takeaway of the Repair-Co Game is that collective brainstorming during a Big Room meeting can help a manager identify numerous potential causes of a challenging problem s/he may not have considered when contemplating the problem alone. Brainstorming with others within an organization often helps ideas emerge that might otherwise be overlooked.

PART II. EXTENDING REPAIR-CO: THE POTENCY OF THREE LEAN TOOLS

The original intent of playing the Repair-Co Game has been to heighten participant awareness of the need for Lean to fix an organization's system with the help of the people in the organization. While the game continues to serve effectively in this capacity, it can further be used as an illustration to show how three additional Lean tools can be used to solve an organization's challenges. These three tools are the Ishikawa Fish Bone (cause and effect) diagram, the Pareto Chart, and the Five-Whys Root Cause Analysis.

Following Part I, which helps participants to appreciate the system as a key area of improvement rather than primarily blaming the repairperson, the facilitator invites participants to consider two different contexts: a large city and a small town. Participants are then provided with a blank template of Ishikawa Fish Bone diagram showing different "bones," that can be used to organize various causes under six categories: measurement, manpower, environment, machines, methods, and materials. The participants are then asked to insert the "reasons for varied performance" they had previously brainstormed into the Ishikawa Fish Bone diagram. One advantage of the fishbone structure is that the categories can help prompt participants to identify causes they may not have previously considered. For example, under "measurement," did the group give thought to the possibility that the repair person's daily performance may not have been accurately measured and recorded? The Ishikawa Diagram reminds us to consider this, as one of the six categorical "bones" of the "fish." To help identify additional causes, the facilitator can also invite participants to assume different roles such as customer, call centre personnel, repairperson, manager, etc. (Bono n.d.).

In reality, not all potential reasons shown in the fishbone diagram are equally responsible for a problem. Typically, a small proportion of causes (i.e. 20%) create the lion's share (80%) of a problem/effect. The identified causes by the participants are entered into a spreadsheet, and the participants are asked to consider the likelihood of the occurrence of each of these causes. The participants are asked to raise their hands if they feel a possible cause can occur in the context of a specific large city—and subsequently—a small town. The raised hands are counted by the facilitator, and this number is entered into the spreadsheet. This process is repeated for each brainstormed reason. This tabulated information is then graphed in the spreadsheet and depicted as a Pareto Chart (i.e., the frequency of reasons is sequenced from left to right, from largest to smallest). As this process of seeking inputs is conducted for both big cities and small towns, two Pareto Charts should be separately generated by the end of this exercise. The ranked histogram format of a Pareto Chart helps viewers readily identify primary culprits (i.e. reasons for performance variability) and focus on a countermeasure to resolve the primary cause(s) first.

The final step is to subject the primary cause(s) identified on the Pareto Chart to a Five-Whys Root Cause Analysis (Liker 2004). The Five-Whys process aims to systematically drill down to identify the ultimate root cause of a problem to ensure that a selected countermeasure will solve the problem permanently. In Five-Whys, a manager sequentially asks, "Why?" a problem has occurred until s/he reaches the last actionable cause. In the Five Whys table of *The Toyota Way* (Liker 2004), the investigator begins with the puddle of oil on the shop floor and asks why it occurred. If one simply wipes up the puddle, the problem will reoccur. However, by repeatedly asking "Why?" the manager discovers the leak is due to a gasket made of inferior material. Why? The purchasing agent is evaluated on short-term cost savings. Once the last actionable cause is identified, the problem can permanently be resolved at its underlying root by applying a countermeasure to change the evaluation policy for purchasing agents. In a similar manner, when participants start their journey to investigate the root cause and develop a countermeasure, they experience, again with greater clarity, that it is typically a "system" that is at fault for the poor performance of the repairman. The process also helps to appreciate one of the key principles of the Toyota Production System (TPS), which is to make decisions slowly by consensus because time taken during collaborative decision-making enables fast, efficient, and often error-free implementation. While conducting the 5 Whys Analysis, participants are urged to avoid arriving at immediate conclusions. Instead, they are invited to delve more deeply into the brainstorming process to identify with fellow participants the final actionable root cause and to suggest a viable countermeasure.

These three simple tools, the Ishikawa Fish Bone Diagram, the Pareto Chart, and the 5-Whys Root Cause Analysis—when implemented during a Big Room Meeting—help Lean managers engage in the plan-do-check-act (PDCA) cycle of continuous improvement where countermeasures to root causes are used to permanently resolve a problem at its core. Using PDCA, the effects of the change are measured, and if successful, the change is standardized. This is the stairstep of continuous improvement (Figure 3). The extended version of the Repair-Co Game also highlights to the managers that during their journey of continuous process improvement, it is important to judiciously select and apply relevant Lean tools during the process of building consensus. For instance, there is a sound rationale for applying the earlier-mentioned Lean tools in a specific sequence.

REPAIR-CO: FIRST RUN STUDIES OF THE THREE LEAN TOOLS

To test the progressive application of the three tools mentioned above in our first-run studies, the authors played the Repair-Co Game with three different audiences in three separate locations. The participants were asked to imagine the Repair-Co scenario in two different contexts: one in a large city with significant urban sprawl and the other in a small town. The purpose of introducing two locations was to help illustrate how problems and their solutions are context-dependent. In other words, the manager must systematically investigate causes for poor performance in a given context rather than arriving at unfounded conclusions and suggesting remedies as a "one size fits all" approach. The rationale behind the addition of these processes is to help students and professionals understand how Lean tools can be helpful for not only analyzing the causes of poor performance but also for suggesting routes to continuous improvement while collaboratively engaging the members of an organization. Images of these tools and processes are depicted in Figure 4.

RESEARCH METHODOLOGY

INDUSTRY WORKSHOP SETUP

Although there are slight variations in how the Repair-Co Game is facilitated, one example for each of the three settings will be presented and discussed for clarity.

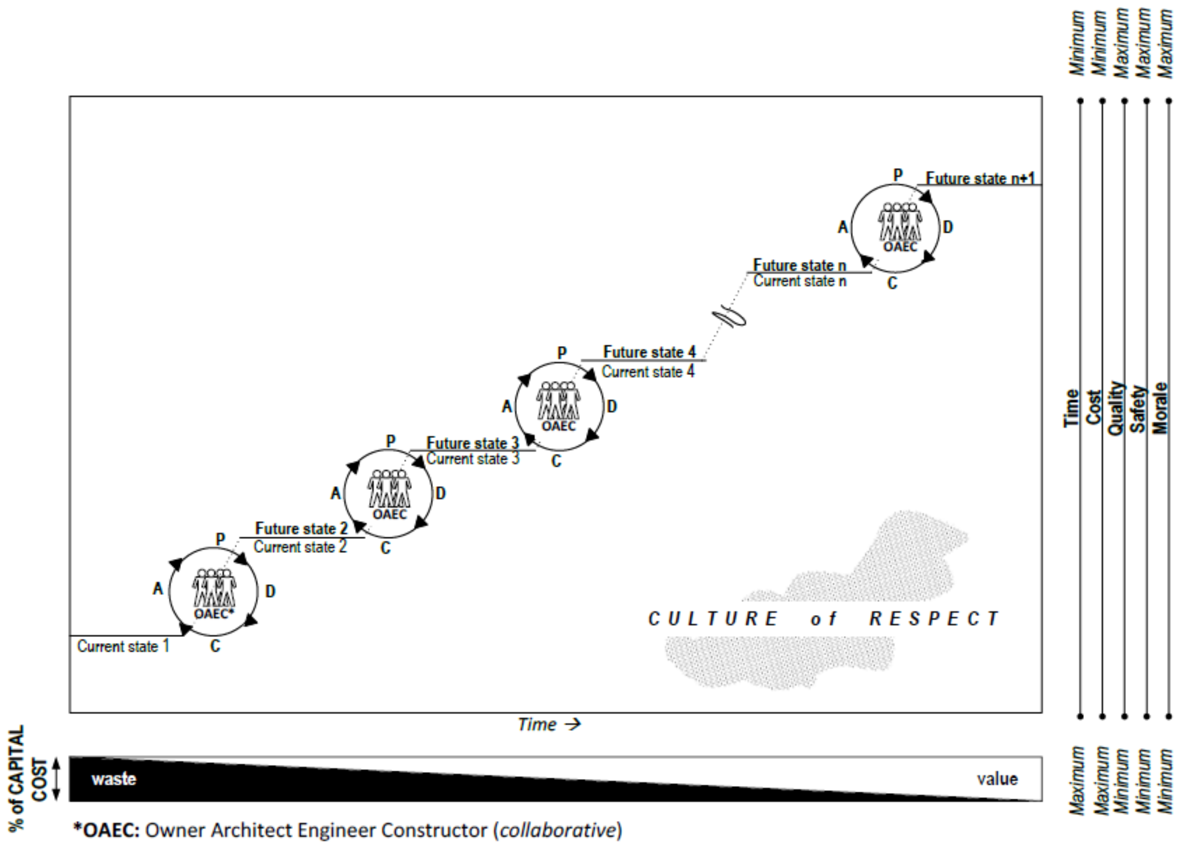

Figure 3: Lean's stairstep of Continuous Improvement (Rybkowski 2013).

The first research setting was a general contractor in India. This company began its Lean transformation journey in 2012 with the support of the Institute for Lean Construction Excellence (ILCE). The contractor had joined ILCE as a chartered member. The human resources department for this contracting organization went through extensive capacity upgrading sessions in the form of training programs and on-site guidance focusing on Lean concepts, principles, and tools. The sessions resulted in the implementation of Lean principles on several projects, with wide-scale adoption of the Last Planner® System of Production

Control (LPS), Value Stream Mapping (VSM), 5S, Work Sampling, and Big Room Meetings. The organization experienced impressive results with the application of Lean concepts and tools in the execution stage of its projects. In the recent past, the organization won prominent Engineering, Procurement, and Construction (EPC) projects, and there was a growing realization that it needed to align its design teams with the growing Lean ethos of the organization. The senior management became aware that Lean principles would reap fruits in a true sense most effectively when the seeds of Lean principles are sown in the early stages of a project's lifecycle, which was the design phase in this organization. The company's Research and Development (R&D) personnel were tasked with disseminating Lean principles and tools to the functional departments involved in the design process. The design departments included: Structural, Architectural, and MEPF. In addition to being applied to construction activities, Lean principles can and should be implemented throughout all phases of project delivery, including design, project accounting, etc. The R&D division crafted a roadmap to align with this goal. The first step involved a brainstorming session with functional heads of the design departments focusing on the identification of current design challenges. Based on these interactions, the organization reached out to CEPT University to help conduct research on the identified challenges and to guide the organization in ways to streamline its design processes. "Lean Champions" were identified from each design department (Architecture, Structural, and MEPF) to facilitate the dissemination and application of Lean principles and tools to their respective departments. The R&D Team conducted a one-day workshop with the theme of "Lean Design." Two authors of this paper served as facilitators and designed and conducted the workshop targeted to specifically assist the organization's design professionals. Because the event marked an important milestone for the organization, the facilitators carefully tailored the workshop agenda to align with the organization's expressed needs. The program was designed by interconnecting two components: Discussion about Lean principles in design processes and facilitation of Lean simulation games. The managing director was especially keen to engage young professionals in the company's design departments. The workshop was held during a weekend (Saturday) in a conference room that enabled participants to sit in groups around tables; the flexibility of the selected space was conducive to keeping participants engaged and focused.

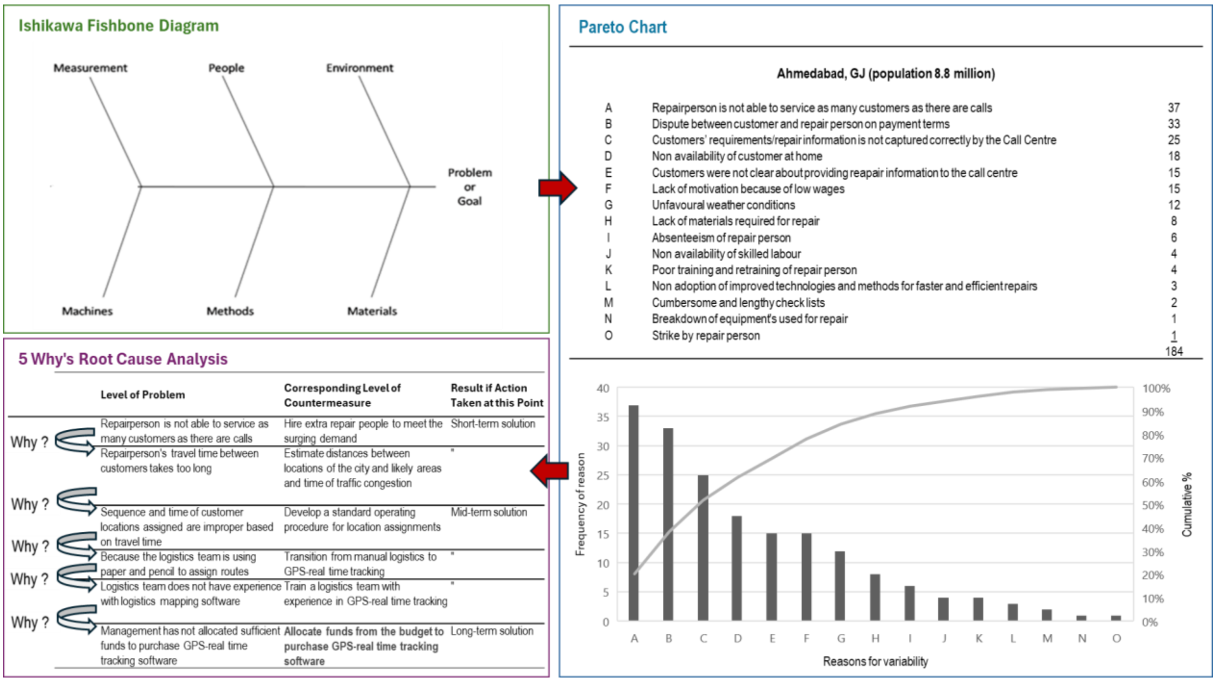

Figure 4: Sequencing of tool application runs clockwise, starting from upper left (in order: Ishikawa Fishbone Diagram, Pareto Chart, 5-Whys Root Cause Analysis table).

ACADEMIC INSTITUTES

In addition to Lean champions in practice and industry, Lean simulation games have been used worldwide by those in academia to impart knowledge of Lean principles to students. The academic settings described in this paper comprised two graduate-level courses focusing on Lean Construction: one in India and one in the US. The co-authors of this paper have been using Lean simulation games as an integral part of their teaching pedagogy in their courses on Lean Construction for a number of years.

FACILITATION OF THE REPAIR-CO-GAME

INDUSTRY WORKSHOP

On the day of the workshop, 33 design personnel in total came to participate. This number was encouraging given the hectic schedule of construction industry professionals. Included in these 33 participants were three (3) heads of each department, two (2) R&D team members, the Managing Director of the approximately 1500-member organization, and the Technical Secretary of ILCE.

The workshop was attended by professionals from multiple disciplines and departments: Architecture (3 No.), Structural (16 No.), MEPF (mechanical, electrical, plumbing, and fire protection) (11 No.), Research and Development (2 No.), and Human Resources (1 No.). The workshop began with self-introductions by participants and facilitators, followed by a playing of the Repair-Co Game in its extended version. The workshop facilitators identified two cities – one large and one small from the state where the headquarters of this organization was located. The purpose of choosing specific cities was to help the participants easily connect with the context. The steps described earlier about the Repair-Co Game in its extended version were followed, and the participants were requested to give their feedback digitally using a Plus-Delta form (Google Form®) at the end of the workshop (LCI 2024).

ACADEMIC INSTITUTES

Out of two academic settings for the facilitation of the extended Repair-Co Game, one consisted of 45 graduate students of the Construction Engineering and Management Program at CEPT University in India while the second involved 35 graduate students of a Construction Science program at Texas A&M University in the US. Before the facilitation of this simulation, the authors collected data on the demographic background of the students. In both settings, most of the students had previously experienced large and small cities. In the Indian University, approximately 20% of the students held an undergraduate qualification in Architecture while 80% of the students held an undergraduate qualification in Civil Engineering. Several had prior work experience as well. In the US-based university, approximately 95% of the graduate students had previously earned undergraduate degrees in Civil / Construction Engineering and had experienced both large and small cities. Facilitation steps described in an earlier section were followed. After finishing the facilitation of the Repair-Co simulation game, post-simulation discussions focused on lessons learned from playing the game.

RESULTS & DISCUSSION

The underlying common thread in the three settings where the Repair-Co Game was facilitated was the context of a large city versus a small town. In the case of the workshop facilitated for URC Construction Company, the large city was Chennai, Tamil Nadu State, India, and the small town was Coimbatore, located in Tamil Nadu State. The academic setting in India considered Ahmedabad and Morbi as large and small cities, respectively, located in the Gujarat State. Houston and College Station in the state of Texas were considered as large and small cities, respectively, for the academic setting in the US. These settings provided fertile grounds to compare and analyse potential causes of variability in the performance of the repairperson in different contexts. It was interesting to observe how game participants primarily attributed their brainstormed causes to the "management system" instead of the "repairperson" during the first phase of the game as was the intent of the original version of the Repair-Co Game. In the extended version of the Repair-Co Game, participants appeared to develop an understanding of the usefulness and interconnectedness of Lean tools as a means to analyse root causes and develop effective countermeasures to address underperformance. In the process of identification of potential reasons for poor performance, suggested causes in the context of a large city were identified, followed by suggested potential causes in a small town.

An analysis of reasons behind variable performance indicated a similarity in the identification of "traffic" as a likely primary cause for the repairperson's variable performance in large cities. After their identification of this potential cause, participants were shown a Google Map™ screenshot with traffic patterns during rush hour (i.e. 5:00 pm; Figure 5). These screenshots supported participant hunches that traffic may indeed represent a key inhibiting factor in large cities. It also strengthened the case that the causes identified by the game participants are not random, but informed by the participants' prior experience with large cities. The students also felt that with the advent of innovative technologies such as GPS and other forms of transport scheduling software, traffic challenges could potentially be addressed by generating more efficient routing of repair calls. Additional suggestions included making repair calls outside of rush hour or hiring and stationing additional repairpersons to service geographically defined zones of a city. "Traffic" did not appear in the list of potential causes for variable performance in small towns, likely because of the lower populations and more sparse distribution of occupants in these regions. The students were shown traffic maps of screen prints during rush hour in smaller towns, indicating significantly lower levels of congestion. The intent of sharing these maps was to impress upon participants the importance of not only generating a hunch but also of seeking evidence to validate the hunch before implementing a countermeasure to resolve the suspected problem.

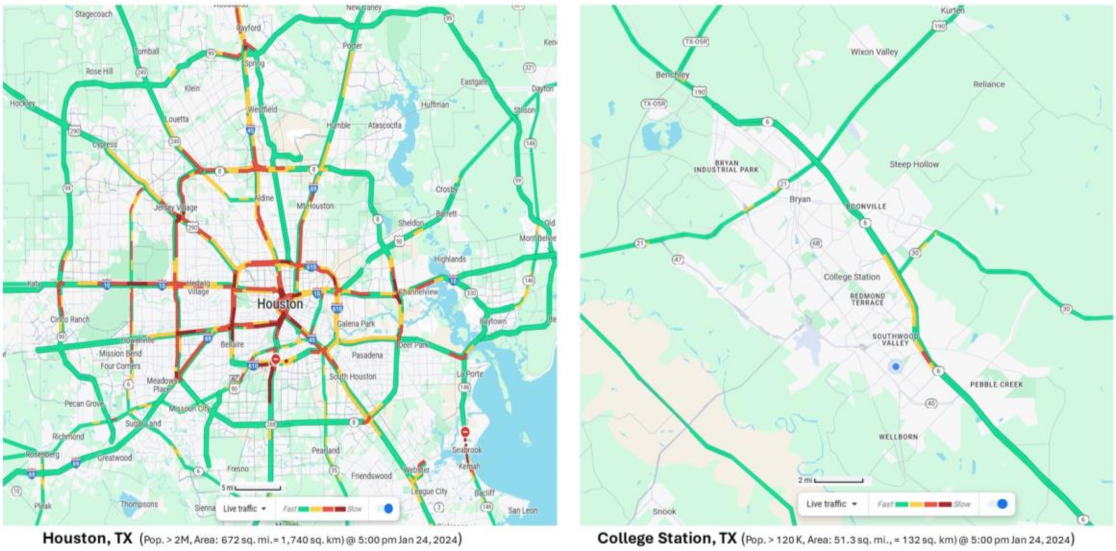

Figure 5: Traffic Pattern in Houston (left) and College Station (right) shown to participants during a trial playing of the Repair-Co Game in the US. Screenshots were taken from Google Maps™ at 5:00 pm in both locations.

For the three smaller cities, "insufficient customer demand" and "non-availability of skilled manpower" for repair work emerged as prominent proposed causes in all three test settings.

These outcomes indicated a commonality in the thought process among the game participants across three different settings. The purpose of presenting the context of two cities, both large and small, within the extended Repair-Co Game, was to impress upon participants that the context surrounding an activity plays an influencing role. Therefore, managers should make systematic efforts to decipher a context and identify “causes” behind poor performance within that given context. In other words, there is no “one size fits all” when seeking solutions to a problem. After all, implementing a countermeasure to post employees in different locations throughout a region or servicing customers outside of rush hour makes sense for large cities where heavy traffic is a primary constraint. However, a different countermeasure for a company to add additional capabilities to their repertoire would make sense for a small town where there is limited need for washing machine repair. Finally, when a manager invites diverse and multiple members within an organization to brainstorm potential causes of a problem that needs to be resolved, the probability that primary causes will be identified increases—reinforcing the importance of implementing these tools during Big Room Meetings with those who do the work.

In both the original and extended versions of the Repair-Co simulation, game participants expressed appreciation that Lean principles not only offer opportunities for systematically analysing causes but also for arriving at potential solutions. During the game, participants embraced the collaborative spirit required to brainstorm potential causes. They also appeared to respond to the thoroughness provided by categorizing causes under different arms (Manpower, Machines, Methods, Measurement, Materials, and Environment) in the Ishikawa Diagram. As managers often have limited resources to improve a given problem context, there is a need to focus on resolving the primary causes for maximum benefit. Generating Pareto Charts for each of the two cities helped participants (and ultimately managers) prioritize their efforts on the most impactful causes. Finally, using a 5-Why analysis to identify a root cause ensures a problem does not recur once resolved.

During the conduct of these three workshops, the work facilitators keenly observed the interactions and behaviour of game participants. As the game participants were seated in groups, the workshop facilitators reached out to members surrounding each table and listened to the conversation of participants over the course of this game. It appeared that improvements occurred through a social process, facilitated by interactions and diverse perspectives. Additionally, their responses suggest that participants experienced a desired “aha” moment in terms of analysis of “system” vs “person,” as well as an understanding of the importance of prioritizing the “vital few” versus “trivial many” causes revealed by a Pareto Chart analysis. Importantly, participants experienced how Lean philosophy and principles have given rise to practical analysis and process improvements armed with Lean tools.

It should also be acknowledged that the Repair-Co game is typically facilitated within a larger context which can affect participant receptivity to specific ideas. For example, to motivate participation in these sessions, participants were often awarded plastic tokens that could be converted to book prizes or grades at the end of the workshop and academic courses, respectively. These sessions were considered effective based on “plus-delta” feedback from participants and students. However, one limitation of this research is that a separate rating for the Repair-Co Game was never asked of participants. Future research should be done to consider what works well and what could be improved, if anything, to the structure of the Repair-Co Game.

CONCLUSION

The Repair-Co Game appears to serve as a valuable tool for introducing stakeholders to the principles of Lean Construction. By highlighting the systemic nature of inefficiencies and the need for collective problem-solving, the game effectively demonstrates the usefulness of Lean methodologies. Moreover, its adaptability allows for expansion to incorporate additional Lean tools such as the Ishikawa Fishbone Diagram, Pareto Chart, and 5 Whys Root Cause Analysis, further enhancing participants' understanding of Lean concepts. Testing the extended version of the game across different locations and participant groups yielded consistent results, indicating its potential for widespread application. However, feedback from participants still suggests areas for improvement, including the need for clearer communication and the inclusion of more design-related examples. In general, the Repair-Co Game presents a promising avenue for promoting Lean practices within the construction industry, facilitating continuous improvement and problem-solving at its core. Finally, the extended version of the Repair-Co simulation further enhanced learning outcomes and helped to drive home a message about the need for a systematic approach to consistent improvement in organizational systems with the collaborative application of selected Lean tools.

DESIGNING AN EFFECTIVE TRAINING PROGRAM FOR SYSTEMATIC LEAN CONSTRUCTION IMPLEMENTATION

Eder Martinez[1], Louis Pfister[2] and Luis F. Alarcón[3]

ABSTRACT

Training and education stand out as pivotal factors for the successful implementation of lean construction. Despite their critical role, current literature lacks comprehensive guidance on the development and implementation of lean training programs within the context of construction organizations. This paper aims to addresses this gap by presenting the case study of a multinational construction service provider developing and implementing a training program aimed at fostering a broader and sustainable integration of lean construction practices within the organization. The analysis includes the insights and perspectives of 95 trainees, gathered through an electronic survey. The results show a positive evaluation of different components of the program after 2 years of implementation. The case study emphasizes the significance of a collaborative approach to find an adequate balance of standardization and flexibility required to effectively deploy a unified training program across diverse local contexts and construction operations within the organization. The valuable insights derived from this case study serve as a resource for both researchers and practitioners, providing practical guidance for those looking to implement training programs. Furthermore, it supports in identifying best practices and potential pitfalls that warrant careful consideration in similar initiatives.

KEYWORDS

Lean construction, Training, Education program.

INTRODUCTION

Lean construction principles, derived from lean manufacturing and the Toyota Production System, have gained widespread recognition in the construction industry for their potential to enhance efficiency, reduce waste, and optimize project outcomes (Ballard, 2000; Koskela, 1992). Central to the successful implementation of lean practices is the imperative for adequate training programs tailored to the specific needs of construction professionals.

Despite the importance of training in achieving overall success in lean construction implementation, there is a lack of literature and documentation providing examples of training approaches aiming to sustainably support its adoption in corporate environments (Tsao et al., 2012). Notably, most of the literature refer to education in university setups with a lack of focus

on how these concepts could be implemented in corporate environments (Alves et al., 2016; Rybkowski et al., 2018).

This paper aims to contribute to this area by presenting a case study of a structured approach to lean construction training program developed and implemented in a large European construction service provider. The authors describe the training program development and analyze the results up to date considering 2 years of effective implementation. The authors also build upon trainees' survey to include the perspective of participant in the case study.

RELATED LITERATURE

Lean construction aims to optimize project delivery by minimizing waste, improving collaboration, and enhancing value for all stakeholders involved. Achieving these objectives requires a paradigm shift in the organizational culture, requiring a workforce that is well-versed in lean principles and practices (Koskela et al., 2002).

Literature emphasizes that skilled professionals and workforce are essential for successful lean construction implementation (e.g., Aslam et al., 2020). Adequate lean construction trainings serve as a vehicle for skill acquisition, providing practitioners with the necessary knowledge to apply lean concepts, fostering a network of capable construction professionals able to execute lean practices at the different phases of the project lifecycle. The transformative impact of lean construction training has the potential to extend beyond individual skill development to encompass a positive organizational culture development. Scholars argue that lean implementation requires a cultural shift towards continuous improvement and collaboration (Ballard & Howell, 1998; Koskela et al., 2002). Therefore, training initiatives contribute to this cultural transformation by instilling a mindset of learning and adaptability, vital components for the sustained success of lean practices within an organization.

Several studies have identified the lack of adequate lean awareness and understanding as critical barriers in successful lean construction implementation (Sarhan & Fox, 2013). According to Watfa and Sawalha (2021), the successful implementation of lean construction requires a certain level of technical proficiency in the tools and techniques essential for its proper execution. In fact, the Lean Construction Journal has recently launched a special issue call for lean education devoted to consolidating best practices and simulations for enhancing lean education (Lean Construction Journal, 2023).

Researchers have dedicated significant attention to lean construction education, offering comprehensive guidelines for the development and implementation of training programs. For instance, Hirota and Formoso (1998) offered guidance in developing lean construction training programs. The authors highlight the ease with which trainees can grasp fundamental concepts like processes, operations, conversion, flow activities, and the overarching notion of waste. However, they also emphasize the challenge trainees face in fully comprehending and seamlessly integrating lean construction principles and approaches. Based on several years of experience, Tsao et al. (2012) provide different perspectives and lessons learned in lean training and education. The authors provide guidelines for developing adequate training that considers a good mix of learning modules, case studies, simulations, and field trips. Similarly, Pellicer and Ponz-Tienda (2014) outline the approach and outcomes of a lean construction course established at as part of a master program in civil engineering. The proposed approach covers key aspects of lean construction, including its historical evolution, value stream mapping, pull production, The Last Planner® system (LPS), standardization, optimization of construction operations, Building Information Modelling (BIM), and Integrated Project Delivery (IPD). The authors credit the course's success to its dynamic approach, which integrates lectures, exercises, classroom games, and a term project. In a similar direction, Nofera et al. (2015) provide detailed descriptions of a teaching approach for lean construction targeted at university students. The authors also offered feedback on the effectiveness of the approach and suggests potential areas for improvement. Only a few studies have addressed lean construction education in corporate environments. For instance, Alarcón et. al (2006) and Pavez and Alarcon (2008) report critical factors, barriers, and recommendations for the implementation of lean in construction organizations. The authors highlight that professionals' adequate social and technical competences are essential for efficient lean construction implementation.

Previous research in lean training and education provides valuable insights and guidance for the formulation of effective training programmes. However, a significant proportion of this literature focuses predominantly on the higher education environment (Tsao et al., 2012). Applying the results of these studies may become challenging when trying to use them directly in corporate settings, where professionals have diverse profiles. Furthermore, literature highlights the variability in the approaches adopted by construction industry companies in relation to lean construction training (Forbes et al., 2018). This variability is attributed to differences in organisational structures and strategic priorities. In particular, the translation of lean training programmes into corporate settings faces additional challenges, including resistance to change and the need to align training initiatives with the operational priorities of professionals tasked with project delivery. This paper aims to address this gap contributing to knowledge by presenting a practical case study of an organisation developing and implementing a training programme aimed at fostering lean construction skills among its professionals.

RESEARCH METHODOLOGY

This research uses case study approach. Case study is an empirical inquiry that investigates a contemporary phenomenon within its real-life context, especially when the boundaries between the phenomenon and context are not clear (Yin, 2014). The authors use different sources of data to describe and analyze the case study. This includes observations, documents produced by people involved in the case study, and surveys. An online survey was conducted at the end of the study to collect feedback and perspectives from individuals who successfully completed the training program. The authors triangulate data from the different sources to build a comprehensive understanding of the case and derive the insights and conclusion of the study.

CASE STUDY

BACKGROUND

The case study involves the development and implementation of a lean construction training program in a multinational construction services provider based in Switzerland. In addition to its presence in Switzerland, the organization conducts active operations across various central European countries, including Germany, France, Austria, Norway, and Sweden.

The main challenges the organization aims to address are related to scalability of lean construction implementation and sustaining lean practices in the long term. Prior to implementing the program, the organization conducted a series of lean construction pilot projects where lean construction specialists acted as coaches, actively supporting the different project teams. Lean construction specialists were centrally recruited by the organization and strategically positioned to provide dedicated support to project teams. The organization soon realized 2 main challenges in this approach. The first relates to resource constraints to efficiently broaden lean implementation. Depending on project complexity, lean construction specialists could only manage a handful of projects simultaneously. Scaling up lean construction implementation to a wider number of projects in different locations would require hiring an important number of additional specialists. The second challenge relates to the transfer of knowledge from one project to another and the dissemination of learnings within the organization. In many cases, people involved in the pilot projects learned the application of a specific tool and method in a given context without having a broader understanding of the fundamentals and principles of lean construction. Furthermore, this project-based approach generated in many cases ad hoc implementation of different tools and methods defaulting the establishment of a certain level of standardization and systematization that supports leveraging learning across different projects.

Consequently, the organization opted for a transition from a project-centric strategy to a more "enabling approach." This involved the training and activation of a supplementary layer of lean construction champions, specifically targeting individuals in closer proximity to operations, such as project managers and site engineers. This strategic shift aimed to cultivate greater autonomy in lean construction implementation, reducing dependence on central designated lean construction specialists and promoting long-term scalability.

LEAN TRAINING PROGRAM DEVELOPMENT

The development of the lean training program involved 3 distinct phases: identification of requirements, development of the training program, and implementation.

Requirements

The program's organizational learning objectives aim to help trainees to gaining the knowledge, skills, and competencies required to implement lean construction independently and effectively. These overreaching objectives guided the creation of the training concept and materials, ensuring a consistent approach in teaching lean principles and methods. By standardizing the training, the organization seeks to improve efficiency and benefit from the shared expertise of participants.

Nevertheless, reaching this standardization posed some challenges considering the broad range of requirements. Along with operating in different countries (different cultures and languages), the organization also executes various types of complex infrastructure projects covering a large variety of construction services including roads, bridges, special foundations, and tunnels. Thereby, the first step in developing the program was to reach a level of understanding of the needs of local contexts and types of projects. For this purpose, the authors conducted semi-structured interviews and workshops with local stakeholders in different locations to capture requirements to steer the training program development. These included target audience, delivery approach (e.g., online, face to face), duration, as well as the relevant specific lean subjects, tools, and methods to be prioritized.

Program development

The overall structure of the program, as well as the content of the different training modules was developed collaboratively by all lean construction specialists involved in previous pilot projects. The content from pre-existing lean construction training modules within the organization was consolidated, enhanced, and supplemented with additional materials to fulfill the specified requirements. This was based on a structured plan to continually review and enhance the program's design and content using a Plan Do Check Act (PDCA) cycle.

Figure 1 depicts the overall program design consisting of 6 phases. The initial phase involves the nomination of employees for the training program. This involves selecting individuals from various business units, either through nominations or volunteering, in collaboration with management. This approach aims to ensure that the participants have the local support to invest time in the program and the personal willingness and commitment of different individuals to participate in the training. The second phase is onboarding and kickoff, where participants are introduced to the components of the program, including scheduling the different training sessions and workshops. In general, the program operates on a yearly basis, with local country units (e.g., Norway, Germany) defining their training schedules according to the local context. This aims to provide the flexibility to adjust the program according to the constraints and planning of the local organization.

Figure 1: Lean training program design

The third phase involves the delivery of different training modules. Except for the module "lean principles," the sequence in training delivery relies on local planning based on business and operational needs. For instance, country units focusing on tunneling construction may prioritize and focus on different modules than units building bridges. Thus, local lean specialists responsible for conducting the trainings are provided with significant flexibility in delivering and adapting module content to meet specific needs.

The next phase considers the execution of a "live case" on an individual basis. During the live case, trainees are tasked with identifying improvement opportunities and applying the knowledge gained from the training to tackle those challenges. In this way, along with the training they can experience the problem-solving approach experimenting with new tools and methods for continuous improvement. Live cases are documented based on the structure provided by the A3 report. Close to the end of the program, trainees in a country unit (or region) get together and present their cases in peer feedback sessions. This provides them with the opportunity to share and exchange their cases and lessons learned with peers, gather feedback, and improve their approach.

At the end of the program, trainees complete a standard proficiency test to receive an external certification. This provides them with the opportunity to obtain proof of their training completion and competences in lean. To finalize the program, all trainees gather for a one-day event/conference organized at the company's central office where they receive their official certificate. In this event, selected cases are presented in parallel sessions (in a conference mode), so trainees can also exchange and learn from cases developed by colleagues in other countries. The event also includes a field visit to partner organizations where they can see lean implementation in other contexts (e.g., manufacturing contexts or other projects). Different networking events are organized after program completion aiming to keep the community active, engaged, and exchanging ideas about continuous improvement.

PROGRAM RESULTS

The results of the program presented in this section correspond to an online survey distributed to trainees at the end of the program. The purpose of this survey is twofold. First, to ensure quality in the delivery of the different modules, as well as to understand the value it delivers to participants in performing their work. Second, identify opportunities for improvement in different areas of the program (e.g., content, timing, organization, etc.). The survey considers a comprehensive analysis of 95 responses, including 38 inputs from the initial program implementation in 2022 and 57 from the subsequent training cohort in 2023.

In Figure 2, participants were initially asked about the overall rating for the training program and how likely they would recommend it to their colleagues. On average, participants rate the program with a 4.3 score (1 – very poor, and 5 – excellent). Similarly, the average score for recommending the program to a colleague is 4.4 (Figure 2).

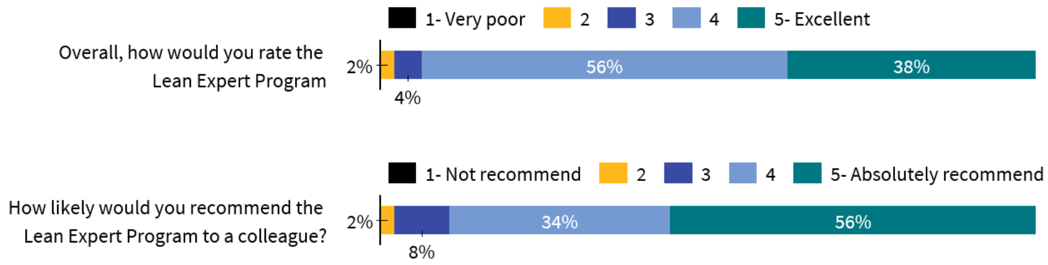

Figure 2: Overall lean training program evaluation

Following a similar approach, Figure 3 summarizes feedback from different aspects of the program. Overall, the program received positive evaluations in all dimensions, especially regarding the knowledge and capabilities of the trainer, as well as the interactive approach to deliver the content.

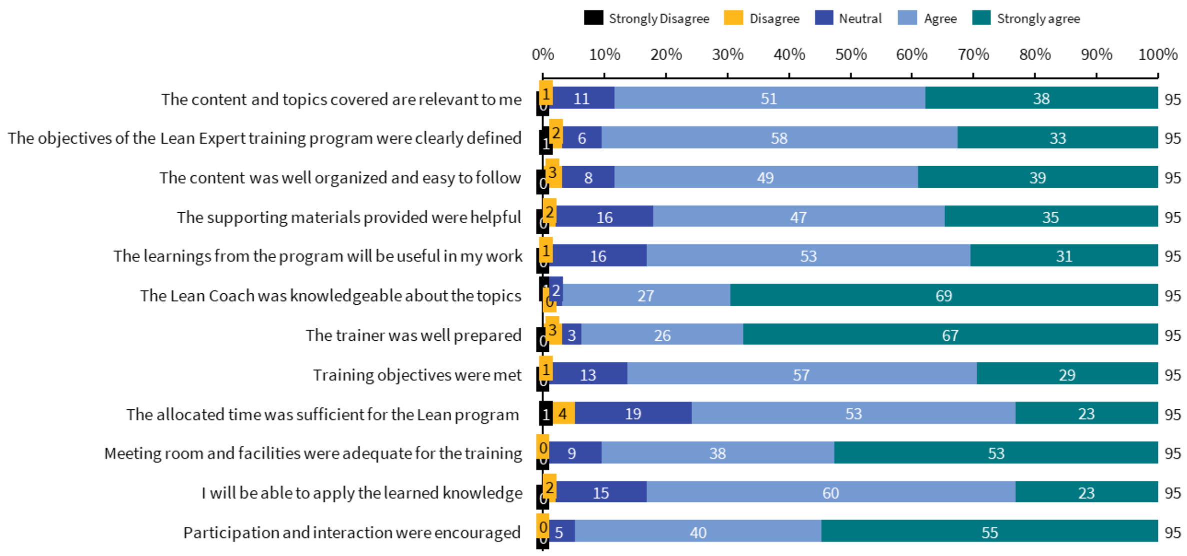

Figure 3: Training program evaluation

Following the plus and delta approach, survey participants were asked to offer written insights regarding the program's strengths and areas for improvement. On the positive side, numerous responses underscored the value of exchanging ideas and experiences with colleagues from diverse business divisions during various training sessions and the program's closing event. Another highlighted aspect is the hands-on approach to training, incorporating real-case implementations and simulations to illustrate the practical application of lean principles. While this aspect received positive evaluations, participants expressed a strong desire for even more hands-on involvement and real-life examples to demonstrate the significance of these principles in their daily work. For instance, some inputs indicate that certain sessions were "still too theoretical and not applicable 1 to 1 to construction operations." Other inputs indicate that "sometimes it was hard to transfer all of the examples to actual situations on site." Further opportunities for improvement relate to the time availability for people to undertake the program and the challenge to balance this with their daily operations. This aligns with the dimension “the allocated time was sufficient for the lean program” in Figure 3 which received the highest “disagree” and “neutral” inputs. Some people indicate that the time required for the program was “difficult to combine during an ongoing project.” Others indicate having “'…little time parallel to work.”

DISCUSSION

The authors build the discussion section triangulating learnings and results of the case study organizing them into 2 main areas: program development and implementation (including survey results).

PROGRAM DEVELOPMENT

Internal vs external training

At the beginning of the process the authors were confronted with the discussion of developing an internal vs external training program. In-house training utilizes internal resources, tailoring content to organizational needs, while external training, leverages external industry experts and practices (e.g., Abhishek et al., 2018). The organization already explored external trainings with dissimilar results. Most of the feedback for this was the lack of practical examples to assimilate the concept and a limited range of practical tools provided in these trainings. For instance, most examples were related to high rise building construction using takt planning but not too related to complex infrastructure (e.g., road, tunnel construction). Furthermore, organizing a training in different countries and languages proved to be complicated with an external provider/consultant, thus the decision was made to develop an in-house training. This approach required significant investment at the beginning of the process. The experience shows that a tailored approach for the organization pays off contributing to increased buy-in from participants. Another positive aspect of an internal training is the flexibility to continuously improve the program based on real case examples and learnings from operations (e.g., incorporating live cases as best practices).

Standardization versus flexibility

The program balances both standardization and flexibility by incorporating in the design modules which can be organized and delivered in the training according to the local operational context of a regional/country unit. The delivery of foundational modules related to lean construction principles and basics is mandatory for all units, while certain method/tool-oriented sessions are emphasized according to the local context. For instance, a region working with different subcontractors and difficult interfaces may emphasize coordination via LPS, while other units working on tunneling projects place more emphasis on Value Stream Mapping to support adequate material flows in critical supply chains. Accommodating the needs of different countries and operations required an intense collaborative development process gathering requirements and building consensus among the lean construction specialists (trainers) to design the training program.

IMPLEMENTATION

Building a strong network and the “multiplier” effect

Along with providing trainees with skills to implement lean construction more independently, the program allows the creation of an additional network of people capable and willing to experiment with new methodologies for continuous improvement. This additional network creates a “multiplier” effect supporting the scalability and transfer of good practices from one project to another. Although not the case for all trainees, the experience shows that in many cases trainees started implementing their learnings (e.g., a lean tool or method) in new projects with little, or no support from a designated lean construction specialist. This is a positive effect that was originally one of the goals of the program. The experience also demonstrates that, in order to keep this network active, it is very important to consider the organization of regular exchanges where trainees can keep exchanging ideas and knowledge.

Quality of live cases

A critical component of the training program is the live case, where trainees can identify opportunities for improvement and put in practice learnings in a structured approach to problem solving documented in an A3. This allows the identification and consolidation of various ideas and approaches to problem solving realized by trainees. However, there is a considerable variation in the quality of the cases in terms of both approach and content. While some live cases are executed exceptionally well, others merely meet the minimum requirements to pass the program. Our experience indicates that the issue lies not so much on the quality of the training but rather on the time availability of participants to invest in their live cases and the accessibility of local trainers to provide support and coaching. Working on the live case demands time and dedication, often underestimated by participants. Therefore, it is advised to recommend trainees to start with the problem formulation of their live case right at the beginning the program and to introduce the basic problem-solving processes as early as possible. As per our experience, participants tend to postpone the live case till the end of the program, prioritizing daily business/operations. This also matches the “time allocation” feedback collected in the survey. Another option could involve facilitating pair or group live cases to encourage collaboration and teamwork in the problem-solving approach simultaneously.

Participants dropping out

While the trainee nomination phase involves aligning with local management and conducting personal discussions to assess both management support and individuals' interest in the training, the program still encounters instances of participants dropping out. Our experience shows that this has something to do with priorities defined by participants. When they have urgent matters to solve at the project level, they prioritize this over the program. When a participant has missed too many sessions, they are asked to leave the program, or alternatively to resume the following year. The time factor and balancing program participation versus daily business activities again plays an important role. The attendance rate for trainings is best when training dates are defined collaboratively involving trainees at the beginning of the program.

Practice-oriented sessions

One of the most important aspects highlighted by the trainees is the inclusion of hands-on sessions and real-life implementation cases. Most of the modules include different types of simulations to support the learning experience. Similarly, the collective and bottom-up approach allowed the identification and centralization of good practices which are shared in the different training modules. The inclusion of these internal success stories demonstrates to trainees the applicability of lean in real context, while at the same time serving as inspiration of good practices to be implemented in projects. These current state best practices, templates and supporting materials to implement are consolidated and shared company-wide via an internal SharePoint “toolbox” website. As highlighted in the survey, trainees express a desire for more real-life cases. In response, the third round of the program incorporates the involvement of past trainees as guest speakers in various modules. These former trainees share insights into their experiences and the practical implementation of lean methodologies in their projects. Incorporating colleagues or peers into discussions on lean implementation not only cultivates participant buy-in, as they observe firsthand how their peers apply lean principles in real-world scenarios, but also enriches the sessions by addressing the challenges encountered during the implementation of specific methodologies in projects.

LIMITATIONS AND FUTURE WORK

The findings of this study should be considered within the following limitations. In particular, the case study considers the specific context of a single organization. While recognizing the potential challenges associated with directly extrapolating the findings to other contexts, the authors assert that the empirical insights gained from this study offer valuable perspectives. These insights are relevant to researchers and practitioners involved in the design and delivery of lean training programs and contribute to a broader understanding of effective practices in similar efforts.

In terms of future work, a post-training survey 12+ months after completing the program would provide insights into whether the training has been integrated into daily operations and sustained. This is something that the authors envision to implement in the next years.

CONCLUSIONS

This paper presents an innovative training program to scale up and support a sustainable implementation of lean construction in a multinational construction service provider. The positive evaluation of the program's various components is based on feedback from 95 trainees who have undergone the program over the 2 years since its effective implementation.

In terms of development, the collaborative and bottom-up approach to training development facilitated the creation of a program that effectively balances the need for standardization and flexibility. This approach ensures the implementation of a training program that leverages internal knowledge while meeting the diverse requirements of an international organization operating in differing geographies and construction-operation contexts. Insights gained through the implementation process highlight the importance of integrating real-life case studies and hands-on sessions into the training methods, fostering a more effective assimilation of various lean concepts. The delicate equilibrium between daily operational demands and the time commitment necessary for program participation also emerges as a pivotal consideration, as it significantly impacts the quality of participant engagement and involvement in the program.

The insights presented in this case study act as a valuable resource for researchers and practitioners alike, offering practical guidance for those aiming to execute training programs. Additionally, it assists in recognizing optimal approaches and potential challenges that require thoughtful consideration in similar initiatives.

ACKNOWLEDGMENTS

We extend our gratitude to all individuals who have contributed to the development and participation of this lean training program. We also appreciate the engagement and valuable insights provided by the participants who have gone through it thus far.
